Sponsored: Manufacturing & Service Oper. Mgmt/Sustainable Operations

Sponsored Session

Chair: Gokce Esenduran, Purdue University, West Lafayette, IN, 47907, United States

1 - Implementing Environmental and Social Responsibility Programs in Supply Networks Through Multi-Unit Bilateral Negotiation

Chengzhang Li, Purdue University, West Lafayette, IN, 47907-2056, United States, Annabelle Feng, Mengshi Lu, George Shanthikumar

We study ensuring environmental and social responsibility (ESR) in general supply chain networks through multi-unit bargaining. We derive the equilibrium negotiation outcome, which captures the imbalance of the bargaining power in the supply chain, and demonstrate its advantages over existing approaches. We also investigate the initiator's preferred implementation structure and various extensions including multiple ESR effort levels, sequential formation of ESR relationships, and multiple ESR programs.

2 - Sustainability in Fashion Industry: A Case for On-demand Production

Adem Orsdemir, University of California-Riverside, Riverside, CA, 92521, United States, orsdemir@ucr.edu, Aydin Alptekinoglu

In recent years, fashion industry has been identified as the one of the biggest polluters of the environment. Several fashion retailers, including Burberry, H&M and Nike, have been accused of burning their left-over inventory. In fact, Burberry has admitted to doing so. Thus overproduction is one of the fundamental sustainability issues in fashion. To tackle the overproduction problem, on-demand customized production is suggested as one of the remedies. In this research, we characterize when on-demand customized production indeed reduces the environmental impact of fashion industry.

3 - Manufacturer's Voluntary Environmental Efforts under Product Ban Uncertainty

Wenli Xiao, University of San Diego, San Diego, CA, 92110, United States, wenlixiao@sandiego.edu, Ximin (Natalie) Huang, Aditya Vedantam

We study a manufacturer's voluntary environmental efforts as a preemptive strategy against potential regulatory action to ban future sales of the product. The manufacturer can exert voluntary efforts by increasing the product's recycling rate and develop a substitute product, to influence the regulator to reduce the level of product ban. We show how the potential for a future product ban impacts the manufacturer's recycling rate decision on an existing product and its effort to develop a greener substitute product. In addition, we provide the insights of how the manufacturer can influence the regulator to relax the strictness of a product ban.

4 - Laissez-Faire versus Intervention: Implications of Regulation Preventing Unauthorized Remanufacturing

Minyue Jin, Chongqing University, Chongqing, China, minyuejin@cqu.edu.cn

To ensure that remanufactured products are as good as new, the Chinese government enacted regulations to prevent unauthorized remanufacturing, i.e., independent remanufacturers (IRs) are not allowed to carry out remanufacturing unless they obtain authorization from original equipment manufacturers (OEMs). While in the US, this kind of regulation does not exist. This regulation seems benefit the OEMs but hurt the IRs because it enables OEMs to prevent unauthorized remanufacturing. We find that the OEM benefits from this regulation. However, the regulation could also benefit the IR. The reason is that free opportunity of unauthorized remanufacturing can cause a prison's dilemma to the OEM (IR).

Simulation-Supported Decision-making in Healthcare

Sponsored: Decision Analysis

Sponsored Session

Chair: Aditya Umesh Kulkarni, Virginia Commonwealth University, Glen Allen, VA, 23059, United States

Co-Chair: Christian Wernz, Virginia Commonwealth University - VCU, Richmond, VA, 23298, United States

1 - Assessing the Impact of Emergency Department Admissions for Grey Area Patients

Sebastian Alvarez Avendano, University of Wisconsin-Madison, Madison, WI, United States, alvarezavend@wisc.edu, Amy Cochran, Brian Patterson, Gabriel Zayas-Caban

Often, it is assumed that the decision to admit a given patient is based on black and white clinical factors. While this is true in some cases, many patients fall into a gray area without clear evidence-based guidelines suggesting admission or discharge as the best course of care. Using observational data, we seek to determine to what extent admissions impoves outcomes for a specific "gray area" patient population: elderly patients in the emergency department presenting with chest pain.

2 - Appointment Scheduling in Primary Care with Recurring Visits

Hari Balasubramanian, Univ of Massachusetts-Amherst, Amherst, MA, 01003, United States, hbalasubraman@ecs.umass.edu, Prashant Meckoni

Traditional queuing systems schedule incoming customers in a queue waiting for service according to some predefined policy—including first in first out (FIFO), shortest job first, or priority queuing. Appointment based schedules used in many primary health care providers follow a different queuing policy. Patients may schedule their appointment several weeks ahead of their desired date. Early scheduling may fill up all slots up to a day much in advance, and may restrict other patients needing those slots at a shorter timeline. Using a simulation model, we explore the use of reservations in handling patients who frequently need to see their doctor at a short notice as compared to most other patients.

3 - Surgical Capacity Allocation via Simulation: The Case of Breast Surgery

Derya Kilinc, Arizona State University, Tempe, AZ, United States, Derya.Kilinc@asu.edu, Narges Shahraki, Kalyan Pasupathy, Esma S. Gel, Amy Degnim, Mustafa Y. Sir

The breast surgical practice at Mayo Clinic, Rochester has experienced an increase in the number of patients with complex conditions in recent years. This caused longer patient care delays and increased workload for the existing resources. We develop a decision tree model to characterize the demand complexity and a simulation tool to quantify the relationship between patient demand (volume, complexity, and trend) and capacity utilization and measure its effect on patients waiting time. Our simulation tool can be utilized to accurately predict and plan the capacity to avoid prolonged waiting times in providing care.

4 - A Simulation Optimization Approach to Real-time Behavioral Therapy in the Medication Assisted Treatment Model of Care

Carolina Vivas-Valencia, Purdue University, West Lafayette, IN, 47906, United States, Nan Kong, Yunan Liu, Paul Griffin

Medication-Assisted Treatment (MAT) is an approach that can be combined with behavioral therapy to treat substance use disorders. Behavioral therapy may help improve adherence to MAT; however, resources such as professional counseling personnel, are not always available. Volunteers can be recruited as peer recovery coaches in this model of care to provide behavioral therapy via an online platform. We develop a simulation-optimization approach to support this and present management insight into emerging digital technology for efficient therapy delivery.

5 - Data-calibrated Agent-based Simulation for Electronic Health Record Downtime Contingency Planning

Christian Wernz, Virginia Commonwealth University, Richmond, VA, 23298, United States, Aditya Umesh Kulkarni, Ethan Larsen, Carlos Rivera, Raj Ratwani

Developing effective Electronic Health Record (EHR) downtime contingency plans for hospital staff is an important challenge for healthcare organizations, but testing such a plan is difficult in practice. Based on real-world data collected at a hospital, we constructed an agent-based model of their emergency department and clinical laboratory. By simulating the agent-based model, we evaluated the effectiveness of different contingency plans to compare their performance and identify the best plan. Our approach allows hospitals to develop, test and optimize various EHR downtime contingency plans without disrupting patient care.

Revenue Management, Pricing I

Contributed Session

Chair: Bobby Nyotta, UCLA Anderson School of Management, Valencia, CA, 91355, United States

1 - Product Quality and Quantity with Responsive Pricing

Yanjun Wang, University of Science and Technology of China, Hefei, China

We study a firm's joint product quality and quantity decisions when the firm uses responsive pricing policy. Consumers differ in two dimensions: quality valuation and reservation utility for the basic product. Quality valuation reflects the intrinsic heterogeneity of consumers and is, hence, always unknown to the firm. Reservation utility is affected by extrinsic market conditions and can, hence, be updated after production. We find that as reservation utility increases or quality valuation decreases, the optimal quantity increases and, counterintuitively, the optimal quality decreases. Furthermore, the firm might not be willing to expand its product line even if given an option to do so.

2 - Randomized Pricing with Consumer Stockpiling

Burak Gokgur, Asst. Prof., Sabanci University, Istanbul, Turkey, bgokgur@sabanciuniv.edu, Selcuk Karabati

We consider a retailer with customers that are heterogeneous along the product valuation and storage capacity dimensions. The retailer's objective is to maximize the expected revenue with a randomized pricing strategy. We discuss the conditions when randomized pricing strategy serves as an intertemporal price discrimination mechanism, and, through a numerical study, we quantify its impact on revenue.

3 - Development of Collaborative Consumption Pricing: An Econometrics Model Approach of Airbnb

Funda Sarican, PhD Student, Bentley University, Boston, MA, United States, fsarican@bentley.edu

On one hand, the sharing economy provides new opportunities on the other hand, it is also raising several issues as more incidents arise concerning bypassing laws. More and more well-known sharing economy companies such as Airbnb, and Uber are struggling against regulation. In order to deal with issues such as consumer and supplier safety, and competitive fairness, some of the cities has begun to practice regulations. The aim of this paper is to determine the effect of these regulations on pricing. In this paper, I apply Difference-and difference (DD) method to identify causal effect and remove unobservable factors that vary in time and listing/room level.

4 - Capacity and Pricing Optimisation in the Presence of Ancillary Items

John G. Wilson, Ivey Business School, London, ON, Canada, jwilson@ivey.ca

Many applications exist where ancillary products are sold with a primary item. E.g., warranties is often offered to those who buy television sets. This has become even more important in the airline industry where ancillary products such as baggage fees have become vital to the financial health of the industry. The question of what price to charge for the primary and ancillary products will be investigated. We look at the optimal assignment of capacity, e.g., the size of an aircraft to assign to a particular route. It is shown that the optimization of prices when demand functions are linear reduces to the solution of a system of linear equations and the optimization of a one variable function.

5 - Dynamic Pricing of Reusable Resources: Experiments, Estimation, and Optimization of On-street Parking

Bobby Nyotta, UCLA Anderson School of Management, Los Angeles, CA, United States, bobby.nyotta.1@anderson.ucla.edu, Fernanda Bravo, Keith Chen

Motivated by dynamic pricing of on-street parking, we analyze a general framework to determine the optimal prices in a system with multiple zones where each zone contains a finite number of reusable resources. We consider a demand model with imperfect substitution, where a price increase for one zone may lead customers to use a different, adjacent zone. First we develop a pricing model to determine optimal set of prices. Second, using real data from a natural pricing experiment in a large metropolitan city, we estimate price and spatial elasticities.

Economic Impact

Contributed Session

Chair: Suning Zhu, Trinity University

1 - Mergers Between On-demand Service Platforms: The Impact on Consumer Surplus and Labor Welfare

Tao Lu, Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands, lu@rsm.nl, Xiaogang Lin, Xin Wang

We study two on-demand service platforms competing in a two-sided market in which customers are waiting time-sensitive and agents provide service based on expected earnings. While a merger reduces competition, we show that customers may benefit from a merger due to the risk-pooling effect; moreover, if customers are sufficiently sensitive to delay, this benefit can spill over to the labor force via cross-side network externalities. We further establish that a win-win-win outcome, in which merging firms, customers and agents are all better off, can be achieved if the merged platform commits to certain ratios between prices and wages.

2 - Studying Quantity Discount and Market Share Contracts under Congestion

Sumanta Singha, Indian School of Business, Hyderabad, India, sumanta_singha@isb.edu, Rajib L. Saha, Subodha Kumar

Unlike in quantity discount contracts, discount can be based on the share of demand the buyer allocates to the seller; typically known as market share contract. We study and compare the optimal decisions of a buyer and a strategic seller under both types of contracts given the demand is congestion sensitive.

3 - A Longitudinal Investigation on Economic Impact of Organizational Big Data and Analytics Implementation

Suning Zhu, Trinity University, San Antonio, TX, United States, Jiahe Song

This study investigates the impact of three aspects of big data and analytics (BDA) implementation (i.e., BDA implementation scope, frequency, and objective) on firm profitability. In addition, we examine the role of BDA human competency in moderating the economic impact of BDA implementation. To perform credible causal evaluation, we construct a panel data set by collecting related information about enterprise BDA and profits from major news sources, Compustat database, and Linkedin between 2010 and 2018. This study contributes to knowledge-based view, complementary theory, and BDA literature. Practical insights from this research are generated for decision makers looking to implement BDA.

4 - Logistics Service Sharing in Dual-online-Channel Supply Chain

Ping He, South China University of Technology, Guangzhou, China, Shanshan Zhang

Logistics service sharing (LSS) becomes increasingly common in E-commerce. We study the impact of LSS on a dual-online-channel supply chain composed of a retailer (LSS provider) and a manufacturer (potential LSS receiver). We find that higher competition intensity level stimulates the retailer to condense delivery lead time without LSS, but to prolong it with LSS. There exists a decision space to let the two firms Pareto improved, but it shrinks a lot if the competition intensity level is relatively high. Furthermore, the social welfare may be decreased with LSS even when the two firms are Pareto improved.

5 - Mining Public Perception – Blockchain-based Services in Mainstream Media

Christopher Grossmann, EBS Universitaet fuer Wirtschaft und Recht, Wiesbaden, Germany, christopher.grossmann@gmail.com, Katrin Merfeld, Sven Henkel

Despite the media hype and increasing market penetration of blockchain-based services, adoption happens slowly outside the universe of cryptocurrency, and blockchain enthusiasts. Actual customer perception remains uncertain and despite the technology's objective benefits, first insights suggest that customers developed negative associations. To exploit blockchain-based features for overcoming adoption barriers of services, adequate communication is essential. This paper provides an overview of the past and current connotation of blockchain-focused news articles by applying a multi-perspective text mining approach.

Empirical Research in Retail Operations

Sponsored: Service Science

Sponsored Session

Chair: Hyun Seok (Huck) Lee, College of Business, Oregon State University, Corvallis, OR, 97330, United States

1 - M-commerce, Sales Concentration, and Inventory Management

Tom Fangyun Tan, Southern Methodist University, Dallas, TX, 75275, United States, ttan@cox.smu.edu, Nitish Jain

We examine the differences in primary online channels - mobile and PC - on shaping sales concentration across products and the cost of ignoring such a difference on inventory management, a core decision for operations managers. We identify the mobile channel's effect on sales concentration using a difference-in-differences strategy that leverages a quasi-experiment stemming from the retailer's decision to discontinue its PC sales channel. We find that the mobile channel increases the share of popular products by 5% as compared with the PC channel. We also identify scenarios where ignoring this significant sales concentration difference will yield sub-optimal inventory stocking by 6.1% to 17.7%.

2 - An Investigation of Peer Effects on Grocery Store Check-out Productivity

Hyun Seok (Huck) Lee, College of Business, Oregon State University, Corvallis, OR, 97330, United States, HyunSeok.Lee@oregonstate.edu, Guanyi Lu, Junbo Son

Using an operational data set in a grocery store setting, we examine how a cashier's productivity level affects other cashiers' performance. Contrary to the literature which suggests positive peer effects in retailing setting, we find employees tend to reduce their efforts (i.e., free-riding) when working with productive peers. In addition, full-time employees reduce their efforts more than part-time employees. Using an alternative measure, we find more experienced employees (hours worked) free-ride more than less experienced employees. We propose suggestions for retailers to address this issue.

3 - Execution Failures in Supply Chains - A Virtual Reality Experiment

Nicole DeHoratius, University of Chicago, 15345 SW Lark Lane, Beaverton, OR, 97007, United States

We conduct a real-effort experiment in a virtual reality context to explore key drivers of execution failures in retail supply chains. We find task intensity and task complexity impact worker output and accuracy. We test the impact of product/packaging design changes on task performance.

4 - The Reference Effect of Delay Announcements: A Field Experiment

Qiuping Yu, Georgia Institute of Technology, Atlanta, GA, 47405-1701, United States, Gad Allon

We explore whether customers are loss averse in time and how delay information impacts such reference-dependent behavior via a field experiment at a call center. Customers are provided with delay announcements or no announcements in a quasi-randomized manner in our field experiment. We show that customers are loss averse regardless of the announcements, (especially when the waiting time is relatively long). While delay announcements do not alter the fact that customers are loss averse, they may facilitate more granular learning of the offered waiting time and thus impact the reference point. Through counterfactual studies, we demonstrate the managerial implications of our behavioral insights.

4 - Execution Failures in Supply Chains – A Virtual Reality Experiment

Özgür Gürerk

We conduct a real-effort experiment in a virtual reality context to explore key drivers of execution failures in retail supply chains. We find task intensity and task complexity impact worker output and accuracy. We test the impact of product/packaging design changes on task performance.

5 - The Reference Effect of Delay Announcements: A Field Experiment

Achal Bassamboo

We explore whether customers are loss averse in time and how delay information impacts such reference-dependent behavior via a field experiment at a call center. Customers are provided with delay announcements or no announcements in a quasi-randomized manner in our field experiment. We show that customers are loss averse regardless of the announcements, (especially when the waiting time is relatively long). While delay announcements do not alter the fact that customers are loss averse, they may facilitate more granular learning of the offered waiting time and thus impact the reference point. Through counterfactual studies, we demonstrate the managerial implications of our behavioral insights.

6 - Execution Failures in Supply Chains – A Virtual Reality Experiment

Dorothee Honhon, Kyle Hyndman

We conduct a real-effort experiment in a virtual reality context to explore key drivers of execution failures in retail supply chains. We find task intensity and task complexity impact worker output and accuracy. We test the impact of product/packaging design changes on task performance.

Transform Healthcare and Retail through Analytics

Sponsored: Service Science

Sponsored Session

Chair: Seokjun Youn, The University of Arizona, Texas A&M University, College Station, TX, 77840-4217, United States

1 - Can Information Technology Improve Inter-generational Health Outcomes of Mothers and of Babies?

Min Chen, Florida International University, Miami, FL, United States, mchen2@fiu.edu, Monica Chiarini Tremblay, Rajiv Kohli

While information technology (IT) holds great promise for improving the quality and efficiency of care and for lowering the health care costs, it is far from certain whether and how electronic health records improve maternal and infant well-being and lower future risk in outcomes. This study constructs a unique dataset that includes rich information about medical interventions as well as a battery of maternal and birth outcomes to investigate the effect of electronic health records in the context of intergenerational health.

2 - Identifying Determinants of Market Share of Specialists: Empirical Investigation

Lavlin Agrawal, State University of New York-Buffalo, Buffalo, NY, 14228, United States, Saeede Eftekhari, Niam Yaraghi, Ram Gopal, Ramaswamy Ramesh

This study is focused on identifying the factors which impact the market share of specialists in terms of patients they receive from other specialists and primary care physicians. We apply econometric analysis to model the patient share of specialists using three categories of variables: competition variables which pertain to availability of the physicians with the same specialty in the area, supply variables which pertain to availability of the physicians who can serve as patients suppliers for the specialists, and physician variables which pertain to the attributes of physicians. The findings of this study has significant implication for health policy makers and healthcare providers.

3 - Does Sharing Make My Data More Insecure? An Empirical Study on Health Information Exchange and Data Breaches

Leting Zhang, Temple Universisty, Philadelphia, PA, 19122, United States, Min-Seok Pang, Sunil Wattal

This paper examines the security implications of participation in inter-organizational systems (IOS) in the context of the healthcare industry. Specifically, we ask - how does joining in a Health Information Exchange (HIE) affect hospitals' data breach risks? We study this issue using a six-year panel data from multiple sources on HIE participation and data breaches. Our results show that joining in an HIE decreases a hospital's probability of a data breach. We also find that this mitigation effect is stronger for hospitals with a higher IT security capability. Surprising, a higher HIE participation rate also lowers the risks in hospitals that are not in the HIE in the same region.

4 - How Customers Choose Among Different Products: Organic, Conventional, and Other Attributes

Zhihao Zhang, University of South Carolina, Columbia, SC, 29033, United States, Sriram Venkataraman, Yan Dong, Mark Ferguson

Using scanner panel data retailers, we examine how customers choose between different attributes of organic and conventional products. In particular, we estimate own-price and cross-price elasticities under different nesting options. Further, we estimate own-elasticity of different variables.

■ TE29

CC- Room 4C-4

Joint Session AMD/Practice Curated: Signaling in Auctions

Sponsored: Auction and Market Design

Sponsored Session

Chair: Olivier Bos, Pantheon-Assas University

1 - Optimal Auction with Signaling Concerns

Olivier Bos, Pantheon-Assas University, Paris, 75006, France, Martin Pollrich, Tom Truyts

We study optimal auctions in a symmetric private values setting with signaling. Every bidder cares about winning the object, but also about an outside observer's inference on her own type. The signaling motive leads to a failure of revenue equivalence. We determine the optimal auction for concave and convex bidders' utilities when they care only about the statistical mean of the observer's inference. For the special case that bidders' utilities depend linearly on the outsider's inference we prove revenue equivalence for auctions with entry fees. Entry fees allow the designer to extract the signaling value of every bidder and thus restores revenue equivalence.

2 - Price Effects of Supply and Demand in Multi-unit Auctions with Affiliated Values

Marion Ott, ZEW, Templergraben 64/V, Mannheim, 52062, Germany, Karl-Martin Ehrhart

We vary the number of units and bidders in multi-unit auctions with affiliated values and single-unit demand. The sampling effect of the signals and the winner's curse correction in the bids have opposed influence on the expected price per unit. In a uniform-price auction with common values and affiliated signals, the expected price per unit increases in the number of units, and, unless there are no more than twice as many bidders as units, also in the number of bidders. Thus, for large numbers of bidders both changes increase the price whereas for low numbers of bidders both changes influence the price in the opposed direction than in the pay-as-bid auction.

3 - VCG, the Core and Assignment Stages in Auctions

Oleg V. Baranov, University of Colorado-Boulder, Boulder, CO, 80309, United States, oleg.baranov@colorado.edu, Lawrence M. Ausubel

The Vickrey-Clarke-Groves (VCG) mechanism is one of the most compelling constructs in mechanism design, but the presence of complementarities creates the theoretical possibility of non-core outcomes. In this paper, we empirically document such outcomes—including three zero-revenue rounds—in the Federal Communications Commission (FCC) Incentive Auction. We then model the two-stage approach commonly used for auctioning spectrum, where bidders bid first for generic blocks and then bid for specific frequencies. We demonstrate that this approach may induce complementarities in the second stage even when the underlying preferences are well-behaved.

4 - Cheap-Talk Communication in Procurement Auctions

Sander Onderstal, University of Amsterdam, Amsterdam, Netherlands

In procurement auctions, the buyer may include a dialogue in the procurement procedure in which it enables the bidders to reveal information that will help the buyer to better specify the terms of the contract. However, a potential downside of such procedure is that the bidders have incentives to manipulate the information they provide as it boils down to 'cheap talk'. This raises questions like: When do buyers benefit from non-binding communication between them and the bidders? When should buyers only allow the winner of the auction to communicate and when should they allow several bidders to communicate before the auction? We address these questions both theoretically and in laboratory experiments.

5 - Subcontracting Requirements and the Cost of Government Procurement

Benjamin Rosa, Virginia Tech, Blacksburg, VA, United States, brosa@vt.edu

I study how subcontracting requirements for the utilization of disadvantaged firms affect procurement auctions using data from New Mexico's Disadvantaged Business Enterprise Program. Theoretically, subcontracting requirements reduce prime contractors' private information on their costs by requiring them to select their subcontractors from a common pool of disadvantaged firms. This feature mitigates subcontracting cost increases by causing prime contractors to strategically lower their markups. I find that New Mexico's past subcontracting requirements led to a minor procurement cost increase.

Enterprise-level and Concept-driven Studies for Defense

Sponsored: Military and Security

Sponsored Session

Chair: Trevor Bihl, Air Force Research Laboratory, Beavercreek, OH, 45434, United States

1 - Defense Enterprise Modeling

Mark A. Gallagher, Air Force Institute of Technology, Columbus, OH, 43229-5535, United States, markgallagherJMJ@gmail.com, Franco Villongco

We explore modeling at the Defense Enterprise level, where decisions regarding military strategy and force structure across all military services as well as against various scenarios and conditions are of primary concern. In particular, we characterize uncertainty, adversarial, and multiobjective aspects that contribute to the complexity of decision making at the Defense Enterprise level. We survey current analytic models that support decision making within this context and define a future research path that has significant potential to mitigate current analytical challenges.

2 - Developing a Taxonomy of Planning for Autonomous Systems

Trevor Bihl, Air Force Research Laboratory, Beavercreek, OH, United States, Chad Cox, Timothy Machin

This presents a vision of automatic planners as applied to unmanned vehicles, while considering the ultimate goal of full autonomy. Planners are presented as components of a hierarchical, modular automaton with increasingly autonomous capabilities as higher functional modules are added. A technical baseline is developed and several methods are described within a taxonomy, highlighting present research interests, demand signals, and possible gaps in the research. This presentation explores relative strengths and weaknesses and suggests ways that these approaches can complement each other. Important topics of research are suggested.

3 - Readiness Modeling: Changing the Question From "Ready or Not?" to "Ready for What?"

Shaun Doheney, Chair, Resources & Readiness Applications, ProbabilityManagement.org, Washington, DC, United States, shaun@probabilitymanagement.org, Sam Savage, Connnor McLemore

Military readiness is expensive in terms of financial costs, time, and military risk, and is usually perishable. While improved readiness accounting will likely be an evolutionary process with inputs from numerous stakeholders, Operations Research analysts are well suited to recommend some key features for an improved military readiness representation framework that is useful, logically consistent, and most importantly is simple enough for incremental adoption by senior military leaders. In this talk, we provide working prototypes of models to demonstrate some of the underlying principles associated with this new readiness representation approach.

CC- Room 6C

Dynamic Programming/Control

Contributed Session

Chair: Duan Li, City University of Hong Kong, School of Data Science, College of Business, Kowloon, Hong Kong

1 - Optimal Traffic Allocation Policy in Dynamic Contracts

Chong Zhang, Tsinghua University, Beijing, China, zhangch.14@sem.tsinghua.edu.cn, Yong Liang, Peng Sun, Runyu Tang

Motivated by practices that platforms such as Taobao, Ele.me, and Toutiao utilize credit points system to connect adverse events caused by the agents (i.e., product/service/content providers) on them with the agents' ranking in the end users' search results, we focus on a principal-agent problem about traffic allocation in dynamic contracts. In particular, we study how the principal should create contractual incentives to encourage effort from agents to reduce the chance of adverse events by traffic allocation. We characterize the optimal traffic allocation policy of the single-agent case and also explore the heuristic policy of multi-agents case.

2 - Resource Allocation in Non-profit Settings- Approximate Dynamic Programming Approach

Faisal A. Alkaabneh, Cornell University, Ithaca, NY, United States, fma34@cornell.edu, H. Oliver Gao

We study stochastic resource allocation decisions in the context of non-profit settings. We formulate the problem as a stochastic dynamic program and develop an approximate dynamic programming framework to generate high-quality solutions. We use real-data obtained by one of the food banks in New York State to demonstrate the performance of the approach. More specifically, our algorithm demonstrates %5.0 improvement in total utility against the policy implemented in practice; furthermore, when compared against the offline algorithm, the optimality gap is less than %6.0.

3 - The Optimal Nonmyopic Gambling Strategy under a More Generalized Kelly Criterion

Christopher M. Rump, Associate Professor, Bowling Green State University, Bowling Green, OH, United States, cmrump@bgsu.edu

We examine the optimal gambling strategy for a sequence of simple "win" or "lose" wagers under a generalization of the Kelly criterion to one of a shifted log utility of terminal wealth. We correct a previous analysis of this problem in the literature, which established a (flawed) nonmyopic optimal policy whose wager is no longer a constant fraction of wealth but, rather, depends on the number of time stages left to play.

4 - Management of Online Server Congestion Using Optimal Demand Throttling

Sandun Perera, College of Business, University of Nevada, Reno, NV, United States, Varun Gupta, Winston Buckley

Bandwidth throttling is widely employed in practice by online-service-providers (OSPs) as a server/network congestion management tool. However, this topic has been largely neglected in the academic literature. To the best our knowledge, this is the first analytical study that aims at achieving an optimal (non-discriminatory) throttling mechanism for bandwidth when user demand is stochastic. Using a dynamic programming (Quasi-Variational Inequality) approach, we show that it is optimal for the OSP to throttle the demand whenever it reaches a threshold level and downgrade the service speed by a fixed factor while the throttling is employed.

5 - The Optimal Length of a Break

Thomas A. Weber, Professor of Operations, Economics and Strategy, EPFL, Lausanne, Switzerland, thomas.weber@epfl.ch

Assuming a decreasing attention level during (uniform) content delivery and an increasing attention level during a break, this paper examines problem of finding the length of a break so as to maximize the knowledge defined as the area under the attention curve during a predefined time of content delivery. Depending on the length of the delivery horizon and the initial attention level, classes may optimally start with a break or feature multiple breaks, approaching a limit cycle in the limit. The latter can be calibrated to various periodic resting processes in nature. The underlying optimal control problem is solved using the Pontryagin maximum principle.

6 - Progressive Hedging Algorithm and Bayesian Reinforcement Learning

Duan Li, Professor, City University of Hong Kong, Kowloon, Hong Kong, dli226@cityu.edu.hk, Xin Huang, Daniel Zhuoyu Long

Stochastic control with both inherent random system noise and lack of knowledge on system parameters constitutes a fundamental challenge in reinforcement learning, especially under non-episodic setting. We propose a novel two-layer solution scheme to separate reducible system uncertainty from irreducible one at two layers (by adopting time-composition based DP at the lower layer and the scenario-decomposition based progressive hedging algorithm at the upper layer) and to approximate the optimal policy directly. Applications in dynamic portfolio selection will be discussed.

1 - Excluded Solutions Presolve Technique for Mixed-integer Linear Programming

Menal Guzelsoy, SAS Institute, Inc., 100 SAS Campus Drive, Cary, NC, 27513, United States, Imre Polik

In this talk, we give an overview of SAS/OR MILP presolver and present a new technique and its extensions where we analyze and derive presolve reductions from the solutions excluded by each row.

2 - Strategies for Solving Infeasible Mixed Integer Programs

Ed Klotz, IBM, Incline Village, NV, 89450, United States

Infeasible Mixed Integer Programs (MIPs) often pose a distinct set of challenges for branch and cut algorithms. The absence of a cutoff value established by an integer feasible solution essentially disables certain features of the branch and cut algorithm, making it less effective. However, for MIPs that are suspected to be infeasible, other tactics are particularly effective at proving infeasibility. We will examine some of these and in doing so show how to prove infeasibility for two open MIPLIB 2017 models that, as of this writing, had an unknown feasibility status.

3 - New Features and Enhancements in the SAS Optimization Solvers

Imre Polik, PhD, SAS Institute, Inc, Cary, NC, United States

We present some exciting new features of the SAS optimization solvers including a cloud-ready architecture, a Python interface, several new solver capabilities, new presolver techniques, performance enhancements and future plans.

Optimization & Aviation

Contributed Session

Chair: K. Jo Min, Iowa State University, Department of Industrial &, Ames, IA, 50011-2164, United States

1 - Study of Team Mental Models Using Particle Swarm Optimization

Deanna Kennedy, Associate Professor, University of Washington Bothell, Bothell, WA, United States, deannak@uw.edu, Sumati Ahuja

To be effective, members of a team need to be aligned in their individual understanding of the task. In other words, the accuracy and sharedeness of the team mental model affects team performance. Herein, we use particle swarm optimization to model and analyze how interactions between team members lead to team mental model convergence and de-convergence. Implications are discussed.

2 - Iterative Linearized Control: Stable Algorithms and Complexity Guarantees

Vincent Roulet, Postdoc, University of Washington, Seattle, WA, United States, vroulet@uw.edu, Siddhartha Srinivasa, Dmitriy Drusvyatskiy, Zaid Harchaoui

We examine popular gradient-based algorithms for nonlinear control in the light of the modern complexity analysis of first-order optimization algorithms. The examination reveals that the complexity bounds can be clearly stated in terms of calls to a computational oracle related to dynamic programming and implementable by gradient back-propagation using machine learning software libraries such as PyTorch or TensorFlow. Finally, we propose a regularized Gauss-Newton algorithm enjoying worst-case complexity bounds and improved convergence behavior in practice. The software library based on PyTorch is publicly available.

3 - Connectivity Properties of Optimal Decentralized Control

Han Feng, UC Berkeley, Berkeley, CA, United States, han_feng@berkeley.edu

The complexity of optimal decentralized control (ODC) problem is reflected in the properties of its feasible set. We consider the design of a static decentralized controller and show that there is no polynomial upper bound on the number of connected components of the set of stabilizing decentralized controllers. In particular, the number can be exponential in the order of the system for a subclass of problems. Good decentralized structures that have tractable connectivity properties are studied with a combination of Routh-Hurwitz Criterion and Lyapunov stability theory. We further give heuristics to overcome exponential complexity with local search and homotopy.

4 - Evidence-based Graph Model for Analyzing Air Carbon Mitigation Conflict in China

Shawei He, Assistant Professor, Nanjing University of Aeronautics and Astronautics, Nanjing, China, schawae@hotmail.com

Interactions among decision makers in reaction to the implementation of air carbon mitigation policies in China are investigated using Graph Model for Conflict Resolution. The preferences for decision makers are elicited by applying the option prioritization approach based on the results suggested by system analysis models depicting their behaviors. Sensitivity analysis is carried out to discuss scenarios at which the governments implement different air carbon policies. The equilibria indicate guidance of actions for the government on how to smoothly implement carbon mitigation policies in order to achieve emission goals in civil aviation industry in China.

5 - Network Optimization for Hybrid Last-mile Delivery with Trucks and Automated Drones

Taner Cokyasar, PhD Student, University of Tennessee-Knoxville, Knoxville, TN, United States, cokyasar@vols.utk.edu, Wenquan Dong, Mingzhou Jin

Drone delivery systems have recently attracted considerable attention from governments, enterprises, and researchers. They have primarily focused on economic benefits, technological adoption, and sustainability. To extend the service range of drones, autonomous battery swap machines (ABSMs) were invented and adopted by some industries. In this study, we propose a mixed integer non-linear programming model incorporating queueing theory that dedicatedly assigns customers to drone or truck transportation channels and determines optimal ABSM locations minimizing the total transportation cost. We provide linearization and solution procedures to deal with high computational complexity.

6 - Infrastructure Decisions and Policies under Uncertainties in Arctic Regions

K Jo Min, Iowa State University, Ames, IA, United States, jomin@iastate.edu, John Jackman, Zhuoyi Zhao

The arctic regions are faced with natural and human-made, uncertain changes on their infrastructures ranging from villages and cities to roads and bridges to ports and depots. Under such circumstances, based on stochastic optimal control models of diffusion and jump processes, we formulate real options models such as option to construct, expand, contract, mothball, decommission, and/or abandon. From the analytical, numerical, and computational results, we will derive managerial insights and economic implications for the academics and practitioners.

Advances in Non-Convex Optimization

Sponsored: Optimization/Integer and Discrete Optimization

Sponsored Session

Chair: Aleksandr M. Kazachkov, QC, H3T1J4, Canada

Co-Chair: Gonzalo Munoz, Montreal, QC, H3T 1N8, Canada

1 - The Convex Hull of a Quadratic Constraint Over a Polytope

Santanu Subhas Dey, Georgia Institute of Technology, School of Industrial and Systems Engineering, Atlanta, GA, 30332, United States, santanu.dey@isye.gatech.edu, Asteroide Santana

We show that the exact convex hull of a general quadratic equation intersected with any bounded polyhedron is second-order cone representable. We present a simple constructive proof of this result.

