CLINICAL PHARMACOLOGY & THERAPEUTICS
VOLUME 46 NUMBER 6 DECEMBER 1989

COMMENTARY

Clinical pharmacology and the choice between theory and empiricism

Lewis B. Sheiner, MD *San Francisco, Calif.*

Empiricism

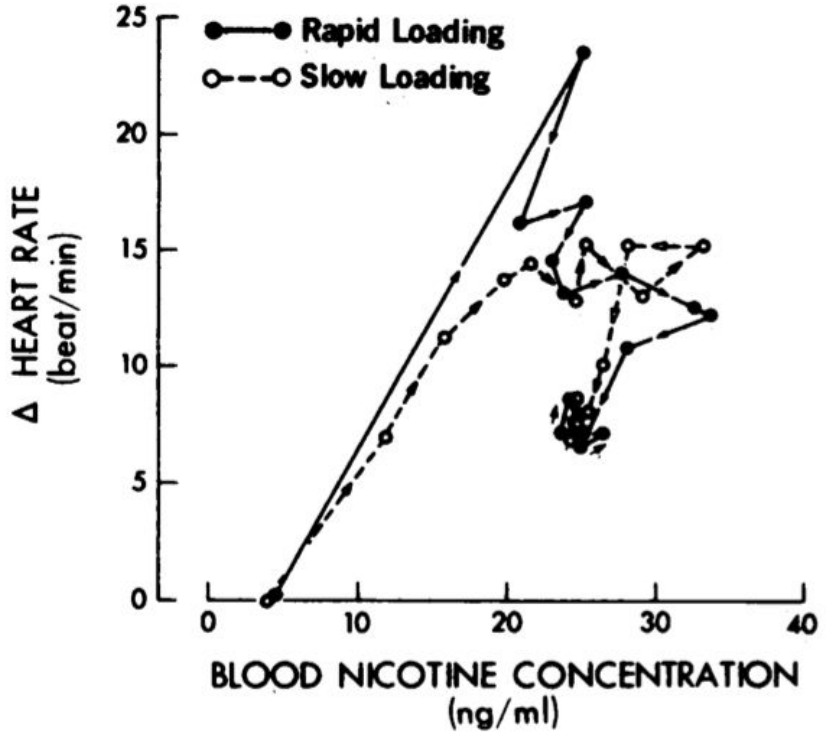

Figure 4. Average increase in heart rate plotted against the simultaneous mean forearm venous blood concentrations of nicotine for the two infusion protocols (see legend of Fig. 3). The points are connected in time order.

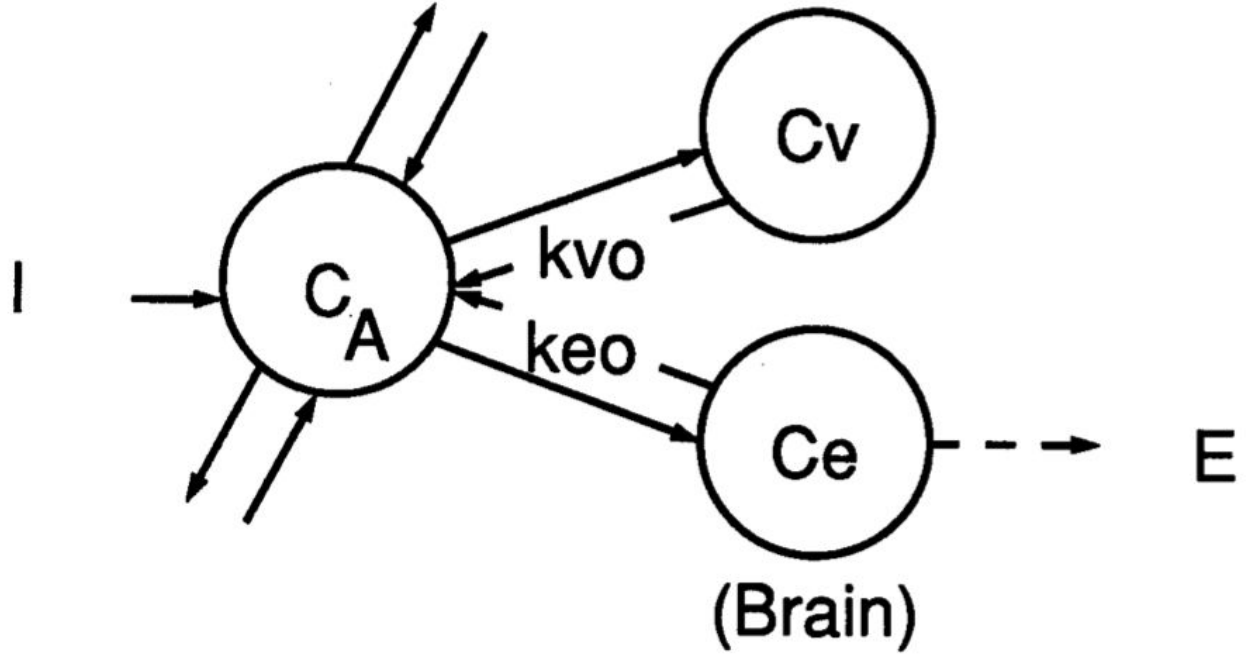
HC Porchet, NL Benowitz, LB Sheiner, JR Copeland. J. Clin. Invest. 80, 1466-1471, 1987.

