## 1 Purpose

This document describes how to use the Bitext Phrase Extraction API.

## 2 Scope

This document applies to the integration and adaptation of the Bitext Phrase Extraction API, provided by Bitext.

Descriptions and instructions contained in this document might be modified in future versions of this same document.

## 3 Documents

### 3.1 Applicable Documents

---

| Code | Name | Version |
|------|------|---------|
| N/A  |      |         |

---

|  |  |  |
|--|--|--|
|  |  |  |

---

### 3.2 Reference Documents

---

| Code | Name | Version |
|------|------|---------|
| N/A  |      |         |

---

## 4 Definitions and Acronyms

### 4.1 Definitions

---

**Phrase:** *An individual meaningful item within a given text. It will normally correspond to noun phrases, adjectival phrases, verbal phrases, or adverbial phrases.*

---

### 4.2 Acronyms and Abbreviations

---

|                    |   |
|--------------------|---|
| <b>ASCII</b>       | <i>American Standard Code for Information Interchange</i> (character encoding set)  |
| <b>API</b>         | <i>Application Programming Interface</i>  |
| <b>SW</b>          | <i>Software</i>   |
| <b>CSV</b>         | <i>Comma Separated Values</i> – (structured plain text format)  |
| <b>UTF-8</b>       | <i>UCS Transformation Format – 8 bits</i> (character encoding set)  |
| <b>UCS</b>         | <i>Universal Character Set</i> (character set standard)   |
| <b>ISO-8859-1</b>  | Character encoding set based on Latin character set for most Western European languages used mainly in Unix/Linux Operating Systems |
| <b>Windows1252</b> | Character encoding set based on Latin character set for most Western European languages used mainly in Windows Operating Systems    |

---

## 6 REST API

The Bitext Phrase Extraction API can be reached by using the following endpoint:

<https://svc02.api.bitext.com/phrases/>

For this API, the following languages are available: Standard Arabic (MSA), Catalan, Croatian, Czech, Danish, Dutch, English, French, German, Hungarian, Italian, Korean, Norwegian Bokmål, Norwegian Nynorsk, Polish, Portuguese, Romanian, Russian, Persian (Farsi), Serbian, Slovak, Slovenian, Spanish, Swedish, Turkish and Ukrainian.

You must specify the language code as parameter for requests:

| Language              | Code |
|-----------------------|------|
| Standard Arabic (MSA) | arb  |
| Catalan               | cat  |
| Croatian              | hrv  |
| Czech                 | ces  |
| Danish                | dan  |
| Dutch                 | nld  |
| English               | eng  |
| French                | fra  |
| German                | deu  |
| Hungarian             | hun  |
| Italian               | ita  |
| Korean                | kor  |
| Norwegian Nynorsk     | nno  |
| Norwegian Bokmål      | nob  |
| Persian (Farsi)       | fas  |
| Polish                | pol  |
| Portuguese            | por  |
| Romanian              | ron  |
| Russian               | rus  |
| Serbian               | srp  |
| Slovak                | slk  |
| Slovenian             | slv  |

|                  |     |
|------------------|-----|
| <b>Spanish</b>   | spa |
| <b>Swedish</b>   | swe |
| <b>Turkish</b>   | tur |
| <b>Ukrainian</b> | ukr |

A person identification token should be added to all requests. Such a token is typically provided by Bitext after creating an account in the API website, below My Profile > API Credentials. For this document we'll use the example token "tokenprovidedbybitext".

The token must be sent as the value of the Authorization header, and should appear with a bearer. For example, using "curl", you can reach the Bitext API like this:

```
curl -X POST --url https://svc02.api.bitext.com/phrases/ -H "Authorization: bearer tokenprovidedbybitext"
```

If you expect a JSON response, you must also specify so in the headers. You must instantiate the header "Content-Type" with the "application/json" value.

```
curl -X POST --url https://svc02.api.bitext.com/phrases/ -H "Authorization: bearer tokenprovidedbybitext" -H "Content-Type: application/json"
```

The Bitext API works asynchronously. You must first request the API to start analyzing a text. After this first request, you can perform additional requests, until the API eventually returns the correct analysis for the text included in the first request.

The first request is a POST request that sends a JSON with two parameters: language and text. The value of the text parameter corresponds to the text to be analyzed, and the value of the language parameter corresponds to the language of this text.

