Application Layer Capture and Assignment

A step-by-step guide to capturing and assigning an application layer using WSM and vWorkspace

Objective

The purpose of this guide is to provide you with detailed, step by step instructions of the process used to capture and assign application layers using WSM and vWorkspace 8.6.

Audience

This document is intended for VDI administrators and technical personnel with moderate to advanced knowledge of vWorkspace, PowerShell, WSM, VDI administration and a broad IT skill set. It is also assumed that advanced Windows operating system knowledge is possessed by the reader.

Configuration Prerequisites

The following list of items must be in place before proceeding:

- vWorkspace installed and operational
- WSM installed and operational
- Application to be captured must be compatible with target OS and bit level
- Master “gold VM image” created for target OS and bit level
- WSM Client Utility installed on client system
1 Application layer capturing

From the client VM (aka "Gold VM"):

1. Launch the Virtual Disk Image Creation utility.
2. Select "Application".
3. Define the size of the file.
4. Assign a name.
5. Select the latest version of the Client Utility tool
6. Click "Create VDisk"

7. In the notification window that appears, click "OK" (the utility will remain open in the background).

8. Install and customize the application you wish to capture into a layer (Firefox is used in this example).
9. After the application has been installed, return to the utility and click “Finalize”.

10. Click “Yes” to finalize the application VDisk.
Application layer registration and enablement

From the WSM Administration Console

1. From the navigation bar on the left: Select Configuration>Applications>Unregistered.
2. Click the "Register" button next to the application that you captured in the previous section.
3. Click "Register" again. At this point the application is registered but the distribution is disabled.

4. From the navigation bar on the left: Select Configuration>Applications>Registered.

5. Click on the application that you captured and registered and select "Content Distribution".
6. Click the “Distribute” button.

7. Confirm the action by clicking the “OK” button.
3 Application layer assignment

Locate the PowerShell script template in the WSM directory as vWorkspace.WebAPI.demo. The text of this script can also be taken from the vWorkspace 8.6 Administration Guide (p.115). See Appendix for script contents.

1. Right click the file and click “Edit”
2. Follow the detailed instructions contained in the PowerShell script to fully customize the PowerShell script template for your own environment (servers, users, groups, etc.)
3. Execute the script. The application should now be available to the users, groups and/or systems that you configured it for in the PowerShell script.
4. Verify that the application has been enabled by logging in to one of the VDI desktops that the application layer was assigned to in the previous step and launching it.
Appendix

# .....................................................

# Step 1: Every new PowerShell session setup
# .....................................................

# This line should point to the location of the vWorkspace.WebApi.psd1 file
# This is installed with the WSM Web API components
Import-Module "C:\Program Files (x86)\Wyse vWorkspace WebAPI\vWorkspace.WebApi"

# Here is where you set up access to the vWorkspace web api
# Replace ‘webApiServer’ in the command below with the server running the web api
# Replace ‘FarmAlias’ in the command below with the name of the farm
# This cmdlet will then prompt the user for credentials, the credential specified
# must be a pre-defined vWorkspace administrator
Connect-DVWFarm -WebApiAddress "http://webApiServer:4500/api/farm/FarmAlias"

# Running the cmdlet above without specifying the -Administrator parameter will prompt the user for a credential
# To specify credentials programmatically, see the example below
# The credential specified must be a pre-defined vWorkspace administrator

# $adminCreds = New-Object System.Management.Automation.PSCredential("domain\username", (ConvertToSecureString
  "password" -AsPlainText -Force))

# Connect-DVWFarm -WebApiAddress "http://webApiServer:4500/api/farm/FarmAlias" -Administrator $adminCreds

# .....................................................

# Step 2: First time setup
# .....................................................

# This lets you review the WSM servers already in your vWorkspace farm
Get-DVWSERVER -WSM

# If there is no WSM Core server defined, the line below (New-DVWServer) will let you put one in
# This will only need to be done once ever per farm
# New-DVWServer -Name "wsm-core-server" -AlternateIpAddress "10.4.167.70" -Type "WSMCore"
# This lets you review the settings that allow the vWorkspace api to contact the WSM api
# If they need adjustment (or don’t yet exist), the line below (Set-DVWSETTING) will let you set them

vWorkspace 8.6
Administration Guide 116
# This will only need to be done once ever per farm

Get-DVWSETTING

# Set-DVWSETTING -WSMAPIPort 8082 -WSMuseSSL $false
# .....................................................
# Step 3: Synchronization
# .....................................................
# This synchronizes the WSM servers and then WSM applications

Sync-DVWSERVER
Sync-DVWWSMAPPLICATION
# This lets you review the WSM application layers present in the farm

Get-DVWWSMAPPLICATION
# .....................................................
# Step 4: Publish a WSM Application to a desktop group
# .....................................................
# This lets you review the desktop groups present in the farm

Get-DVWDESKTOPGROUP
# This publishes our application to our desktop group

Publish-DVWWSMAPPLICATIONTODESKTOPGROUP -GroupName “WSM01” -WSMAPPLICATIONName “firefox”
# This lets us review what we just did by listing off all WSM applications published to our desktop group

Get-DVWWSMAplication -GroupName "WSM01"

# ............................................................

# Step 5: Assign a WSM Application to a target

# ............................................................

# This lets you review the targets present in the farm

Get-DVWTarget

# This assigns our application to our target

Publish-DVWWSMAplicationToTarget -WSMAplicationName "firefox" -TargetName "Domain\Domain Users"

# This lets us review what we just did by listing off all WSM applications assigned to our target

Get-DVWWSMAplication -TargetName "Domain\Domain Users"