2 - On the Complexity of Binary Polynomial Optimization Over Acyclic Hypergraphs

Silvia Di Gregorio, University of Wisconsin, Madison, WI, 53715, United States, sdigregorio@wisc.edu, Alberto Del Pia

In this work, we settle the computational complexity of binary polynomial optimization over acyclic hypergraphs. We give a strongly polynomial-time algorithm for -acyclic hypergraphs, and show that for -acyclic hypergraphs the problem is NP-hard. The idea behind our algorithm is to successively remove nest points from the hypergraph, until there is only one node left. Our algorithm can also be applied to any binary polynomial optimization problem that contains -cycles. In this case, the algorithm returns a smaller instance together with a rule to extend any optimal solution for the smaller instance to an optimal solution for the original instance.

3 - Submodularity and Lifting in Nonlinear Optimization with Indicators

Andres Gomez, University of Pittsburgh, Pittsburgh, PA, 15217, United States, agomez@pitt.edu

We propose new classes of valid inequalities for mixed-integer nonlinear optimization problems with indicator variables. The inequalities are obtained by projecting out the continuous variables, exploiting submodularity to derive valid linear inequalities in the space of the discrete variables, and lifting back the inequalities to obtain nonlinear valid inequalities involving both the continuous and discrete variables. The proposed inequalities are shown to describe the convex hulls of many sets involving the mixed-integer epigraphs of quadratic and conic quadratic functions.

4 - Generalized Surrogate Duality for Mixed-Integer Nonlinear Programs

Andrea Lodi, École Polytechnique de Montréal, Montréal, QC, H3T2A7, Canada, Maxime Gasse, Ambros Gleixner, Bemjamin Müller, Gonzalo Muñoz

The most important ingredient for solving mixed-integer nonlinear programs (MINLPs) to global optimality with spatial branch-and-bound is a tight, computationally tractable relaxation. Due to both theoretical and practical considerations, these relaxations are usually required to be convex. Nonetheless, current optimization solvers can often handle a moderate presence of non-convexities efficiently, which opens the door for the use of potentially tighter non-convex relaxations. One way to construct such a relaxation is by aggregating nonlinear constraints of the problem into a single non-convex constraint. The resulting relaxation is called surrogate relaxation, which is similar to the well-known Lagrangian relaxation but provides stronger dual bounds in general. In this talk, we make use of the surrogate dual in a non-convex setting and show the benefits and challenges such relaxation can have in general MINLPs. Additionally, we present a generalization of the surrogate relaxation that allows for multiple aggregations of non-convex constraints. Based on a known Benders-type approach, we present an algorithm that can solve our generalized surrogate relaxation, along with several computational enhancements for improving its practical performance. Finally, we conduct extensive computational experiments on instances of the MINLPLib using the global solver SCIP.

Distributionally Robust Optimization: Theory and Applications

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Ran Ji, George Mason University, Fairfax, VA, 22030, United States

1 - A Sequential Sampling Method for Distributionally Robust Stochastic Programs

Manish Bansal, Virginia Tech., Blacksburg, VA, 24060, United States, bansal@vt.edu, Harsha Gangammanavar

In this talk, we will present a sequential sampling method to address the two-stage distributionally robust linear programs. A key feature of this method is that it involves assessing the relevance of additional observations in determining the worst-case distribution from the set of probability distributions that is approximated with increasing information on uncertainty. We will provide conditions under which this algorithm is convergent and results of our computational experiments to evaluate the performance of this method.

2 - Distributionally Robust Combinatorial Bottleneck Problem with Wasserstein Distance

Jie Zhang, Virginia Tech, Blacksburg, VA, 24060, United States, jiezhang@vt.edu, Weijun Xie, Shabbir Ahmed

This paper considers data-driven distributionally robust combinatorial bottleneck problem (DR-CBP), where the cost vector is stochastic, and its probability distribution is from a family of distributions centered at the empirical distribution based on Wasserstein metric. We first show that CBP admits an equivalent dual form. Based on this result, we are able to derive a compact mixed integer linear programming (MILP) formulation for DR-CBP, which can be solved efficiently by the decomposition algorithm with binary search. Our numerical study demonstrates the effectiveness of the proposed method.

3 - Joint Stocking and Pricing Decisions for Distributionally Robust Inventory Problems with Decision-dependent Demands

Hamed Rahimian, Postdoctoral Fellow, Northwestern University, Evanston, IL, 60208, United States, hamed@northwestern.edu, Sanjay Mehrotra

We study a distributionally robust approach to multi-product inventory problems, where the joint probability distribution of the products demands is unknown and depends on the products prices. Our goal is to obtain the optimal joint stocking and pricing decisions for some classes of decision-dependent ambiguity sets. We reformulate these models as optimization problems with bilinear terms. We study convexification techniques for the bilinear terms and propose a solution algorithm to solve the models. We illustrate our results on stylized problems.

4 - Distributionally Robust Service Center Location Problem with Decision Dependent Utilities

Fengqiao Luo, IEMS Northwestern University, Evanston, IL, 60208, United States, fengqiaoluo2014@u.northwestern.edu, Sanjay Mehrotra

We investigate a service center location problem with stochastic demand and utility gain. This type of problem arises from public healthcare project of building basic medical service clinics in rural communities where residents need to visit the clinics to get medical services. The utility gain by a resident after receiving the medical service from a specific clinic may vary when the resident tries to compare the service quality, the waiting time, the traveling distance and some other features with other nearby clinics in the area. The problem is formulated to be a two-stage distributionally-robust stochastic mixed 0-1 second-order cone program to maximize the total utility gain.

Bayesian Machine Learning

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Matthias Poloczek, Uber AI Labs & University of Arizona, San Francisco, CA, 85721, United States

1 - Active Machine Learning for Automating Scientific Discovery

Roman Garnett, Washington University in St. Louis, St. Louis, MO, United States

Analyzing data to determine properties of interest can be very expensive, requiring human intervention or costly experiments. In this case it is critical that we allocate limited resources effectively. In active machine learning, we consider how to collect the most-useful data to achieve our experimental goals. We will discuss a particular setting modeling scientific discovery: “active search,” where we seek to discover rare, valuable points from a large set of alternatives. We will discuss the surprising difficulty of this problem and introduce efficient, nonmyopic polices. We will also outline a vision for automating scientific discovery by incorporating automated model construction.

2 - Exploration via Sample-efficient Subgoal Design

Yijia Wang, University of Pittsburgh, Pittsburgh, PA, 15213, United States, yiw94@pitt.edu, Matthias Poloczek, Daniel Jiang

The problem of exploration in unknown environments continues to pose a challenge for reinforcement learning algorithms. In this paper, we consider a new problem domain where an agent faces an unknown task in the future, assumed to be drawn from an unknown distribution of Markov decision processes, that it must learn within a small number of samples. Prior to this, the agent has opportunities to ``practice” in related tasks from the same distribution. We propose a sample-efficient Bayesian approach for subgoal design to maximize the expected performance over a distribution of tasks, given a limited number of interactions with the environment.

3 - Non-myopic Bayesian Optimization as a Markov Decision Process

Eric Lee, Cornell University, Ithaca, NY, United States

We present Bayesian optimization (BO) as a Markov decision process (MDP), in which global optimization is equivalent to maximization of a reward over a finite horizon. In this MDP setting, myopic acquisition functions are greedy policies maximizing immediate reward, whereas non-myopic acquisition functions are long-horizon policies maximizing a combination of immediate and future reward(s). We discuss qualitative behavior of these non-myopic acquisition functions with a few examples. We then present experimental results demonstrating the benefits of non-myopic BO. Finally, we discuss when non-myopic BO is appropriate by examining trade-offs between model accuracy and performance.

4 - High Dimensional Bayesian Optimization via Subspace Embeddings

Matthias Poloczek, Uber AI Labs & University of Arizona, San Francisco, CA, 85721, United States, Amin Nayebi, Alexander Munteanu

We present a theoretically founded approach for high-dimensional Bayesian optimization based on low-dimensional subspace embeddings. The error in the GP is bounded tightly when going from the original high-dimensional search domain to the low-dimensional embedding. This implies that the optimization process in the embedding proceeds essentially as if it were run directly on an unknown active subspace of low dimensionality. The argument applies to a large class of algorithms and GP models, including non-stationary kernels. We demonstrate empirically that this subspace embedding achieves better results than the previous methods based on Gaussian matrix projections and structure-learning.

Learning Algorithms - Theory and Applications

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Huanan Zhang, Penn State University, State College, PA, 16803, United States

1 - Fast Algorithms for Online Personalized Assortment Optimization in a Big Data Regime

Sentao Miao, University of Michigan-Ann Arbor, Ann Arbor, MI, 48104, United States, semiao@umich.edu

We consider an online personalized assortment optimization problem where customers arrive sequentially and make choices following a multinomial logit (MNL) model with unknown parameters. We develop an algorithm which uses an idea similar to UCB, while updating the estimated demand parameters using an online convex optimization method. By applying this parameter updating strategy, the computational complexity of the algorithm remains constant. Theoretical performance upper bounds for both low and high dimensional problems are derived, and numerical experiments demonstrate that our algorithms perform well compared with several benchmarks.

2 - Marrying Stochastic Gradient Descent with Bandits: Learning Algorithms for Inventory Systems with Fixed Costs

Hao Yuan, University of Michigan, Ann Arobor, MI, United States, haoyuan@umich.edu, Qi Luo, Cong Shi

We consider a periodic-review single-product inventory system with fixed cost under censored demand. We assume the firm does not know the demand distribution a priori. We develop a nonparametric learning algorithm termed the (, S) policy that combines the powers of stochastic gradient descent, bandit controls, and simulation-based methods in a seamless and non-trivial fashion. We prove that the cumulative regret is O(log(T)T1/2), which is provably tight up to a logarithmic factor.

3 - Learning in Structured MDPs with Convex Cost Functions: Improved Regret Bounds for Inventory Management

Randy Jia, Columbia University, New York, NY, 10027, United States, rqj2000@columbia.edu, Shipra Agrawal

We consider a stochastic inventory control problem under censored demands, lost sales, and positive lead times, and design a learning algorithm for this problem when the underlying demand distribution is unknown. The goal is to bound regret of the algorithm when compared to the best base-stock policy. Our main contribution is a learning algorithm with a regret bound of $O(L\sqrt{T})$, where L is the known lead time. Our results significantly improve the previously best known regret bounds for this problem where the dependence on L was exponential and many further assumptions on demand distribution were required.

4 - Self Guided Approximate Linear Programs

Selvaprabu Nadarajah, College of Business, University of Illinois at Chicago, UH 2406, Chicago, IL, 60607, United States, selvan@uic.edu, Parshan Pakiman, Negar Soheili, Qihang Lin

Approximate linear programs (ALPs) provide policies and bounds for Markov decision processes (MDPs) arising in challenging applications in operations management and other domains. Using ALP entails designing parametric MDP value function approximations, which poses a significant implementation hurdle. We develop an ALP scheme that side-steps this issue by leveraging sampling techniques from machine learning.

Transportation, Freight

Contributed Session

Chair: Ioannis Fragkos, Rotterdam School of Management, Burg. Oudlaan 50, Rotterdam, 3062 PA, Netherlands

1 - A Stochastic Model for Correlated Freight Parking Systems

Abhishek Abhishek, Kuehne Logistics University, Hamburg, Germany, abhishek.abhishek@the-klu.org, Jan C. Fransoo

We propose a stochastic model in the framework of queueing theory for a correlated parking system consisting of a delivery bay and a street parking. If freight vehicles find vacant parking spots at the delivery bay, they enter the bay parking and complete their deliveries. Otherwise, they immediately move to street parking in order to find vacant parking spots so that they can make their deliveries. We investigate the proportion of lost vehicles and prove some lower and upper bounds of the probability of lost vehicles in the parking system. We numerically show the impact of allocating more or less parking spots to dedicated delivery bays on the probability of lost vehicles, and on the bay utilization.

2 - Optimization of Variable Speed of Batch of Trucks in Supply Chain under Uncertain Demand

Jasashwi Mandal, Indian Institute of Technology Kharagpur, Kharagpur, India, Adrijit Goswami, Manoj Kumar Tiwari

In this study, the issue of varying speeds of a batch of vehicles in a truck shipping problem is explored considering fuel consumption and carbon emission for vehicles. The aim is to minimize the supply chain cost including the transportation, holding costs and back ordering costs where transportation cost consists of fuel cost, truck and driver costs considering carbon emission. The problem is divided into some sub problems leading to a set of differential equations of total chain cost and solving these differential equations the optimal dynamic speeds are obtained. Furthermore, a numerical case study related to truck transportation is given to realize the advantages of varying speed policy.

3 - Stochastic Truck Appointment Systems

Mohammad Torkjazi, PhD Candidate at University of South Carolina, University of South Carolina, Columbia, SC, United States, Nathan Huynh, Ali Asadabadi

Truck appointment systems are used at marine container terminals to mitigate port congestion. Past studies have not considered uncertainty in port operations. This study proposes a model to consider stochastic factors contributing in designing truck appointment systems.

4 - Integrated Scheduling for Port-centric Supply Chain Considering Seaborne Uncertainties and Dynamic Tidal Levels

Xinglu Xu, Dalian University of Technology, Dalian, China, Wenyuan Wang, Yun Peng, Yong Zhou, Ying Jiang

This paper proposes a practical integrated scheduling model for a typical port-centric supply chain with consideration of seaborne uncertainties. Such uncertainties include the ship's uncertain arrival time and uncertain departure time caused by varying draft requirements and tidal levels. A multilevel genetic algorithm with reduced feasible region is developed. The results show that integrated scheduling can significantly reduce the overall cost. If the origin port allows ships to increase loading volume by taking a tide, a drastic fluctuation in inventory will be observed, especially in the destination port.Resource bottleneck can also be identified and analysed from our results.

5 - Strategic Planning of Multimodal Transportation Networks

Ioannis Fragkos, Rotterdam School of Management, Rotterdam, Netherlands, fragkos@rsm.nl, Joris Wagenaar, Martin Faro

We study the efficient strategic planning of multimodal transportation networks. We look at the common situation of a 3PL that can lease train wagons on an annual basis and respond to demand fluctuations via ad-hoc spot train rentals. We formulate the problem as a two-stage stochastic mixed-integer program. We use structural properties of the formulation and a column generation-based procedure that greatly reduce the search space of optimal solutions. Computational results illustrate the efficiency of our approach.

CC- Room 609

Optimization, Continuous and Nonlinear Programming

Contributed Session

Chair: Michael Perregaard, FICO, FICO House, International Square, Starley Way, Birmingham, B37 7GN, United Kingdom

1 - The Value of Coordination in Ride-sharing Platforms

Arash Haddadan, PhD student, Carnegie Mellon University, Pittsburgh, PA, United States, ahaddada@andrew.cmu.edu

Ride-sharing is a two sided platform of riders and drivers. The objective for ride-sharing algorithms is to maximize a combination of the profit for the ride-sharing platform, drivers' utilization, and riders' satisfaction. The main problems in running an effective ride-sharing are (1) long term procedure of setting base prices and (2) short term control triggers to filter and modulate demand by setting surge prices. These optimization problems are often solved independently. In this project we seek to introduce optimization procedures that allow for more elaborate coordination between different levels of this (multi-period) optimization problem. We will use a simple yet practical model.

2 - Implementation of Interior Point Method for Nonlinear Optimization Problems with Arbitrary Precision Arithmetic

Koei Sakiyama, Kansai University, Osaka, Japan, k620042@kansai-u.ac.jp, Masashi Noguchi, Hiroshige Dan

The interior point method is one of the efficient methods for solving nonlinear optimization problems (NLPs). The interior point method basically works well, but it sometimes fails to solve some numerically ill-posed NLPs. On the other hand, arbitrary precision arithmetic has attracted attention for avoiding numerical errors. In this research, we implemented an optimization solver which can solve NLPs by using the interior point method with arbitrary precision arithmetic. Moreover, this solver uses the automatic differentiation software which are implemented by ourselves.

3 - Smooth Quasi-newton Methods for Nonsmooth Optimization

Jiayi Guo, Shanghai University of Finance and Economics, Shanghai, China, Adrian S. Lewis

Sporadic informal observations over several decades (and most recently in Lewis-Overton, 2013) suggest that quasi-Newton methods for smooth optimization can also work surprisingly well on nonsmooth functions. This talk explores this phenomenon from several perspectives. First, we compare experimentally the two most popular quasi-Newton updates, BFGS and SR1, in the nonsmooth setting. Secondly, we study how repeated BFGS updating at a single fixed point can serve as a separation oracle (for the subdifferential). Lastly, we show how Powell's original 1976 BFGS convergence proof for smooth convex functions in fact extends to some nonsmooth settings.

4 - Airline Fleet Assignment Problem: Extensions and Solution Methods

Fan Xiao, Tongji University, Shanghai, China, 892225786@qq.com

In this talk, we will introduce two extensions to the traditional airline fleet assignment problem (FAP). In the first extension, we consider the crew resource availability and balance in FAP. In the second extension, we model the demand-price relationship use a piece-wise linear function. We adopt the traditional time-space network model to handle these extensions. Several decomposition algorithms are proposed to solve these models efficiently. Our computational results show that the proposed solution methods can be used for mid and large scale airline companies.

5 - Understanding Adaptive Gradient Algorithms and Non-gradient Algorithms for Training Neural Nets

Anirbit Mukherjee, Research Assistant, Johns Hopkins University, Baltimore, MD, United States, amukhe14@jhu.edu, Amitabh Basu, Enayat Ullah, Soham Dey, Anup Rao

There is burgeoning experimental evidence that arbitrarily large neural nets can be trained with simple iterative algorithms. This remains a fundamental mystery in the field though over the last year progress has happened towards explaining this in certain unrealistic edge cases particularly for asymptotically large nets. In this talk I will present the progress that our group has made in two different aspects of this question. Firstly we will present our new convergence theorems about adaptive gradient algorithms like RMSProp and ADAM which are empirically known to be the best algorithms to train nets in general. Secondly we will present certain non-gradient algorithms (``Trons") which under appropriate conditions can provably train neural nets at speeds one would expect from stochastic gradient algorithms but these work for constant sized nets where hardly any gradient based algorithms have been proven to work.

6 - Recent Developments in the FICO Xpress Solver

Michael Perregaard, FICO, FICO House, International Square, Starley Way, Birmingham, B37 7GN, United Kingdom

We will present recent developments in the linear, mixed integer and non-linear programming solvers within the FICO Xpress Optimization Suite.

Power Flow Optimization and Control

Sponsored: Optimization/Network Optimization

Sponsored Session

Chair: Mostafa Sahraei-Ardakani, University of Utah, Salt Lake City, UT, 84112, United States

Co-Chair: Sang Yuanrui

1 - Effective Power Flow Control via Distributed FACTS Considering Future Uncertainties

Yuanrui Sang, The University of Texas at El Paso, El Paso, TX, United States

Distributed FACTS (D-FACTS) is a light-weight version of flexible AC transmission systems (FACTS), which has a low cost and can be redeployed conveniently. This study proposes a computationally efficient stochastic allocation model for D-FACTS and studies their economic benefits compared to that of conventional FACTS under a wide range of future uncertainties. The results show that, with the same level of investment, D-FACTS can more effectively reduce transmission congestion and enhance renewable energy integration than conventional FACTS, and can better accommodate future uncertainties.

2 - Derivation and Generation of Path-based Valid Inequalities for Transmission Expansion Planning and Optimal Transmission Switching

Kyle Skolfield, Arizona State University, Tempe, AZ, United States, jskolfie@asu.edu, Adolfo Raphael Escobedo

To meet power demand under a limited budget, it is necessary to determine a low-cost transmission expansion plan (TEP). One way to increase savings and operational flexibility in this design is to allow for network reconfigurations via optimal transmission switching (OTS). TEP and OTS decisions can be jointly modeled in a DCOPF-based large-scale MIP. We develop a solution methodology based on valid inequalities (VIs) that incorporate network insights from path-based bus angle-differences to tackle this intractable problem. The VIs are used in a branch-and-cut framework. We also design a data-driven scheme for selecting the more effective VIs and test it via benchmark instances.

3 - Optimal Power Flow Control Dispatch Using a Series Voltage Source Formulation

Tom R. Nudell, PhD, Smart Wires Inc, Union City, CA, United States, Tom.Nudell@smartwires.com

Power flow control (PFC) installed strategically and dispatched optimally could save US electricity consumers 10s of billions of dollars annually. Efficiently solving the optimal PFC dispatch problem is important and impactful. For certain problems, we focus on optimizing PFC deployments and ignore the famous unit commitment economic dispatch problems. Previously, many approaches to this problem modeled PFC devices as variable series reactance. We have reformulated the problem using a voltage source model of PFC deployments. This talk will introduce the motivation for and the results from using algorithm approaches based on the voltage-source formulation.

4 - Topology Control for Power System Reliability

Mojdeh Khorsand, Assistant Professor, Arizona State University, Tempe, AZ, United States, mojdeh.khorsand@asu.edu, Mostafa Sahraei-Ardakani

Power system operators acquire reserves in an attempt to guarantee reliability; yet, reserve deliverability is not guaranteed. Prior research has shown that the use of transmission switching, or topology control, may help improve reserve deliverability. In this paper, transmission switching is used as a corrective mechanism to help the system achieve N-1-1 reliability. The methodology can be employed at the day-ahead time stage to ensure the system has acquired sufficient supplemental reserves. The results demonstrate that not only can corrective transmission switching be beneficial after N-1 contingency, but it can also help obtain an N-1-1 reliable solution.

5 - Novel Hybrid Magnetic/Electronic Control Devices for Power Systems

Aleksandar Dimitrovski, University of Central Florida, FL, United States

The concept of magnetic amplifier – an electromagnetic device that used to be common in electronic applications – has seldom been used in power systems. Several years ago, an innovative low-cost magnetic amplifier-based power flow control device (MAPFC) has been proposed. The uniqueness of MAPFC in comparison with the current state-of-the-art, flexible ac transmission system devices (FACTS), is in complete separation of control and controlled circuits. MAPFC uses the saturation property of the ferromagnetic core shared by ac and dc windings. The common magnetic field is used as the medium to control the ac winding reactance inserted in series with the controlled transmission line. Large power flows in the line can be regulated by small power dc currents in the control winding. A multimillion-dollar project on MAPFC for transmission systems was funded by DOE's ARPA-e GENI program. A follow up work on MAPFC for distribution systems is currently being funded by DOE OE's TRAC program. Some results from both projects will be presented and plans for future developments will be discussed.

6 - Power Flow Control and Optimization in Active Distribution Networks

Panagiotis Andrianesis, Boston University, Brookline, MA, 02446, United States, panosa@bu.edu, Michael C. Caramanis, Pablo Ruiz

We will present a coordination and control framework for grid-connected Behind-the-Meter (BTM) Solar PV and Distributed Energy Resources (DERs), which optimizes their net benefits to overall system operating cost while increasing grid asset utilization. The framework integrates small scale BTM Solar PV with DERs, including energy storage, storage-like loads (notably Electric Vehicles), flexible loads, building controls, and smart appliances. It estimates spatiotemporal marginal costs of real and reactive power and uses them to optimize both the grid and the PV/DER operational profiles.

CC- Room 611

Network Optimization Algorithms and Applications

Sponsored: Optimization/Network Optimization

Sponsored Session

Chair: Oscar Guaje, Universidad de los Andes, 111021, Colombia

1 - A Hybrid Algorithm for Generating Multivariate Correlated Random Vectors

Oscar Guaje, Universidad de los Andes, Bogotá, 111021, Colombia, oo.guaje10@uniandes.edu.co, Andres L. Medaglia, Jorge A. Sefair

Existing methods to generate multivariate correlated random numbers rely on the properties of the input distributions. In this talk, we present a distribution-free algorithm to reorder independently generated samples to induce a target Pearson (and other) multivariate correlations. Our network-based algorithm combines an iterative local search with mathematical programming elements to both exploit the underlying problem structure and to diversify and intensify the search. Our results compare favorably against existing methods in terms of speed and solution quality.

2 - Mobility Problems with Predicted Uncertainties in Infrastructure Flow Capacities

Pitu Mirchandani, Arizona State University, Tempe, AZ, United States, Ketut Gita Ayu

Primary hurricane phenomena of concerns for disaster response operations are storm surge, torrential rain, and strong winds. These storm hazards can inflict significant amount of damage, particularly on the land transportation network, affecting population's ability to move during/after the storm event. We developed a cascading network failure model to accentuate this mobility issue. The model takes the scenario-level spatial-temporal storm impacts generated by the data-driven probabilistic scenarios model from our previous work, as input to predict uncertainties in network flow capacities in Florida during Hurricane Irma.

3 - Control of Stochastic Disease Network Games via Influential Individuals

Ceyhun Eksin, Texas A&M University, College Station, TX, United States, eksinc@tamu.edu

We consider control of a disease spreading on a network. The current state of the disease sets up a network game between healthy and sick individuals in contact. Both types can take preemptive measures according to an equilibrium of the game which stochastically determine the next disease state. Individuals learn an equilibrium action solution via a decentralized iterative learning process. Our goal is to induce behavior that minimizes risky interactions by identifying a small number of influential individuals during the iterative learning process. We numerically establish the efficacy of influential individuals in eradicating an outbreak in comparison to a centrality metric-based isolation.

4 - Optimizing Intercity Transportation Network Considering Passengers' Tour Behavior

Arata Suzuki, Narita International Airport Corporation, Chiba, Japan, Hiromichi Yamaguchi, Daisuke Fukuda

This study proposes a novel method of intercity transport network optimization incorporating tour-based (e.g. home or airport -> a primary destination -> a secondary destination -> home or airport) passenger behavior. The model is formulated as mixed integer-linear programming without enumerating enormous combinations of possible destinations and routes. Concepts of destination attractiveness and cross-cut constraints have been incorporated to describe tour-based travel. We apply the proposed method to the transport network in Japan with nine major cities and find that the optimal network can be significantly changed in terms of topology with the increase in tour-based passenger.

5 - Shortest Paths in Railyard Networks

Mina Aliakbari, Texas A&M University, College Station, TX, United States, Joseph Geunes

We consider the problem of moving a set of connected railcars from an initial location to a final location in a railyard network. This problem is routinely encountered in hub yards, where inbound trains are broken down and then used to build outbound trains. We provide an integer programming formulation and propose a customized shortest-path network that defines key states on the underlying railyard network, as well as allowable state transitions, implicitly accounting for all feasible paths in the railyard network. We discuss the advantages of each approach and present computational results.

1 - A Hybrid Algorithm for Tri-level Optimization with Partial Protection and Interdiction

Nafiseh Ghorbani Renani, Graduate Research Assistant, University of Oklahoma, Norman, OK, United States, nafiseh.ghorbani@ou.edu, Kash Barker, Andres David Gonzalez

We explore the tradeoff between investments in vulnerability reduction and recoverability improvement in systems of interdependent networks by proposing a tri-level protection-interdiction-restoration model, depicted as a defender-attacker-defender model. We propose a hybrid solution technique to solve the tri-level optimization formulation by iteratively solving smaller nested bi-level problems. To demonstrate the application of the model and efficient solvability of the proposed solution method, we apply this resilience interdiction formulation to a system of water, gas, and power networks in Shelby County, Tennessee.

2 - Dynamic Network Flow Problems Having Temporary ARC Activation Costs

Robert Curry, United States Naval Academy, Annapolis, MD, United States, rcurry@usna.edu, Cole Smith

Time-dependent network applications may require dynamic flows to be transmitted according to a non-simultaneous schedule of path-flows. We thus study a dynamic network flow problem that considers the presence of set up costs required to begin transmitting flow on an arc. This problem can be modeled as a dynamic version of the minimum cost flow problem having arc activation costs (MCF-A). We employ a relaxation-based algorithm for obtaining upper and lower bounds for this problem that solves a series of smaller MIPs. We present computational results to demonstrate the efficacy of our approach and extend this technique to other dynamic network flow problem variations having complicating constraints.

3 - A Stochastic Optimization Model for Evaluating Preparedness and Restoration Strategies of Interdependent Networks

Jin-Zhu Yu, Vanderbilt University, Nashville, TN, United States, yujinzhu88@gmail.com, Hiba Baroud

Interdependent infrastructure systems are particularly vulnerable to disruptions when compared to a single infrastructure system. Effective preparedness and restoration plans are critical to the management of infrastructure systems. This study develops a two-stage stochastic optimization model that integrates preparedness and restoration strategies to (i) reduce the expected total cost of disaster planning (e.g., network hardening scheme) and recovery activities (e.g., the number of repair crews required and their schedule) and (ii) enhance the time-dependent resilience of interdependent infrastructure systems post-disruption.

1 - Learning Optimal Combination of Forecasts using Best Subset Selection

Brad J. Johnson, PhD Candidate, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, bradj@andrew.cmu.edu, Nick V. Sahinidis

For decades, using a combination of forecasts has been shown to improve forecasting accuracy and robustness; however, there has been continued debate over the selection and weighting of individual methods. This work proposes the use a mixed integer formulation of the best subset selection problem to simultaneously select forecast methods and their weights by minimizing the Bayesian Information Criterion. The proposed algorithm is then applied to the 100k time series used in the M4 Forecasting Competition to learn novel combinations.

2 - Imbalanced Learning with Linear Programming Support Vector Machine with Application in Weather Data

Elaheh Jafarigol, University of Oklahoma, Norman, OK, 73071, United States, elaheh.jafarigol@ou.edu, Theodore B. Trafalis

Learning from imbalanced data sets is one of the aspects of predictive modeling and machine learning that has taken a lot of attention in the last decade. The model proposed in this presentation is a Linear Programming Support Vector Machine with applications in weather data, collected from the Bureau of Meteorology system in Australia. The proposed approach has yielded a significant improvement in predicting the minority class and decreased the model's bias towards the majority class as it is seen in most machine learning algorithms.

3 - Scale Invariant Power Iteration

Cheolmin Kim, Northwestern University, Evanston, IL, 60201, United States, cheolminkim2019@u.northwestern.edu, Diego Klabjan, Youngseok Kim

Several machine learning models can be formulated as maximization of a scale invariant function under a Euclidian ball constraint, for example, PCA, GMM, NMF. We generalize power iteration to this setting and analyze convergence properties of the algorithm. Our main result states that if initialized close to a local maximum, then the algorithm converge to this local maximum. Also, the convergence rate is linear and thus equal to the rate of power iteration. Numerically, we benchmark the algorithm against state-of-the-art methods to find out that the algorithm outperforms benchmark algorithms.

4 - The Optimization Methods in SAS Deep Learning Software

Yan Xu, SAS Institute Inc., Cary, NC, United States, Yan.Xu@sas.com

Deep learning is a popular type machine learning that trains computers to perform human-like tasks, such as recognizing speech, identifying image objects or making predictions. Optimization is the core component of deep learning systems. In this talk, we present the implementation details and computational results of the optimization methods that power SAS deep learning toolkit.

1 -Linear Interpolation vs. Gaussian Smoothing in Derivative-free Optimization

Katya Scheinberg, Cornell University, Ithaca, NY, 18015, United States, Albert Solomon Berahas, Liyuan Cao

We consider derivative free optimization problems, where the objective function is smooth but is computed with some amount of noise. We are motivated by policy optimization in reinforcement learning. We provide a convergence rate analysis for a first-order line search method, and derive the conditions on the gradient approximations that ensure this convergence. We then demonstrate via rigorous analysis of the variance and by numerical comparisons on reinforcement learning tasks that the Gaussian sampling method for gradient approximation is significantly inferior to the orthogonal sampling as well as more general interpolation methods.

2 - Solving Chance-constrained Problems via a Smooth Sample-based Nonlinear Approximation

Alejandra Pena-Ordieres, Northwestern University, Evanston, IL, 60208, United States, James Luedtke, Andreas Waechter

In this talk, we introduce a method for solving nonlinear continuous optimization problems with chance constraints. The method reformulates the probabilistic constraint as a quantile function and approximates the quantile using a differentiable sample average approximation. This formulation can be directly used by standard nonlinear optimization solvers in the case of single chance constraints. Furthermore, we propose an Sl1QP-type trust-region method to solve instances with joint chance constraints. We illustrate empirically that the method scales well with the sample size and that the smoothing can be used to counteract the bias in the approximation induced by sampling.

3 - Reduced Space Optimization for Problems with Group Sparsity

Daniel Robinson, Associate Professor, Lehigh University, Bethlehem, PA, 21218, United States

I discuss an optimization framework for solving problems with sparsity inducing regularization. Such regularizers include Lasso (L1), group Lasso, and latent group Lasso. The framework computes iterates by optimizing over small dimensional subspaces, thus keeping the cost per iteration relatively low. Theoretical convergence results and numerical tests on various learning problems will be presented.

4 - Stochastic Linear Bilevel Programs: Overcoming Degeneracy in the Lower Level Problem.

Francisco I. Jara-Moroni, Universidad de Santiago, Av. Santiago, Chile, francisco.jara.m@usach.cl, Andreas Waechter

This is a numerical study for Stochastic Linear Bilevel problems. We solve a sampled version by means of a global/local search together with an alternating weights technique which steers towards better solutions, by overcoming degeneracy of the lower level problem. We are able to find the global solution of the true problem in small instances, while in larger ones the local solutions obtained overtake those found from globally solving smaller subsamples. Computation time is drastically reduced, as compared to the best performing subsampled global solution. We show that our technique manages to find good approximations of global solutions, even if the subsample is not solved to globally solved.

1 - Decentralized Game-theoretical Approaches for Behaviorally-stable and Efficient Truck Platooning

Xiaotong Sun, University of Michigan, Ann Arbor, MI, United States, Yafeng Yin

Vehicle platooning enabled by the connected automated vehicle (CAV) technology has been identified to bring energy savings and labor-saving. However, vehicles from different owners may not willing to platoon together since benefits vary over different positions in a platoon. This study investigates a decentralized multi-agent system where individual-rational agents form platoons under designated mechanisms which also decide the benefit reallocation simultaneously. Specifically, mechanisms based on auction, bargaining game and stable matching are introduced for different scenarios. By leveraging CAV technology, such a system is flexible, scalable and real-time implementable.

2 - Do Self-driving Cars Swallow Public Transport? A Game-theoretical Perspective on Transportation Systems

Maximilian Schiffer, Technical University of Munich, Munich, Germany, schiffer@tum.de, Stanford University, Stanford, CA, United States, schiffer@tum.de, Nicolas Lanzetti, Gioele Zardini, Michael Ostrovsky, Marco Pavone

The advent of autonomous mobility-on-demand (AMoD) systems constitutes a paradigm shift for future transportation systems. While many experts envision huge benefits from AMoD systems, others warn against negative externalities, e.g., cannibalization of public transport. To this end, we develop a game-theoretical framework that captures the dynamics between mobility service providers and non-cooperative customers. We study the corresponding game equilibrium and assess the impact of an AMoD system competing with public transport in a transportation system where customers select their trips in a multimodal fashion. We present results for a real-world case study for the city of Berlin.

