• Concept

An active power filter is a large power filter device for real time monitoring of three-phase current and effectively filtering out harmonics by providing an equally opposite phase to the affected component. It is connected in parallel with the grid and uses current transformers to monitor a real time 3-phase current waveform and obtain the required compensation harmonic current and reactive power elements. An active power filter unit creates an opposite current input to the power system and achieves a harmonic filter effect. Using a real current phase compensates a leading/lagging reactive current to improve grid power factor and the compensating reactive power.