Theory



LB Sheiner. Clin. Pharmacol. Ther. 46, 605-615, 1989.

Informed Empiricism

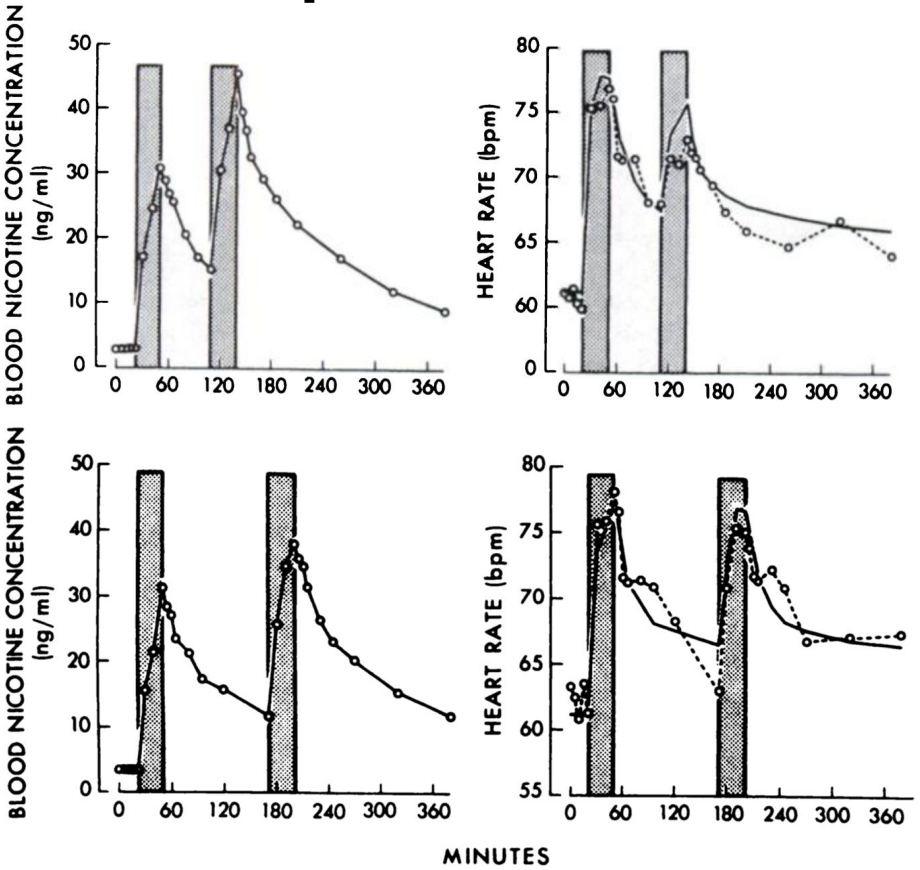


Fig. 2. Mean blood concentrations of nicotine (left panel) and the corresponding mean heart rate (right panel) in eight subjects after two 30-min i.v. infusions of 25 μg/kg/min of nicotine beginning 1 hr apart (treatment A; see text). The shadowed area indicates the periods during which nicotine was infused. The solid line in the right panel shows the fit of the model of figure 1 to the effect data.