3 - Traffic and Vehicle Assignment of Shared Autonomous Vehicles: A Nash-Cournot Game Formulation

Emmanouil Chaniotakis, Technical University of Munich, Munich, Germany, m.chaniotakis@tum.de, Santhana Krishnan Narayanan, Constantinos Antoniou

Road users select paths and departure time to minimize their disutility forming a Dynamic User Equilibrium (DVI - fixed point problem); SAV Service Operator try to maximize their performance forming appropriate SAV chains (combinatorial problem). The final objective of this formulation a traffic assignment and SAV chain formation, such that both road users and SAV service operator obtain their optimal solutions simultaneously, forming a Nash-Cournot equilibrium, where no player is better o by unilaterally changing decisions. An iterative is proposed with convergence criteria based on change in path flow from DUE and change in total system cost from SAV operations.

4 - A Coordinated Route-guidance System for Connected Vehicles under Mixed-strategy Congestion Game with Information Perturbation

Stephen Spana, University of Florida, Gainesville, FL, United States, sspana@ufl.edu, Lili Du, Yafeng Yin

This project develops a coordinated routing scheme for connected vehicles, where the mixed-strategy route choice for drivers is based on strategically perturbed traffic information. Analytically we show that for small perturbation amounts, significant system improvement is achieved with a relatively low corresponding user optimality loss. Through simulation we verify our analytic results, and explore the impacts of information perturbation on various performance measures (e.g. travel time) for different congestion levels using the Sioux Falls network.

5 - VCG-inspired Value-of-time Auctions for Road Intersection Priority

Carlin Liao, University of Texas, Austin, TX, United States, Stephen Boyles

Intersection auctions with automated vehicles increase social welfare by accounting for drivers' relative priority levels. Prior research has developed a preliminary mechanism, but use of second-price payments and fixed-value bids disincentive truthful behavior. This study proposes bidding values of time (instead of fixed valuations) and a payment mechanism derived from Vickrey-Clark-Groves, charging drivers in the auction-winning lane the cost they impose on others: the value of the time the winning movement prevents the second highest bidding movement from taking action.

Joint session TSL/OPT.Under Uncertainty: ADP/Reinforcement Learning in Vehicle Routing I

Sponsored: Transportation Science & Logistics/Freight Transportation & Logistics

Sponsored Session

Chair: Maciek A Nowak, Loyola University Chicago, Chicago, IL, 60611, United States

1 - Anticipatory Synchromodal Transportation Planning

Martijn Mes, University of Twente, Building Ravelijn, PO Box 217, Enschede, 7500 AE, Netherlands, m.r.k.mes@utwente.nl

We present the problem of selecting transport modes and transfers in a synchromodal network over a multi-period horizon, with freights becoming known gradually over time. We model this problem as a Markov Decision Process (MDP) and combine Approximate Dynamic Programming (ADP) and the Value of Perfect Information (VPI) to solve it. We show that VPI drastically reduces the number of ADP iterations and that our look-ahead approach has significant benefits compared to benchmark heuristics. We also present a serious game, called Trucks and Barges, illustrating the described problem and solution methods.

2 - Multi-period Workload Balance in Last-mile Urban Delivery

Yang Wang, Tsinghua University, Tsinghua University, Beijing, 100084, China, yang-wan15@mails.tsinghua.edu.cn, Lei Zhao, Martin W. P. Savelsbergh

In urban delivery, the last-mile station manager needs to consider workload balance among couriers when dispatching delivery orders. While couriers expect to deliver more packages to increase their piecework-based incomes, they favor the assignments that demand less effort (travel distance, time, etc.). We model the workload balance problem over a finite planning horizon as a stochastic dynamic program and study the impact of various dispatching policies that differentiate these two types of workload balance.

3 - Control of Autonomous Electric Fleets for Ridehail Systems

Nicholas D. Kullman, University of Tours, Tours, 98119, France, nicholas.kullman@etu.univ-tours.fr, Jorge E. Mendoza, Justin Goodson, Martin Cousineau

We consider a ridehail company operating a fleet of autonomous electric taxis that serve requests arising randomly throughout a region. The operator is responsible for assigning taxis to requests, as well as repositioning and recharging the taxis in anticipation of future requests. We model the problem as a Markov decision process. We compare solution methods from classical approximate dynamic programming — heuristic policies and lookaheads — with those of deep reinforcement learning — deep Q networks. We also provide a dual bound to gauge the effectiveness of these approaches by calculating the expected value with perfect information.

4 - Customer-driver Familiarity in Service Routing

Maciek A. Nowak, Loyola University Chicago, Information Systems and Supply Chain Mgmt, Quinlan School of Business, Chicago, IL, 60611, United States, mnowak4@luc.edu, Marlin Wolf Ulmer, Dirk C. Mattfeld, Bogumil Kaminski

We develop and solve a tactical model to specify the long-term implications of improved customer-driver familiarity, introducing a solution methodology for the stochastic and dynamic multi-period routing problem with customer-driver familiarity. Our methodology utilizes a policy that explicitly invests in the familiarity between selected customer-driver pairs, encouraging the development of relationships that are tactically beneficial. We show that this investment policy leads to a reduction in cost compared to a myopic policy focused on routing and service costs in the short term, while increasing the overall level of familiarity between customers and drivers.

1 - Urban Bike Lane Planning with Bike Trajectories

Sheng Liu, University of California, Berkeley, Berkeley, CA, 94709, United States, lius10@berkeley.edu, Xiang Ji, Zuo-Jun Max Shen

In this paper, we develop a novel bike lane planning model based on the bike trajectory data. We formulate the bike lane planning problem as an integer program to maximize the coverage of cyclists as well as the continuity of bike lanes. Based on the structural properties of the model, we develop a Lagrangian relaxation method as well as a mixed integer linear programming (MILP) method. The Lagrangian relaxation dual is proved to be solved in polynomial time for a special class of utility functions. We apply the model to the Zhuhai city of China using a large-scale trajectory data set collected from a dock-less bike sharing company.

2 - Optimal Transit Planning: Interactions with Ridehailing, Congestion and Passenger Choice

Vikrant Vaze, Dartmouth College, Murdough Center, Hanover, NH, 03755, United States, vikrant.s.vaze@dartmouth.edu, Keji Wei, Alexandre Jacquillat

Ride-hailing services introduce additional vehicles on the road, contribute to urban traffic congestion, and are sometimes responsible for falling public transit ridership. On the other hand, a high quality public transit system is an effective means to alleviate urban road traffic congestion. This interdependence motivates the following question: can public transit and ride-hailing co-exist and thrive to improve the overall social welfare? We develop a new mixed-integer linear optimization model, and a new set of algorithms, to optimize transit networks while explicitly accounting for the road congestion and passengers' mode-switching behavior between transit and ride-hailing services.

3 - Robust Repositioning for Vehicle Sharing

Zhenyu Hu, National University of Singapore, Singapore, 119245, Singapore, Long He, Meilin Zhang

Our paper discusses the operational decision of dynamic fleet repositioning for vehicle sharing. We first formulate the problem as a stochastic dynamic program to minimize the expected total repositioning cost and lost sales penalty. To solve for a multi-region system, we deploy the distributionally robust approach that can incorporate demand temporal dependence, motivated by observations from real trip data. In a real-world case study, we quantify the "value of repositioning" and compare with several benchmarks to demonstrate that the proposed solutions are computationally scalable and in general result in lower cost with less frequent repositioning.

4 - An Equilibrium Analysis of the Parking Problem with Autonomous Vehicles

Neda Mirzaeian, PhD Candidate, Carnegie Mellon University, Pittsburgh, PA, 15217, United States, mneda@andrew.cmu.edu, Soo-Haeng Cho, Zhen Qian

We investigate a potential of autonomous vehicles (AVs) to solve the problem commuters face when traveling to a city center for work. We characterize the user equilibrium for commuters by developing a continuous-time traffic model that takes into account parking fees and traffic congestion as the main economic deterrent to driving. In this model, commuters decide their departure time as well as their parking location among central, peripheral, and external facilities. We show that, due to congestion, the expensive central facility can still be a viable option, even though AVs have the ability to travel to the cheap external facility.

5 - Customer Preference and Station Network in the London Bike Share System

Pu He, Columbia University, Uris Hall, Cub 4H, New York, NY, 10027, United States, Fanyin Zheng, Elena Belavina, Karan Girotra

We study customer preference for the bike share system in the city of London. We estimate a structural demand model on the station network to learn the preference parameters and use the estimated model to provide insights on the design and expansion of the bike share system. We highlight the importance of network effects in the system. We find that, in London city, allocating resources to some areas of the station network can be 10 times more beneficial than others in terms of system usage, and that the currently implemented station density rule is far from optimal. We develop a new method to deal with the endogeneity problem of the choice set in estimating demand for network products.

1 - The Impact of Perceived Corporate Social Responsibility on Employee Engagement: The Case of Qatar

Fatma H. Al Amri, Ministry of Energy & Industry, Doha, Qatar, Amit Das, Omar Ben-Ayed

This work investigates the role of preceived corporate social responsibility (CSR) in enhancing employee engagement (EE) in the State of Qatar. The scope of CSR included activities targeted at employees, customers, the government, and society at large. We measured EE by organizational engagement and job engagement. We examined how these dimensions of EE are associated with employees' perception of the firm's CSR activities, controlling for the type of firm and the type of employee. Our results reveal that CSR to society and CSR to employees affect organizational engagement, whereas CSR to customers affects job engagement. CSR to the government is not significantly related to either aspect of EE.

2 - Trajectory Planning for Autonomous underwater Vehicles Using Mixed Integer Nonlinear Programming

Ricardo M. Lima, Research Scientist, King Abdullah University of Science and Technology, Thuwal, Saudi Arabia, ricardo.lima@kaust.edu.sa, Tong Wang, Loïc Giraldi, Omar Knio

This talk presents a detailed mixed integer nonlinear programming (MINLP) model for the time-optimal trajectory planning for autonomous underwater vehicles. The model takes into account vehicle kinematic constraints, obstacle avoidance, and a nonlinear flow field to represent the ocean current. A novel solution approach is proposed, involving an initialization strategy using multiple waypoints, MILP and MINLP approximated models, and a parallel computing approach. The performance of the various models and methodology is discussed. Insights regarding trajectory planning are presented.

3 - Do Low Emissions Zones Reduce Air Pollution in Cities?

Virginie Lurkin, Assistant Professor, Eindhoven University of Technology, Eindhoven, Netherlands, v.j.c.lurkin@tue.nl

The urbanization trend gave rise to increased traffic flows in areas with dense population, creating more traffic congestion and air pollution. In order to tackle this problem, many cities around the world have chosen to introduce Low Emission Zones (LEZ). LEZ are geographical areas in which the operations of more polluting vehicles are restricted. Few quantitative studies have been published on the effectiveness of these policy interventions. In this paper, we show that Low Emission Zones (LEZ), as currently defined by most cities, can only constitute a quick win to decrease CO2 emissions within the restricted area, but are not sustainable stand-alone solutions to globally reduce air pollution.

4 - Injury Severity Analysis of Motorcycle Crashes in Florida Work Zones with Mixed Logit Approach

Rahul Deshmukh, University of South Florida, Tampa, FL, United States, deshmukh@mail.usf.edu

Injury Severity Analysis for Motorcycle Crashes In Work Zones In Florida with Mixed Logit Approach Work zone related crashes are increasing in Florida since 2014. There were 8,494 crashes in work zone in 2017 relative to 5,409 crashes in 2014. This equates to one work zone crash in almost every hour in 2017 as opposed to one crash in every 1.6 hour. As such, work zone safety is considered one of the important emphasis areas in Florida Strategic Highway Safety Plan (SHSP).

Sponsored Session

Chair: Fredrik Altenstedt

1 - Alternative Pricing in Column Generation for Airline Crew Rostering

Emily Curry, Jeppesen, Gothenburg, Sweden, Emily.Curry@jeppesen.com

In column generation for airline crew rostering, rosters with the potential of improving the current solution are generated by solving the pricing problem. The generated rosters must satisfy all rules that are applied at the airline. Since these vary between different carriers, the pricing problem can be treated as a black-box optimization problem, where rules and costs are considered unknown. We suggest three alternative methods for solving the black-box pricing problem. The first method uses binary particle swarm optimization to search for rosters. The other two methods use surrogate modeling to fit a nonlinear surrogate function that captures the unknown cost and legality functions.

2 - Why More Aircraft Performance Data Means a More Powerful Flight Plan Optimisation

Jacques Wild, Jeppesen, Gothenburg, Sweden, jacques.wild@jeppesen.com

An important aspect of flight planning optimization is being able to compare cost of aircraft operation at any feasible state, i.e. at all altitudes, weights, and weather conditions. However, not all aircraft have enough data to evaluate each flight state, either because of the lack of the flight test data or not appreciating the benefits of providing high resolution data to flight planning. In this presentation, we demonstrate the benefits of using high resolution aircraft performance data.

3 - Teaming in Airline Crew Schedule Optimization

Fredrik Altenstedt, Jeppesen, Odinsgatan 9, Göteborg, SE-411 03, Sweden

Operational stability of a crew schedule is improved by keeping crew together as much as possible. The cost of the plan can however often be lowered by splitting the crew. The benefit of splitting is driven by base imbalances, different costs for different crew categories as well as varying staffing need for different flights. In the case of teaming between cabin and cockpit splitting is also driven by different work time rules In this presentation we will address how teaming is specified and enforced in the Jeppesen Crew Pairing optimizer, as well as discuss the benefit to some of our clients.

4 - Optimizing the Pilot Manpower Problem under Career Bid Uncertainty

Pontus Ekh, Jeppesen Systems AB, Gothenburg, 41512, Sweden, pontus.ekh@jeppesen.com

The pilot manpower problem focus on creating a resource plan for airlines. A key decision is assigning qualification training. Airline regulations based on pilots' seniorities and preferences impose restrictions on who can be assigned training. The problem can be formulated as a MIP if the pilots' preferences are known a priori. However some airlines postulate that a vacancy posting must be done before collecting preferences. Pilots are then awarded training according to a fixed process. Creating a good posting is essential for these airlines. We propose a solution approach combining the previous MIP model and simulating several bid outcomes and awards.

1 - Simple Bayesian Algorithms for Best-arm Identification

Daniel Russo, Columbia University, New York, NY, United States

This talk considers the optimal adaptive allocation of measurement effort for confidently identifying the best among a finite set of options or designs. I propose top-two sampling, a template for designing algorithms that adaptively allocate measurement effort. Four simple Bayesian algorithms designed via this template are shown to have strong performance in numerical experiments, and a unified analysis establishes each satisfies strong asymptotic optimality properties.

2 - Inferring Consideration Sets from Sales Transaction Data

Dmitry Mitrofanov, New York University, New York, NY, 10012, United States, Srikanth Jagabathula, Gustavo J. Vulcano

In this paper, we study a methodology to identify competition sets from sales transactions in a data-driven way. First, we address the problem of identifiability of consider-then-choose models from the data. Then, we suggest the framework to estimate these models and infer competition sets. We apply the proposed methodology to the data obtained from a car-sharing platform and analyze the real-world settings where accounting for consideration sets can boost the predictive performance of the choice models. Our findings show that consider-then-choose models tend to be robust to the noise in the data and their relative importance in prediction tasks increases with the growing noise factor in the data.

3 - Learning Customer Preferences from Personalized Assortments

Yifan Feng, University of Chicago, Chicago, IL, 60637, United States, yifan.feng@chicagobooth.edu, Rene A. Caldentey, Christopher Ryan

A company wishes to commercialize the best version of a product out of a menu of available alternatives. The company does not know customers' preferences over the set of alternatives and relies on a voting system that allows potential buyers to vote for their preferred version. Under a general ranking-based choice model framework, we study how to dynamically customize each individual voter's choice set, so as to identify the top-ranked alternative with a fixed probabilistic confidence level, while using a minimal number of votes.

4 - Online Matching with Stochastic Rewards: Optimal Competitive Ratio via Path Based Formulation

Rajan Harish Udwani, Columbia University, 639W 204th St, 6D, New York, NY, 10034, United States, Vineet Goyal

Online matching with stochastic rewards is a generalization of the online bipartite matching problem, with applications in resource allocation, internet advertising, crowdsourcing, and other domains. Various algorithms have been proposed for special cases of this problem, yet finding one with the optimal competitive ratio has proven hard. We show that natural generalizations of classical algorithms achieve (near) optimal competitive ratios for this problem in various cases of interest. Our analysis relies on finding a tight bound on the clairvoyant via a novel path based formulation, a technique we believe could be useful more broadly in other online-stochastic settings.

1 - Pricing for Heterogeneous Products: Analytics for Ticket Reselling

Max Biggs, University of Virginia, Charlottesville, VA, 02139, United States, maxbiggs@mit.edu, Rim Hariss, Michael Li, Georgia Perakis, Charles Hermann

We develop a framework for estimating heterogeneous price sensitivity in applications such as ticket reselling. We introduce a orthogonalized machine learning approach for a classification setting with confounding. The loss function we derive can be easily incorporated into off-the-shelf machine learning algorithms, including gradient boosted trees and neural networks. Using a wide range of synthetic data sets, we show this approach beats state-of-the-art machine learning approaches for estimating price sensitivity and prove analytical properties for this estimator.

2 - Joint Pricing and Production: An Analytics Perspective

Qinshen Tang, National University of Singapore, Singapore, 117592, Singapore, tang@u.nus.edu, Georgia Perakis, Melvyn Sim, Peng Xiong

We integrate K-means clustering with robust optimization to address a two-period joint pricing and production problem. We construct a K-means ambiguity set and propose an affine recourse approximation to reformulate it as a MILP. Our framework can increase expected profits by 1.11% on average when applied to most out-of-sample tests.

3 - Joint Prediction and Optimization in Pricing

Lennart Baardman, University of Michigan, Operations Research Center, Ann Arbor, MI, 02139-4307, United States, baardman@umich.edu, Tamar Cohen-Hillel, Georgia Perakis

Most applications of analytics involve solving optimization models that include uncertain parameters. Models from statistics and machine learning are estimated and substituted for these uncertain parameters, after which the problem can be optimized. Instead of this two stage approach, we propose a single optimization model that jointly predicts and optimizes. We consider an application in pricing for a large paper product manufacturer while accounting for uncertain reorder quantities and timing by their retail clients. On real-world data, we show a significant improvement by using our one stage method.

4 - Dynamic Learning with Frequent New Product Launches

Junyu Cao, Berkeley IEOR, Berkeley, CA, 94706, United States, Wei Sun

Motivated by the phenomenon that companies introduce new products to keep abreast with customers' rapidly changing tastes, we consider a novel online learning setting where a profit-maximizing seller needs to learn customers' preferences through offering recommendations, which may contain existing products and new products that are launched in the middle of a selling period. We propose a sequential multinomial logit (SMNL) model to characterize customers' behavior when product recommendations are presented in tiers. For the online problem, we propose a learning algorithm that simultaneously explores and exploits, and quantify its regret bound.

1 - LP-Based Pricing for Bayesian Online Selection

Amin Saberi, Stanford University, Palo Alto, CA, 94105, United States, saberi@stanford.edu, Nima Anari, Rad Niazadeh, Ali Shameli

In the Bayesian online selection problem, the goal is to design a pricing scheme for a sequence of arriving buyers that maximizes the expected social-welfare (or revenue) subject to different types of structural constraints. I will present a Polynomial-Time Approximation Scheme (PTAS) for special cases of this problem. The approach is based on rounding the solution of a hierarchy of linear programming relaxations that approximate the optimum online solution with any degree of accuracy plus a concentration argument that shows the rounding incurs a small loss.

2 - Constant-regret Policies for Online Resource Allocation

Siddhartha Banerjee, Cornell University, Ithaca, NY, 14853, United States, sbanerjee@cornell.edu

I will present online control policies with the first constant regret guarantees (i.e., additive optimality-loss that is constant in the horizon and resource budgets) for a wide variety of problems, including online resource-allocation, dynamic pricing with discrete price levels, online budgeted probing, and contextual bandits. All our policies are built out of a meta-algorithm, where we first construct a tractable offline benchmark that satisfies a notion we refer to as the Bellman inequalities, and then use this benchmark with re-solving to construct a feasible online policy.

3 - Online Resource Allocation under Partially Predictable Demand

Vahideh Manshadi, Yale University, New Haven, CT, 06511, United States, vahideh.manshadi@yale.edu, Patrick Jaillet, Dawsen Hwang

For online resource allocation problems, we propose a new demand arrival model where the sequence of arrivals contains both an adversarial component and a stochastic one. Our model requires no demand forecasting; however, due to the presence of the stochastic component, we can partially predict future demand as the sequence of arrivals unfolds. Under the proposed model, we study the problem of the online allocation of a single resource to two types of customers, and design online algorithms that outperform existing ones. We also study the classical secretary problem under our proposed arrival model, and we show that randomizing over multiple stopping rules may increase the probability of success.

4 - Autobidding Algorithms

Ashwinkumar Badanidiyuru, Research Scientist, Google Research, Mountain View, CA, United States

Autobidding is becoming increasingly important in the domain of online advertising, and has become a critical tool used by many advertisers for optimizing their ad campaigns. These tools offer to optimize advertiser goals (post click purchases/total clicks) subject to various constraints (ROI/budget). In this work we formulate and study several allocation and learning related problems in the area of automated bidding.

5 - Pandora's Problem with Nonobligatory Inspection

Hedyeh Beyhaghi, Cornell University, Ithaca, NY, 14853, United States, Robert Kleinberg

Weitzman's Pandora's problem furnishes the mathematical basis for optimal search theory in economics. Nearly 40 years later, Doval introduced a version of the problem in which the searcher is not obligated to pay the cost of inspecting an alternative's value before selecting it. In this work we provide the first non-trivial approximation guarantees for this problem. We introduce a family of "committing policies" such that it is computationally easy to find and implement the optimal committing policy. We prove that the optimal committing policy is guaranteed to approximate the fully optimal policy within a $1-1/e=0.63...$ factor.

6 - Adaptive Submodular Ranking and Routing

Fatemeh Navidi, University of Michigan, Ann Arbor, MI, 48105, United States, Prabhanjan Kambadur, Viswanath Nagarajan

We study a general stochastic ranking problem where an algorithm needs to adaptively select a sequence of elements to cover a random scenario at minimum expected cost, where the coverage is captured by some submodular function. We obtain a logarithmic factor approximation algorithm for this problem, which is the best possible. We also extend our results to an adaptive routing problem, where costs are determined by a metric. Our approximation ratio nearly matches the best bound known for some special cases. Finally, we present experimental results for some applications of adaptive ranking.

Revenue Management with Social and Digital Technologies

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Joline Uichanco, University of Michigan, Ross School of Business, Ann Arbor, MI, 48109-1234, United States

1 - Dynamic Optimization in Display Advertising

Elaheh Fata, Massachusetts Institute of Technology, Aeronautics and Astronautics, Cambridge, MA, 02139, United States, efata@mit.edu, Lennart Baardman, Abhishek Pani, Georgia Perakis

The large growth of online advertising and the associated growth in personalized data allows advertisers to customize their advertisements for specific customers. The level of customization varies between different types of advertising. The ability of showing the right creative look of the ad to the customer is valuable, as it increases the chance of the customer interacting. Focusing on product display advertising, we are interested in dynamically customizing the product that is shown, but also potentially the creative look of the display itself.

2 - Pricing Fast-moving Products

Mengzhenyu Zhang, University of Michigan, Ann Arbor, MI, 48105, United States, zhenyuzh@umich.edu, Hyun-Soo Ahn, Christopher Ryan, Joline Uichanco

With the rise of social technologies, the traditional view of treating consumers as isolated entities no longer holds for some markets. For instance, in influencer-driven commerce markets, social media platforms can significantly accelerate new product adoptions to create fast-moving markets with demand hype. We propose a dynamic pricing model for the setting where future demand is dependent on current and past adoptions. In this setting, price not only affects the current revenue and sales, but also, the future demand pattern and revenues. We propose a certainty equivalent (CE) policy (pricing and initial inventory) with re-optimization and show that this policy is asymptotically optimal.

3 - Revenue Management with All-or-Nothing Constraint

Longyuan Du, University of San Francisco, San Francisco, CA, 94117, United States, ldu5@usfca.edu, Ming Hu, Jiahua Wu

We consider a revenue management problem under the all-or-nothing constraint. The seller will receive her revenue if and only if the number of sales exceeds a predetermined sales target at the end of sales horizon. Over the course of the sale horizon, the sales process can be moderated by the seller though her costly effort. We show that the optimal sales rate is not monotone with respect to the remaining time or the number of sales required to reach the target. We then study easy-to-compute heuristics that can solve the problem efficiently. We propose a modified resolving heuristic and show that it is asymptotically optimal, and achieves a logarithmic performance loss.

1 - The Effects of Consumption Type, Self-view, and Gender on Susceptibility to the Partner's Influence in Romantic Relationships— A Conceptual Paper

Qiuling Li, University of Macau, Macau, Macao, Chanthika Pornpitakpan

This conceptual paper aims to provide insights into how individuals' decision-making is influenced by their partners in romantic relationships. Using regulatory fit theory, it proposes several hypotheses about the interaction effects between consumption type and self-view and between consumption type and gender on susceptibility to interpersonal influence.

2 - Maximizing the Potential of Targeted Marketing: A General Framework for Customized Category Promotions in Retail

Bernhard von Mutius, WHU - Otto Beisheim School of Management, Vallendar, Germany, Arnd H. Huchzermeier

We develop the first general framework for category selection in targeted marketing based on segmenting customers in terms of churn, frequency, and loyalty. For the latter attribute, we propose a novel data-mining methodology that can distinguish between customers who shop at several retailers versus mostly at a single retailer. Using our framework, marketing managers can identify customers to target with category-specific promotions and with what objective function to target them. Our analysis reveals that the personalized targeting strategy exploits the full potential of customized marketing by optimizing the trade-off between CLV considerations and short-term campaign profitability.

3 - Mobile Targeting Effectiveness: Heterogeneity and Contingency

Zhuping Liu, Baruch College, City University of New York, New York, NY, United States

This research contributes to the literature by studying the heterogeneity and contingency of mobile targeting effectiveness. Leveraging a unique data tracking the timing and contents of each targeting message and targeted user responses, we examine how targeting effects vary across mobile devices, retailer category, and coupon characteristics. Our results reveal interesting insights which can help marketers target users at the right timing with the right contents.

4 - Influence Maximization in Social Networks under Deterministic Linear Threshold Model

Dilek Günneç, Özye in University, Istanbul, Turkey, dilek.gunnec@ozyegin.edu.tr, Furkan Gürsoy

We define the Targeted and Budgeted Influence Maximization under Deterministic Linear Threshold Model Problem and develop a novel and scalable algorithm which allows for optional methods to solve it. It is a greedy algorithm that relies on investing in potential future gains when choosing seed nodes. We suggest real-world mimicking techniques for generating influence weights, thresholds, profits, and costs. Computational experiments on four real network (Epinions, Academia, Pokec and Inploid) show that our proposed heuristics perform significantly better than benchmarks. We equip our algorithm with novel scalability methods which reduce runtime trading-off with spread performance.

Logistics III

Contributed Session

Chair: Dinghao Ma, Northeastern University, Boston, MA, 02115, United States

1 - The Use of Hybrid Crowd-sourcing Model in the Last-mile-delivery of CEP Services

Mingwei Guo, Doctoral Student, North Dakota State University, Fargo, ND, United States, mingwei.guo@ndsu.edu, Joseph Szmerekovsky

The boost of E-commerce and Cyber Sales has posted great development on the way customers shop. In the past years, third party logistics (3PL) service has been growing rapidly by the utilization of online shopping. Under dynamic business environment, such growing patterns has been initiating huge pressure on the Carrier, Express and Parcel (CEP) service. This research will be utilizing Crowd-Sourcing Logistics (CSL) tools to work with CEP last-mile delivery (LMD) to help solve the peak demand occasion problems, using conjoint analysis look into the potential reasons and causes which will trigger CSL, as well as working as a partnership for the improvement of the entire CEP logistics dynamics.

2 - Managing Drones and Battery Inventories on Last-mile Logistics under Uncertainty

Ali Tolooie, PhD Candidate and Graduate Research Assistant, Kansas State University, Manhattan, KS, United States, alit@ksu.edu, Ashesh Sinha

Nowadays, last-mile logistics using drones present practical applications in various industries. However, limited and uncertain flight range of a large fleet of drones and randomness in demand creates a complex issue in last mile logistics. Using stochastic models and concept of Matrix Geometric approach, we provide exact analysis on the logistics and inventory decisions.

3 - With a Little Help from My Truck: Parcel Delivery Assisted by Autonomous Vans

Stefan L. Fedtke, Friedrich-Schiller-Universität Jena, Jena, Germany, Nils Boysen

Especially in urban areas, the implementation of last-mile logistics is associated with high efforts and costs for companies, customers, and the environment. Managing the increasing amount of parcel deliveries without negative effects such as congestions, pollution, and disgruntled customers turns out as a challenging task. This talk addresses an innovative solution concept, i.e., autonomously driving delivery vans, and their effects on last-mile logistics. We discuss different aspects on how self-driving vans can assist a human delivery person, introduce respective optimization problems, formulate mathematical models, and suggest solution procedures in order to reduce delivery time.

4 - Last Mile Delivery and Sharing Economy

Dinghao Ma, Northeastern University, Boston, MA, United States, ma.di@husky.neu.edu, Mehdi Behroozi

This paper tries to combine the last mile delivery and sharing economy, which crowd base drones are considered, together to decrease the last mile delivery time. A truck will first delivers all the packages in an area to the local center, next several crowd base drones will come from their origin to the center to pick up the packages and then delivery them to the customers. Tabu Search Algorithms are used to solve this NP-hard problem while sensitive analysis are made to check the influence of different speed ratio of drones and trucks, and the influence of number of drones in that area.

Disaster Management in Preparedness, Response and Recovery

Sponsored: Public Sector OR

Sponsored Session

Chair: Kyoung Yoon Kim

1 - An Integrated Optimization Framework in Modeling Patient Evacuation Before Hurricanes

Kyoung Yoon Kim, University of Texas at Austin, Austin, TX, United States, erickim@utexas.edu, Erhan Kutanoglu, John Hasenbein

We propose an integrated optimization framework in modeling patient evacuation before hurricanes. First, in order to capture the probabilistic nature of hurricanes, we generate hurricane scenarios by parameterizing the hurricane forecasts and generating the multiple inundation maps using the state-of-art hydrology and hydraulics models. Then, we input the scenarios into a stochastic integer program to make decisions on patient movements, staging area locations and positioning of emergency medical vehicles.

2 - Post-disaster Joint Repair of Road and Power Networks

Erhan Kutanoglu, University of Texas-Austin, Or/Ie Graduate Program, Dept of Mechanical Engineering, Austin, TX, 78712, United States, Brian French

This presentation covers the interaction between the competing desires of road and power grid repair agencies in the wake of a hurricane. We formulate integer programming models for both aspects of the problem and partially relax the routing aspects to make them computationally tractable. A framework is presented to iterate between the two solutions to find a solution that meets both objectives.

3 - Resilient Transportation Networks with Humanitarian Logistics

Yusuf Secerdin, University of Miami, 1251 Memorial Drive McArthur, Engineer Building, Coral Gables, FL, 33146, United States, yusufsecerdin@miami.edu, Murat Erkoc

Natural disasters such as hurricanes can cause major disruptions for transportation networks. During recovery of their commercial operations, many cargo carriers are also expected and involved in logistics of humanitarian aid to disaster-stricken regions. In this study, we propose a two-stage decision framework that combines recovery of commercial transportation operations with humanitarian logistics for a cargo carrier. We illustrate our model using a case study that is based on a real transportation network in the Caribbean basin.

4 - GIS-integrated Predictive Modeling for Nursing Home Evacuation Decision

Nazmus Sakib, University of South Florida, Tampa, FL, 33612, United States, nsakib@mail.usf.edu, Kathryn Hyer, Debra Dobbs, Lindsay Peterson, Dylan J. Jester, Nan Kong, Mingyang Li

Whether to evacuate or shelter in place against hurricane is one of the most difficult and complicated decisions often encountered by nursing home (NH) administrators. There is a lack of evidence-based analytical models to inform such decision. This work proposes a GIS-integrated predictive analytics framework to improve both prediction and understanding of evacuation decision. Environmental features are extracted from rich GIS data and further integrated with various facility and resident characteristics to enhance prediction accuracy. A real-world case study is provided to investigate the multi-factorial and nonlinear nature of NH evacuation decision in a real application context.

5 - Proactive Planning for Slow Onset Weather Event

Mahsa Ghanbarpour, Northeastern University, Boston, MA, 02115, United States, ghanbarpourmamagh.m@husky.neu.edu, Ozlem Ergun

Preparedness and response planning are necessary to reduce the adverse impacts of severe weather and other environmental emergencies. This study introduces a decision-making framework that optimizes the level and timing of proactive actions in healthcare by analyzing the trade-offs between making more accurate decisions with better weather forecasts vs. increasing cost of action as the event approaches. We develope this framework by incorporating: (i) a pattern recognition method based on large-scale patients claim dataset for determining the impact of weather events on hospital operations and (ii) developing a stochastic dynamic programming model which captures the trade-offs.

4:35-5:20 Responsive Learning Technologies 5:20-6:05 GoldSim

Vendor Tutorial

1 - Online Games to Teach Operations and Supply Chain Management

Samuel C. Wood, Responsive Learning Technologies, Los Altos, CA, 94022, United States

Littlefield Technologies, the Supply Chain Game, and the Sourcing Game are online competitive assignments used to teach topics including process analysis, inventory control, supply chain management, and sourcing and purchasing. We will describe the games' learning objectives, typical assignments, and actual game results.

2 - A Probabilistic Simulation Platform for Dynamically Modeling Complex Systems

Richard Kossik, GoldSim Technology Group LLC, Issaquah, WA, United States

GoldSim is a probabilistic simulation platform used for dynamically modeling complex systems. GoldSim supports decision-making and risk analysis by simulating future performance while quantitatively representing the uncertainty and risks inherent in all complex systems. The software is used primarily for engineering and scientific applications in over 60 countries worldwide.

You build a model in an intuitive manner by literally drawing a picture (an influence diagram) of your system using a collection of specialized model objects. GoldSim provides a wide variety of model objects to make models less abstract (and hence more transparent). Because the real world is inherently uncertain, GoldSim provides powerful probabilistic simulation capabilities to support representation of uncertain and/or stochastic systems. GoldSim is a hybrid simulator, allowing you to superimpose the occurrence and consequences of discrete events (e.g., financial transactions, accidents, failures) onto continuously varying systems (i.e., material and information flows). This ability, coupled with features to support the construction of hierarchical, top-down models, facilitates the simulation of large, complex systems while keeping the models easy to understand, navigate and explain to others.

