With worldwide data doubling every two years, IT teams spend an inordinate amount of time and money improving their storage infrastructures instead of implementing technology solutions that improve business productivity. Microsoft Azure StorSimple 8000 series hybrid storage arrays help customers shift their attention from their storage infrastructures to other projects by breaking the cycle of storage purchases driven by data growth and automating time-consuming data protection and storage capacity scaling.

StorSimple 8000 series hybrid storage arrays at a glance

8000 series hybrid storage arrays integrate cloud services with hybrid storage technologies. They use three different kinds of storage in a tiered structure that matches three broad classes of data. The top tier uses SSDs (solid state disks) for data that was most recently accessed, the second tier uses HDDs (hard disk drives) for data that is accessed less frequently and the third tier uses cloud storage for data that is inactive and for off-site data protection. Array software determines which tier data is placed and provides quality of service for storage. The SSD tier provides the lowest cost per IOP (IOs per second), the cloud tier provides the lowest cost per GB and the HDD tier provides a balance between optimal performance and capacity. Figure 1 below illustrates the three tiers in the 8000 series arrays.

Consolidate management over an Internet-connected control plane

8000 series arrays use a hybrid cloud management model where management information is sent across Internet connections linking on-premises 8000 series arrays to the Microsoft Azure StorSimple Manager service in the cloud. This design allows storage administrators to control any array in the enterprise from virtually any location through a management portal and consolidates management of storage and data, including data protection schedules and expiration parameters for protected data.
The Microsoft Azure StorSimple Manager manages 8000 series arrays and Microsoft Azure StorSimple Virtual Appliances over an Internet-connected control plane, providing applications running in Azure virtual machines (VMs) with access to uploaded data. It can be used to deploy, develop and test applications as well as for disaster recovery (DR) purposes. Customers looking to migrate on-premises applications running on Windows Server, Hyper-V, VMware and Linux platforms can use 8000 series arrays and the StorSimple Virtual Appliance to transfer their data. Having access to enterprise data in Azure enables the IT organization to use Azure IaaS services to offload constrained data center resources and use the cloud to expand their datacenter infrastructures to the cloud.

Figure 3 shows the control plane connecting the Azure StorSimple Manager to three different 8000 series arrays and a Microsoft Azure StorSimple Virtual Appliance. With no off-site storage media to manage and no on-premises capacity upgrades, StorSimple 8000 series arrays are designed for complete setup and operations through the Manager. One of the advantages of this top-down hybrid management approach is having near-real time status and reports for all 8000 series arrays across the enterprise. An example of the Manager’s dashboard for viewing aggregated information from multiple arrays is in Figure 4.

Access enterprise data with applications running in Azure

The Microsoft Azure StorSimple Virtual Storage Appliance is an implementation of StorSimple technology running as an Azure service, allowing Azure VMs to access on-premises data uploaded by 8000 series hybrid storage arrays.
Manage data growth and get rid of the anxiety of running out of capacity

High data growth is a constant irritation to many IT teams who must always be, acquiring, deploying, managing and planning storage. 8000 series arrays use data reduction technology and hybrid cloud tiering to increase storage capacity on-demand, relieving the anxiety of running out of capacity. As new data enters an 8000 series array it is initially written in raw form before it is deduplicated, or deduped. As data ages further, it is moved from the SSD to the HDD tier and is compressed. As the amount of deduped and compressed data approaches the capacity limits of the array, the least recently used data is automatically migrated to the cloud tier. Data that is being used by applications remains in the array and is called the working set. Many applications have working sets that stay relatively constant in size over time while the amount of inactive data continues to increase and is migrated to the cloud tier. Figure 6 illustrates how data reduction and hybrid cloud tiering relieve the pressures of managing array capacity and minimize storage consumption.

If a disaster strikes, DR operations can start as soon as there is an operational 8000 series array or a StorSimple Virtual Appliance running in Azure to access cloud snapshot data there. Customers using 8000 series arrays in multiple sites can begin recovery immediately at one of their other sites, saving many hours, if not days or weeks, in the process. Cloud snapshot data is remotely mounted as synthetic full volume images that consolidate data from multiple cloud snapshots and present it to applications as a virtual volume on-premises. As applications access their data, the array downloads it from the cloud and it becomes part of the array’s working set. Instant recovery with 8000 series arrays is very fast and avoids wasting time downloading inactive data that is not needed. These recovery efficiencies are why 8000 series arrays have such short recovery time objectives (RTOs) and enable IT teams to test DR plans without causing major disruptions to datacenter operations.

Retain data without having to dispose of it prematurely

Many IT teams have problems maintaining enough storage capacity to keep all the copies of data they are expected to in order to comply with regulations and policies. When there isn’t enough capacity available, it is much easier to delete older copies than purchase and deploy more storage. StorSimple 8000 series arrays fix this problem by storing and retaining this data in the cloud where running out of capacity is not a problem.

Increase IT agility with streamlined storage and data management

Many of the tasks associated with storage management are either automated or unnecessary with StorSimple 8000 series arrays. Data protection, capacity management and performance optimization are all painstaking tasks that typically consume many hours, but are automated processes in 8000 series arrays. Not only that, but the tasks of moving and deleting data, adding capacity and re-balancing application workloads are unnecessary because 8000 series arrays dynamically expand storage capacity using hybrid cloud tiering. Figure 6 compares the storage management tasks used for traditional storage environments with those of the 8000 series.
Use case scenarios for 8000 series arrays

8000 series arrays excel at solving data growth and data protection problems as well as reducing the time and effort IT teams spend managing storage. They are well-suited for use as large file shares for document management and archiving applications where historical files are seldom accessed but need to be readily available. Similarly, application development environments where there are a lot of inactive VMs make good use of 8000 series hybrid cloud tiering by storing data from “zombie VMs” online in the cloud.

Data protection can be improved in most organizations, particularly for line-of-business applications that need automated off-site data protection, but without the high cost of remote replication. Moving the data for these applications to 8000 series arrays greatly improves both their protection and recoverability. Many IT teams cannot test or practice disaster recovery scenarios because it is too costly and disruptive to do. Storing data on 8000 series arrays facilitates DR testing, enabling the IT team to set realistic recovery time objectives (RTOs) for applications.

Tier 2 and 3 database applications are also good workloads for 8000 series arrays. For instance, customers can run departmental SQL Server databases on 8000 series arrays and take advantage of automated off-site data protection as well as VSS-compliant application-consistent backups.

Two new arrays: the 8100 and 8600

There are two models of 8000 series arrays: the StorSimple 8100 and the StorSimple 8600. The usable internal storage capacity of the StorSimple 8100 is expected to be between 15TB and 40TBs, and the usable internal storage capacity of the 8600 is expected to be between 40TB and 100TB - depending on the degree that the data stored in the arrays can be deduplicated and compressed. Including integrated cloud storage, StorSimple 8100 arrays have a maximum usable capacity of 200TB and StorSimple 8600 arrays have a maximum usable capacity of 500 TB.