Currently, the limit of characters per API call is 50.000

For example, in "curl", a first request for the analysis of "Your house is great" will look as follows:

```
curl -X POST --url https://svc02.api.bitext.com/phrases/ -H "Authorization: bearer tokenprovidedbybitext" -H "Content-Type: application/json" --data '{"language": "eng", "text": "Your house is great"}'
```

This request is calling to the "phrasesanalysis" endpoint. The API will immediately return a JSON response that looks like this:

```
{
```

```
"resultid": "9a23759db4ae46d8bfbbab47ac4dff1f",
"success": true,
"message": "Request accepted"
}
```

The **resultid** field in this response is crucial. It will be used to build the subsequent requests asking if the result for a given previous request is already available or not. These new requests are GET type (not POST) and they **MUST** include the **resultid** in the URL. To ask the Bitext API if the results for one of the texts previously sent, you would write the following request with “curl”:

```
curl -X GET --url https://svc02.api.bitext.com/phrases/9a23759db4ae46d8bfbbab47ac4dff1f/ -H "Authorization: bearer tokenprovidedbybitext" -H "Content-Type: application/json"
```

If the analysis is already available, the response to that request would be the following:

```
{
  "resultid": "9a23759db4ae46d8bfbbab47ac4dff1f",
  "phrasesanalysis": [
    {
      "phrase": "house",
      "type": "NP"
    },
    {
      "phrase": "is",
      "type": "VP"
    },
    {
      "phrase": "great",
      "type": "JP"
    }
  ]
}
```

If the analysis is not yet available the (202 HTTP code) will be returned, and you will need to try the same request again.

## 7 Phrase Extraction Analysis

The Bitext Phrase Extraction service provides the relevant phrases and the type of phrase (nominal, verbal, adjectival or adverbial) for a sentence, using syntactic and morphological analysis. For example, for the sentence "The front wheel has a broken spoke", the Phrase Extraction service will return the phrases "the front wheel" (nominal phrase), "has" (verbal phrase) and "a broken spoke" (nominal phrase).

## 7.1 POST Request

### Request

- Endpoint: /phrases/
- Protocol: HTTPS
- URL: https://svc02.api.bitext.com/phrases/
- Method: POST
- Headers:

```
{
  "Authorization": "bearer tokenprovidedbybitext",
  "Content-Type": "application/json"
}
```

- Data parameters:

```
{
  "language": "eng",
  "text": "...
}
```

Being “**text**”, the string you want to analyze.

### Successful responses:

- Code: 201

```
{
  "success": true,
  "message": "Request accepted",
  "resultid": "...
}
```

## 7.2 GET Request

### Request

- Endpoint: /phrases/
- Protocol: HTTPS
- URL: https://svc02.api.bitext.com/phrases/:resultid/
- Method: GET
- Headers:

```
{
  "Authorization": "bearer tokenprovidedbybitext",
  "Content-Type": "application/json"
}
```

Being “**resultid**” the identifier of the analysis request (retrieved by the POST transaction)

Successful responses:

- Code: 202

The analysis with ID “**resultid**” is not yet complete and must be requested again.

```
{
  "resultid": "...
}
```

- Code: 200

```
{
  "success": true,
  "resultid": "...",
  "phrasesanalysis": [
    {
      "phrase": "...",
      "type": "..."
    },
    {
      "phrase": "...",
      "type": "..."
    },
    {
      "phrase": "...",
      "type": "..."
    }
  ]
}
```

- Code 200: The analysis with ID “**resultid**” is complete
- resultid: Identifier of the analysis request (retrieved by the POST transaction and sent in the current request)
- phrase: the extracted phrase
- type: the type of phrase extracted. Types can be “NP” (nominal phrase), “VP” (verbal phrase), “JP” (adjectival phrase) or “AP” (adverbial phrase)

## 7.3 Example

### POST Request

```
-s -X POST --url https://svc02.api.bitext.com/phrases/ -H "Authorization: bearer tokenprovidedbybitext" -H "Content-Type: application/json" -- data '{"language": "eng", "text": "Your house is great"}'
```

### POST Response

```
{
  "success": true,
  "message": "Request accepted",
  "resultid": "123451234512345123451234512345ab"
}
```

### GET Request

```
curl -s -X GET --url https://svc02.api.bitext.com/phrases/123456789abcdefg123456789abcdefg/ -H "Authorization: bearer tokenprovidedbybitext" -H "Content-Type: application/json"
```

### GET Response

```
{
  "resultid": "1b84e78a8655448db6b1730927fba1a2",
  "phrasesanalysis": [
    {
      "phrase": " house",
      "type": "NP"
    },
    {
      "phrase": "is",
      "type": "VP"
    },
    {
      "phrase": "great",
      "type": "JP"
    }
  ]
}
```