Although the basic GoldSim framework is quite generic (allowing it to be used to model the behavior of nearly any kind of physical, financial or organizational system), it also provides several specialized modules to support Risk and Reliability Analysis, Financial Modeling, and Mass Transport Modeling.

GoldSim has been used for a wide range of diverse applications, ranging from modeling complex environmental systems such as mines and large water resource systems, to comparing alternative business strategies, to evaluating the risks associated with space missions. This Tutorial will provide an overview of GoldSim's features and capabilities and illustrate a number of existing applications.

Joint Session QSR/Practice Curated: Advances in the Gaussian Process

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Raed Al Kontar

1 - Mapping Based Additive Gaussian Process with Sequence Order Inputs

Xinwei Deng, PhD, Virgina Tech, Blacksburg, VA, United States, Qian Xiao, Abhyuday Manda

In modern pharmaceutical industry, combinatorial drugs have been widely applied in disease treatment, especially chemotherapy for cancer, where both the dosage and order-of-addition of each drug component are important. In this work, we propose a novel Mapping-based Additive Gaussian Process (MaGP) model to provide both accurate predictions and clear interpretations. The proposed method is an efficient probabilistic model of complex input-output relationship to guide the searching for optimal solutions, e.g. the optimal drug dosages as well as orders-of-addition for combinatorial drugs. We illustrate our method via two real drug experiments on lung cancer and several simulation studies.

2 - Gaussian Processes Interpolation with Matérn Kernels: Uniform Convergence and Robustness

Rui Tuo, Texas A&M University, College Station, TX, United States, ruituo@tamu.edu, Wenjia Wang

We derive some non-asymptotic error bounds for the prediction error under the uniform metric when the spectral densities of both the true and the imposed correlation functions decay algebraically. The Matérn families is a prominent class of correlation functions of this kind. We show that, when the smoothness of the imposed correlation function exceeds that of the true correlation function, the prediction error becomes more sensitive to the space-filling property of the design points. We also derive a lower bound of the prediction error and show that the kriging predictor reaches the optimal rate, if the experimental design scheme is quasi-uniform and the correlation function is oversmoothed.

3 - Variational Inference of Joint Model Using Multivariate Gaussian Convolution Process

Xubo Yue, University of Michigan, Ann Arbor, MI, United States, maxyxb@umich.edu

We present a prognostic framework for individualized event prediction based on joint modeling of both longitudinal and survival data. Our approach exploits a multivariate Gaussian convolution process (MGCP) to model the evolution of longitudinal signals and a Cox model to map survival data with longitudinal data modeled through the MGCP. Taking advantage of the structure imposed by convolved processes, we provide a variational inference framework to simultaneously estimate parameters in the model. This reduces computational complexity and safeguards against model overfitting. Experiments show that our framework outperforms state-of-the art approaches built on two-stage inference.

4 - Distributed Multivariate Gaussian Processes

Raed Al Kontar, University of Michigan, IOE 2769, Ann Arbor, MI, 48109, United States

We present a generic distributed estimation scheme for functional data that scales efficiently to high dimensions and minimizes the negative transfer of knowledge between uncorrelated functional outputs is proposed. Consistency in estimation and variable selection (oracle property) are then established. The methodologies are validated using numerical studies and a case study with real world data in the application to cloud-based vehicle health monitoring service systems.

Data Science for Disaster Management

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Youngjun Choe, University of Washington, Seattle, WA, 98105, United States

1 - Tweet Diffusion Life-cycle: A Twitter Tale of Hurricanes

Ridwan Al Aziz, University at Buffalo, The State University of New York, Buffalo, NY, United States, ridwanal@buffalo.edu, Jun Zhuang

Online social media (OSM) has become a popular platform for people to share information on diverse topics. OSM has been widely used as an information dissemination agent, particularly during crisis situations such as hurricanes, earthquakes, floods or political conflicts. This paper studies the temporal tweet behavior of people during hurricanes and determines the data diffusion trends. A novel concept of “Tweet Diffusion Life-cycle” is introduced which will help to determine the efficient timing of tweeting life-saving critical information during hurricanes for the responsible agencies.

2 - Modeling Uncertain and Dynamic Interdependencies of Infrastructure Systems with Stochastic Block Model

Jin-Zhu Yu, Vanderbilt University, Nashville, TN, 37212, United States, yujinzhu88@gmail.com, Hiba Baroud

Modeling the resilience of interdependent critical infrastructure (ICI) requires a careful assessment of interdependencies as these systems become interconnected. The interdependency across ICIs are often subject to uncertainty due to lack of data. This paper develops an approach to modeling the interdependency of ICIs with probabilistic graphical models. Specifically, the approach estimates the probability of links between individual systems considered as blocks in the stochastic block model. The proposed model uses several nodal attributes as predictors. The proposed approach is illustrated with a case study of the interdependent water and power networks in Shelby County, Tennessee.

3 - Data Simulation to Support Interdependence Modeling of a Multimodal Transportation Network

Basem Alkhaleel, University of Arkansas, Fayetteville, AR, 72701, United States, baalkhal@email.uark.edu, Jose Azucena

In this research, data about natural extreme events affecting inland waterways are collected and used to predict possible occurrences of such events in the future using spatio-temporal statistical models. A simulation tool built on these statistical models is used to investigate the effect of waterways disruptions on interconnected transportation systems. A case study based on the Mississippi River and the McClellan-Kerr Arkansas River Navigation System (MKARNS) is provided to illustrate the use of the simulation tool in interdependence modeling and decision making for the operation of a multimodal transportation network.

4 - Personal Fitness Monitoring App Data to Assess Community Recovery at Scale: Case Study on Post-hurricane Harvey Recovery of Harris County, Texas

Zhanlin Liu, University of Washington, Seattle, WA, 98105, United States, zhanlliu@uw.edu, Pariyakorn Maneekul, Scott Miles, Nicole Errett, Youngjun Choe

During the disaster recovery process, it is challenging to continuously assess community health and well-being. This study used cycling and running activity records from a personal fitness monitoring app as a proxy for community health and wellbeing. This large-scale data enabled us to assess the post-Hurricane Harvey recovery of the fitness activity level throughout Harris County, Texas. The data revealed geospatial patterns of fitness activity level recovery and demonstrated its value in supporting a near real-time, scalable method to monitor the recovery of affected communities.

5 - Hurricane-damaged Building Identification Using Satellite Imagery and Geographical Features

Quoc Dung Cao, University of Washington, Seattle, WA, 98105-0002, United States, Youngjun Choe

Rapid damage assessment after hurricane events using satellite imagery has the potential to transform emergency response to the events. However, relying solely on the imagery would underutilize valuable geographical features such as locality of the buildings, ground elevation, and flood inundation risk. We study the contribution of each feature to the improvement of damaged building identification task using the convolutional neural network. The proposed method is applied to the case study of 2017 Hurricane Harvey.

Smart Manufacturing Systems: Challenges, Opportunities, and Solution Methodologies

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Mohammed Shafae, University of Arizona, Tucson, AZ, 85721, United States

1 - Data-informed Decision Process for the Polishing Process of 3D Printed Titanium Alloy Parts

Shilan Jin, Texas A&M University, College Station, TX, United States, jin0541@tamu.edu, Yu Ding, Satish Bukkapatnam, Asif S. Iquebal

Polishing is a crucial post-processing step to finish additive manufacturing products. Important decisions in polishing operations, such as pad changing and ending point determination, currently rely on practitioners’ experience and subjective visual inspection of surface quality. For delivering consistency and reducing variability, Gaussian process model-guided decision making is developed for the polishing process of a Titanium alloy product. The series of Gaussian process models appear capable of capturing surface changes and variation over the polishing process, resulting in a decision protocol informed by the correlation characteristics over the sample surface.

2 - Opportunities and Challenges of In-Situ Monitoring in Additive Manufacturing

Marco Grasso, Politecnico di Milano, Via La Masa 1, Milano, 20156, Italy, marcoluigi.grasso@polimi.it, Bianca Maria Colosimo

This talk revises exiting solutions for in-situ monitoring of Additive Manufacturing via signal, image and video-image data. Appropriate methods for statistical data modelling and monitoring are discussed.

3 - Spatiotemporal Gaussian Process for Image Guided Quality Control of Additive Manufacturing

Farhad Imani, The Pennsylvania State University, State College, PA, 16802, United States, fxi1@psu.edu, Ruimin Chen, Hui Yang

Additive manufacturing (AM) is a new paradigm in a design-driven build of customized products. Nonetheless, AM quality assurance is extremely challenging due to the existence of multiple factors that impact the quality of a build. The proposed research introduces a novel real-time and sparse spatiotemporal Gaussian process (STGP) which approximates a standard layerwise profile while quantifying the spatiotemporal deviations from the standard. Experimental results show that the proposed STGP methodology is highly effective to monitor the quality of layerwise images. This provides a significant opportunity to reduce inter-layer variation in AM prior to completion of a build.

4 - Gauge Capability Studies for High-density Data

Romina Dastoorian, Western Michigan University, Kalamazoo, MI, 49009, United States, romina.dastoorian@wmich.edu, Lee Wells

In manufacturing, advanced measurement systems are continually being incorporated into modern SPC systems. Significant amount of research efforts has been placed in the development of Phase I and II SPC tools. However, the study of the quality and adequacy of a measurement system which is a prerequisite to implementing any SPC tool; has mostly been neglected for high-density (HD) data. Therefore, this work performs a holistic Gauge study on HD data by using spatial statistics data models. The main objectives of this work are listed as: 1) Studying how to analyze the repeatability and reproducibility of HD data, 2) Quantifying the uncertainty associated with measurement systems from multiple factors.

5 - Physics-based Detection of Cyber-Attacks on Cyber-Physical Manufacturing Systems

Mohammed Shafae, University of Arizona, Tucson, AZ, 85721, United States, shafae1@email.arizona.edu

Modern manufacturing systems face an unprecedented threat of cyber-physical attacks due to the increased connectivity between manufacturing systems entities. This work introduces a fundamental theory to understand cyber-physical attack designs and implementation approaches. Through this fundamental theory, a systematic method was developed to identify the elements of attack design and implementation space. In addition, a designation system was created to enumerate all possible approaches to design and implement attacks on part quality. The use of this method is demonstrated through several experimental machining case-studies covering a wide variety of unique attack scenarios.

Empowering Smarter Healthcare Decisions Using Operations Research and Data Analytics

Sponsored: Health Applications

Sponsored Session

Chair: Sharan Srinivas, University of Missouri, Columbia, MO, 65211, United States

1 - Predicting Patient Punctuality Using Machine Learning Algorithms

Sharan Srinivas, University of Missouri, Department of Industrial and Manufacturing, Systems Engineering, Columbia, MO, 65211, United States, srinivassh@missouri.edu

Late patient arrivals in outpatient clinics disrupt the schedule, increase subsequent patient’s waiting time and decrease physician productivity. This research aims to predict the patient-specific risk of tardy arrival based on several pertinent variables. Four machine learning algorithms are built to conduct a comparative analysis of predictive performance. The models are tested using real data obtained from two outpatient clinics. Gradient boosting machine yielded the best predictive performance (Clinic1 AUC = 0.904 and Clinic2 AUC = 0.863). Further, insights drawn from our analysis will enable healthcare administrators to manage and mitigate late arrivals.

2 - Positional Flexibility and Consistent Assignment in Long-Term Care Staffing

Vincent Slaugh, Cornell University, Ithaca, NY, United States, vws8@cornell.edu, Alan Scheller-Wolf

We study the assignment of caregivers to residential households for each shift. We show that prioritizing part-time employees to work in their “home unit” can significantly improve consistency of care. Analysis of one facility’s schedules reveals a 40% possible reduction in the number of unique caregivers assigned to each household.

3 - Evaluation of Dexketoprofen Trometamol Efficacy in Postoperative Pain Management for Open Heart Surgery

Umit Tursun

Please check the mobile app for this abstract.

4 - A High-Fidelity Model to Predict Length-of-Stay in the Neonatal Intensive Care Unit (NICU)

Kanix Wang, University of Chicago Booth School of Business, Chicago, IL, 60637, United States, Kanix.Wang@chicagobooth.edu, Walid Hussian, John R. Birge, Michael D. Schreiber, Daniel Adelman

The widespread implementation of electronic medical record systems has enabled hospitals to collect massive amounts of health data. To integrate this data into healthcare operations, we impose expert knowledge when grouping raw clinical data into medically meaningful variables, which summarize patients’ health trajectories. We use dynamic predictive models to output patients’ remaining lengths of stay, future discharges, and census probability distributions based on their health trajectories up to the current stay. Evaluated with large-scale EMR data, our model significantly improves the predictive power and remains medically interpretable.

1 - The Role of Model Structure in Predicted Effectiveness of Policy Interventions for Infectious Diseases

Giovanni S. Malloy, Stanford University, Stanford, CA, United States, malloyg@stanford.edu, Jeremy D. Goldhaber-Fiebert, Eva A. Enns, Margaret L. Brandeau

We analyze the role of model structure in determining the predicted effectiveness of policy interventions for infectious diseases such as HIV. We create four models which vary with respect to population mixing (compartmental vs. network structure) and risk stratification (uniform vs. stratified risk). We calibrate the four models to the same baseline prevalence and then evaluate the effects of a simple policy intervention. The observed differences between the model outputs suggest the need for careful consideration of model structure when modeling interventions to control infectious diseases.

2 - Human Mobility and Infectious Disease Dynamics

Amy Wesolowski, Johns Hopkins Bloomberg School of Public Health, Batlimore, MD, United States

Infectious disease transmission depends on the dynamics of human movement. However, in many settings there is limited data to quantify human travel patterns on spatial and temporal scales relevant to disease control. Increasingly novel data sources are available, such as mobile phone calling records, that can be used to understand the impact of travel on disease dynamics and can provide additional information about human mobility. We will outline work done to analyze various sources of travel data, the utility of these data to understand directly-transmitted and vector-borne disease dynamics, and models developed to capture epidemiologically relevant mobility patterns.

3 - Physical-statistical Modeling and Optimization of Complex Systems with the Application in Healthcare

Bing Yao, PSU, State College, PA, 16801, United States, Hui Yang

This talk will present a novel physics-driven spatiotemporal regularization method for high-dimensional predictive modeling in complex healthcare systems. This model not only captures the physics-based interrelationship between time-varying explanatory and response variables that are distributed in the space, but also addresses spatial and temporal regularizations to improve the prediction performance.

4 - Use of Simulation to Investigate Effects of Distributions on Pancreatic Cancer Progression Model

Julie Simmons Ivy, North Carolina State University, Raleigh, NC, Lena Abu-El-Haija, Osman Ozaltin, Walter G. Park

Pancreatic cancer is a low-incidence disease, where tumor progression studies using patient longitudinal data had limited sample sizes. Estimating the tumor inverse growth rate and its distribution are a challenge. Pancreatic cancer progression models were built as a function of age, race, and gender under Uniform and Gamma inverse growth rate distributions. This study uses simulation to evaluate the effect of the tumor inverse growth rate distribution on tumor progression. The tumor timeline was found to be nine months longer with the Gamma assumption. It was inconclusive whether tumor progression is faster in older patients with the different underlying assumptions on the inverse growth.

1 - Introducing Swing Shifts to Dynamically Respond to Emergency Department Workload Uncertainty

David L. Kaufman, University of Michigan - Dearborn, Fairlane Center South, Dearborn, MI, 48126, United States, davidlk@umich.edu, Jianing Man, Kalyan Pasupathy, Daniel Cabrera, Mustafa Y. Sir

A fundamental problem of emergency care is matching resources to uncertain patient demands. Staffing allocation decisions require good matching with workloads but also consider the needs of emergency providers at very high risk of burnout. Mayo Clinic Emergency Department recently introduced a "swing shift," which allows physicians to leave early depending on a workload threshold. While popular, swing shifts introduce several challenges: How to design a threshold mechanism? What is the optimal length of the furlough? When should these shifts start and what is their impact? We introduce an effective and tractable data-driven optimization model for a complex stochastic problem.

2 - Optimizing Lung Transplantation Waitlist Composition from the Transplant Program's Perspective

David Mildebrath, Rice University, Houston, TX, 77005, United States, dtm3@rice.edu, Taewoo Lee, Andrew J. Schaefer

Under regulations by the Centers for Medicare and Medicaid and Organ Procurement Transplantation Network, the United States has seen a rise in risk-adverse behavior among transplant programs, resulting in an increase in organ discard rate. In this work, we optimize the mix of patients on the transplant waitlist to maximize transplantation volume and manage the risk of penalization under the regulations. We present a chance-constrained mixed-integer program for the waitlist composition problem and derive analytical results to provide clinical insight on the decision-making process. Our tractable approximation model provides the first qualitative comparison between different regulations.

3 - A Bayesian MCMC Model to Study the Spread of Antibiotic-Resistant Bacteria in the Hospital

Diego A. Martinez, Johns Hopkins University, 1800 Orleans Street, Billings Building 401E, Baltimore, MD, 21287, United States, Katherine E. Goodman, Rajib Paul, Jeremiah S. Hinson, Aria Smith, Matt Toerper, Scott R. Levin, Patricia J. Simner, Justin Lessler, Aaron M. Milstone, Eili Y. Klein

Spread of antibiotic-resistant bacteria that cause healthcare-associated infections is an enduring problem linked with high mortality and morbidity. There is debate on the value of interventions that target specific pathogens such as carbapenem-resistant organisms (CRO). We used temporal networks of the location of patients within the hospital to model a patient's risk of CRO acquisition, and to determine the impact of contact precautions on this risk while adjusting for healthcare worker-mediated connectivity, colonization pressure, carbapenem use, hand hygiene, and environmental cleaning.

4 - Readmission Risk Trajectories for Heart Failure Patients Using a Dynamic Prediction Approach

Sauleh Ahmad Siddiqui, Johns Hopkins University, 3400 N. Charles Street, Baltimore, MD, 21218, United States, siddiqui@jhu.edu

We develop a dynamic readmission risk prediction model that yields daily predictions for hospitalized heart failure patients toward identifying risk trajectories over time and identify clinical predictors associated with different patterns in readmission risk trajectories. A two-stage predictive modeling approach combining logistic and beta regression was applied to electronic health record (EHR) data accumulated daily to predict 30-day readmission for a cohort of 534 heart failure patient encounters over 2,750 patient-days. Unsupervised clustering was performed on predictions to uncover time-dependent trends in readmission risk over the patient's hospital stay.

Appointment System and Physician Behavior

Sponsored: Health Applications

Sponsored Session

Chair: Aditya Jain, Baruch College, Zicklin School of Business, New York, NY, 10010, United States

1 - Wait and Then Hurry Up. The Effect of Flexible Service Rates in Appointment Scheduling Systems

Aditya Jain, Baruch College, Zicklin School of Business, New York, NY, 10010, United States, aditya.jain@baruch.cuny.edu, William P. Millhiser

Recent empirical evidence suggests that ambulatory care healthcare workers intentionally vary service rates in response to two factors: time of day and queue length, where workers choose work speeds to balance their own overtime and the patient's wait. We explore a theoretical justification of this behavior and show that workers speed up if the cost of patient waiting is relatively small compared to workers' overtime cost. We analyze the implications of such worker behavior on various performance metrics for established appointment systems, and how appointment systems should be adapted.

2 - Capacity Planning for Post-discharge Follow-up

Alex Mills, Baruch College, City University of New York, New York, NY, 10010, United States, Alex.Mills@baruch.cuny.edu, Jonathan Helm

Many hospitals now schedule patients for follow-up care at the time of discharge, in an effort to reduce readmissions. We show that careful capacity planning is needed to make a follow-up program effective.

3 - Appointment Scheduling: The Disconnect Between Theory and Practice

William P. Millhiser, Zicklin School of Business, Baruch College, One Bernard Baruch Way, New York, NY, 10010, United States, william.millhiser@baruch.cuny.edu, Emre Veral

We explore the potential for theory-driven appointment schedules to make significant improvements in operational outcomes for medical practices. Our results show that potential benefits may fail to make a strong enough business case for adopting complex scheduling systems. IT integration difficulties, centralized processes, and staff buy-in exacerbate misgivings for adoption.

4 - Managing Interruptions in Appointment Schedules in Physician Clinics

Ali Dogru, University of Southern Mississippi, Hattiesburg, MS, United States, ali.dogru@usm.edu, Sharif Melouk

Physician clinics often encounter interruptions that affect their operations and impact the patient experience. Thus, in this research, we develop an interruption management procedure employing real-time patient notification. We use stochastic optimization to determine optimal appointment intervals and simulation optimization to establish a notification policy. Experimentation provides managerial insights. Keywords: Appointment Scheduling, Interruptions, Patient Notification, Simulation Optimization, Stochastic Optimization.

Joint Session QSR/DM: Improving Machine Learning Algorithms for Causal Inference

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Arman Sabbaghi, Purdue University, West Lafayette, IN, 47907, United States

1 - Controlling Confounding and Selection Biases in Causal Inference

Elias Bareinboim, PhD, Purdue University, West Lafayette, IN, 47907, United States, eb@purdue.edu

One of the fundamental challenges in scientific endeavors is the systematic discovery of cause and effect relations from a combination of non-experimental data and substantive knowledge about the phenomenon under investigation. Two of the most common obstacles to inferring these relations appear in the form of two biases, namely, confounding and selection. In this talk, I briefly describe a general solution on how to infer causal effects when these biases are simultaneously present. This approach generalizes the pervasive and celebrated strategies such as the Backdoor criterion and Inverse probability weighting (IPW).

2 - Transfer Learning for Estimating Causal Effects Using Neural Networks

Jasjeet Sekhon, PhD, University of California, Berkeley, CA, United States, Bradley Stadie, Sören R. Künzel, Nikita Vemuri, Varsha Ramakrishnan, Pieter Abbeel

We develop new algorithms for estimating heterogeneous treatment effects, combining recent developments in transfer learning for neural networks with insights from the causal inference literature. By taking advantage of transfer learning, we are able to efficiently use different data sources that are related to the same underlying causal mechanisms. We compare our algorithms with those in the extant literature using extensive simulation studies based on large-scale voter persuasion experiments and the MNIST database. Our methods can perform an order of magnitude better than existing benchmarks while using a fraction of the data.

3 - Collaborative Design for Improved Causal Machine Learning on Big Observational Data

Yumin Zhang, Purdue University, West Lafayette, IN, 47907, United States, zhan2013@purdue.edu, Arman Sabbaghi

The successful application of machine learning for inferring causal effects from an observational study requires consideration of the design of the observational data. In general, the workload of designing a study with high dimensional covariates could be unwieldy for a single researcher. We propose a framework to match or subclassify subjects in such an observational study based on the collaborative efforts of multiple analysts, and to infer causal effects via the application of flexible machine learning algorithms to the designed study. Ultimately, our framework reduces the workload of each study designer, and enables improved causal machine learning from large observational studies.

4 - Black Box Methods for Causal Inference: Lessons Learned from the 2016 ACIC Data Analysis Competition

Vincent Dorie, Associate Research Scientist, Columbia University, New York, NY, United States, vdorie@gmail.com, Jennifer Hill, Uri Shalit, Marc Scott, Dan Cervone

The comparison of causal inference methods is complicated by the requirement of foundational assumptions, leading to a reliance on simulation. However, methods are rarely compared on equal footing as it is difficult to create plausible-yet-interesting simulations and to best apply a competitor's work. The simulations generated by the data analysis challenge of the 2016 Atlantic Causal Inference Conference provide a way for developers to evaluate their methods, compare them to their competitors, and create default implementations for applied researchers. Here, we review the structure of that competition, its results, and what we've learned about causal inference methodology since.

Co-Chair: Shane Henderson, Cornell University, Ithaca, NY, 14853, United States

1 - Ranking and Selection under Input Uncertainty

Enlu Zhou, Georgia Institute of Technology, Atlanta, GA, 30332-0205, United States, enlu.zhou@isye.gatech.edu, Di Wu

We study ranking and selection (R&S) under input uncertainty (IU) by allowing the possibility of acquiring additional data. Two classical R&S formulations are extended to account for IU: (i) for fixed confidence, we consider when data arrive sequentially so that IU can be reduced over time; (ii) for fixed budget, a joint budget is assumed to be available for both collecting input data and running simulations. New procedures are proposed for each formulation using the frameworks of Sequential Elimination and Optimal Computing Budget Allocation, with theoretical guarantees provided accordingly.

2 - Convergence Rates of Global Optimization under Randomized Sampling

Jialin Li, PhD Candidate, University of Maryland, College Park, MD, United States, jl233@math.umd.edu, Ilya O. Ryzhov

We propose a new way of approaching global (black-box) optimization in a high-dimensional setting. Rather than developing new adaptive algorithms, we consider the design of static policies based on randomized sampling, by analogy with the literature on sampling laws for ranking and selection. We report our progress on the theoretical analysis of the convergence rates of such policies.

3 - Best Arm Identification and Hypothesis Testing in Very Large Action Spaces

Kevin Jamieson, University of Washington, Seattle, WA, United States, jamieson@cs.washington.edu

In multi-armed bandits, to identify a single good alternative among many sub-optimal alternatives, the number of total measurements necessarily scales linearly with the total number of alternatives. However, if many of the alternatives (e.g., a constant fraction) are "good enough" then far fewer measurements may be necessary to find one of them. Indeed, if half of the alternatives are good, then a random sample of constant size of them should contain at least one good enough alternative. In this talk I will ground this intuition in a theoretical framework known as infinite armed bandits and describe applications.

4 - Posterior-Based Stopping Rules for Bayesian Ranking-and-Selection Procedures

David J. Eckman, Northwestern University, Evanston, IL, 14850, United States, Shane Henderson

Ranking-and-selection procedures deliver Bayesian guarantees by repeatedly evaluating a posterior quantity of interest - e.g., the posterior probability of correct selection or expected opportunity cost - and terminating when this quantity crosses some threshold. Motivated by settings in which there are many alternatives, we develop several methods for improving the computational efficiency of checking such stopping rules. Simulation experiments give a sense of the savings in the number of observations taken relative to existing procedures that instead use cheaply computable bounds on the posterior quantity of interest.

Joint Session Sharing Econ & Crowdsourcing/MSOM/SERV OP/Practice Curated: Operational Flexibility in On-Demand Services

Emerging Topic: Sharing Economy & Crowdsourcing

Emerging Topic Session

Chair: Daniel Freund, Cornell University, Ithaca, NY, 14850, United States

1 - Understanding the Value of Large Time Windows in Scheduled Delivery Problems

Yeqing Zhou, Columbia University, 550 W. 120th St, New York, NY, 10027, United States, yz2714@columbia.edu, Adam Elmachtoub

Online grocers sell groceries online and provide a menu of time windows for customers to select a specific one to receive their delivery. We study the benefit of consumer flexibility in online grocery industry by offering large time windows (LTW) which can improve the delivery capacity utilization. We compare consumer flexibility with process flexibility and discover similar properties such as limited flexibility is good enough in both settings. However, chain structure is not essential in consumer flexibility due to the lack of submodularity and we conclude that non-overlapping LTWs can capture most of the benefits.

2 - Balancing Supply and Demand: Queuing Versus Surge Pricing Mechanisms

Yueyang Zhong, University of Chicago, Booth School of Business, Chicago, IL, United States, yzhong0@chicagobooth.edu, Zhixi Wan, Zuo-Jun Max Shen

At the end of 2017, DiDi Express replaced "surge pricing" mechanism by "observable queue" mechanism in a number of cities across China due to the uncertainty of surge pricing. In order to compare these two mechanisms, we build an M/M/s+M queueing model with balking and reneging and analytically and numerically find insightful results regarding consumer surplus, GMV, demand satisfaction rate and fairness. Using DiDi's real data, we implement a case study in Beijing and further statistically find correlations between system efficiency and driver's idleness.

3 - The Inefficiency of Dynamic Pricing in Ridesharing Systems

Garrett van Ryzin, Columbia University, New York, NY, United States, Daniel Freund

We identify a fundamental inefficiency of dynamic pricing and dispatch in ridesharing systems that is created by current market designs. We analyze the resulting inefficiencies using a fluid model and suggest an alternate mechanism that provably increases throughput. We complement our theoretical results through numerical experiments.

4 - Escrow Payment: A Smoother Driver Pay Mechanism

Arash Asadpour, Lyft inc., Stern School of Business, Kaufman Management Center, New York, NY, 10012, United States, aasadpour@lyft.com, Daniel Freund, Garrett J. van Ryzin

Dynamic pricing is a frequently used tool to match supply and demand in the gig economy. The comparatively fast-paced dynamics of supply and demand have also led to dynamic pricing featuring prominently in the recent operations research literature. In practice, ridesharing platforms like Lyft and Uber no longer employ the strictly proportional commission. Further, beyond the driver's expected pay, the volatility in prices affects drivers' decision-making. We discuss a mechanism to smooth the driver's dynamic pay and analyze its properties in a stylized stochastic setting. We demonstrate both numerically and analytically the characteristics of the mechanism and discuss its potential benefits.

1 - Optimal Sensor Placement: Power Domination, Set Covering, and Zero Forcing Forts

Logan A. Smith, Rice University, Rice University, Houston, TX, United States, logan.smith@rice.edu, Illya V. Hicks

To monitor electrical activity throughout power grids, sensors known as phasor measurement units can installed. Due to implementation costs it is desirable to minimize the number of sensors deployed, while ensuring that the grid can be effectively monitored. This optimization problem motivates the graph theoretic power dominating set problem. We propose a novel IP for identifying minimum power dominating sets by formulating a set cover problem. This problem's constraints correspond to neighborhoods of zero forcing forts; we show that they can be effectively separated and that this approach consistently improves upon the runtime performance of the state of the art method by an order of magnitude.

2 - A Local Search Method for the Maximum Induced Cluster Subgraph Problem

Seyedmohammadhossein Hosseinian, Texas A&M University, College Station, TX, 77843-3131, United States, hosseinian@tamu.edu, Sergiy Butenko, Richard Forrester, Fred W. Glover

A cluster graph is a graph whose every connected component is a complete graph. Given an input graph, the maximum induced cluster subgraph problem, which finds applications in network-based data analysis, is to find a maximum-cardinality subset of vertices inducing a cluster graph. We present a local search method based on a (cubic) pseudo-Boolean formulation of this problem. The advantage of this method is its ability to evaluate complex local moves in a very efficient manner. We use this method within a metaheuristic procedure for the maximum induced cluster subgraph problem, and present the results of our computational experiments.

3 - A Branch-and-cut Algorithm for the Distance-based Critical Node Problem

Hosseinali Salemi, Oklahoma State University, Stillwater, OK, 74075, United States, hosseinali.salemi@okstate.edu, Austin Buchanan

Recently, researchers have studied the problem of identifying so-called "critical nodes" in a network, which are small subset of nodes whose deletion maximally reduces some connectivity metric. In this talk, we consider a class of this problem in which the task is to delete at most b nodes so as to minimize the number of node pairs that remain connected by a path of length at most k. We propose new IP formulations and a preprocessing procedure. Also, we compare our results with previous approaches.

1 - Risk Culture in the Insurance Industry: A Machine Learning Approach

Abena Fosua Owusu, Rensselaer Polytechnic Institute, Troy, NY, United States, owusua@rpi.edu

Is the risk culture of insurance firms different from that of banks? In this paper, we identify the risk culture in both industries using unsupervised machine learning techniques. We use k-means clustering to group our sample of 10-K text documents into three distinct risk culture clusters: good, fair and poor risk culture groups. For both industries, we identify uncertain and litigious risk leadership and strategy features to be more defining of their risk culture. Unlike banks, we find the risk culture of insurance firms to be defined by uncertain and litigious risk training, education and recruitment features. This emphasizes the role of risk professionals like actuaries in the insurance industry.

2 - Dynamic Portfolio Optimization with Contingent Liabilities

Satya Krishna Sharma, Doctoral Scholar, BIMTECH, Noida, India, rsk.sharma_fpm18@bimtech.ac.in

Fund management problem in Agricultural insurance is two pronged problem of deciding optimal cash holdings to meet contingent liabilities while allocating rest of the funds into various assets so as to maximize the Return vs Risk ratio, over multiple time horizon.This work addresses the two pronged problem by applying extreme value theory to estimate maximum loss that could be claimed,while it uses DCC GARCH to optimize asset allocation in an ever changing investment environment.

3 - Identifying Market Manipulation & Abusive Trading Using Anomaly Detection Techniques

Robert James, PhD Student, The University of Sydney, Sydney, Australia, r.james@sydney.edu.au, Henry Leung, Artem Prokhorov

This study presents a novel semi-supervised procedure to detect intraday abusive trading in financial markets, addressing the limitations in existing rule based expert surveillance systems. We use the K-NN Dynamic Time Warping Algorithm to compute similarity scores between multivariate time series sub-sequences of trading activity. Using extreme value theory, we construct thresholds based on similarity scores observed under estimated normal trading conditions. Using real world tick data provided by a global investment bank, we highlight the utility of the procedure in identifying insider trading and demonstrate its competitiveness with respect to several benchmark algorithms.

4 - Family Firms' Digital Transformation: Insights from a Qualitative Study

Ricarda Bouncken, Prof. Dr., University of Bayreuth, Bayreuth, Germany, Beate Cesinger, Jochen Pampel, Viktor Fredrich

The present study is interested in the specifics of digital transformation. On the fundament of an explorative case study of six German family firms, we develop propositions regarding family control, openness, learning, and external sources of digitization expertise in the context family firms' digital transformation. Results indicate that that digital transformation of family firms follows specific logics. The strong influence of family ownership on mobilizing digitalization efforts, points to further theoretic development of a metastructuring perspective. In sum the the present study contributes first theoretical and practical insights on digital transformation of family firms.

Joint Session BOM/Practice Curated: Behavioral Supply Chain Management

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Ozge Tuncel, PhD., Eindhoven University of Technology, Eindhoven, Netherlands

1 - Leak or Not Leak? A Behavioral Investigation of Information Leakage

Lijia Tan, Eindhoven University of Technology, Stevertsemolen, Eindhoven, 5612DT, Netherlands, ljtan.wise@gmail.com, Meng Li

We experimentally investigate an information leakage problem in supply chains where two retailers competing in a market are scouring from the same supplier. The retailer who first places an order has known the real state market while the others only know the distribution of the market states. A revenue-sharing (S) contract is considered to incentivize the supplier to not leak the information in the rational model. We design an experiment to test the performance of the S contract, while the Wholesale price (W) contact is as a benchmark. We find the S contract does not yield supply chain surplus as high as the rational model predicts.

2 - Gender Differences in Supply Chain Contracting Decisions

Ummuhan Akbay, Ozyegin University, Ozyegin Universitesi Endustri Muhendisligi, Sarigazi Vergi Dairesi 717 024 0129, Istanbul, 34794, Turkey, ummuhan.akbay@ozyegin.edu.tr

In this study we examine the effects of gender differences on contracting decisions in a simple supply chain setting consisting of a manufacturer and a retailer. The relationship between the firms is governed by a buyback contract of which the parameters are determined by the manufacturer. And the retailer is faced with a newsvendor problem. We answer the following questions: 1) How does decision maker's own gender affect contracting behavior? 2) How does the opposing decision maker's gender affect contracting behavior? 3) How does the gender composition of the supply chain affect contract efficiency?