Fig. 3. The same as figure 2 for two 30-min infusions of nicotine as for treatment A, but beginning 2 hr apart (treatment B).

HC Porchet, NL Benowitz, LB Sheiner. J. Pharmacol. Exp. Ther. 244, 231-236, 1988.

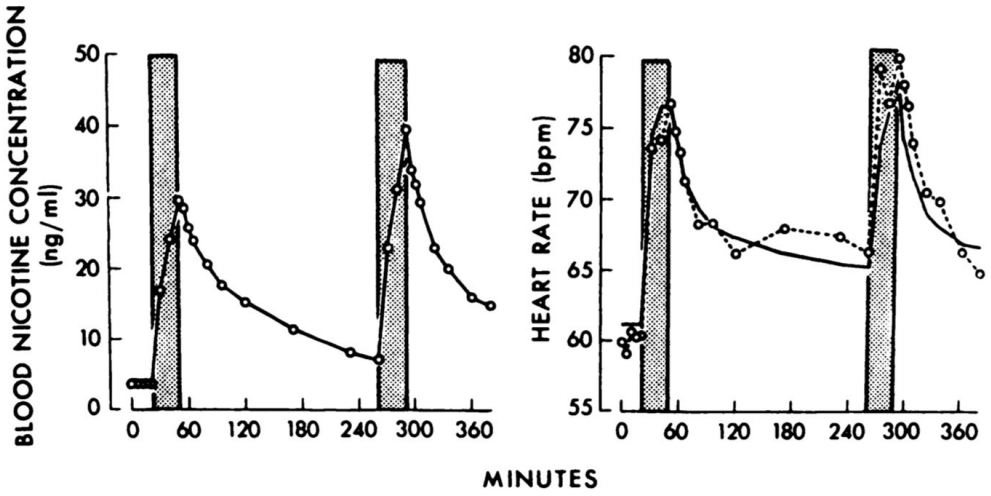

Fig. 4. The same as figure 2 for two 30-min infusions of nicotine as for treatment A, but beginning 3.5 hr apart (treatment C).