## 8 Code Samples

### 8.1 Perl

```
use Mojo::UserAgent;
use Mojo::JSON qw(encode_json);

# User token, required for API access
my $oauth_token = "tokenprovidedbybitext";

# API request data: Language and text to be analyzed
my $user_language = "eng";
my $user_text = "Your house is great";

print "\nBITEXT API. Phrase Extraction endpoint. PERL sample code\n";
print "-----\n\n";

my $ua = Mojo::UserAgent->new;

# Building the POST request to phrase extraction analysis endpoint
my $endpoint = "https://svc02.api.bitext.com/phrases/";
my $headers = { Authorization => "bearer $oauth_token", 'Content-Type' => 'application/json' };
my $params = {"language" => "$user_language", "text" => "$user_text"};

# Sending the POST request
$tx = $ua->post($endpoint, $headers, json => $params);

# Processing the result of the POST request
my $post_result = $tx->res->json->{success};           # Success of the request
my $post_result_code = $tx->res->code;                 # Error code, if applicable
my $post_msg = $tx->res->json->{message};              # Error message, if applicable
my $action_id = $tx->res->json->{resultid};            # Identifier to request the analysis results

print "POST: '$post_msg'\n\n";

# 401 is the error code corresponding to an invalid token
if ($post_result_code == 401)
{
    print "Your authentication token is not correct\n";
}

if ($post_result)
{
    print "Waiting for analysis results...\n\n";
}
```

```
answer # GET request loop, using the response identifier returned in the POST
my $analysis;
until ($analysis)
{
    $tx = $ua->get($endpoint.$action_id.'/ ', $headers);
    eval { $analysis = $tx->res->json };
}

# The loop ends when we have response to the GET request
my $get_msg = $tx->res->message;
print "GET: '$get_msg'\n\n";

# In the GET response we have the result of the analysis
print "Analisys results:\n\n";
print encode_json $analysis;
print "\n";
}
```

## 8.2 Python

```
import requests, json

# User token, required for API access
oauth_token = 'tokenprovidedbybitext'

# API request data: Language and text to be analyzed
user_language = "eng"
user_text = "Your house is great"

print ("\nBITEXT API. Phrase Extraction endpoint. PYTHON sample code\n")
print ("-----\n\n")

# Building the POST request to phrase extraction analysis endpoint
endpoint = "https://svc02.api.bitext.com/phrases/"
headers = { "Authorization" : "bearer " + oauth_token, "Content-Type" : "application/json" }
params = { "language" : user_language, "text" : user_text }

# Sending the POST request
res = requests.post ( endpoint, headers=headers, data=json.dumps(params) )

# Processing the result of the POST request
post_result = json.loads(res.text).get('success')           # Success of the request
post_result_code = res.status_code                         # Error code, if applicable
post_msg = json.loads(res.text).get('message')            # Error message, if applicable
action_id = json.loads(res.text).get('resultid')          # Identifier to request the analysis results

print ( "POST: '" + post_msg + "'\n\n" )

# 401 is the error code corresponding to an invalid token
if ( post_result_code == 401 ):
    print ( "Your authentication token is not correct\n" )

if ( post_result ):
    print ( "Waiting for analysis results...\n\n" )

    # GET request loop, using the response identifier returned in the POST answer
    analysis = None
    while analysis == None:
        res = requests.get(endpoint + action_id + '/', headers=headers)

        if res.status_code == 200 :
            analysis = res.text
```

```
# The loop ends when we have response to the GET request
get_msg = res.reason
print ( "GET: '" + get_msg + "'\n\n" )

# In the GET response we have the result of the analysis
print ( "Analysis results:\n\n" )
print ( analysis )
print ( "\n" )
```

## 8.3 Ruby

```
require 'httpclient'
require 'json'

# User token, required for API access
oauth_token = 'tokenprovidedbybitext'

# API request data: Language and text to be analyzed
user_language = 'eng'
user_text = "Your house is great"

puts ''
puts 'BITEXT API. Phrase Extraction endpoint. Ruby sample code'
puts '-----'
puts ''

clnt = HTTPClient.new

# Building the POST request to phrase extraction analysis endpoint
endpoint = "https://svc02.api.bitext.com/phrases/"
headers = { "Authorization" => "bearer " + oauth_token, "Content-Type" => "application/json" }
params = { "language" => "" + user_language + "" , "text" => "" + user_text + "" }
        .to_json

# Sending the POST request
res = clnt.post(endpoint,params,headers)

# Processing the result of the POST request
content = JSON.parse(res.content)

post_result_code = res.status # Error code, if applicable
action_id = content["resultid"] # Identifier to request the analysis results
post_msg = content["message"] # Error message, if applicable
post_result = content["success"] # Success of the request

puts 'POST: ' + post_msg
puts ''

# 401 is the error code corresponding to an invalid token
if ( post_result_code == 401 )
    puts 'Your authentication token is not correct'
end
```

```

if ( post_result )

    puts 'Waiting for analysis results...'
    puts ''

    # GET request loop, using the response identifier returned in the POST
answer
    analysis = ""

    while analysis == "" do

        res = clnt.get(endpoint + action_id + "/", {}, headers)
        if res.status == 200
            analysis = res.content
        elsif res.status != 202
            puts "GET: Error code (#{res.status}), message: " +
res.reason
                exit
        end
    end

    # The loop ends when we have response to the GET request
    get_msg = res.reason
    puts 'GET: ' + get_msg
    puts ''

    # In the GET response we have the result of the analysis
    puts 'Analysis results:'
    puts ''
    puts analysis
    puts ''
end

```

## 8.4 Java

```
import java.net.HttpURLConnection;
import java.net.URL;
import java.io.*;
import org.json.JSONObject;

public class codeSample {

    // User token, required for API access
    public static String oauth_token = "tokenprovidedbybitext";

    // API request data: Language and text to be analyzed