3 - Why are Minimum Order Quantity Contracts Popular in Practice? A Behavioral Investigation

Özge Tüncel, Eindhoven University of Technology, Veelakker 36, Eindhoven, 5625 WK, Netherlands, o.tuncel@tue.nl, Niyazi Taneri, Sameer Hasija

The minimum order quantity (MOQ) contract is observed to be more popular in practice compared to other coordinating contracts. We seek to understand whether the differences in complexity across the different coordinating contracts can explain why. Using laboratory experiments, we find that subjects perform better with the MOQ contract which can be attributed to the differing cognitive burden induced by complexity and risk inherent in the different contracts; and subjects choose the MOQ contract more frequently over theoretically equivalent coordinating contracts. Our results show that the tradeoff between efficiency and complexity can be mitigated by simpler yet efficient contracts.

4 - Risk and Fairness in Channel Relationships: Evidence of Behavioral Inconsistencies

Emilio Cuilty, Amazon, Seattle, WA, United States, cuilte@amazon.com, Paola Mallucci, Jordan D. Tong

In channel negotiations there might be uncertainty that is unevenly distributed. While there is evidence that both risk preferences and fairness would matter in such contexts, there is a lack of evidence on how subjects' beliefs, risk and fairness interact. We model a wholesale pricing decision between a supplier and a retailer. We then compare the prediction of the theoretical model with data from two incentive-compatible experiments. We find that suppliers squeeze retailers more when retailers face risk. This behavior is incompatible with correct beliefs about the other players preferences. We estimate the behavioral parameters and find that suppliers underestimate retailers risk aversion.

Chair: Ni Huang, Arizona State University, Gilbert, AZ, 85233, United States

1 - Is Uber Helping or Hurting Mass Transit? An Empirical Investigation

Yang Pan, Louisiana State University, 2208 Business Education Complex, Baton Rouge, LA, 70803, United States

Sharing economy reshapes the distribution of unused or underutilized asset through digital platforms to individuals who are willing to pay for the services. The new economy model has introduced dramatic impact on the traditional industries by matching the demand and supply in real time. In this paper, we examine how the entry of Uber, a ride-sharing services digital platform, influences the demand of public transportation. Significant debate has surrounded whether the new ride-sharing model siphoned riders from public transit, or made transit feasible for more riders. However, limited empirical research has been done to uncover whether Uber is helping or hurting public transportation systems. Leveraging a natural experiment setting, the entry of Uber, with a difference-in-differences approach, we find a significant drop in the number of passenger trips with bus. Further, our results suggest that the effect of Uber is not uniform - the reduction in bus passenger trips is mitigated when the proportion of old age people in a local urban area is large; the decrease is amplified when the populations of disable people, including with language difficulty, and self-employed people are large. However, the moderating effect of poverty is mixed.

2 - Organizational Attributes and Knowledge Sharing in Corporate Online Community

Jingchuan Pu, University of Florida, Gainesville, FL, 32607, United States, jingchuan@ufl.edu

Knowledge-sharing online communities are widely used in corporations. We empirically examine whether the organizational attributes of the knowledge seeker and provider affect the provider's knowledge sharing decisions. We find that location, hierarchical status, job similarity, and departmental position of the knowledge seeker can significantly influence whether and how the provider contribute. We also discuss the underlying mechanisms of these results.

3 - Peer Awards Increase User Content Generation but Reduce Content Novelty

Qinglai He, Arizona State University, Tempe, AZ, 85281, United States, Yili Hong, Gordon Burtch, Dokyun "DK" Lee

Platforms that depend on user-generated content spend a great deal of effort crafting policies and mechanisms that can yield a steady stream of engaging content. In this work, we consider the effects of awards offered by peers, a feature that many platforms provide to enable users to recognize the quality of peers' contributions. We conduct a large-scale field experiment on Reddit, one of the largest social news aggregation and discussion platforms in the world, evaluating the effect of peer awards (via awards) on content generation, in terms of both volume and novelty. We leverage Reddit's native peer award feature, the Gold Award, purchasing and randomly assigning Gold to more than 900 posts, anonymously, over the course of two months. Collecting and analyzing users' behavioral trace data and posting content over the period leading up to and following our treatments, via Reddit's API, we find that peer awards raise treated subjects' probability of making additional posts to Reddit by 6.6%, and lengthen subjects posts by 95.3%, on average, over the two weeks following treatment. Interestingly, however, we also observe that the content that users post under treatment exhibits greater similarity to past content (particularly the intervention post), indicating a decline in content novelty. Based on this result, we conclude that peer awards are a double-edged sword. On the one hand, per awards foster increased engagement and content production among recipients. On the other hand, the additional content that awards elicit is less novel.

4 - The Role of Participation Costs in Online Procurement Auction Performance: Evidence from an Online Labor Market

Jingbo Hou, Arizona State University, Tempe, AZ, 85287, United States, jhou27@asu.edu, Ni Huang, Yili Kevin Hong, Pei-yu Chen

Online labor markets have facilitated transactions worth billions of dollars. Yet, a noticeable inefficiency in these markets is the low matching rate. This study intends to evaluate the economic implications of the participation costs on increasing the matching rate. Our identification strategy hinges on a quasi-natural experiment on a large online service procurement platform. We theorize and empirically examine three mechanisms through which the introduction of participation costs may increase the service buyer's contract willingness: screening, effort, and selectivity.

Flash Session

Chair: Lu He, Binghamton University, Mississippi State, MS, 39762, United States

1 - Inpatient Bed Management Optimization Considering Patient Flow

Lu He, Binghamton University, Vestal, NY, United States, lhe9@binghamton.edu, Sreenath Chalil Madathil, Mohammad T. Khasawneh

This study reviews 92 published papers between 2013 and 2017 on existing work in inpatient bed management and identifies research gaps following the PRISMA guideline. Inpatient bed management is an important task for hospital strategic and operational management. Hospitals in the United States usually have a dedicated bed allocation team that assigns the beds and works as a bridge between the upstream departments (such as operating rooms (OR), emergency departments (ED), and referrals) and the inpatient units for most decisions and manually allocates the rooms. An efficient inpatient bed management can not only save time and financial cost, but also increase patient safety and satisfaction.

2 - Inventory Competition in an Online Marketplace: The Impact of Traffic Channeling

Zhoupeng Zhang, Rotman School of Management, University of Toronto, Toronto, ON, Canada, Zhoupeng.Zhang19@rotman.utoronto.ca, Peiwen Yu

This paper examines the impact of online platform's Traffic Channeling (TC) mechanism on third-party sellers' inventory competition. After observing sellers' market performance in the first period, the platform allocates visitors traffic to maximize total sales in the second. We find that, TC always increases sellers' equilibrium inventory and their aggregate sales. However, TC can either increase or decrease sellers' equilibrium profits, depending on the product margin and the characteristics of demand distribution. Our work offers insights into why sellers of some product categories are hurt even when TC improves sales, and discuss implications for the designing of TC mechanism.

3 - Innovation Service Platform Based on S&T Resources for Beijing-Tianjin-Hebei, China

Ning Xiang, Beijing Science and Technology Information Research Institute, Beijing, China, xiangning_xn@163.com

Demand-oriented for the collaborative innovation and industrial development, the Innovation Service Platform based on Science and Technology(S&T) Resources for Beijing-Tianjin-Hebei in China integrates information of nine major types of S&T resources and adopts a three-integration mode, i.e. "S&T resource + digital map, internet + S&T service, expertise wisdom + intelligence forecasting" to provide big-data information service and consulting service. Based on Web GIS framework, the platform formulates data standards and constructes a "3+12" cooperation network in the region.

4 - Ladies First, Gentlemen Third! The Effect of Narrative Perspective on Medical Crowdfunding

Xitong Li, HEC Paris, Jouy-en-Josas, France, lix@hec.fr

In practice, a majority of medical fundraising campaigns are narrated from the third-person perspective without knowing whether it is the most effective approach or not. We propose that the relative effectiveness of the first- vs. third-person perspective depends on patient gender. To test the hypotheses, we conduct a randomized field experiment on a leading medical crowdfunding platform, involving more than 1.2 million potential donors. The results show that the third-person perspective is more effective in motivating donation-related behaviors for male-patient fundraising campaigns, whereas the first-person perspective is more effective for female-patient fundraising campaigns.

1 - Block Ownership in Vertical Relationships in the Presence of Downstream Competition

Fang Fang, Cal State Los Angeles, Los Angeles, CA, United States, ffang2@calstatela.edu, Baojun Jiang, Jiong Sun

We study the economic impacts of partial vertical ownership (PVO) in the presence of downstream competition and its impact on consumer surplus. We show that both the acquiring and target firms prefer an intermediate size of PVO and consumers may get hurt in PVO by a low-valuation retailer.

2 - Partner Selection Strategies for Market Entry: Should an Entrant Firm Form an Alliance with a Major Firm, or with a Local Firm?

Kazuhiro Negoro, Keio University, Yokohama, Japan, negoro.keio@gmail.com, Nobuo Matsubayashi

In this study, we provide a game-theoretic analysis to investigate an entrant firm's partner selection for offering its new product to a market. We assume Salop's circular city market where a single major firm and two local firms exist at the center of the circle and on the circumference, respectively. We analyze two scenarios independently, where the entrant has either brand advantage or technological superiority over all of the incumbent firms. It is shown that forming a partnership with a firm who currently has the largest market share is not necessarily optimal for the entrant.

3 - Optimal Pricing Strategy Based on the Component Innovation

Weizhe Yang, University of Science and Technology of China, Hefei, China, ywz123@mail.ustc.edu.cn

Consider a two-period pricing problem for two profit-maximization firms under the following setting. While the two firms compete in the final products, the final product has a critical component which monopolized by one of them. The core component supplier can therefore firstly launch a new generation of final products in period 1 once it brings about a new generation of the key component. But for period 2, the supplier will not only determine whether to supply its competitor the newly component, but also will decide whether to sell its final product. Those two decisions lead to different competition situations. The result of our model fits the case of current smartphone market.

4 - Mobile Geo-fencing Targeting with Firms' Spatial Differentiation

Pengcheng Xia, Xi'an Jiaotong University, Xi'an, China, xiapengcheng@stu.xjtu.edu.cn, Gang Li

We investigate a competitive duopoly model of mobile geo-fencing targeting, based on consumers' real-time mobility behavior and firm's spatial differentiation. Two unique characteristics of mobile geo-fencing targeting are featured. First, consumers could move across different locations to maximize their total utilities. Second, firms' locations are not permanent, i.e., the relative position between consumers and firms is flexible. Our paper complements Chen et al. (2017) by studying mobile geo-fencing targeting with a different spatial structure, and new insights are obtained about the impact of price discriminationthe on firm's mobile targeting strategies and profits.

5 - Pre-Order Competition under Asymmetric Consumer Preference

Xuhan Tian, Hong Kong University of Science and Technology, Hong Kong, Hong Kong, xtianab@connect.ust.hk, Xiangtong Qi

This paper studies the pre-sale competition between two sellers offering horizontally differentiated products on an e-commerce platform. We consider a two-period model where consumers preference is realized in the second period and is asymmetrically distributed on a unit hoteling line. The pre-sale policy allows consumers to get a discounted price by paying a non-refundable deposit in the first period. We found that the less popular seller is more likely to operate the pre-sale strategy, which in some cases mitigates the competitive advantage of the other one. Besides, we proved the existence of some asymmetric equilibrium, where only one seller joins the pre-sale.

6 - Buy-One-Get-One Promotions in a Two-Echelon Supply Chain

Jing Zhou, Associate Professor, University of North Carolina-Charlotte, Charlotte, NC, United States, jzhou7@uncc.edu, Yuefeng Li, Moutaz J. Khouja, Jingming Pan

With "buy-one-get-one" (BOGO) promotions, the first unit of the product is sold for regular price and if a consumer buys a second unit, then it is discounted by some percentage. We analyze the working of BOGO promotions in a manufacturer-retailer supply chain. We find that for some type of consumer goods, with or without consumers stockpiling, a BOGO promotion always outperforms the commonly used price reduction promotion. We also find that the retailer's share of the supply chain profits is largest under BOGO while consumer surplus is smaller with BOGO than with price reduction promotion. When consumers are time-inconsistent, a price reduction promotion may outperform a BOGO promotion.

Scheduling V

Contributed Session

Chair: Juan-Carlos Ferrer, Pontificia Universidad Catolica de Chile, Santiago, Chile

1 - Determining the Emergency Facility Location for Hazardous Materials via the Shapley Value

Ginger Yi Ke, Memorial University of Newfoundland, St. John's, NL, Canada, gke@mun.ca, Xun-Feng Hu

The consequence of possible incidents caused by the storage and transportation of hazardous materials may be catastrophic due to the harmful nature of the goods. To effectively mitigate such risks, an analytical approach rooted in the transferable utility cooperative game theory is proposed to find appropriate locations of emergency facilities, following a novel risk utility assessment method based on the response time. A small network example is studied to reveal the cooperative relationships among various facility locations and their corresponding marginal contributions to the overall performance of the emergency logistics system.

2 - Cooperative Games of Parallel Machine Scheduling Problems

Shoshana Anily, Professor, Tel Aviv University, Tel Aviv, Israel, anily@tauex.tau.ac.il, Tzvi Alon

In today's competitive market, firms have to supply goods to consumers under deadlines and penalties. In order to keep the schedule, and improve the operational efficiency, collaborations among manufacturing units of partners in a supply chain, are formed. The stability of such collaborations depends on the cost sharing principles agreed upon in the partnership contract. In this talk, the theory of cooperative games is used to design principles for core cost allocation schemes that can help maintain the stability of collaborations in various off-line Parallel Machine Scheduling (PMS) settings, under a few common cost functions, as e.g., the minimum makespan and the minimum sum of completion times.

3 - Service Point Worker Scheduling under Forecasting Demand for an Express Company

Qianru Ge, SF Technology, Shenzhen, China, geqianru9@hotmail.com

Labor cost accounts for a large proportion of the operating cost of the distribution network in express companies. This paper describes a model formulation for the service point worker scheduling problem in S.F. Express company. In this model, we first generate a monthly schedule that determines which shifts to use among all possible shifts, then a daily schedule is generated with the number of workers that are responsible for each shift in the monthly schedule. Moreover, this model also incorporates the prediction error of the forecasting demand by adding redundant workers in certain shifts according to an algorithm.

4 - Efficient Multi Break Shift Scheduling for Full Time Employees

Juan-Carlos Ferrer, Professor of Operations Management, Pontificia Universidad Catolica de Chile, Santiago, Chile, jferrer@ing.puc.cl, Esteban Alvarez, Juan-Carlos Muñoz, Cesar Henao

A shift scheduling methodology is presented to assign shifts with multiple breaks for providing flexibility to service companies and thus improve staff demand coverage. The approach is built around four modules that implement a sequential iterative process to solve the problem. A test case, using different daily demand profiles, generated results showing that the coverage obtained by the methodology under each profile was within one percent of the maximum attainable, despite assigning only one additional break to the mandatory lunch break period.

Chair: Gerd J Hahn, German Graduate School of Management and Law, Bildungscampus 2, Heilbronn, 74076, Germany

1 - Using an Extended Heterogeneous Game Cross-efficiency Model to Improve Performance of Community Health Service Institutions: A Case Study

Yuwei Hu, the First Affiliated Hospital of Anhui Medical University, Hefei, China, Xiang Ji

Community health service institutions show obvious heterogeneity in their operations. We propose an extended heterogeneous game cross-efficiency model via incorporating the advanced heterogeneous DEA techniques into the classical game cross-efficiency model. The proposed model is then applied into a real case study of community health service institutions in Hefei, China.

2 - Performance Evaluation of Healthcare System

Babak D. Rouyendegh, AYBU, Ankara, Turkey, babek.erdebilli2015@gmail.com

Performance evaluation of health care system Abstract This paper aims to evaluation the performance of Health care system in Ankara during the period of the 2016-2017 by using the combination of Intuitionistic Fuzzy TOPSIS and DEA. This paper demonstrates the utilization of the proposed methodology to solve the real life problem of healthcare management, DEA-IFTOPSIS methodology provides an opportunity to make the most suitable decision thought the value of the weights calculated by the data. Keywords Data envelopment analysis (DEA), Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS), Healthcare

3 - Drum-Buffer-Rope in an Engineering-to-Order System: An Analysis of an Aerospace Manufacturer Using Data Envelopment Analysis (DEA)

Daniel P. Lacerda, Universidade do Vale do Rio dos Sinos, São Leopoldo, Brazil, dlacerda@unisinos.br, Eduardo S. Telles, Maria I. Morandi, Ricardo A. Cassel

Increased productivity and efficiency in industries with engineering-to-order (ETOs) production systems have attracted growing interest. The application of the Drum-Buffer-Rope (DBR) of Theory of Constraints is considered an alternative to traditional improvement programs. This study aims to analyze the effects of implementing DBR on the efficiency of three ETO production lines of an aerospace manufacturer. The effects were evaluated longitudinally through a case study using Data Envelopment Analysis, Wilcoxon test and Analysis of Variance. The results show that the DBR implantation resulted in an increase of up to 19% efficiency, helped the prioritization and reduced lead times.

4 - Supply Chain Performance and Industry Sector Competitiveness: A Financial Market Perspective

Gerd J. Hahn, German Graduate School of Management and Law, Heilbronn, Germany, Marcus Brandenburg, Jochen Becker

Financial performance and analysis of value driver performance in supply chains (SC) is mostly studied using accounting data. In this paper, we use data from financial markets to investigate the impact of distinct value drivers on SC performance. Performance within and across several sectors is compared.

1 - Scenario Selection for Iterative Stochastic Transmission Expansion Planning

Faezeh Akhavizadegan, Iowa State University, Ames, IA, United States, Faezeh.akhavizadegan@gmail.com, Lizhi Wang

Reliable transmission expansion planning is a critical part of a power system development due to existing numerous sources of uncertainty. We develop a new approach to selecting a small number of high-quality scenarios as representative of all scenarios. A bilevel optimization model was used to generate reasonable scenarios and regression model was used to estimate social welfare of scenarios to select high-quality scenarios. The US Eastern and Western Interconnections power system was used as the case study to select ten high-quality out of one million scenarios for two transmission plans.

2 - The Impact of Transportation Electrification on Power System Planning and Operation

Jonghwan Kwon, Argonne National Laboratory, Lemont, IL, United States, kwonj@anl.gov, Omer Verbas, Aymeric Rousseau, Zhi Zhou

The electricity industry is facing a rapid deployment of electric vehicles due to technological advances, cost reductions, and a desire for transportation electrification. This study will present the impact of the increased electricity demand from the transportation sector on power system planning and operations in both transmission and distribution system. This study will introduce an open-loop modeling framework that links the power system simulation tool, Argonne Least Cost Electricity Analysis Framework (ALEAF), and the transportation system modeling tool, POLARIS.

3 - Stochastic Transmission Expansion Planning: Approximating the Annual AC Operating Cost with the DC Subproblem

Jesse Bukenberger, Penn State, State College, PA, United States, jbukenbe@gmail.com, Mort David Webster

The nonlinear AC Optimal Power Flow (OPF) formulation has been too intractable to incorporate into transmission planning studies of a meaningful size and the linear DC OPF has been widely used instead, but accuracy improvements would result in large annual savings. We present a method for approximating the annual AC operating cost of a transmission plan from a sample of DC subproblems. The method uses AC OPF simulations from several feasible transmission plans and draws on multivariate statistics to relate the DC subproblem to the annual AC cost. Optimizations using this approximation scheme have better convergence properties than the AC model and produce better solutions than the DC model alone.

4 - A Lattice Method for Jump-diffusion Process Applied to Transmission Expansion Investments under Demand and Distributed Generation Uncertainties

Fikri Kucuksayacigil, Principal Financial Group, Des Moines, IA, United States

Decision makers of generation units and transmission networks do not often cooperate, which creates severe uncertainties for both. The growth of demand for electricity and installation or removal of distributed generation (DG) are among uncertainties encountered by transmission network owners. Expansion decisions for transmission lines should be strategically made, because installations of DGs may create a stranded cost for transmission owners. In this study, we propose a real options framework that quantifies the values of transmission networks and investments under demand and DG uncertainties. The proposed framework is demonstrated on a realistic transmission network.

5 - Resilience-based Design of a Microgrid System with Optimal Placement of Distributed Generators under Random Transmission Line Failures

Zhetao Chen, Rutgers University, Piscataway, NJ, United States, Zhimin Xi

This paper proposes a systematic framework for reliability and resilience quantification and design optimization for microgrid system considering random transmission line failures. Uncertainties of the system-level performance of interest, such as power recoverability and transmission efficiency, are quantified by Monte Carlo simulation (MCS) based on the power flow analysis. Given design constraints such as the minimum reliability requirements for the power factor and recoverability, optimal placement of distributed generators can be eventually obtained through the optimization. The proposed framework is demonstrated through a 12-bus power system.

Joint Session ICS/ENRE-Electricity: Power Systems Planning

Sponsored: Computing

Sponsored Session

Chair: Cheng Guo, University of Toronto, Toronto, ON, M5T 1K5, Canada

1 - Incentive Compatibility for Power System Planning

Cheng Guo, University of Toronto, 204-222 Elm Street, Toronto, ON, M5T 1K5, Canada, cguo@mie.utoronto.ca, Merve Bodur

Power systems capacity expansion models have traditionally taken a centralized planner's perspective to find cost-optimal generation capacity to reliably meet load. Unfortunately, such models do not ensure individual generators are adequately remunerated. We present an expansion model that determines optimal generation/storage capacity investment decisions, while ensuring individual units achieve profitability.

2 - Breaking Temporal Correlations in Energy Storage Operation

Bolun Xu, Postdoc, MIT, Cambridge, MA, United States, xubolun@mit.edu, Audun Botterud, Magnus Korpas, Francis O'Sullivan

This talk introduces a dual decomposition method for the fast solution of multi-period energy storage control problems. The proposed method solves deterministic single storage control problems to optimal within milliseconds in all application scenarios regardless of the look-ahead horizon, offering significant improves compared to commercial optimization solvers. The talk will also introduce our current effort of applying this algorithm in optimizing multiple storage operations, and on incorporating uncertainties.

3 - Distribution Systems Hardening Against Natural Disasters

Arindam K. Das, Eastern Washington University, Seattle, WA, United States, adas@ewu.edu, Yushi Tan, Payman Arabshahi, Daniel Kirschen

Distribution networks are often crippled by catastrophic damage following a natural disaster. A suitably hardened system can significantly improve the performance of post-disaster restoration operations. We formulate a two-stage stochastic problem, where the inner operational problem addresses the proper scheduling of post-disaster repairs and the outer problem chooses the network components to harden. We propose a deterministic single crew approximation with two solution methods, an MILP formulation and a heuristic approach. Computational evidence on various IEEE test feeders illustrates that the heuristic approach provides near-optimal hardening solutions efficiently.

4 - Variability Constraints in Capacity Expansion Models: A Data-driven Approach

Mehrdad Pirnia, University of Waterloo, Waterloo, ON, N2L3G1, Canada, mpirnia@uwaterloo.ca, John David Fuller, Hassan Shavandi

We present a data-driven approach to include temporal operational constraints in a long-term electric capacity expansion plan, by incorporating variation constraints . The generation variation limits are estimated from historical data on maximum rates of change of each generation type. The proposed model is linear and therefore its execution time is incredibly fast. We discuss that although the results of this data-driven approach is not as accurate as a detailed mixed (nonlinear) integer capacity expansion model, it is plausible enough for analysts to consider rapid changes in demand. We illustrate the performance of the proposed model using data from Ontario's electricity market.

5 - Predictive Online Convex Optimization for Demand Response

Antoine Lesage-Landry, University of Toronto, Toronto, ON, Canada, Iman Shames, Joshua Adam Taylor

We incorporate side information in the form of the estimated value of future gradients in online convex optimization (OCO). This is motivated by demand response in power systems, where forecasts about the next rounds, e.g., the weather or the load patterns, can be used to improve on predictions made with only past observations. We introduce an additional predictive step that follows the standard OCO step and yields strict improvement over the latter when certain sufficient conditions are met. We provide a sublinear regret bound for all our algorithms. We apply our framework to demand response and demonstrates its superior performance to a standard OCO algorithm in regulation and curtailment settings.

Underground Mine Planning

Sponsored: Energy, Natural Res & the Environment/Natural Resources Mining

Sponsored Session

Chair: Alexandra M Newman, Colorado School of Mines, Golden, CO, 80401, United States

1 - Optimizing underground Mine Design with Method-Dependent Precedences

Pete Nesbitt, MS, Colorado School of Mines, Golden, CO, 80401, United States, Levente Sipeki, Alexandra M. Newman

Large underground hard rock mines are complex industrial projects by which success depends on intelligent design and detailed scheduling. We present an integer programming-based procedure for designing a mine consisting of two extraction methods in order to maximize profitability via its corresponding production schedules over the life of the mine. Solutions determine (i) by which methods an area of the mine is extracted and (ii) the time at which each activity takes place. We solve large-scale problems in a matter of hours; current industry practices require a month per solution, result in 35% less profit and, based on solution time, preclude strategic sensitivity analysis.

2 - Underground Production Scheduling with Ventilation

Oluwaseun Ogunmodede, MS, Colorado School of Mines, Golden, CO, 80401, United States

Mine production scheduling determines when, if ever, notional three dimensional blocks of ore should be extracted. The accumulation of heat in the tunnels where operators are extracting ore is a major consideration when designing a ventilation system. The production scheduling and ventilation decisions are not made in concert. Heat limitations from activities are largely ignored. Our model maximizes net present value subject to constraints on precedence, and mill and extraction capacities with the consideration of heat. The model produces more realistic schedules that could increase revenue by lowering ventilation costs for the mine.

3 - Short and Medium Term Planning in Underground Mines

Michel Gamache, Polytechnique Montreal, Montreal, QC, H3C 3A7, Canada, michel.gamache@polymtl.ca, Louis-Pierre Campeau

This presentation proposes linear programming and constraint programming models to solve the problem of short- and medium-term planning in underground mines. A comparison of the results obtained by the two models is carried out. Adapting these methods to solve real-time scheduling problems will also be discussed.

4 - Implementation of an Optimization Model for Sample Test Scheduling, the Case of a Metallurgical Laboratory in Antofagasta, Chile.

Pablo Orquera, Universidad Catolica del Norte, Antofagasta, Chile, pog005@alumnos.ucn.cl, Hernan Caceres

In the mining industry, quality control is essential. Quality controls are carried out by metallurgical laboratories that are responsible for taking samples of the mine processes and reporting their results promptly; the mine decision making depends on these results. This study aims to solve the problem of sample test scheduling in a metallurgical laboratory in Antofagasta, Chile. In our work, we study a multi-product and multi-stage problem, where several machines work in parallel depending on the type of sample being tested. We developed a MILP to determine the optimal sequence of the works. Heuristics and numerical tests will be presented for a real-world case study.

Policy-Enabling Models for the Power Sector

Sponsored: Energy, Natural Res & the Environment/Environment & Sustainability

Sponsored Session

Chair: Afzal Siddiqui, University College London, London, WC1E 6BT, United Kingdom

1 - Multi-objective Infrastructure Investment under Uncertainty: Reconciling Private and Public Incentives.

Maria Lavrutich, Norwegian University of Science and Technology, Warandelaan 2, Trondheim, 5037AB, Norway, maria.lavrutich@ntnu.no, Verena Hagspiel, Afzal Siddiqui

We study optimal infrastructure investment decisions of a social planner (SP) that anticipates capacity investment of a private company (PC) in a market characterized by uncertain demand. The model captures the investment decisions of the SP and PC and accounts for the conflicting objectives and game-theoretic interactions of the distinct agents. Taking an option-based approach allows us to study the effect of uncertainty on the investment decisions and to take the agents' discretion over investment timing as well as size into account. We show if and how the SP can align the decision of the PC with the social optimum by exploiting the dependence of the PC's capacity on the SP's infrastructure design.

2 - A New Approach for Performing and Measuring the Quality of Data-aggregation Techniques in Power Systems Planning

Fabricio Oliveira, Assistant Professor, Aalto University, Espoo, Finland, fabricio.oliveira@aalto.fi, Lucas Condeixa, Afzal Siddiqui

Data aggregation (DA) is a key feature in modeling real-world energy systems. Considering existent DA techniques in long-term power systems models, we present two methodological contributions: the use of a statistically consistent metric to evaluate different DA algorithms and a novel DA method that maintains the chronological information. Results indicate improvements in the implementation of large-scale capacity expansion models in power systems using low temporal resolution. The analysis can be especially relevant for modeling systems with increasing amounts of renewable energy production.

3 - Green Electricity Investments Environmental Target and the Optimal Subsidy

Verena Hagspiel, Norwegian University of Science and Technology, Alfred Getz' vei 3, Trondheim, 7491, Norway, verena.hagspiel@ntnu.no

We investigate the optimal investment decision in renewables under market demand uncertainty, in the context of the Italian strategy for renewable deployment under the EU policy. The firm has to decide about the time and size of the investment. We find that a higher subsidy level induces the firm to invest earlier with a smaller investment capacity. This implies that a given environmental target cannot be reached by a too high (too low) subsidy level since this will cause the investment level to be too low (too late). There exists an optimal subsidy level to reach the environmental target. We propose a heuristic for policy makers to determine a subsidy level to reach the environmental target level in time.

4 - Can the European Intraday Market Be Designed as a Congestion Management Tool?

Mette Bjorndal, NHH Norwegian School of Economics, Helleveien, Bergen, 5045, Norway, mette.bjorndal@nhh.no, Somayeh Rahimi Alangi, Endre Bjorndal

With the large-scale penetration of intermittent generation resources in Europe, intraday markets have become more important. Since both day-ahead and intraday markets are based on zonal pricing, where the physical characteristics of the transmission networks are not fully taken into account, large amounts of unscheduled flows make it di cult for the networks to be in balance close to the delivery time. In this paper, we suggest a new design for the European intraday market, based on a coordinated multilateral trade approach. This approach lets us capture more of the benefits of the nodal pricing method, while it is compatible with the European electricity market structure.

Data-driven Optimization in Energy Systems

Sponsored: Energy, Natural Res & the Environment/Energy

Sponsored Session

Chair: Spyros Chatzivasileiadis, Technical University of Denmark, Lyngby, 2800, Denmark

1 - Verification of Neural Network Properties for Power System Optimization

Andreas Venzke, Technical University of Denmark, Lyngby, 2900, Denmark, Spyros Chatzivasileiadis

Neural networks have been applied successfully to highly complex classification tasks including the security assessment of power systems. Current studies in power systems, however, use neural networks as black-box tools which presents a major obstacle towards their application in practice. To obtain provable performance guarantees, we verify target properties of neural networks used for power system optimization. To this end, we formulate the verification problem as a mixed-integer linear program. We verify properties of a security classifier that is then incorporated as a power system optimization constraint for an illustrative example and demonstrate the scalability for a 162 bus system.

2 - Learning-based Optimization of Power Grids

Emiliano Dall'Anese, University of Colorado Boulder, Boulder, CO, United States

We consider a time-varying optimization problem associated with a power system, with an objective that comprises a known time-varying cost and an unknown function modeling user's satisfaction. Gaussian processes (GP) are leveraged to learn the unknown cost function from noisy functional evaluation. We then advocates time-varying optimization tools to design an online algorithm that exhibits tracking of the oracle-based optimal trajectory within an error ball, while learning the user's function with no-regret. The algorithmic steps are inexact to account for possible limited computational budgets or real-time implementation considerations. Joint work with Andrea Simonetto, IBM Ireland.

3 - The Value of Including Unimodality Information in Distributionally Robust Optimal Power Flow

Bowen Li, Argonne National Laboratory, Lemont, IL, 60439, United States, bowen.li@anl.gov, Ruiwei Jiang, Johanna Mathieu

We assess the value of using both moment and unimodality information, which shrinks the ambiguity set and reduces conservatism, in distributionally robust OPF problems. Exact reformulations, approximations, and efficient solving techniques from previous work are compared on large scale systems with high uncertainty penetration. We also develop an optimal parameter selection approach that searches for an optimal approximation, significantly improving the computational time and solution quality. Results show that including unimodality information reduces solution conservatism without significantly degrading reliability.

4 - Optimal Adaptive Linearizations of the AC Power Flow Equations

Daniel K. Molzahn, Georgia Institute of Technology, Atlanta, GA, 60605, United States, molzahn@gatech.edu, Sidhant Misra, Tillmann Mühlpfordt, Bowen Li

The power flow equations relate the voltages and power injections in an electric power system. The nonlinearity of these equations results in algorithmic and theoretical challenges, including non-convex feasible spaces. Accordingly, many practical approaches for solving power system optimization and control problems employ linearizations of the power flow equations. This presentation describes a method for computing linearizations that are adaptive (tailored to a specific system and operating range of interest) and optimal (minimize a metric for the linearization error relative to the nonlinear AC power flow equations).

5 - D

istributionally Robust Data-enabled Predictive Control

Jeremy Coulson, ETH Zürich, Zürich, Switzerland

We study a data-enabled predictive control (DeePC) algorithm applied to unknown stochastic linear time-invariant systems. The algorithm uses noise-corrupted input/output data to predict future trajectories and compute optimal control policies. To robustify against uncertain data, the control policies are computed to minimize a worst-case expectation of a given objective function. Using techniques from distributionally robust optimization, we prove that for certain objective functions, the worst-case optimization problem coincides with a regularized algorithm. Probabilistic guarantees for its performance are provided. We illustrate the results on a grid-connected power converter.

6 - Chance-constrained AC Optimal Power Flow – A Polynomial Chaos Approach

Line A. Roald, Univeristy of Wisconsin - Madison, Madison, WI, 87544, United States, roald@wisc.edu, Tillmann Mühlpfort, Timm Faulwasser, Veit Hagenmeyer, Sidhant Misra

Chance-constrained optimal power flow, which allows us to limit the probability of constraint violations, has gained interest as a method to manage power systems uncertainty. Here, we propose polynomial chaos expansion as a method to formulate a tractable chance-constrained optimal power flow which explicitly considers the full nonlinear AC power flow equations. Beyond handling the non-linear, non-convex AC power flow constraints, polynomial chaos allows for a more detailed and flexible description of the system response to uncertainty. Two case studies highlight the efficacy of the method, with a focus on satisfaction of the AC power flow equations and on the accurate uncertainty propagation.