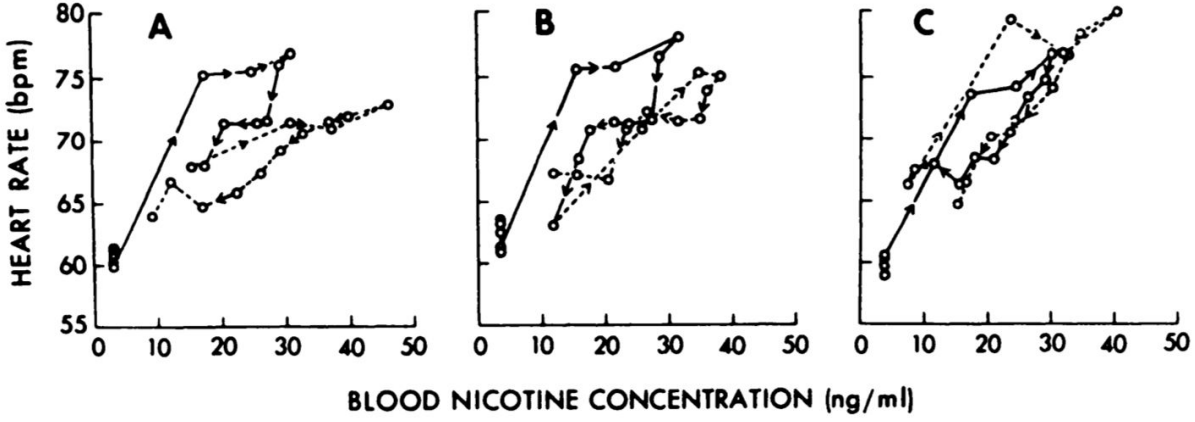

Fig. 5. Mean heart rate plotted against simultaneous mean blood concentrations of nicotine (hysteresis loops) for treatments A, B and C. The solid line correspond to the first infusions; the dashed lines correspond to the second infusions. Arrows indicate the progression of time during and after nicotine infusion.

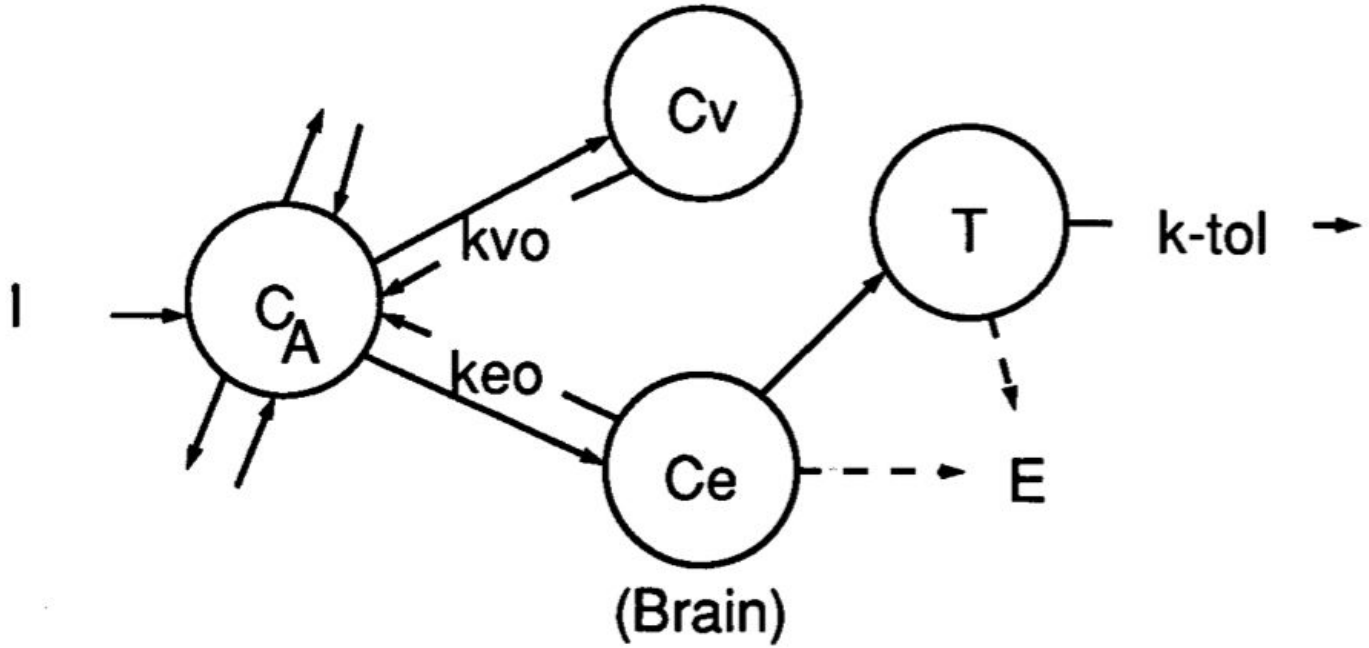
HC Porchet, NL Benowitz, LB Sheiner. J. Pharmacol. Exp. Ther. 244, 231-236, 1988.

Revised Theory



LB Sheiner. Clin. Pharmacol. Ther. 46, 605-615, 1989.

