Aquamizer F - Flocculation
Waste Water Treatment System

Flocculation Water Treatment

Flocculation is a chemical process in which a suspending agent binds to contaminants in water to remove them. The contaminants bound to the agent are filtered from the water and then disposed. It is used in a wide variety of water treatment applications such as drinking water purification, sewage treatment and industrial waste water treatment. By removing the contaminants in an industrial water stream, manufacturers can significantly reduce their waste disposal costs as the treated water can either be reused or put into the sewage system. Many water based paints, coatings and rinsing agents can be purified well with flocculation. As each system is designed based on your specific waste stream and volumes, please contact us and we will help analyze your needs and suggest a system for you.