Innovative Approaches to Integrated Multisector Modeling

Sponsored: Energy, Natural Res & the Environment/Energy

Sponsored Session

Chair: Stuart Cohen, National Renewable Energy Laboratory, Golden, CO, 80401, United States

1 - Modeling Opportunities for Coordinated Electric-water Utility Operations

Clayton Barrows, NREL, Golden, CO, 80401, United States

Water infrastructure system operations can create significant electrical energy consumption. Additionally, many water delivery systems are designed with excess pumping and storage capacity that present opportunities to shift pumping schedules and adjust electrical demand patterns. This research explores various levels of electric-water utility coordination by optimizing both water and power system schedules.

2 - Capturing Energy-water-Economy Interactions in an Integrated Modeling Framework: The Economic Impacts of Water Shortages on the Western Power Grid

Mort Webster, Pennsylvania State University, University Park, PA, United States, Karen Fisher-Vanden

The interactions between energy, water, and land systems are poorly understood, yet have important implications for food security, reliability of electric power supply, demographic patterns, and the resilience of communities and critical infrastructure. Doing this type of work requires working on multidisciplinary teams and coupling a variety of tools including statistical tools, data products, and computational models. In this paper, we present our initial results from coupling a water balance model, power system model, and a socioeconomic model to assess the impacts of a severe water shortage in the western U.S. on the power system.

3 - Spine: An Open-source and Flexible Energy-system Model Generator

Kris Poncelet, PhD, KU Leuven, Leuven, Belgium, kris.poncelet@kuleuven.be

Due to the increasing complexity of the energy system, there is a growing need to integrate or link models covering different energy sectors or time frames. Currently, the vast majority of models have been developed with a specific purpose in mind (e.g., investment planning, unit commitment, simulation of gas flows, etc.). Within the H2020 Spine project, the goal is to develop an open-source and flexible energy system model generator that is designed from the offset to perform these different functions and facilitate linking of models. In this regard, key features of Spine are the model's generically formulated equations and the interface enabling a direct link between the data and the source code.

4 - A Co-Simulation Framework to Study Future Energy-Economy Interactions

Stuart Cohen, Electricity System Analyst, National Renewable Energy Laboratory, Golden, CO, 80401, United States, stuart.cohen@nrel.gov

Energy-economy interactions are often studied using top-down integrated assessment or economy models that have broad scope but lack the resolution and process detail to consider complex emerging trends across the energy sector. This presentation describes an approach to maintain both detail and scope by linking NREL's highly resolved models of the electricity, transportation, and buildings sectors with a MIT's USREP computable general equilibrium model of the U.S. economy. We will discuss strategies for linking across disparate models along with preliminary results describing the economy-wide impacts of future energy technology innovation.

Emerging Topic: Advanced Manufacturing

Emerging Topic Session

Chair: Feng Ju, Arizona State University, Tempe, AZ, 85281, United States

1 - Unified New Product Introduction Model with Learning and Congestion Effects

Atchyuta Bharadwaj Manda, North Carolina State University, Raleigh, NC, United States, amanda@ncsu.edu, Reha Uzsoy

The adverse impact of new product introductions on the performance of semiconductor wafer fabrication facilities is widely acknowledged. We develop a deterministic new product introduction production planning model that captures the initial drop in efficiency and the learning effects that follow. The model captures learning by gaining production experience and learning through deliberate experimentation. We incorporate the congestion effects and capture the effect of the product introduction on the output of the fab as a whole. We develop a solution methodology to solve the resulting nonlinear non-convex formulation using nonlinear programming and genetic algorithms.

2 - Semi-supervised Constrained Hidden Markov Model Using Multiple Sensors for Remaining Useful Life Prediction and Optimal Predictive Maintenance

Yunyi Kang, Arizona State University, Tempe, AZ, 85281, United States, ykang37@asu.edu, Feng Ju

In this work, we propose a framework to demonstrate the optimal preventative maintenance decision making using multiple-sensor data. A semi-supervised left-to-right constrained Hidden Markov Model (HMM) model is used to learn the hidden states, which is the first to simultaneously address the challenges of semi-supervised setting, left-to-right constraint, and monotonicity constraints. The a Partial Observable Markov Decision Process (POMDP) is built up to demonstrate how the hidden states can be effectively used for optimal preventative maintenance decision making. We apply this technique to the data, such as the NASA Engine data, and demonstrate the effectiveness of the proposed method.

3 - Prognostics for Ion Mill Etching Process Through Deep Learning Multimodal Data Fusion

Xiaoning Jin, Assistant Professor, Northeastern University, Boston, MA, 02115, United States, xi.jin@northeastern.edu, Anqi He, Xiaomeng Peng

Ion Mill Etching (IME) is an advanced process technology that uses ion-beam sources to remove materials by atomic sandblasting in order to reveal a specific pattern on the substrate. The high-precision capability requires stringent process monitoring and control of the flowcool system. This study focuses on a multi-sensor data analytics to monitoring the IME process condition-enabling diagnostics and prediction of three main failure mechanisms of the IME flowcool system. A generalizable framework of engineering-based data-driven failure diagnostics and prediction is developed using random forest-based classification and a Deep Long Short-Term Memory based failure prediction.

4 - Design and Operation of Individualized Single-use Systems: Car-t Cell Therapy

Gaurav Sharma, Arizona State University, Tempe, AZ, 85281, United States, gsharm16@asu.edu, Mohammad Hekmatnejad, Giulia Pedrielli, Georgios Fainekos

The success of genetically-modified T-cells in treating hematological malignancies has accelerated the registration timeline for CAR-T cell therapy. The individualized nature limits inventory and creates a high risk of product loss due to supply chain failure. The sector needs a new manufacturing paradigm capable of quickly responding to single-use demands while considering complex system dynamics. Our research formulates the problem of CAR-T manufacturing design and control, understanding the performance of centralized and decentralized single-use systems for large scale production of personalized therapies.

1 - Developing a Cox Proportional Hazards Model with Time-dependent Covariates to Evaluate the Risk of Acute Kidney Injury

Farnaz Babaie Sarijaloo, PhD student, University of Florida, Gainesville, FL, United States, farnazbs@ufl.edu, Shounak Datta, Ying-Chih Peng, Matthew Ruppert, Subhash Nerella, Arsenios Tsokas, Tezcan Ozrazgat-Baslanti, Parisa Rishidi, Panayote (Panos) M. Pardalos, Azra Bihorac

Acute Kidney Injury (AKI) is a serious complication in patients with a rising incidence and high mortality rate. Most of the models for AKI risk prediction are developed for patients with a cardiac surgery and analyzed their risk after a surgery. Accurate AKI severity assessments would help identify patients in need of life-saving interventions prior to the occurrence of an unexpected AKI. In this study, a cohort of 15239 patients admitted at University of Florida Health from 2014 to 2016 have been examined. The main purpose of this study is to develop a survival model to determine time to AKI for patients in a daily basis. We used survival and statistical analysis to model the time to AKI.

2 - An Innovative Tumor Response Model for Personalized Breast Cancer Treatment

Melike Hazal Can, Northeastern University, Boston, MA, United States, Abe Zeid, Sagar Kamarthi, Stephen O. Agboola, Kamal Jethwani, Ramya S. Palacholla

Breast cancer is the most common cancer diagnosed among women in the US and worldwide. Even though there has been a dramatic increase in our knowledge of cancer on multiple scales leading to a host of potential drug targets and subsequent clinical trials, outcomes for many cancers have not improved significantly. A tailored treatment approach can help avoid overtreatment in breast cancer patients. In this study, we aim to develop a novel data-driven model that considers individual variability in baseline patient characteristics and tumor characteristics to predict the probability of a complete pathological response in breast cancer patients that is a proxy for improved survival and better outcomes.

3 - Optimization of Diagnostic Follow-ups for Effective Lung Cancer Screening

Mehrad Bastani, Postdoctoral Scholar, Stanford University, Stanford, CA, United States, bastani@stanford.edu, Iakovos Toumazis, Julien Hedou, Ann Leung, Sylvia Plevritis

Lung cancer screening with low-dose computed tomography (LDCT) has been recommended, based primarily on the results of the NLST (National Lung Screening Trial). In response to the high rates of false-positive findings observed in NLST, the American College of Radiology recently released Lung-RADS, a classification system for LDCT lung cancer screening. Diagnostic follow-ups recommended by Lung-RADS could be potentially modified to improve the effectiveness of LDCT. To this end, we propose a population-level simulation-based optimization model to maximize life-year gained and mortality reduction.

1 - Evidence-based Comparison of Queuing and Discrete-event Simulation Models for Patient Flow Improvement

Farzane Asgari, Visdom, New York, NY, United States, cf@visdom.org, Sadegh Asgari

Queuing theory and discrete-event simulation have been extensively utilized to improve patient flow in healthcare systems. Using the patient flow data of an obstetric unit, we develop different simulation and queuing models and compare their results to assess their accuracy, strengths, and limitations. The results show that simulation models, compared to queuing models M/M/K and M/G/K, obtain more realistic estimations of performance metrics of patient flows if admissions are partially scheduled. However, queuing models M/M/K and M/G/K can be appropriate estimators for performance metrics if admissions are only unscheduled.

2 - Optimizing Nurse Schedules for a Community Health Centre Serving a Marginalized Population in Vancouver, Canada

Samantha Zimmerman, Simon Fraser University, Burnaby, BC, Canada, Alan Bi, Trevor Dallow, Krisztina Vasarhelyi, Cameron Bye, Latham Nicole, Andrew Day, David Hall, Tamon Stephen, Alexander R. Rutherford

We modeled a community health centre serving marginalized individuals, with complex clinical and psycho-social needs, who experience barriers to accessing healthcare. To improve service delivery, a mixed integer linear programming model was built to optimize nurse schedules. The model draws on appointment data to maximize patient-nurse contact time while maintaining coverage and hours. Key performance indicators for the optimized schedule were assessed using discrete event simulation. Without increasing staffing levels, optimization can increase patients seen by ten per week, remove gaps in coverage, and reduce the percentage of walk-in patients waiting over 90 minutes from 34% to 13%.

3 - Using Linear Program and Simulation to Optimize CRNA Regular and Call Shift to Accommodate Anesthesia Care Needs

Luqing Lu, Senior Health Systems Engineer, Mayo Clinic, Scottsdale, AZ, United States

Certified Registered Nurse Anesthetists (CRNAs) are highly utilized resources in integrated hospitals. Although most of CRNA staffing needs happen between 0630 and 1700, emergency surgeries can occur past hour needing resources. We review the variation in number of CRNAs needed at different time of the day, the frequency of on-call staffs are called due to understaffing given current shift assignment and other factors to build a model. The model can be used by CRNA supervisors to determine shift schedule (starting time, duration, and number of staff per shift) to minimize staffing costs while maintaining call shifts at the industry-average level.

4 - Modeling Parallel and Sequential Random Delays in Capacity Adjustment of Supply-demand Systems

Sara Nourazari, California State University, Long Beach, Long Beach, CA, United States, sara.nourazari@csulb.edu

Closed-loop supply-demand models can be used to manage capacity adjustments in healthcare systems. However, these methodologies are traditionally organized around deterministic delays. When the delay is non-deterministic, in order to apply the tractable deterministic models, the mean of the probability distribution of delays is often used as a crude estimate. This work assesses the cost of over-simplifying delay distributions, proposes a methodology to holistically incorporate multiple probabilistic delays in the system, and optimizes systems parameters to assist in informed capacity management decision-making. Parallel, sequential, and mixture delays are modeled and analyzed.

5 - Keep Pushing or C-section? A Machine Learning Approach Using Optimal Trees

Daisy Zhuo, Interpretable AI, Cambridge, MA, United States, daisy@interpretable.ai, Dimitris Bertsimas, Jack W. Dunn, Jordan Levine, Alexis Gimovsky

In the delivery room, it highly time sensitive for a obstetrician to make an informed decision as the woman in labor is pushing whether and when to switch to a Cesarean section, as both involve risk of mother and child mortality and morbidity. Using data from Consortium of Safe Labor with 140,000 deliveries, we have developed a highly accurate machine learning model to predict the mode of delivery. The model is trained using Optimal Trees, a state-of-the-art algorithm that finds an interpretable decision tree with high predictability. We also present the mother and child risk over time within each cohort, providing guidance on optimal time of switching.

6 - Real-time Prediction of the Optimal Configuration of an Intelligent Gateline System Using Queueing Theory

Eric Enkele Longomo, Research Fellow in Applied Operational Research, University of Portsmouth, Portsmouth, United Kingdom, eric.longomo@port.ac.uk

This work develops and operationally demonstrates -using queuing theory and combinatorial optimisation, a gateline that is capable of automatically self-reconfiguring to maximise peak and average throughput and prevent train station overcrowding. The technology will identify flows of people within the station environment, and learn to predict crowds before they arrive at the gateline. The technology will allow each gate to be configured to be inflow or outflow to deliver reliability and capacity improvements and give the passengers the best experience possible

Quantitative Methods in Financial Engineering

Sponsored: Finance

Sponsored Session

Chair: Ning Cai, Hong Kong University of Science & Technology, Kowloon, Hong Kong, Hong Kong

Co-Chair: Li Lingfei, University of Hong Kong, Hong Kong, China

1 - Distributionally Robust Mean-Variance Portfolio Selection

Xunyu Zhou, Liu Family Professor of Financial Engineering, Columbia University, New York, NY, 10027, United States

We revisit Markowitz's mean-variance portfolio selection model by considering a distributionally robust version, where the region of distributional uncertainty is around the empirical measure and the discrepancy between probability measures is dictated by the so-called Wasserstein distance. We reduce this problem into an empirical variance minimization problem with an additional regularization term. Moreover, we extend recent inference methodology in order to select the size of the distributional uncertainty as well as the associated robust target return rate in a data-driven way.

2 - On the Equilibrium Strategies for Time-inconsistent Problems in Continuous Time

Zhaoli Jiang, Chinese University of Hong Kong, Shatin, N.T, Hong Kong, zljiang@se.cuhk.edu.hk

In a continuous-time setting, the notion of weak equilibria employed in the literature to study continuous-time time-inconsistent decision problems is not aligned with the standard definition of equilibria in the game theory. To address this issue, we propose two new notions of equilibrium strategies for time-inconsistent problems, named regular equilibria and strong equilibria. We derive sufficient conditions as well as necessary conditions for a strategy to be a regular equilibrium and to be a strong equilibrium. We exemplify that a regular equilibria may not be a strong equilibria and that a weak equilibria may not be a regular equilibria.

3 - Partially Egalitarian Portfolio Selection

Yiming Peng, Northwestern University, Evanston, IL, United States, ypeng@u.northwestern.edu, Vadim Linetsky

We develop a novel portfolio selection framework via machine learning.

4 - Conditional Monte Carlo Methods under Stochastic Volatility Models

Gianluca Fusai, City, University of London, London, United Kingdom, Riccardo Brignone, Kyriakou Ioannis

We develop conditional Monte Carlo methods for simulating the Heston, SABR, and OU stochastic volatility models. Sampling from these models represents a nontrivial longstanding problem and various solution have been attempted in the literature. Our method exploits the moments of the conditional integrated variance to develop accurate approximation methods. Besides the more standard case of path-independent derivatives, we show the applicability of our method to path-dependent options as well, such as barrier, lookback and hindsight options. Numerical experiments highlight the accuracy-runtime benefits of our proposed methodologies.

Joint Session MSOM/HC/Practice Curated: Healthcare Applications

Sponsored: Manufacturing & Service Oper. Mgmt/Healthcare Operations

Sponsored Session

Chair: Sandeep Rath, University of North Carolina at Chapel Hill - Kenan Flagler, NC, 27599, United States

1 - Staff Planning with Cost Estimation and Optimization

Sandeep Rath, University of North Carolina at Chapel Hill-Kenan Flagler, Chapel Hill, NC, 27599, United States, sandeep@unc.edu, Kumar Rajaram

We consider the staff planning problem of anesthesiologists which consists of determining how many anesthesiologists have to be on regular duty and on call each day. We model this problem as a two-stage integer stochastic dynamic program. We use data from the anesthesiologist staff planning at UCLA Ronald Reagan Medical Center to first estimate the inconvenience costs of on-call staffing. We use these estimated cost parameters in a two-stage integer stochastic dynamic programming model of staff planning. We develop a solution algorithm, and test the model with real data from the UCLA medical center.

2 - Optimal Dynamic Appointment Scheduling of Base and Surge Capacity: Early Follow-up for Congestive Heart Failure

Benjamin Grant, Kellogg School of Management, Evanston, IL, 60201, United States, Itai Gurvich, R. Kannan Mutharasan, Jan A. Van Mieghem

We study dynamic stochastic appointment scheduling when delaying appointments increases the risk of incurring costly failures, such as readmissions in health care. When near-term base appointment capacity is full, the scheduler faces a trade-off between delaying an appointment at the risk of costly failures versus the additional cost of scheduling the appointment sooner using surge capacity. We present sufficient conditions for the optimality of simple policies.

3 - The Interplay Between Online Reviews and Physician Demand: An Empirical Investigation

Yuqian Xu, University of Illinois at Urbana-Champaign, Champaign, IL, 61820, United States, Mor Armony, Anindya Ghose

Social media platforms for healthcare services are changing how patients choose physicians. The digitization of healthcare reviews has been providing additional information to patients when choosing their physicians. In this paper, we derive various service-quality proxies from online reviews and study the relationship between these quality proxies and physician demand. To do so, we study a unique data set from one of the leading appointment booking websites in the United States, that contains online physicians' appointments made over a five-month period, along with other online information.

4 - Tradeoffs in the Use of Cohort Matching to Estimate Causal Effects from Observational Data on the Use of an Online Healthcare Navigation Service.

Shishir Dash, PhD, Grand Rounds, San Francisco, CA, United States

We studied the use of various cohort matching tools to design an observational study of medical claims data to estimate the causal effect of using healthcare navigation platforms on medical spend. We explore tradeoffs in using methods such as propensity-scoring, distance and matching to account for the dependence of cohort-assignment on the covariate distributions, and present simulated and actual results.

1 - An Indirect Prioritization to Optimizing Sample Referral Networks for HIV Early Infant Diagnosis

Reut Noham, Northwestern University, Evanston, IL, United States, noham.reut@northwestern.edu, Michal Tzur, Dan Yamin

We developed a supply chain network-model for delivering HIV test samples between clinics-to-labs in Tanzania. Our model is used to minimize the expected number of infants who die from AIDS due to delays in the return of test results. We present an analytical framework to evaluate the distribution of the samples' waiting times at the testing labs, which we incorporated into the model. Our findings indicate that redesigning clinics-to-labs assignments, yielded an indirect prioritization of samples that are more likely than others to be positive. We demonstrate the applicability of our findings and its potential benefit to reduce mortality compared to the current assignment policy in Tanzania.

2 - Access to Safe Water: Operational Challenges of Water Filter Supply in Ethiopia

Chengcheng Zhai, Indiana University, Bloomington, IN, United States, zhaic@iu.edu, Alfonso Pedraza Martinez, Jorge Mejia, Kurt M. Bretthauer

More than 60 million Ethiopians lack access to safe water. Using daily data, we study an NGO that tackles this problem by distributing water filters in the country. The NGO faces challenges regarding manufacturing, storage and distribution of their product.

3 - Sample Transport Optimization

Emma L. Gibson, MIT, Cambridge, MA, 02142, United States, Jonas Oddur Jonasson, Sarang Deo, Kara Palamountain, Mphatso Kachule

Sample transportation systems are an integral component of diagnostic networks in many developing countries, enabling physical transportation of samples (e.g., dried blood spots, plasma, or sputum samples) from health centers to medical laboratories. We have partnered with Riders For Health Malawi to improve the efficiency of their sample transport operations through data-driven analytics and optimization.

4 - Supply Chain Network Design Considering Investments that Drive Demand

Jarrod D. Goentzel, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, Tim Russell, Francisco Jauffred

Demand in supply chain network design is usually given and exogenous to optimization models that minimize cost. However, proximity to supply facilities may influence price and service sufficiently to affect customer behavior. In such cases, investment in network infrastructure may be more than offset by returns from serving more demand. We present a model developed for price- and time-sensitive commodities at a chemical company. We then consider application of this model for investment in non-profit health facilities to increase vaccine penetration.

1 - Using Surrogate Modeling for Complex Systems Design

Reza Alizadeh, The University of Oklahoma, Norman, OK, United States, reza.alizadeh@ou.edu

Many decision-making problems include two levels of decision making, where one decision is nested within the other. these problems are known as bilevel decision-making problems and are computationally intensive. in this paper, we exploit a mapping of the bilevel problem which using that we relate the upper-level variables with the corresponding expense by iteratively approximating the exploited mapping function. This is an initial study with that we examine the idea on a small set of test problems.

2 - Community Detection Based on Graph Neural Network

Lee Chul Hee, Myongji University, Yongin-si, Korea, Republic of, Dohyun Kim

Communities in social networks are the dense subgroups of the nodes, which are tightly connected to each other within the group. Detecting communities is one of the importance tasks because it plays a key role in understanding the functionality of complex networks. Recently, many deep learning algorithms to detect communities in social networks have been studied due to their robust performance. In this paper, we propose a unified community detection method combined hidden feature extraction and clustering algorithms. The proposed method combines graph Auto-Encoder (GAE) and Deep Embedding Clustering (DEC) in social network.

3 - A Projection-based Framework for Prediction of Binary Labels for Links in Signed Networks

Mukul Gupta, Indian Institute of Management Indore, Indore, India, mukulg@iimidr.ac.in, Saurabh Kumar

The prediction of labels for links in a signed network where the links between nodes have a positive or negative sign is relatively less explored and very challenging problem. In this work, we consider the problem of binary label prediction for links in undirected and unweighted signed networks. We propose a novel projection-based framework that projects the network into positive-links and negative-links networks with unlabelled links and uses the concept of random-walk for prediction of binary labels for links. In this work, we demonstrate the viability and effectiveness of the proposed approach using a real-world network.

4 - A Novel Optimization Based Algorithm for Multi-Class Data Classification Problem

Fatih Rahim, Koç University, Istanbul, Turkey, Metin Turkay

Multi-class data classification is a supervised machine learning problem that involves assigning data to multiple groups. We present a novel MILP-based algorithm that splits each class's data set into subsets such that the subsets of different classes are linearly separable. At each iteration we form a subset of samples out of the set of unassigned samples by a MILP model that maximizes the cardinality of the new subset. The algorithm terminates when all the samples are assigned. We build classifiers based on the convex hulls of the subsets and the polyhedral regions for the testing phase. We conclude that our optimization based algorithm provides competitive results in terms of prediction accuracy.

5 - One-class Peeling for Anomaly Detection in High Dimensions

Waldyn Martinez, Miami University, Oxford, OH, United States, martinwg@miamioh.edu

Outlier detection is important for preprocessing data and/or for detecting anomalous observations. Numerous outlier detection methods have been proposed in the fields of statistics, machine learning, and data mining. These methods can be computationally infeasible for high dimensional data. In this paper we propose a flexible framework to detect multiple outliers that does not require covariance estimation, is well-suited to high-dimensional datasets with a high percentage of outliers, and is robust to parameter specification. We evaluate our framework using both synthetic and benchmark data sets, showing that it works well in high dimensions and performs better than benchmark methods.

6 - Partial Change Detection Using Homogeneity Tests

Maziar Kasaei Roodsari, Arizona State University, Tempe, AZ, United States, mkasaeir@asu.edu, George Runger

In this work, we address partial change detection. We refer to a change as partial when not all measurements within the sample are affected by the assignable cause. Nowadays, in statistical quality control, the subgroups can be much larger than they used to be and identifying a change in which only a subset of the instances are affected, would not be trivial. We investigate partial change detection using homogeneity tests under two scenarios for which the changed part of the data follows: 1. a Gaussian distribution, 2. an unspecified distribution. Through simulations, we show that the sample statistics based on likelihood ratio test can have higher power than the sample average.

Chair: David Fuessler, Friedrich-Schiller-University Jena

1 - Industry 4.0 Concepts to Improve Agroindustry Supply Chains

Alcides Santander-Mercado, Universidad del Norte, Barraquilla, Colombia, asantand@uninorte.edu.co, Maria A. Jubiz-Diaz, Juan C. Urueta-Urueta

This research focuses on the development of integrated solutions to improve the synchronization of supply chains on rural areas (palm oil industry in Colombia), where the uncertainty about the supporting infrastructure is high. The analysis is based on the implementation of industry 4.0 concepts to enhance their key performance indicators related to logistic processes. The implementation of RFID technologies as well as Business Process Modeling (BPM) and supply chain synchronization techniques, helped them to achieve better performance indicators and improve their competitiveness.

2 - New Switch Mechanism Design and GPU Parallel Computing Implementation for Large Scale VRP

Rui Yu, Senior Algorithm Engineer, Zhejiang Cainiao Supply Chain Management Co., Ltd., Hangzhou, China, geminikop@gmail.com, Haoyuan Hu

In this presentation, a switching mechanism is introduced to realize and control both exploration and exploitation in the evolutionary algorithm, to accelerate the discovery of good solutions for large-scale problems. The switching mechanism "guides" the algorithm to find better solutions more quickly. Moreover, we also introduce the GPU parallel computing implementation based on CUDA. Experimental results on Gehring and Homberger's benchmark show that this algorithm outperforms previous approaches and improves 71 best-known solutions out of 180 large-scale instances.

3 - Performance Evaluation for a New Compact Automated Vehicle Parking System with Double Storage Rings

Guangmei Wu, School of Information Management, Central China Normal University, Wuhan, China, Bipan Zou

Compact robotic parking system is a new system with higher storage utilization and rapid response to store and handle cars. This system has double storage rings, instead of one storage ring in old compact automated parking (CAP) system for storing cars in each tier, and each tier is equipped with inner rotating ring and tier-captive automated guided vehicle for horizontal transport.

4 - Trolley Line Picking: Storage Assignment and Order Sequencing to Increase Picking Performance

David Fuessler, Friedrich-Schiller-University Jena, Jena, Germany, david.fuessler@uni-jena.de, Nils Boysen, Konrad Stephan

In a trolley line picking system, unit loads of stock keeping units (SKUs) are positioned along a path passed by automated trolleys. Once a trolley reaches a requested SKU, it automatically stops, and an accompanying human picker puts the demanded items onto the trolley. After an order is completed the subsequent picking order is served. The performance of a trolley line system is mainly influenced by the picker's unproductive walking between SKUs during order processing and switching trolleys. It is investigated how the storage assignment of SKUs along the path and the order sequence influence picking performance.

Chair: Murtaza Nasir

1 - Predicting Patient No-shows via a Hybrid Business Analytics Methodology

Nichalin S. Summerfield, University of Massachusetts Lowell, OIS Department, One University Avenue, Lowell, MA, 01854, United States, Murtaza Nasir, Asil Oztekin, Ali Dag

Patients who fail to show up for an appointment (no-shows) are a major challenge for medical settings. They reduce revenues and in turn negatively affect overall healthcare quality. Understanding the reasons for no-shows and predicting them are key to developing a successful, proactive strategy in healthcare operations. In this study, we propose a data analytics framework to explore the underlying factors of noshows. We employ Support Vector Machines, Artificial Neural Networks, Decision Tree, Logistic Regression, and Random Forest to predict whether a patient is a noshow. Information fusion based sensitivity analysis is deployed to understand how such variables contribute to this prediction.

2 - Impact of Peer Influence on Product Adoption: Evidence from Video Game Platforms

Yang Li, Drexel University, Philadelphia, PA, United States, yl837@drexel.edu

We investigate how peer influence affects customers' product adoption behaviors in emerging video game platforms. Using data from the world's largest digital distribution platform for video games, we leverage the state-of-the-art recommender system algorithms and propose an innovative framework to identify social influence in the adoption of video games when a confounding homophily effect is present. The results show that peer influence has a positive impact on the adoption behaviors of platform users (i.e., a user tends to adopt a video game that has been purchased by his peer) and this impact will be overestimated if homophily was not properly accounted for.

3 - The Impact of an Augmented-Reality Game on Local Businesses: A Study of Pokemon Go on Restaurants

Vandith Pamuru Subramanya Rama

Upon release, Pokemon Go, an augmented-reality technology-based game, garnered tremendous interest in the public with an average of 20 million active daily users. Using online reviews of restaurants as a proxy for consumer engagement and perception, we study the impact of Pokemon Go, on local restaurants. We treat the release of Pokemon Go, as a natural experiment and study the post-release impact on the associated restaurants. Thereby, our research lays the foundations of how augmented-reality games affect consumer economic behavior. It also helps to build insights into the potential value of such associations for business owners and policymakers.

4 - Firm Automation and the Gender Gap in Human Capital Acquisition

Amanda Chuan, Michigan State University, East Lansing, MI, United States, chuan.amanda@gmail.com

Women now exceed but used to lag behind men in college enrollment. I use census data to show that the automation of the labor market from 1960-2000 contributed to the growth in female college enrollment over male college enrollment. Using a shift-share instrumental variable approach, I find that local labor markets which experienced greater automation experienced larger declines in the jobs that typically employed non-college women. The response was a significant rise in the enrollment rates of women, with no discernible change in the enrollment rates of men. Thus, the automation of the office appears to have contributed to the gender gap in college enrollment.

1 - Value of Continuous Monitoring System in Recurrent Decision Scenarios

Xinyang Liu, University of Illinois at Urbana-Champaign, Urbana, IL, United States, Pingfeng Wang

Continuous monitoring systems have been applied to diversified systems for well-informed operations. Plenty research has devoted to system state prediction using the continuous data flow while engineering system owners still lack a systematic decision-making framework to maximize their benefits on adopting monitoring systems. This paper constructs such a decision-making framework, with which system owners can evaluate the operation cost change under specific operation modes. State-of-the-art system degradation models and maintenance policies have been reviewed. Finally, a battery asset management case study has been implemented to illustrate the efficiency of the framework.

2 - End-to-end Learning of Personalized Driver Behavior Models

Jundi Liu, University of Washington, Seattle, WA, United States, jundiliu@uw.edu, Ashis Banerjee

Modeling and forecasting driver behavior are crucial in developing efficient and comfortable driver assistant systems in automated vehicles. Short-term behavior has been well studied using high frequency video data. However, long-term behavior is closely related to driver's individual preference. For example, conservative drivers tend to maintain a larger gap between the front vehicle and decelerate earlier compared to aggressive drivers. In this study, we focus on learning personalized driver behavior models for different groups of drivers. Results show promising accuracy and individual difference in predicting driver behavior.

3 - Optimizing Movie Profits via Deep Learning-based Cast Recommendation

Michael T. Lash, Assistant Professor, University of Kansas, Lawrence, KS, 66045, United States, michael.lash@ku.edu, Kang Zhao, Nick Street

The average movie garners approximately $50 million in investment dollars, yet has only a 30% chance of producing a return on this investment. A major factor that contributes to the box office success of a movie is the cast, which can be represented as a network of co-staring individuals from which movie-centric, network-based measures can be derived and used to predict profitability. Therefore, in this work, we propose leveraging predictive models to elicit cast recommendations that optimize for movie profitability.

4 - Data-driven Size-based Scheduling in Queues

Xu Sun, University of Florida, University of Florida, Gainesville, FL, United States

Consider an M/GI/1 queue operating under a two-class nonpreemptive priority scheduling policy parameterized by a cut-off point p where customers with service requirement less than p get higher priority. The goal is to find the optimal cut-off value that minimizes the mean waiting time, but the underlying service-time distribution is not known. Instead, the only information available is a random, independent sample drawn from the service-time distribution. This study analyzes the sample average approximation approach for the problem and establishes performance guarantee.

1 - Performance-based Reimbursements of Health Providers under Comorbidities

Stefan Feuerriegel, ETH Zurich, Zurich, Switzerland, sfeuerriegel@ethz.ch, Patrick Zöchbauer

Health care reimbursements in the US exceeded USD 3.7 trillion in 2018. However, these reimbursements to healthcare providers are variable if providers fail to achieve a pre-defined quality of care. Key to performance-based reimbursements is a quality measure of hospital performance that caters for the fact of providers serving different patient cohorts. Despite extensive research on performance measures, prior attempts neglect comorbidities, i.e., co-occurring patterns of secondary diseases. We introduce a novel statistical model based on deep learning in order to accommodate comorbidities. In fact, we find that this results in extensive annual misallocation of reimbursements.

2 - Proposing a Mobile-based Outpatient Healthcare Service Delivery Framework and Investigating the Acceptance from Outpatients' Perspective

Muhammad Adnan Zahid Chudhery, Assistant Researcher, School of Economics and Management, Tongji University, Shanghai, China, adnanch@mail.ustc.edu.cn, Sarah Safdar, Jiazhen Huo, Hakeem-Ur Rehman, Raza Ali Rafique

Emergency department (ED) overcrowding in the territory-tier hospitals (TTH) of China is getting worsens even after enriching with sufficient ED capacity while primary care resources (PCR) are about 41% under-utilization. The government is trying to reduce the outpatient's flow from TTH, promote the utilization of primary care units (PCU), and to establish an efficient referral system between TTH and PCU. We proposed a framework in the public-private healthcare sharing economy perspective to divert outpatients flow before visiting TTH to PCU and then empirically investigating the acceptance. The findings can help to mitigate ED overcrowding from TTH and to achieve optimal utilization of PCR.

3 - The Optimal Use of Antibiotics with Fitness Cost under the Economic Dynamics

Weifen Zhuang, School of Management, Xiamen University, China, Xiamen, China, wfzhuang@xmu.edu.cn

This paper studies the optimal usage policy of antibiotics with fitness cost under the economic dynamics. The objective is to minimize the total treatment and resistance cost subject to the population dynamics by the SIS epidemiological model. We compare the optimal usage policy of antibiotics with zero and positive fitness cost, as well as the different paths leading to the steady state. In contrast to the antibiotics with zero fitness cost (depletable resource) which eventually loses the efficacy by consumption, the antibiotics with positive fitness cost (renewable resource) may remain positive in the steady state by determining the optimal usage quantity.

4 - Does Hit Deliver on its Promise? A Case of Pennsylvania Hospitals

Balaraman Rajan, Assistant Professor, California State University East Bay, Hayward, CA, United States, Dinesh R. Pai, Subhajit Chakraborty

This study examines the relationship between health information technology (HIT) and patient care characteristics for Pennsylvania acute care hospitals. Specifically, we examine the impact of HIT functionalities such as electronic health record (EHR) and health information exchange (HIE) on quality of care measures such as risk-adjusted mortality and risk adjusted readmission rates; hospital efficiency measures such as cost per inpatient day and cost per inpatient admission, and on patient flow measure such as average length of stay. While we find evidence for efficiency improvement, HIT seems to adversely impact patient care and patient flow indicators. The conclusions point to a mixed bag.

Advances in High Throughput Data Mining for the Chemical Process Industry

Sponsored: Data Mining

Sponsored Session

Chair: Apratim Bhattacharya

Co-Chair: Sivaraman Ramaswamy

Co-Chair: Ankur Kumar

1 - Using Historical Data to Facilitate Production Scheduling: An Industrial Air Separation Case Study

Ankur Kumar, Linde, 175 East Park Drive, Tonawanda, NY, 14150, United States, ankur_kumar@praxair.com, Calvin Tsay, Michael Baldea

Electricity-intensive air separation units (ASUs) are natural candidates for interacting with the power grid via demand response: excess product can be produced during off-peak hours, stored, and sold during times of peak electricity demand. However, scheduling such operations with detailed process models is often intractable for online deployment. In this work, we take a data-driven approach for scheduling an industrial ASU. We identify low-order dynamic models using historical data, and we solve the associated scheduling problem to show the significant economic benefits of demand response.