Application of the Theory

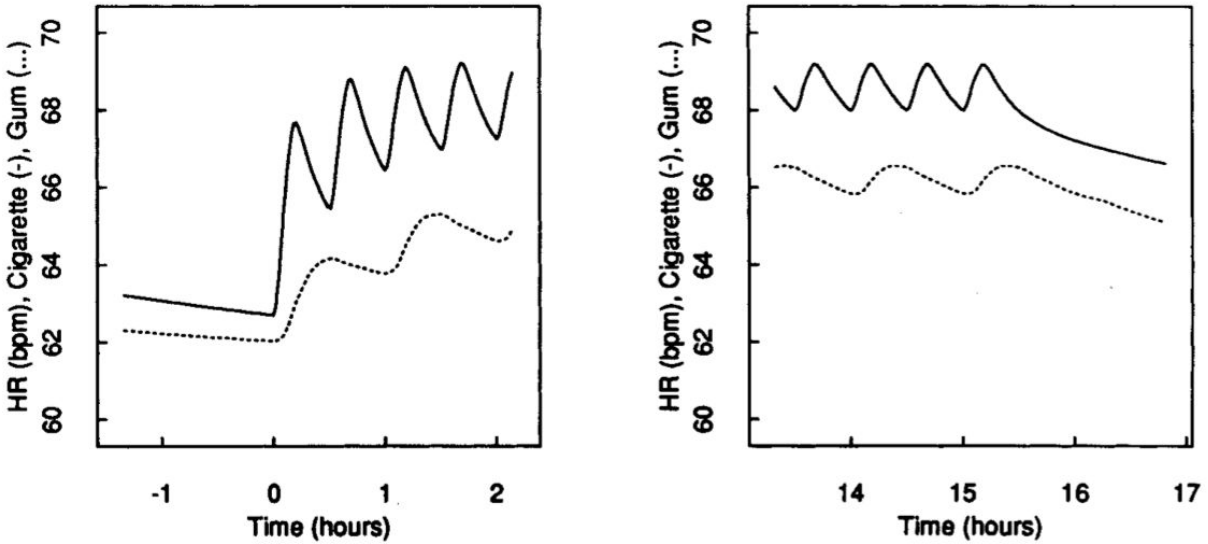


Fig. 9. Simulation of HR response (ordinate) to usual daily intake of cigarettes (——) or gum (- - -) versus time of day. Simulation with model of Fig. 4, fit of Fig. 5, and individual input functions from Figs. 7 and 8. **Left panel**, morning—intake begins after ovenight abstinence. **Right panel**, evening—input ceases for sleep.

LB Sheiner. Clin. Pharmacol. Ther. 46, 605-615, 1989.

“Thus, by going beyond empiricism and stressing understanding, not data collection, we not only answer our first question, but we also gain far more. For clinical pharmacology, as for all other sciences, the goal is theory, not data. The pursuit of theory involves both induction (imagination) and deduction (with subsequent empiric verification); one is useless without the other. If theory is kept as the goal, it will not only be more aesthetically satisfying, but will inevitably lead to insight and technique applicable far beyond the original locus of study. In short, and in truth, there is nothing so practical as a good theory.”

LB Sheiner. Clin. Pharmacol. Ther. 46, 605-615, 1989.