2 - A Variational Autoencoder for Nonlinear Process Monitoring

Bhushan Gopaluni, University of British Columbia, Vancouver, BC, Canada, bhushan.gopaluni@ubc.ca, Kai Wang, Michael Forbes, JUnghui Chen, Zhihuan Song

We provide a novel algorithm for nonlinear process monitoring and fault detection. The algorithm is based on Deep Neural Networks (DNNs) which are known to provide highly accurate nonlinear models in the presence of large volumes of data. The latent variables generated by DNNs are often difficult to interpret. We use a variant of DNN called auto-encoder to generate a latent space from the measured variables. In particular, we design this auto-encoder in such a way that the latent variables are orthogonal. The orthogonality of the latent variables helps us in developing a statistical measure for process monitoring and fault detection. We illustrate this novel approach through examples.

3 - A Smart Manufacturing Testbed to Explore the Role of Human Learning in the Machine Learning World

Peter He, Associate Professor, Auburn University, Auburn, AL, United States, qhe@auburn.edu, Devarshi Shah, Jin Wang

The emergence of the industrial Internet of Things (IIoT) and ever advancing computing and communication technologies have fueled a new industrial revolution. In this talk, we will discuss an IIoT-enabled smart manufacturing testbed and develop process inferential models using deep neural networks. We demonstrate that rote applications of deep/machine learning algorithms may result in underperforming models that lead to incomplete or misleading conclusions, while by incorporating domain knowledge and human learning, simple and robust models can be developed that significantly outperform machine learning alone.

4 - An Adaptive Alarm Prioritization, Reduction, and Optimization Algorithm for Enhanced Process Safety

Rui Nian, University of Alberta, Edmonton, AB, Canada, Jinfeng Liu, Biao Huang

This study combines reinforcement learning (RL) and data mining to improve alarm systems. The algorithm is threefold: 1) Apply RL to learn value functions online or using historical data via a reward function designed based on safety and production considerations. 2) Group common alarm successions into alarm sequences. 3) In implementation, new alarms are assigned nuisance scores (NS) corresponding to the state's value; negative scores denote important alarms. Finally, the alarms are sorted by NS in ascending order. This algorithm was simulated on a water treatment plant showing reduction in total alarms of up to 82%. The alarms were also prioritized and prioritization has adaptive capabilities.

Sponsored Session

Chair: Xiaorui Zhu

Co-Chair: Brittany Green

1 - Protecting Privacy of Household Panel Data

Shaobo Li, Asst. Professor, University of Kansas, Lawrence, KS, United States, Matthew Schneider, Yan Yu, Sachin Gupta

We investigate how vulnerable the widely used consumer/household panel data is to intruders who intend to re-identify individual customers through linking to external databases. With the evidence of low privacy-preserving being shown, we establish a framework to protect household panel data without reducing the commercial value. That is, retailers and manufacturers are able to use the household panel data to perform marketing research such as modeling brand choice, while they are not able to re-identify individuals by using external dataset. We demonstrate our framework using IRI household panel data, where we use the yogurt category for assessing the data utility with a brand choice model.

2 - Machine-Learning Approaches for Hedge Fund Return Prediction and Fund Selection

Wenbo Wu, Asst. Professor, University of Texas San Antonio, San Antonio, TX, United States

Various machine learning methods including the least absolute shrinkage and selection operator, random forest, gradient boosting, and deep neural network are applied to select superior funds within major hedge fund style categories into the investment portfolios based on the predicted future returns.. Utilizing the predictive power of advanced machine learning methods, a set of predictive features are derived from historical returns. The empirical results demonstrate the remarkable advantages of the machine learning approach in the out-of-sample performance compared to the benchmarks.

3 - Tree-based Algorithm for Observational Study

Yuyang Zhang, PhD Candidate, Ohio State University, Columbus, OH, United States, BO LU

The subpopulation effects are required when the treatment effect varies systematically with a different part of the data. For this reason, we propose a strategy that identifies the subpopulation structure via tree-based methods. When the number of the subgroups is small, two tree-based methods, Classification and Regression Tree (CART) and Causal Tree (CT) are applied in this study. When the number of subgroups is large, the corresponding forest methods are considered to estimate the subpopulation effects. Based on the results of extensive simulation studies using pre-identified potential subpopulation indicators, the CART performs slightly better than CT.

4 - Tree-based Method for Longitudinal Data

Brittany Green, University of Cincinnati, Carl H. Linder School of Business, 2925 Campus Green Dr., Cincinnati, OH, 45221, United States, Peng Wang

Decision trees for longitudinal data are flexible and powerful predictive models which incorporate nonlinearity yet preserve interpretability. We propose an algorithm to incorporate time varying covariates, eliminate selection bias and avoid estimating the correlation structure between subjects' observations at each node. We use a quadratic inference function classifier along with tests of independence to improve prediction and eliminate selection bias. Numerical experiments and a study of an online health clinic demonstrate performance.

5 - Demystifying Differences between Bankruptcy and Other Failures in Terms of Major Drivers and Risk-Return Relationship

Xiaorui Zhu, University of Cincinnati, Lindner College of Business, Blue Ash, OH, 45236, United States, Yan Yu, Shaonan Tian

We consider a broad definition of failure and dissect distress firms into bankruptcy and other failures that are due to financial reasons other than bankruptcy. Then, we demystify the differences between bankruptcy and other failures from two sides: major drivers and risk-return relationship. Firstly, we apply the LASSO variable selection and find different drivers for two groups of distress events. Secondly, we find factors in valuation models perform differently for bankruptcy and other-failure firms. Our results shed some new lights on the distress puzzle that financially more distressed stocks earn lower returns.

Chair: Joe Zhu, Worcester Polytechnic Institute, School of Business, Worcester, MA, 01609, United States

1 - A Two-stage DEA Problem with Shared Outputs: Modeling Efficiency in Regional Innovation Systems

Sonia V. Avilés-Sacoto, Associate Professor, Universidad San Francisco de Quito, Quito, Ecuador, svaviless@usfq.edu.ec, Wade D. Cook, David Güemes-Castorena, Joe Zhu

Regional innovation systems literature usually focuses on the comparative performance of different regions and analyzes how each region is utilizing its own dedicated resources. This paper uses DEA to study a region in Mexico and the companies within that region with the aim being to identify which of those companies are using the available resources in the best way. The problem in this setting is that some inputs and outputs are shared among the companies in each industry. To address this, the current article presents a modified DEA methodology for measuring efficiency in situations where DMUs share outputs/inputs with other units within the same group.

2 - Service Quality and Efficiency in the U.S. Airline Industry

Sepideh Kaffash, Suffolk University, Boston, MA, United States, skaffash@suffolk.edu, Reza Kazemi Matin, Marianna Marra

This paper investigates the impact of service quality on American airlines efficiency. We analyze a sample of quarterly data of 13 airlines during the period of 2005-2015. We employ a network Data Envelopment Analysis (DEA) approach. First, we propose a new approach to calculate efficiency scores dealing with negative data; secondly, we used the second step of the Simar and Wilson method to regress the efficiency scores with the variable of interest. The results of this study could inform policy and managerial decision

3 - Dynamic Innovation Performance Evaluation for High-tech Companies Using a Network Data Envelopment Analysis Approach

Anyu Yu, Tongji University, Shanghai, China, Joe Zhu

This study aims to examine dynamic innovation performance for China's 506 high-tech companies. Overall company innovation process is conceptualized as R&D and commercial processes. We developed an innovation index that measures the overall innovation performance, which integrated by a R&D index and a commercialization index. A network DEA model is developed to compute the innovation index and its components. A dynamic network model is further extended to represent multi-period processes. One difficulty is programming solving is complex and nonlinear. Thus second order cone programming and nested partitions strategy are integrated to locate the global optimal solution for a large sample.

4 - Performance Evaluation Regardless the Relationship between the Numbers of Units and performance Metrics

Dariush Khezrimotlagh, Pennsylvania State University, Harrisburg, PA, United States, dk@psu.edu, Joe Zhu, Wade D. Cook

Performance measurement is an essential approach to assess how well decision making units (DMUs) are managed. A rule of thumb says that the number of DMUs should be at least three times the numbers of input-output factors. A delta-neighbor technique is discussed to allow discrimination between DMUs regardless the relationship between the numbers of DMUs and inputs-outputs. The technique ranks all DMUs and increases the discrimination power of data envelopment analysis (DEA). Several simulation experiments and real-life applications are designed to examine the power of the delta-neighbor technique. The results strongly support the advantages of the technique versus conventional DEA models.

5 - Efficiency Measurement for Hierarchical Situations

Wanghong Li, York University, North York, ON, M2N 0C2, Canada, whli@schulich.yorku.ca

The measurement and monitoring of the efficiency of processes in organizations has become an important undertaking in today's competitive environment. A fundamental tool for this undertaking is data envelopment analysis (DEA). The current paper looks at a problem setting somewhat related to a multistage situation but pertaining to a particular form of hierarchical structure. We develop a DEA-like methodology that evaluates, in a two-stage manner, both the efficiency of the sub-units and of the aggregates of those subunits (the plants). This two-stage approach is implemented in such a way that optimization is done both at the plant and subunit levels.

6 - A Global Evaluation of CSR: A Weight-constrained Approach

Chien-Ming Chen, Nanyang Technological University-Singapore, 50 Nanyang Avenue, Singapore, 639798, Singapore, Sheng Ang

CSR is a broad concept concerning company practices across multiple social dimensions. While different aggregation weights have been proposed in the literature, there is no clear guideline as for how we can use these weights to rank CSR performance. To address this issue, we develop a novel DEA method with special weight constraints. We use a panel of global KLD data as a case study.

1 - Clinical Gait and Balance Screening for the Risk Assessment of Falls in Elderly Population Utilizing Machine Learning Techniques

Venous Roshdibenam, University of Iowa, Iowa City, IA, United States, venous-roshdibenam@uiowa.edu, Stephen Baek

Falling is an increasingly important public health problem which can cause serious and fatal injuries among elderly population. Although the CDC has developed an initiative to intervene for fall risks using clinician's evaluation, it is expensive and time-consuming. Hence, we need to find some algorithms that can be both precise and fast in evaluation. We utilize subjects' gait acceleration and angular velocity signals along with the geriatrician's evaluation of fall risk and exploit Convolutional Neural Networks (CNNs) to create a fall risk prediction algorithm. Our CNN model not only performs the prediction with high accuracy, but also learns the gait patterns and features that result in fall.

2 - Data Visualizations to Analyze Railroad Operations and Safety

Trefor Williams, Professor Emeritus of Civil Engineering, Rutgers University, Piscataway, NJ, United States, tpw@soe.rutgers.edu, Christie Nelson, John F. Betak

Railroads in the United States collect data about accidents, maintenance activities, track conditions and operations. Data visualization can be used on this data to identify trends and problems from diverse data sources. Data visualization allows dashboards of visualizations that can be easily interpreted by railroad operating personnel. This presentation will show the application of data visualization to the analysis of railroad grade crossing accidents and to the analysis of the effects of maintenance work on train performance for a short line railroad.

3 - Using Optimization Techniques in Treemap Partitioning

Reyhaneh Mohammadi, Northeastern University, Boston, MA, 02148, United States, mohammadi.re@husky.neu.edu

In data visualization field, treemap are used to display hierarchical data with a space-filling approach. This method partitions a shape into some nested shapes. One of the important factors in organizing a treemap is creating shapes which are fat enough to be visible. The other factor is preserving the order of information. Currently there are several algorithms for partitioning a treemap most of them ignoring one factor to make the other factor better. In this research, we aim to combine optimization techniques and computational geometry structures such as "Voronoi diagrams", "Power diagrams" and "Delaunay triangulations" to develop treemaps which are both more informative and perceivable.

4 - Understanding Complex Ecosystems Using Text Mining and Interactive Visualization

Hyunwoo Park, Ohio State University, School of Interactive Computing, 85 5th Street Nw, Columbus, OH, 30332, United States, park.2706@osu.edu, Rahul C. Basole

We present the design and implementation of an interactive visual analytic tool that leverages advanced text mining and graph visualization techniques to help decision makers understand the complex public narrative surrounding business ecosystems.

1 - A Deep Learning Based Framework for Connected and Autonomous Vehicle Simulation

Sikai Chen, Purdue University, West Lafayette, IN, United States, chen1670@purdue.edu, Yue Leng, Samuel Labi

Motor vehicle crashes are one of the leading cause of deaths worldwide. For a vast majority of these crashes, human error continues to be a dominant contributory factor. It is expected that the adoption of connected and autonomous vehicles (CAVs) will drastically reduce human errors in driving. To overcome CAV testing limitations at in-service roads and test tracks, this paper proposes a deep learning based CAV simulation framework, which incorporates human prior knowledge and temporal information. The proposed framework facilitates CAV testing and safety impact evaluation in a safe setting.

2 - A Data-driven Trajectory Generation Model in Terminal Airspace

Ning HONG, PhD Candidate, City University of Hong Kong, Kowloon, Hong Kong, neil.hong@my.cityu.edu.hk, Lishuai Li

Quantifying and predicting uncertainties of aircraft trajectories is important when designing or modifying standard routes in an airspace. In this paper, we propose a deep learning method to predict actual aircraft trajectories given a new standard instrument departure (SID) or standard terminal arrival route (STAR) design by learning from historical ADS-B data. We find that the method captures statistical properties of aircraft trajectories and can generate realistic trajectories.

3 - Cooperative Intersection Management of Connected and Autonomous Vehicles

Anye Zhou, Georgia Institute of Technology, Atlanta, GA, United States

We address the problem of controlling connected and autonomous vehicles through an intersection without traffic signals. A two-layer optimization framework is proposed to guarantee safety and increase throughput at the intersection. Results from numerical simulations will be used to illustrate the ability of the proposed method to enhance capacity and efficiency of the intersection compared to traditional signal-timing control.

1 - Oboe: Collaborative Filtering for AutoML

Madeleine Udell, Cornell University, Ithaca, NY, United States, udell@cornell.edu

Algorithm selection and hyperparameter tuning remain two of the most challenging tasks in machine learning. Automated machine learning (AutoML) seeks to automate these tasks toenable widespread use of machine learning by non-experts. This talk introduces Oboe, a collaborative filtering methodfor time-constrained model selection and hyperparameter tuning. Experiments demonstrate that Oboe delivers state-of-the-art performance faster than competing approaches on a test bed of supervised learning problems. Moreover, the success of the bilinear model used by Oboesuggests that AutoML may be simpler than was previously understood.

2 - Combining No-regret and Q-learning

Ian Kash, University of Illinois at Chicago, Chicago, IL, United States

Most reinforcement learning algorithms do not provide guarantees in settings with multiple agents or partial observability. A notable exception is Counterfactual Regret Minimization (CFR), which provides both strong convergence guarantees and empirical results in settings like poker. We seek to understand how these guarantees could be achieved more broadly. To take a first step in this direction, we introduce a simple algorithm, local no-regret learning (LONR), which captures the spirit of CFR, but can be applied in settings without a terminal state. We prove its convergence for the basic case of MDPs and discuss research directions to extend our results to address richer settings.

3 - Exploiting Correlation in Finite-armed Structured Bandits

Gauri Joshi, Carnegie Mellon university, Pittsburgh, PA, United States

We consider a structured multi-armed bandit problem in which mean rewards of different arms are related through a hidden parameter and propose generalizations of UCB and Thompson sampling for this problem. Our approach is based on exploiting the structure in the problem to identify some arms as sub-optimal and pulling them only O(1) times. This results in a significant reduction in cumulative regret and in fact our algorithm achieves bounded (i.e., O(1)) regret whenever possible. Moreover, our model subsumes several previously studied frameworks such as Global, Regional and Structured bandits with linear rewards.

4 - Structural Causal Bandits: Where to Intervene?

Elias Bareinboim, Columbia University, New York City, NY, United States, eb@cs.columbia.edu

We study a version of the structural causal bandit problem (Lee and Bareinboim, 2018) where pulling an arm corresponds to an intervention and not all variables are manipulable. We develop a procedure that uses partially specified causal knowledge and identifies the optimal arms in structural bandits with non-manipulable variables. We can also uncover non-trivial dependence structure among the possibly-optimal arms. Finally, we show empirically that MAB solvers enhanced with causal knowledge and leveraging the newly discovered dependence structure among arms consistently outperform their causal-insensitive counterparts.

5 - Bandits with Temporal Stochastic Constraints

Theja Tulabandhula, UIC, FF07 Ajanta Vihar, Yelahanka, Chicago, IL, United States, Priyank Agrawal

We study the effect of impairment on stochastic multi-armed bandits and develop new ways to mitigate it. Impairment effect is the phenomena where an agent only accrues reward for an action if they have played it at least a few times in the recent past. It is practically motivated by repetition and recency effects in domains such as advertising and vocational training. Impairment can be naturally modeled as a temporal constraint on the strategy space, and we provide two algorithms that achieve sub-linear regret, each working with different assumptions on the impairment effect. Our work complements recent work on modeling delays and corruptions in multi-armed bandits.

1 - In Search of the True Worth of a 'Like': A Network Externality Approach

Gohar Khan, University of Waikato, New Zealand, Manar Mohaisen, Matthias Trier

We argue that the social media returns are derived not only from the actions per se but also from the additional exposure that results from the network externality associated with these actions. Hence, leveraging the notion of network externality, we proposed, modelled, and experimentally measured network and discrete ROI.

2 - TOPIC: Framing Effect on Social Lending Platforms: A Topic Modelling Approach

Shivendu Pratap Singh, Waikato University, Waikato University, Waikato, New Zealand

Social lending platforms explore ways to engage lenders on the platform and help those making informed choices. We explore the effect of content framing on lending selection by network of lenders on lending platforms. Using topic modelling, we measure the impact of content framing on financial choices by lenders.

3 - Influencing Donation Choice in Social Networks After Disasters

Trilce Encarnacion, Rensselaer Polytechnic Institute, Jonsson Engineering Center,Troy, NY, 12180, United States

In order to effectively influence donation choice in a social network setting after disasters, a network influence model is formulated, incorporating behavior research regarding individuals' attitudes. Operations research techniques are used to select an appropriate influencing strategy to effect change in donation choice towards better donation practices after disasters.

Queueing Theory and Applications

Sponsored: Applied Probability

Sponsored Session

Chair: Vahid Sarhangian, University of Toronto, Toronto, M5S 3G8, Canada

1 - The Power of Two in Queue Scheduling

Yan Chen, Columbia University, New York, NY, 10027, United States, yc3107@columbia.edu, Jing Dong

We study a scheduling policy with two priority classes. In the single-server heavy-traffic regime, our scheduling policy achieves similar scaling for the queue length processes as the shortest remaining processing time first policy. Our analysis quantifies on how the tail of the service time distribution will affect the benefit one can gain from smart scheduling policies. When the service time information is estimated/predicted, we further analyze how prediction error will affect the performance our scheduling policy. Our results provide insights on the interplay between the service time distribution and the estimation error distribution on system performance.

2 - Staffing and Scheduling to Differentiate Service in Time-varying Multiclass Service Systems

Xu Sun, University of Florida, Gainesville, FL, United States

Motivated by the Canadian triage and acuity scale (CTAS) that classifies patients in the emergency department into five acuity levels, we consider a joint staffing and scheduling problem for a multiclass queue with the objective of achieving differentiated service for each customer class. We propose new control principles (via staffing and scheduling) to guarantee that each class can achieve its prescribed performance target. Effectiveness of proposed policy is substantiated by limit theorems. We also conduct computer simulations to provide engineering confirmation and to gain insights.

3 - Parallel Queues with Arrivals Driven by a Discrete Choice Model

Yichuan Ding, Assistant Professor, McGill University, University of British Columbia, Montreal, QC, V6T 1C3, Canada, daniel.ding@mcgill.ca

We consider a parallel-queue system in which each queue is served by a dedicated service provider. The arrival process is driven by a discrete choice model, in which the mean arrival rate of a queue is a function of the queue lengths and the service attributes. We show that with such arrival rate functions, even without Lipschitz-continuity assumption, the queue-length process converges to a unique equilibrium, and the diffusion limit process is a reflected multi-dimensional Ornstein-Uhlenbeck process centered at that equilibrium. We then use these properties to derive the optimal staffing levels at each location subject to service level constraints.

4 - Discharge Control with Patient Readmissions: A Decentralized Optimization Approach

Hossein Abouee Mehrizi, University of Waterloo, Department of Management Sciences, Waterloo, ON, N2L 3G1, Canada, haboueem@uwaterloo.ca, Ya-Tang Chuang, Michael Kim, Xinyuan Zhang

This paper concerns discharge control of patients in a hospital considering patient readmissions. We formulate the problem as an MDP where patients' health conditions and readmission dynamics are explicitly modelled. Discharge control of patients with the goal of optimizing the system efficiency is generally intractable as it involves considering the status of patients simultaneously. To overcome this challenge, a decentralized control procedure is proposed where discharge decisions are made patient-by-patient by adjusting some parameters. We show that the proposed procedure achieves the optimality of the integrated system.

Scheduling in Parallel and Distributed Systems

Sponsored: Applied Probability

Sponsored Session

Chair: Mor Harchol-Balter, Carnegie Mellon University, Pittsburgh, PA, 15213, United States

1 - Optimal Scheduling of Parallel Jobs

Benjamin Berg, PhD Student, Carnegie Mellon, Pittsburgh, PA, 15213, United States, bsberg@cs.cmu.edu

Nearly all data center workloads can exploit parallelism. When a job is parallelized across multiple servers it will complete more quickly, but jobs receive diminishing returns from being allocated additional servers. Thus, it is not clear how to allocate servers to each job in order to minimize overall mean response time. Specifically, one must balance a tradeoff between granting priority to short jobs and maintaining overall system efficiency. We derive the optimal policy for allocating servers to jobs in the case where job sizes are unknown and exponentially distributed, as well as the case where job sizes are known to the system. Joint with: Jan-Pieter Dorsman, Rein Vesilo and Mor Harchol-Balter

2 - Online Algorithms for Unrelated Machine Stochastic Scheduling

Benjamin Moseley, Assistant Professor, Carnegie Mellon University, 5000 Forbes Av, pittsburgh, PA, 15208, United States, moseleyb@andrew.cmu.edu

We derive the first performance guarantees for a combinatorial online algorithm that schedules stochastic, nonpreemptive jobs on unrelated machines to minimize the expectation of the total weighted completion time. Prior work on unrelated machine scheduling with stochastic jobs was restricted to the offline case and required sophisticated linear or convex programming relaxations for the assignment of jobs to machines. Our algorithm is purely combinatorial, and therefore it also works for the online setting. As to the techniques applied, this paper shows how the dual fitting technique can be put to work for stochastic and nonpreemptive scheduling problems.

3 - Load Balancing with Ultra Low Communication Overhead

Weina Wang, Carnegie Mellon University, Pittsburgh, PA, 15213, United States

We consider load balancing of parallelizable jobs in a system with a large number of servers. In this model, each job consists of a batch of parallel tasks that need to be placed onto the servers upon arrival. Due to the large size of the system, the communication overhead of a load-balancing policy is prohibitive if it samples the queue lengths of too many servers for each job. In this work, we study two policies: batch-filling and (batch) power-of-d-choices. We explore a new regime for batch-filling where fewer than one sample is incurred per task. We show that with this ultra low communication overhead, batch-filling achieves comparable job delay to power-of-2-choices, which uses two samples per task.

4 - Load Balancing Guardrails: Keeping Your Heavy Traffic on the Road to Low Response Times

Isaac Grosof, Carnegie Mellon University, CMU, Pittsburgh, PA, United States, igrosof@cmu.edu, Ziv Scully, Mor Harchol-Balter

Load balancing systems, comprising a central dispatcher and a scheduler at each server, are widely used in practice, and their response time has been extensively studied. While much is known for the case where the servers use First-Come-First-Served (FCFS) scheduling, to minimize mean response time we must use Shortest-Remaining-Processing-Time (SRPT) scheduling at the servers. Much less is known in this scenario. Unfortunately, traditional dispatching policies often have poor performance in systems with SRPT servers. We devise guardrails, a simple fix that can be applied to any dispatching policy to ensure optimal mean response time under heavy traffic when used in a system with SRPT servers.

Forecasting I

Contributed Session

Chair: Nicolò Bertani, INSEAD, Boulevard de Constance, Fontainebleau, 77300, France

1 - A Hybrid Approach with Step-size Aggregation to Forecasting Hierarchical Time Series

Hakeem Ur Rehman, Shanghai Jiao Tong Univesity, Shanghai, China, hakeem@mail.sjtu.edu.cn, Guohua Wan, Raza Ali Rafique

We develop a new hybrid approach with step-size aggregation for hierarchical time series forecasting, which performs better compared to either the "top-down" approach or the "bottom-up" approach. The new approach is a weighted average of the two classical approaches with the weights being optimally chosen for all the series at each level of the hierarchy to minimize the variance of the HA forecast errors. We demonstrate the hierarchical forecasting approaches performance by applying it to the monthly data of 'Industrial' category of M3-Competition as well as on Pakistan energy consumption data.

2 - Machine Learning Blending Approach to Improving Forecasting Accuracy

Misuk Lee, Seattle University, Seattle, WA, United States, leem@seattleu.edu, James Lee

This research suggests a machine learning architecture for more accurate forecasting. We examine several different forecasting models including traditional time-series models and machine learning models, and propose neural network blending models to improve forecasting accuracy. Using real-life hotel price data, we provide empirical results of the proposed approach along with a comparison to traditional forecasting methods.

3 - Portfolio of Time Series Forecasting Models to Predict Container Throughput at the Port

Sonali Shankar, Indian Institute of Technology Delhi, Hauz Khas, New Delhi, 110016, India, 03shankarsonali@gmail.com, P.Vigneswara Ilavarasan

The paper proposes a portfolio of time series forecasting models constituting 1) conventional econometric model like ARIMA, TBATS etc. ; 2) Machine learning based model like neural network; 3) Hybrid model; 4) Deep learning based long short-term memory (LSTM) network. The models are evaluated on the real-world dataset of container throughput at the port of Singapore. The dataset contains monthly throughput generated at the port from year 1995-2018. The performance metrics is evaluated to measure bias, variance and accuracy. The LSTM network is found to outperform other widely used time series methods. The results obtained are further substantiated via Diebold-Mariano statistical test.

4 - Revisiting Bottom-Up Forecasting for Hierarchical Time-Series Data

Nicolò Bertani, INSEAD, Fontainebleau, France, nicolo.bertani@insead.edu, Ville Satopaa, Shane Jensen

Time-series are often structured in a hierarchy. For instance, tourism is recorded and forecasted at regional, state, and national level. Reconciliation methods claim to use "information" in the hierarchy, modelling each node independently and enforcing consistency ex-post. But hierarchies are merely summing constraints, and data generation occurs at the disaggregated level. We show that the hierarchy carries no informational value in the minimization of squared residuals: the leaves and their contemporaneous covariance suffice. We revisit the classical bottom-up methods accordingly, obtaining hierarchical uncertainty measures - a difficult task, if at all possible, in reconciliation.

Last Mile Delivery Challenge: Food and Grocery Retailing

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Xuanming Su, University of Pennsylvania, Philadelphia, PA, 19104, United States

Chair: Chloe Kim Glaeser, Chapel Hill, NC, 27514, United States

1 - Product Line Management for On-demand Services

Kaitlin Daniels, Olin Business School, Washington University in Saint Louis, St. Louis, MO, United States

We study an on-demand service platform's capacity management problem when the platform offers vertically differentiated services. We show that the relationship between the cost of capacity and the utilization of capacity in this setting leads to job allocation polices that differ from traditional settings. We discuss implications for settings with strategic consumers.

2 - Order Assignment with Travel Time Predictors

Sheng Liu, University of California, Berkeley, Berkeley, CA, 94709, United States, lius10@berkeley.edu, Long He, Zuo-Jun Max Shen

We study how delivery data can be applied to improve on-time performance in last mile delivery service. Motivated by a food delivery service provider, we discuss a data-driven framework to model the delivery performance and optimize the decision on how to assign orders to drivers. Leveraging classical results in routing literature and machine learning approaches, we propose a prediction model for the delivery travel time, which captures driver's routing behavior in practice. We then demonstrate how we can integrate the prediction model with stochastic and robust optimization models.

3 - Online Food Ordering Platforms: Commission Rates and Delivery Fees

Chloe Kim Glaeser, University of North Carolina, Kenan-Flagler Business School, 714 Greenwood Rd, Chapel Hill, NC, 27514, United States, chloe_glaeser@kenan-flagler.unc.edu, Xuanming Su, Jaelynn Oh

We study the commission rates and delivery fees of online food ordering platforms. We document how much a platform can benefit from jointly determining commission rates and delivery fees.

4 - Grocery Store Density and Food Waste

Elena Belavina, Associate Professor, Cornell University, Ithaca, NY, United States, eb733@cornell.edu

Food waste is a major contributor to carbon emissions. Identifying market conditions that can decrease waste is thus important to combat global warming. We study the impact of grocery-store density on the waste generated at stores and households. Our analysis shows that higher density reduces food waste up to a threshold; it leads to higher food waste beyond this threshold. Calibration using grocery industry, economic and demographic data reveals that actual store density in most American cities is well-below this threshold, and modest increases in store density substantially reduce waste; e.g. in Chicago, just 3-4 more stores (per 10 sq-km) can lead to a 6-9% waste reduction.

Chair: Yasar Levent Kocaga, Sy Syms School of Business, New York, NY, 10033, United States

1 - Perils and Benefits of Free Trials in Large Scale Service Systems: an Operational Perspective

Yasar Levent Kocaga, Associate Professor of Operations Management, Sy Syms School of Business, Belfer Hall Room # 403/A, 2495 Amsterdam Ave, New York, NY, 10033, United States, kocaga@yu.edu

We consider a firm that serves a market of price and delay sensitive customers and that has optimized the static per use price and capacity, before offering free trials to generate further demand. We first analyze the case where the firm offers free trials without changing the capacity or price, and we show that the benefit of offering free trials is of second order (and thus negligible for large systems), if beneficial at all. Next, we consider the case where capacity can be adjusted, and show that offering free trials can yield significant benefits.

2 - Optimal Seller-induced Learning: Joint or Decoupled Product Trials

Eren Basar Cil, University of Oregon, Lindquist College of Business, Eugene, OR, 97403-1208, United States, erencil@uoregon.edu, Michael Pangburn, Monire Jalili

We study a firm selling multiple products to heterogeneous customers. To help customers resolve valuation uncertainty, the firm offers product trials, joint or decoupled, as are common in practice for vineyards. We investigate the trial structure and pricing to understand when joint trials are the optimal form of seller-induced learning.

3 - Service Product Design and Consumer Refund Policies

Xiao Huang, Associate Professor, John Molson School of Business, Concordia University, 1455 De Maisonneuve Blvd. West, Montreal, QC, H3G 1M8, Canada, xiao.huang@concordia.ca, Dan Zhang

We consider the joint product customization and refund policy decisions of a monopolistic firm selling to a heterogeneous customer base. Our results shed light on how customers' valuation uncertainty, characterized by the ex-ante signal quality and the ex-post valuation heterogeneity, drives the interaction between product line and refund policy designs. Interestingly, allowing refunds may lead to a variety reduction in the product line, and partial refunds may arise even though our setup does not involve demand uncertainty, capacity, competition, or channel conflicts. We investigate the firm's information provision strategies and discuss practical implication of the results.

4 - Selling Freemium Products to Loss Averse Consumers

Sami Najafi-Asadolahi, Santa Clara University, Santa Clara, CA, United States, Sajjad Najafi, Nishant Mishra, Andy A. Tsay

We consider a firm selling two versions of a single product, a free version for free and a premium version at a regular price, to consumers who are loss-averse. We show that when consumers become slightly dissatisfied with the free version, they are more willing to buy the premium version.

Empirical Research in Service Systems

Sponsored: Manufacturing & Service Oper. Mgmt/Service Operations

Sponsored Session

Chair: Qiuping Yu, Kelley School of Business, Indiana University, Kelley School of Business, Indiana University, Bloomington, IN, 47405-1701, United States

1 - Low-acuity Patients Delay High-acuity Patients in an Emergency Department

Danqi Luo, Stanford University, 655 Knight Way, Stanford, CA, 94305, United States, dluo@stanford.edu, Mohsen Bayati, Erica Plambeck

This work provides theoretical and empirical evidence that in an ED, the arrival of an additional low-acuity patient significantly increases high-acuity patients' wait times. Two stylized models are built to provide theoretical lower bounds for the extra wait times caused by a low-acuity patient on the high-acuity patient wait times. Empirically, to estimate the effect, we propose a method motivated by queueing theory and involving quasi-randomization in the wait time forecast at triage for low-acuity patients, which influences their propensity to leave without being seen.

2 - Linking Delay Announcements, Abandonment, and Service Time: A Behavioral Perspective

Eric Michael Webb, University of Cincinnati, Cincinnati, OH, 45226, United States, Qiuping Yu, Kurt M. Bretthauer

Using field data from a call center, we study how delay announcements induce reference-dependent behavior that impacts customer abandonment and service time. Customers who have waited less (more) time than expected are experiencing a gain (loss) in time. These gains and losses impact both abandonment behavior and service time. A loss (gain) in waiting time increases (decreases) the likelihood to abandon. The loss is more impactful than the same sized gain, signifying that customers are loss averse. Interestingly, the effect of loss aversion carries over into service. Conditional on the same total waiting time, customers who incur a loss in waiting time while in queue spend longer in service.

3 - Engineering the Delay Announcement to Improve Patient Satisfaction

Sina Ansari, Tuck School of Business, Hanover, NH, United States, Sina.Ansari@tuck.dartmouth.edu, Seyed Iravani, Laurens G. Debo

Using predictive analytics and two years of hospital data, an institution specific application is developed to predict wait-times. We use linear regression models with time and patient-related control variables to identify the effect of delay announcement on patient waiting experience and understand the underlying dynamics. We observe that providing patients with their estimated wait-times improves their self-reported satisfaction up to 18%. The highest increase in wait-time satisfaction in our experiment was obtained by adding 40 to 80 minutes to the expected wait-time (which corresponded with reporting the 70th percentile of the wait time distribution).

4 - Can "Very Noisy" Information Go a Long Way? An Exploratory Analysis of Personalized Scheduling in Service Systems

Seyed Emadi, UNC-Chapel Hill, Chapel Hill, NC, United States, seyed_emadi@kenan-flagler.unc.edu, Rouba Ibrahim, Saravanan Kesavan

In this work, we focus on the implementation of personalized scheduling policies which exploit noisy individual customer information. In particular, we consider the shortest job first policy with noisy service time predictions. We use a combination of three methodologies. Through our empirical study, we investigate how personalized scheduling using service-time predictions from a real call-center performs in practice. Then, we use both simulation modeling and queueing theory to deepen our understanding into that operational performance.