Diagnostics for Time-Variant Pharmacodynamics

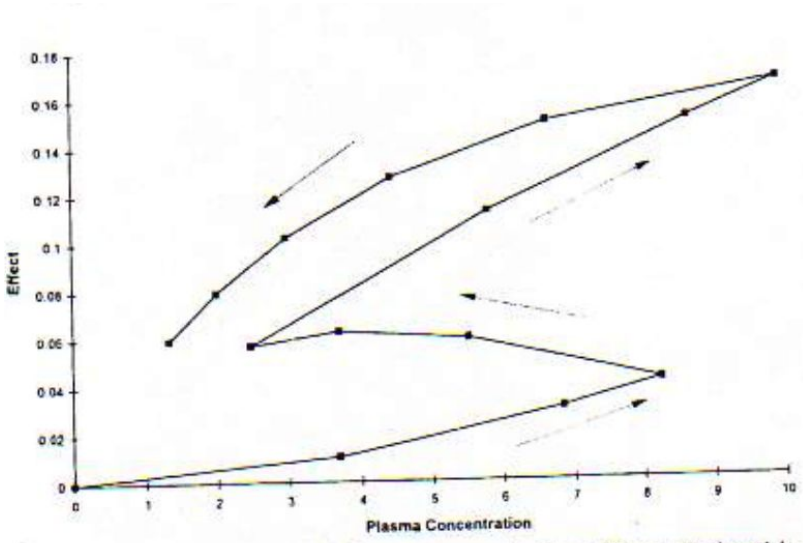

Figure 1: Model-simulated plasma concentration-effect relationship of a multiple infusion experiment showing sensitization. The pharmacodynamic model in this simulation generated an effect which was proportional to plasma drug concentration and sensitized with time. Effect and concentration are expressed in arbitrary units. Arrows indicate the sequence of events over time.

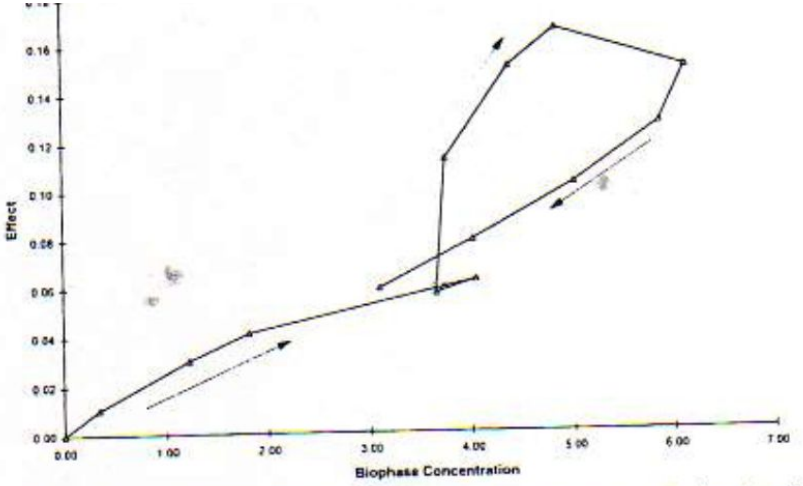

Figure 3: Pharmacodynamic system analysis of the model-simulated multiple infusion experiment with sensitization. The entire data set (0 to 50 minutes) from the multiple hysteresis simulation shown in Figure 1 was analyzed with ATTRACT. The resulting biophase concentration-effect relationship is shown. Effect and concentration are expressed in arbitrary units. Arrows indicate the sequence of events over time.

MR Gastonguay, SL Schwartz. Pharm. Res. 11, 1825-1828, 1994.

Theory-Driven Science: Influence on My Work

Bayesian Modeling Methods and Tools	Pediatric Dosing, Trial Design, and Extrapolation	Simulation with Uncertainty & Global Sensitivity Analysis	Big Data and Causal Inference in Pharmacometrics
Nonlinear Dynamics in PKPD Modeling	Covariate Modeling	Missing Data in Pharmacometric Analyses	Dose Selection and Trial Designs in Rare Diseases

Design & Empirical Data: Non-Random Dropout

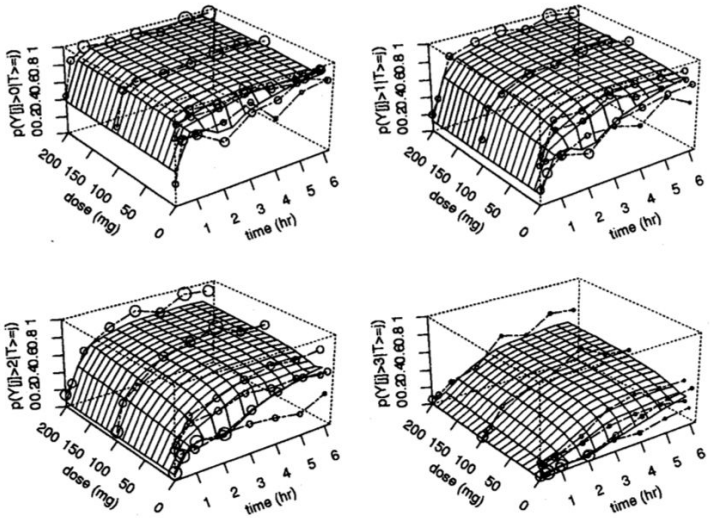

Figure 5. $p(Y_j > m | T \geq j)$, Denoted by $p(Y[j] > m | T >= j)$, Versus Dose and Time for m = 0 (Upper Left), 1 (Upper Right), 2 (Lower Left), and 3 (Lower Right). Data-based estimates of the appropriate quantities, obtained as described in the legend to Figure 4, are shown in all panels. As for Figure 4, the circles are proportional to the reciprocal standard errors of the data-based estimates.

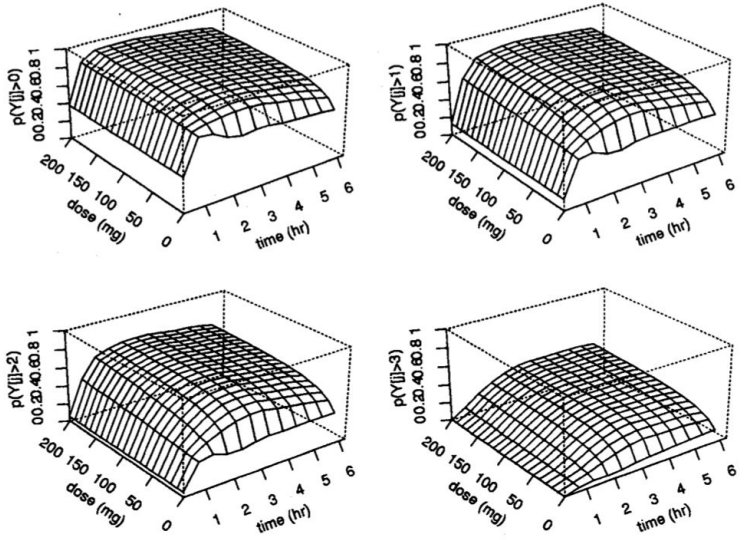

Figure 6. $p(Y_j > m)$, Denoted by $p(Y[j] > m)$, for m = 0–3 Versus Dose and Time. See the legend to Figure 5.

Subject: Re: BQLs

Date: Tue, 26 Jun 2001 09:32:34 -0700

This has been discussed before ...

First, let's be clear on what is the "right" thing to do in principle. If you are using ML, then the right thing to do is use the marginal likelihood, integrating out the "missing value", that is, if the usual likelihood contribution for datum y is L(y) = p(y|params), and y is censored (i.e., known to be < QL, but not known further), then the likelihood contribution should be L*(y) = p(y<=QL|params) = Integral[p(y|params)dy], where the integration is from -infinity to QL. In the case of normal residual noise with var = sigma**2, this would be the CDF of a Standard Normal density (i.e. with mean = zero and variance = 1) evaluated at (QL-yhat)/sigma, where yhat = E(y|params) -- in fact the "Y" usually defined in $ERROR.

Here are the two approximations Pete discusses: [*detail omitted*]

Growing the Science: LBS

COURSES ON POPULATION PHARMACOKINETIC DATA ANALYSIS USING THE NONMEM SYSTEM

BASIC COURSE

Kyoto, Japan (1989),
San Franciso, CA (1990,92,93,95,97)
Lyon, France (1991,93,97,01),
Uppsala, Sweden (1995,99)
Rockville, MD (1998).

INTERMEDIATE WORKSHOP

San Francisco, CA (1992,93,95,97),
Lyon, France (1993,97,01),
Uppsala, Sweden (1995, 99),
Rockville, MD (1998).

BASIC AND INTERMEDIATE LEVEL SHORT COURSE
Uppsala, Sweden (2003)