Learning and Robust Optimization in Service Operations

Sponsored: Manufacturing & Service Oper. Mgmt/Service Operations

Sponsored Session

Chair: Chaithanya Bandi, 1987, 1987, Evanston, IL, 60208, United States

1 - Using Geometry for Improving Policies in Multistage Robust Optimization

Eojin Han, Northwestern University, Evanston, IL, 60208, United States, eojinhan2020@u.northwestern.edu, Chaithanya Bandi, Omid Nohadani

We develop a framework to construct a hierarchy of dynamic policies for multistage robust optimization problems. We leverage the geometry of the uncertainty set and the geometry imposed by the set of constraints to lift the uncertainty set to higher dimensions, which leads to generalized non-linear dynamic policies. Numerical experiments demonstrate that our framework significantly improves over linear decision rules without losing computational tractability.

2 - Robust Lot Sizing Problem under Adversarial Demand Uncertainty

Omar El Housni, Columbia University, New York, NY, 10027, United States, oe2148@columbia.edu, Vineet Goyal, David B. Shmoys

We consider a two-stage robust lot-sizing problem in a network where each node is facing an uncertain demand that is realized in the second stage. In the first stage the decision maker needs to decide the inventory levels for each node while in the second stage he can make recourse transportation decisions after observing the uncertain demands. We model uncertainty in the second stage using a budget of uncertainty set and present algorithms with provable guarantees.

Emerging Operations Management Problems on 3D Printing

Sponsored: Manufacturing & Service Oper. Mgmt/Supply Chain

Sponsored Session

Chair: Jing-Sheng Jeannette Song, Duke University, Duke University, Durham, NC, 27708-0120, United States

Chair: Yue Zhang, Pennsylvania State University, Pennsylvania State University, University Park, PA, 16827, United States

1 - Managing Self-replicating Innovative Goods

Zhankun Sun, City University of Hong Kong, 7-268, 7/F, Academic 3, Tat Chee Avenue, Kowloon, Hong Kong, zhanksun@cityu.edu.hk, Bin Hu

We study optimal production and sales policies for a manufacturer of self-replicating innovative goods. We adopt the continuous-time optimal control framework and marry a self-replication model on the production side to the canonical innovation diffusion model on the demand side. By analyzing the model, we identify Strong and Weak Replicability regimes wherein production and sales respectively take priority over the other, and fully characterize their distinct optimal policies. These insights prove highly robust in several model extensions, including backlogged demand, repeated purchases, and additional exogenous and endogenous production constraints.

2 - Decentralized Customization with 3d Printing

Ali Kemal Parlakturk, University of North Carolina at Chapel Hill, Kenan-Flagler Business School, Chapel Hill, NC, 27599-3490, United States, Jayashankar M. Swaminathan, Nagarajan Sethuraman

In this paper, we study the trade-offs involved in decentralized customization enabled by 3D printing at retail stores. We develop an analytical model that considers in-store 3D printing as a component of the firm's broader product line strategy. Managerial insights from our novel model can guide the adoption of 3D printing at retail stores.

3 - 3d Printing of Spare Parts via LP License Contracts

Jing-Sheng Jeannette Song, Professor, Duke University, Fuqua School of Business, Durham, NC, 27708-0120, United States, jssong@duke.edu, Bram Westerweel, Rob Basten

3D printing has the potential to shift supply chains from global networks that rely on centralized production with traditional manufacturing technologies to largely digital networks with decentralized, local 3D printing, i.e., digital inventory. In this paper we propose that the OEM acts as an intellectual property (IP) licensor by selling spare parts designs, rather than physical spare parts. With these designs a buyer can print spare parts locally at much shorter lead times and at lower setup costs. We consider both an OEM who serves multiple identical buyers, and an OEM who serves non-identical buyers. For both cases we characterize the optimal IP license contract.

4 - How 3d Printing and Other Emerging Technologies Can Help MRO Parts Inventory Management

Yu-Ning Liu, Tech Leader, Manufacturing & Supply Chain Analytic, Ford Motor Company, Dearborn, MI, 48105, United States, yliu4@ford.com, Jing Chen, Oleg Gusikhin, William Finkenstaedt

Maintenance, Repair, and Operations (MRO) parts inventory management is challenging. Additive manufacturing, Internet of Things (IoT), big data analytics, machine learning, and new smart mobility logistics models are emerging technologies that enable efficient inventory solutions for different types of MRO parts. There is no single universal strategy that works for all MRO parts due to wide variety of part attributes including usage patterns, lead-time, and cost. We propose the clustering of MRO parts into different groups and discuss the potential strategy to improve inventory management efficiency by leveraging emerging technologies for each MRO part group.

Behavioral Operations I

Contributed Session

Chair: Nur Cavdaroglu, Kadir Has University, Bostanci Mah Mehmet Sevki Pasa Cad 27/13, Istanbul, 34744, Turkey

1 - Analyzing Supply Chain Decision Behavior with Online Beer Game

Chialin Chen, National Taiwan University, Taipei, Taiwan, cchen026@ntu.edu.tw, Shu-Jung Sunny Yang, Yi-Chun Wu

The bullwhip effect describes the famous phenomenon where demand variability is typically higher for firms upstream in a supply chain. In this research, we study the factors which influence human supply chain decisions with the online beer game. Decision makers are classified into several groups based on different degrees of inventory fluctuations. A panel data analysis is conducted to study how different decision makers react to demand variation under different settings. Our study explores the behavioral factors of the bullwhip effect in terms of information processing as well different numbers of factors considered in their decision making processes.

2 - The Role of Emotions in Operations Management: An Experimental Analysis of Newsvendors

Santiago Forero, University of Houston, C. T. Bauer College of Business, Houston, TX, United States, sforero@bauer.uh.edu, Norman Johnson, David X. Peng

The influence of emotions on judgment and decision making has received the attention of researchers in several fields, but it has received scant attention in operations management. We conduct a series of experiments to explore how a negative, cognitive-based emotion, impacts ordering decisions made by newsvendors.

3 - Do Attractive People Make a Better Deal? An Investigation of Social Factors in Supply Chain Management

Lyudmyla Starostyuk, University of Texas-Arlington, Arlington, TX, United States, lyudmyla.starostyuk@mavs.uta.edu, Kay-Yut Chen, Edmund L. Prater

Although it is well known that people form impressions of others based on their appearance, little is known about the role of facial character judgments in contracting. We present results of the experiment designed to reveal the effect of attractiveness, trustworthiness and dominance on pricing behavior in a supply chain game. To measure the shift in bounded rationality of a supplier, we apply the quantal choice model.

4 - Eyes on the Game: Eye-tracking Analysis of the Beer Game

Andres I. Musalem, University of Chile, Santiago, Chile, Rene San Martin, Juan Pablo Torres

The beer distribution game is a simulation game designed to illustrate the complexities of inventory decisions within a supply chain. We consider a simplified version of the beer game and use eye-tracking to study the attentional patterns of players. This allows us to study differences between good and bad players in terms of the attention they allocate to the different pieces of information (e.g., initial inventory, demand). We are also able to study differences in attentional strategy depending on the context faced by the players (i.e., positive initial inventory versus backorder).

5 - A Behavioral Experiment Regarding Pricing Decisions

Nur Cavdaroglu, Assistant Professor, Kadir Has University, istanbul, Turkey, nur.cavdaroglu@khas.edu.tr

In this paper, we analyze the pricing decisions of a seller in an environment where there exists a competitor. The demand the seller faces is uniformly distributed, where the average demand increases in the price of the competitor and decreases in her own price. We study the pricing decisions of the seller in a 2x2 design where the first factor is the price of the competitor (either too low or too high with respect to the optimal price of a Nash equilibrium with two homogeneous sellers), and the second factor is the variance of the demand function. According to the preliminary results, the subjects exhibit anchoring behavior (on the price of the competitor) and regret, and decisions worsen with the variance.

Using OR/Analytics Methods for Higher Education Process Improvement

Contributed Session

Chair: Scott Warren, University of North Texas, Denton, TX, 76207, United States

1 - Lean Six Sigma Black Belt Higher Education Project

Marsha Jance, Associate Professor of Business Administration, Indiana University East, Richmond, IN, United States

A higher education based Lean Six Sigma Black Belt project will be discussed. The presentation will cover the DMAIC (Define, Measure, Analyze, Improve, and Control) methodology phases for the project and how using the DMAIC methodology lead to improvements in this higher education process.

2 - Lean Six Sigma and Higher Education Improvements

Rebecca Clemons, Assistant Professor, Indiana University EAst, Richmond, IN, United States, reclemon@iu.edu, Marsha Jance

Lean Six Sigma methodology is used to identify areas of improvement in the higher education processes. The authors discuss how analyzing student survey feedback data lead to Lean Six Sigma Black Belt project ideas. The presentation will cover how the DMAIC methodology (Define, Measure, Analyze, Improve, and Control) is applied. An overview of the Lean Six Sigma and higher education literature will also be provided.

3 - Master Scheduling in K-12 Education

Neil Desnoyers, Saint Joseph's University, Philadelphia, PA, United States

For almost all those individuals who are tasked with performing it, the Master Scheduling process in K-12 education is painful. As one K-12 administrator responsible for Master Scheduling in her school commented recently, "...it's a very daunting and time-consuming task." Significant advances in K-12 Master Scheduling have not occurred frequently. In fact, the last significant advance in the field ("block scheduling") was developed over 20 years ago. Improvements in data availability, scheduling algorithms, and programming languages since that time should change the landscape of the problem.

4 - Report on the Development of an Academic Program's Operational Model, Information Systems, and Supporting Documentation to Improve Customer Service

Scott J. Warren, Professor, University of North Texas, Denton, TX, United States, scott.warren@Unt.edu, Matthew Bonhamgregory

In academic departments at universities, operations management is usually created each day and therefore an inefficient process where stakeholders respond to problems as they arise. Lack of an operational model for academic programs has negative consequences. Reactionary operations may fail to capture recruiting leads, provide poor advising service to students during and creates heavy staff workload. This can lead to low morale and costly turnover. This presentation describes the systems engineering research process used to develop a functional operations model for a graduate degree program. We explain our approach to improving customer experience while reducing staff workload.

Joint Session MIF/PSOR: Stochastic Models in Disaster Response Logistics

Sponsored: Minority Issues

Sponsored Session

Chair: Diana Gineth Ramirez-Rios, Rensselaer Polytechnic Institute, Troy, NY, 12180, United States

1 - Stochastic Models for Facility Location and Allocation of Relief in Disaster Response Logistics

Diana G. Ramirez-Rios, Rensselaer Polytechnic Institute, Troy, NY, 12180, United States, ramird2@rpi.edu, Jose Holguin-Veras

This research focuses on the facility location and prepositioning of relief distribution in the event of a disaster where decisions made affects total social costs. This includes the private costs associated to logistic operation and the external costs associated to the suffering of the population in need in terms of deprivation costs. The decisions considered are both in the planning and post-disaster stages. In the planning stage, optimal facility location and prepositioning is decided. In the post-disaster stage, decisions are made regarding distribution of relief. Due to the stochastic nature of the problem, several demand patterns and the model aims at minimizing total expected social costs.

2 - A 2-Stage Stochastic Model to Allocate Water in Post-Disaster Environments

Sofia Perez-Guzman, Rensselaer Polytechnic Institute, Troy, NY, 12180, United States, perezs@rpi.edu, Diana Gineth Ramirez-Rios, Mario E. Arrieta-Prieto, Abdelrahman Ismael

This research extends on previous work on anticipation effects caused by the lack of aid in post-disaster environments which focused on the time when aid will be available and conditions go back to normal. The allocation of the aid must also respond to the actual demand for it, i.e. its randomness and its split among the different shelters. The following work develops a two-stage stochastic model that captures the uncertainty from both returning to normal conditions and demand dynamics. This allows incorporating the humanitarian suffering, by using deprivation cost functions, and a dynamic, interrelated and time-dependent demand of aid, by following the Lotka-Volterra model.

3 - Planning Relief Distribution After Disasters Considering Social Costs

Ruben Yie, Universidad del Norte, Barranquilla, Colombia, Johanna Amaya Leal

Coordinating the arrival of relief groups responding to a disaster is a major issue for disaster managers on the ground. This paper describes a methodology to solve the problem of Districting and Vehicle Routing for relief distribution after disasters (D-VRP). Using the total social costs of the operation as objective, the model assigns relief groups to cover small areas (i.e. district) within the impacted zone, and proposes a routing solution to serve the demand of survivors located at the points of distribution. The model considers the resources brought by the relief groups, capacity of available sites, and the needs of the population to minimize human suffering.

Joint Session MSOM/SUS/Practice Curated: Sustainable and Socially Responsible Operations

Sponsored: Manufacturing & Service Oper. Mgmt/Sustainable Operations

Sponsored Session

Chair: Can Zhang, Duke University, Durham, NC, 27708, United States

1 - Optimizing First-mile Logistics in Smallholder Supply Chains

Sergio Camelo, Stanford University, Stanford, CA, United States, camelo@stanford.edu, Dan Andrei Iancu, Joann de Zegher

We study the logistics surrounding pick-ups and deliveries of palm fruit in the Indonesian smallholder palm oil supply chain. Using data from smallholder farmers and transport providers from our field site in Sumatra, we reconstruct current transportation routes, and propose novel algorithms that rely on spatial or temporal optimization. We find that centralized vehicle routing algorithms can improve the transportation distances by 25%, and reduce the number of days that middlemen have to work by 30%. We expect the implementation of our results to reduce overall costs in the market, and ease the digitization of agricultural data in smallholder palm oil supply chains.

2 - To Bribe or not to Bribe in a Procurement Auction under Disparate Corruption Pressure

Xiaoshuai Fan, Hong Kong University of Science and Technology, Kowloon, Hong Kong, xfanaf@connect.ust.hk, Ying-Ju Chen, Christopher S. Tang

We examine a (large) manufacturer's bribery decision arising from a procurement auction under ''disparate corruption pressure" when another (small) manufacturer is known to bribe the auctioneer for the right of first refusal. We discover that the large manufacturer should refuse to pay bribes at all times to prevent from leaking its cost information and intensifying competition. However, even when the large manufacturer is disadvantaged by the intermediary, we show that it can benefit from the corrupted auction process when the difference in production efficiency or the bribe is high so that the cost advantage derived from the right of first refusal dominates the information disadvantage.

3 - Where Should I Sell? Optimal Market Selection for Farmers in an Agricultural Network

Somya Singhvi, MIT, 235 Albany Street, Cambridge, MA, 02139, United States, ssinghvi@mit.edu, Retsef Levi, Yanchong Zheng

Farmers' selection of markets to sell their produce is limited due to logistical constraints and lack of access to price information in many developing countries. In this work, we collaborate with Digital Green-Loop, an app that pools farmers' produce, and transports it to the wholesale markets in Bihar, India. Using transaction data from the platform, we first predict prices and then solve a network optimization model that takes various operational constraints into account and maximize farmers' overall revenue. Finally, we implement a field experiment to test the model's effectiveness.

4 - Matching Supply and Demand for Renewable Energy: The Case of Smart Meters

Bhavani Shanker Uppari, Singapore Management University, Singapore, 178899, Singapore, bhavaniu@smu.edu.sg, Kashish Arora

A large proportion of world's electricity demand is going to be met by renewable sources in the next decade. This poses a huge operational challenge: balancing the highly variable renewable electricity supply and the (relatively more) static demand. Using data from a large scale experiment in London, we examine the effect of dynamic prices (pushed through smart meters) on the response of consumers' demand. We build a consumer-level structural model of pricing and electricity consumption. Using the resultant estimates, we evaluate the efficacy of various policies (e.g., different tariff schemes and capacity allocations across different power sources) in terms of matching supply with demand.

■ WA23

CC- Room 3A

Spatial Decision Analysis

Sponsored: Decision Analysis

Sponsored Session

Chair: Valentina Ferretti, London School of Economics and Political Science, London School of Economics and Political Science, London, United Kingdom

1 - Sustainability Assessment of Potential Areas for Deep Geothermal Energy Systems in Switzerland

Matteo Spada, Paul Scherrer Institut, OHSA/D19, Switzerland, matteo.spada@psi.ch, Marco Cinelli, Peter Burgherr

Within the Swiss Energy Strategy for 2050 one of the potential technologies expected to replace the current nuclear-related electricity production is Deep Geothermal Energy (DGE). DGE is a secure base-load renewable technology, however, its feasibility strongly depends on local conditions such as, for example, geological and social ones. This study presents a methodology to assess the sustainability of potential areas of interest for DGE in Switzerland. The proposed method is based on a Stochastic Multicriteria Acceptability Analysis (SMAA) applied to an outranking approach combining uncertain inputs of explicit (e.g., heat flux) and calculated (e.g., risk indicators) criteria.

2 - Geospatial Visualization of Stakeholder Preferences

Tobias Fasth, Public Health Agency of Sweden, Kista, Sweden, tobias.fasth@foi.se

Decision problems in public decision-making involve stakeholders with a diverse demographic background. The stakeholders naturally have differing and conflicting preferences regarding the alternatives under consideration. To aid a decision maker to explore the stakeholders' opinions, we present a web-based open source application, enabling a geospatial analysis of the stakeholders' preferences and conflicts.

3 - Affect or Preferences in Urban Planning Decision Analysis

Aron Larsson, Stockholm University, Stockholm, Sweden
Aron Larsson, Mid Sweden University, Sundsvall, Sweden

In our experience, decision analysis in urban planning typically involve rather loosely defined alternatives rendering elaborated techniques for preference elicitation hard to utilise. On the other hand, stakeholders typically have rather strong mindsets with respect to their affect towards different higher level alternatives. This leads to some intriguing opportunities, and problems, when aiming to interpret affect statements for decision analysis purposes to stimulate a rational and resource efficient planning process. We here present a couple of tested approaches in a Swedish context.

4 - Map- Based Choice Architecture for Scope Insensitivity

Valentina Ferretti, Politecnico of Milano and London School of Economics and Political Science, Via Sismonda 7, Milano, 10143, Italy, V.Ferretti@lse.ac.uk, Yesmean Luk

Scientific research has demonstrated that subjective values are highly sensitive to the presence or absence of a stimulus (i.e., a change from zero to some number), but are largely insensitive to further variations in scope. This phenomenon is known as scope insensitivity and is a cognitive bias with relevant implications for both policy making and management. This paper is part of an ongoing research program aiming to investigate the impacts associated to the use of geographical maps in spatial decision analysis. The talk will discuss a behavioral laboratory experiment on map-mediated willingness to pay for the remediation of certain environmental areas.

CC- Room 3B

Energy Technology, Climate Change, and Uncertainty

Sponsored: Decision Analysis

Sponsored Session

Chair: Erin Baker, Univ of Massachusetts-Amherst, Amherst, MA, 01003, United States

1 - Optimal Residential Battery Storage Operations Using Robust Data-driven Dynamic Programming

Benjamin D. Leibowicz, Assistant Professor, University of Texas-Austin, ETC 5.128D, 204 E. Dean Keeton St. C2200, Austin, TX, 78712-1591, United States, bleibowicz@utexas.edu, Nan Zhang, Grani A. Hanasusanto

We consider operating battery storage in a home with rooftop solar PV to minimize expected electricity costs under uncertain electricity usage, PV generation, and electricity prices. It is difficult to solve this dynamic program using standard techniques, and to estimate conditional distributions from sparse data. To overcome these challenges, we implement a data-driven dynamic programming (DDP) algorithm that uses historical data to generate empirical conditional distributions and approximate the cost-to-go function. Then, we formulate robust DDP (RDDP) algorithms that consider the worst-case expected cost over a set of conditional distributions centered at the empirical distribution.

2 - Uncertainty in the Future Cost of Wind Energy Leads to Uncertainty in Climate Change Mitigation

Franklyn Kanyako, University of Massachusetts, Amherst, 52 Blackberry Lane, Hadley, MA, 01002, United States

We assess under uncertainty in future cost of wind energy and climate policies the impact of wind energy on electricity generation and the abatement cost. The IPCC forecast that wind energy could provide 13-14 percent of electricity supply under median climate change mitigation scenario by 2050. Using a Monte Carlo simulation method with the global change integrated assessment model (GCAM), we investigate the distribution over the share of wind energy in electricity generation mix and the impact of wind energy on other electricity generation technologies under three policy scenarios. A scenario that limits global temperature rise to less than 1.5 degrees Celsius, RCP 2.6 scenario and a carbon tax.

3 - Implications of Foresight in Electricity Capacity Expansion Models

Maxwell Leonard Brown, National Renewable Energy Laboratory, Golden, CO, 80401, United States

Electricity capacity expansion models are typically myopic. The optimization algorithms employed largely consider current-year conditions (e.g., fuel prices, load, technology costs and performance, policies and regulations) with limited to no knowledge of expected future changes in conditions. In this work, I evaluate how different levels of foresight—myopic through perfect foresight—impact investment and retirement decision-making within the context of a capacity expansion model. Both the mechanics for making this scaling possible as well as the results for a wide range of policy and cost scenarios are presented.

4 - Effect of Accidents on Energy Technology Adoption

Robert Barron, Western New England University, Springfield, MA, 66047, United States, Mary Hill

Integrated assessment models often neglect the impact of accidents on energy technology adoption. However, energy accidents can be costly, and negative public opinion can create significant obstacles to energy deployment, as evidenced by the effects of Three Mile Island, Chernobyl, and Fukushima on nuclear power. We develop the Energy Accidents Cost and Constraint (EACC) model to quantify these effects. The EACC model characterizes the likelihood and severity of energy accidents, then estimates their cost and effect on public acceptance of energy technologies. Initial results indicate that energy accidents have a non-trivial impact on energy technology adoption.

Revenue Management, Pricing II

Contributed Session

Chair: Hao Su, University of Maryland-College Park, College Park, MD, 20743, United States

1 - Product and After-sale Maintenance Service Pricing Decisions in Arisk-averse Supply Chain

Azmat Ullah, Shanghai Jiao Tong University, Shanghai, China, azmatullah@sjtu.edu.cn, Jiang Wei

This paper focuses on a problem where the manufacturer sells a repairable product while an agent provides after-sale service under uncertain demand. Due to demand volatility, either manufacturer or agent or both the players are risk-averse toward their decisions. The goal of this paper is to design various after-sale service strategies where the optimal price of repair or maintenance contract for the agent whereas the optimal product price for the manufacturer are explicitly determined such that the utility of both players can be maximized. A numerical example is presented to further illustrate the results and related issues.

2 - Opaque Selling and Customer Mistrust

Vinaysingh Jaisingh Chawan, Indian Institute of Management Indore, Indore, India, vinaysingh@iimidr.ac.in

Opaque selling focuses on differences in customer's valuations for different variants of the product. Customers who buy the opaque product expect some discount over the full information product. Thus, their WTP depends upon their prior belief about the probability of each product variant being delivered. Here, we consider the case where one product variant is more likely to be delivered, and it is also the less preferred variant. In this case, customers are likely to develop mistrust about the seller's intentions if huge discount is not offered for opaque product. We analyze this case to find conditions where opaque selling will work in the face of customer mistrust.

3 - A Quality-based Choice Model for Vertical Differentiation with Reference-dependent Preferences

Wenhan Zhao, University of Science and Technology of China, HeFei, China, 1612094758@qq.com, Xiaoming Yan

In markets with heterogeneous consumers, the attractiveness of a product may be influenced by other products within a context. Motivated by the goals of managing reference-dependent preferences and product line design, we consider a quality-based choice model that takes into account how preferences for a product vary with alternatives to the context. We show that the firm has more incentives to change the variety and relative standing of its products. In particular, when the importance of unfavorable comparisons among products and fixed setup cost are relatively low, the firm may offer a variety of distinct products. Otherwise, the firm may give up discrimination among consumers.

4 - Optimal Sales Policies for a Virtual Assistant Platform

Wenjia Ba, Stanford, Stanford, CA, United States, wenjiaba@stanford.edu, Haim Mendelson, Mingxi Zhu

We study the operating characteristics of a sales platform that interacts with consumers through a virtual assistant. The platform decides which product to offer and at what price, seeking to maximize its expected profit. Consumers are impatient and rational, seeking to maximize expected utility given the information available. We solve for the equilibria and develop efficient algorithms for implementing the solution. We examine the effects of information asymmetry and study how incentive misalignment depends on the consumer's private valuations. We compare the performance to that of a traditional web interface, where multiple products are presented at a time.

5 - Digitization and Profitability

Yasushi Masuda, Keio University, Yokohama, Japan, yasushi.masuda@gmail.com, Seungjin Whang

Consider a monopolistic vendor facing a known demand curve. Digitization lowers the variable production cost. Can we conclude that digitization always improves the vendor's profitability? Not necessarily. The physical product vendor prepares the exact quantity of the product to sell. By contrast, the digital product vendor will have more, and infinitely more, "leftover" stock, thanks to the nature of the digital product. This may lead to the downward spiral of price for the digital product vendor. We develop an economic model to formally analyze the impact of digitization on the profitability to the vendor.

6 - Win the Buy Box: Product Characteristics and Reselling-or-marketplace Choice

Hao Su, University of Maryland-College Park, College Park, MD, United States, haosu@rhsmith.umd.edu, Laharish Guntuka, Martin E. Dresner

This paper will determine product characteristics that predict a third-party seller's decision to sell a product through a marketplace (or a marketplace operator's decision to directly sell a product). We will empirically analyze the product-level data scraped from one of the largest online marketplaces in the U.S. for the purpose of this study. Our findings will provide implications to third-party sellers seeking to avoid direct competition with the marketplace operator.

Chair: Sait Tunc, The University of Chicago Booth School of Business, Chicago, IL, 60615, United States

1 - Monitoring Length of Stay Through Control Charts: a Comparative Study of Diabetic Patients

Nasibeh Azadeh Fard, Assistant Professor, Rochester Institute of Technology, Rochester, NY, United States, azadehfard@gmail.com, Fatma Pakdil, Afsun Ezel Esatoglu

Monitoring length of stay (LOS) can help medical decision-makers identify areas of potential improvements and improve resource management, which results in a better quality of care for patients. This study aims to monitor process performance at hospitals by implementing a statistical process control (SPC) approach on LOS. The study focuses on diabetic inpatients admitted to hospitals in two national healthcare systems, i.e., US and Turkey. I-MR charts were used to analyze the datasets and monitor the variations of LOS.

2 - Capacity Reservation of Nursing Homes in Elder-care Management

Caiyuan Xiong, University of Science and Technology of China, Hefei, China, wx123456@mail.ustc.edu.cn, Xiaobei Shen, Yugang Yu

We consider a periodic-review capacity allocation problem with multiple resources and two demand classes in a finite planning horizon consisting of T periods. We translate the complex optimization problem to a problem with only two decision variables and adopt the decomposition to derive optimal solutions. In numerical studies, the optimal algorithm in the basic model is used as a heuristic to chech its robustness.

3 - Expanding the Donor Pool: Incentivizing the Use of Marginal Organs for Transplantation

Sait Tunc, University of Chicago Booth School of Business, Chicago, IL, United States, sait.tunc@chicagobooth.edu, Burhaneddin Sandikci, Bekir Tanriover

Transplantation emerged as the standard treatment for organ failure. Despite the growing shortage for donor organs as demand outpaces supply, a significant fraction of organs harvested for transplantation are rejected and discarded. We study the problem of organ wastage in a queueing-theoretic framework. We investigate socially efficient and equilibrium utilizations of donor organs, and discuss an incentive mechanisms that help increase the utilization of organs while also improving social welfare.

4 - Wafer Defect Inspection Optimization: Models, Analysis and Algorithms

Siyang Gao, Assistant Professor, City University of Hong Kong, Kowloon, Hong Kong, siyangao@cityu.edu.hk, Zhongshun Shi, Ming Qin, Weiwei Chen, Leyuan Shi

We consider the defect inspection optimization problem (DIOP) in this research. We formulate it as a mixed integer linear programming (MILP) model, and enhance the formulation using variable reduction. To address the computational challenge of solving large-scale DIOP instances, we further propose three approximation methods with theoretical bounds, namely, a constant-factor approximation algorithm that provides heuristic solutions quickly, a polynomial-time approximation scheme (PTAS) that has a strong performance guarantee, and an MILP-based hybridmethod that combines the PTAS framework and MILP formulation and is suitable for parallel computing by design.

Joint Session Serv Sci/Practice Curated: Empirical Research in Service Management

Sponsored: Service Science

Sponsored Session

Chair: Simin Li, Kellogg School of Management, Northwestern University, Evanston, IL, 60208, United States

Chair: Nil Karacaoglu, Evanston, IL, 60201, United States

1 - Improving Customer Compatibility with Operational Transparency

MoonSoo Choi, Harvard Business School, Boston, MA, 02215, United States, mochoi@hbs.edu, Ryan Buell

Recent research has demonstrated the impact of customer compatibility - the degree of fit between the needs of customers and the capabilities of the operations serving them - on service performance. Companies with more compatible customers receive higher satisfaction scores and exhibit faster growth. However, when marketing their offerings to prospective customers, companies often shroud the operational tradeoffs inherent in their offerings in favor of emphasizing their advantages. Through a large-scale field experiment with a nationwide retail bank, we investigate how providing prospective customers with transparency into an operation's tradeoffs affects acquisition and engagement.

2 - Impact of Food Delivery Platforms on Traditional Restaurants: An Empirical Analysis

Varun Karamshetty, INSEAD, Boulevard de Constance, Singapore, 77300, Singapore, Varun.Karamshetty@insead.edu, Michael Freeman, Sameer Hasija

Online food delivery platforms (e.g. UberEats, GrubHub) represent a growing segment of the on-demand economy. As popularity of these platforms increases among consumers, restaurants are depending more on these channels to drive top-line growth. We empirically investigate the impact of such platforms on operational performance of traditional restaurants. We find, for example, that as the share of demand from 3rd party delivery platforms increases, overall demand becomes harder to forecast which leads to restaurants making sub-optimal labor scheduling decisions, increasing their labor costs.

3 - Gender Difference and Inequality in Leadership: Evidence from a Sport Retailing Chain

Susan F. Lu, Purdue University, Krannert 441, West Lafayette, IN, 47907, United States, lu428@purdue.edu, Ruoran Chen, Simin Huang, Lauren Xiaoyuan Lu

Using the data from a store retailing chain, we find that male managers are associated with better store performance. The gender differences are not caused by gender capability but mainly caused by the gender bias in store assignment: male managers are more likely to be assigned to good stores with high capability in sales.

Trust Issues in E-Commerce/Business

Sponsored: Service Science

Sponsored Session

Chair: Cong Cao, University of Wollongong, Wollongong, NSW 2500, Australia

1 - understanding User Ads-click Intention in the Mobile Social Platform: the Mediation Effect of Trust and Moderation Effect of Prior Experience

Zhen Shao, Doctor of Philosophy, Harbin Institute of Technology, Harbin, 150006, China, shaozhen@hit.edu.cn, Zhengyuan Pan, Rui Zhao, Lin Zhang

This study developed a theoretical model to examine the mediation effects of cognitive vs. affective trust between dual routes and users' ads-click intentions in the mobile social platform. Particularly, user's prior experience was incorporated in the model to examine its moderating effect. A scenario-based survey was conducted in China and empirical results suggested that content personalization and vendor reputation were positively associated with cognitive trust, and their influences were stronger for users with prior experience. While social recommendation was positively related with affective trust, and its impact was higher for users without prior experience.

2 - Trust and Privacy Concern in the Digital Age: A Meta-analysis

Yeolib Kim, Ulsan National Institute of Science and Technology, UNIST, Ulsan, Korea, Republic of, yeolib.kim@unist.ac.kr

In this study, a meta-analysis of the relationship between trust and privacy concern in an information systems context was conducted. Overall, trust and privacy concern have a modest negative relationship. However, this relationship is idiosyncratic (significant heterogeneity) and certain moderators (e.g., privacy concern scale, sample type) were able to explain some of this variance.

3 - An Investigation of Cultural Proximity Between Hosts and Clients on Sharing Economy Driven Accommodation Platforms

Jianshan Sun, Doctor of Philosophy, Hefei University of Technology, Hefei, 230011, China, 2014800051@hfut.edu.cn, Shixuan Fu, Yezheng Liu, Yuanchun Jiang, Xiayu Chen, Chunli Liu, Chunhua Sun, Le Wu

Sharing economy driven accommodation platforms (SEDAP) are widespread for lodge reservations, however, still face the risk of privacy and ethical concerns. Trust is an important in the sharing economy driven peer-to-peer transactions to mitigate potential risks. Existing research fails to study the antecedents of trust from the interaction role of both hosts and clients. Taking SEDAP as our research context, we investigate whether cultural proximity between hosts and clients influences interpersonal trust, and how it relates to occupancy rate. Data from Airbnb.com were used to answer the research questions.

4 - The Role of Trust in the Sharing Economy: Analysis & Simulations of an AirBnB Market

Eyal Ert, Doctor of Philosophy, The Hebrew University of Jerusalem, Rehovot, 76100, Israel, eyal.ert@mail.huji.ac.il, Aliza Fleischer

In markets like Airbnb consumers face many attributes, including property, spatial (neighborhood), and seller (trustworthiness) attributes. Some are straight forward (e.g. price), others are inferred from images (e.g. trustworthiness) or text (self-disclosure-text). Yet there is no full market analysis on Airbnb that addresses the role of these attributes. Here we analyze Airbnb Stockholm market, using an aggregate nested logit equilibrium model with product differentiation. Our results indicate that the host's virtual attributes play an important role in this market as much as the property and spatial attributes. The seller's trustworthiness is as important as the location of the property

5 - Trust Creation in Online Chat

Xin Xu, Prof., The Hong Kong Polytechnic University, Hong Kong, xin.xu@polyu.edu.hk, Katherine Feng, Michael Mei

Online chat supported by both the Live Chat technology and recently the Chatbot technology is gaining significant popularity in E-Commerce. Online chat is not only the important channel for an e-commerce brand to answer ad hoc inquiries from customers, but also lays the foundation for creating trust between potential customers and the brand. In this research-in-progress, we propose a structure for online conversation analytics and examine the impacts of a number of key features of online chat on trust creation. We provide preliminary evidence supporting both the theoretical and the practical significance of online chat to trust creation in e-commerce.

6 - Evaluating the Helpfulness of Online Consumer Reviews in Social Networking Service Environment

Cong Cao, Tutor, University of Wollongong, Wollongong, NSW 2500, Australia, cong.cao@outlook.com, Jun Yan, Mengxiang Li

Given that Online Consumer Review (OCR) can effectively influence consumers' trust behavior and further the product sales, especially the booming social networking service (SNS), allow for consumers' sharing of review information in the vast social network beyond the limitation of time and space. Therefore, it is essential to understand the influence and mechanism of action of OCR and facilitate the widespread sharing in SNS. This research examines five types of essential factors that influence the helpfulness of OCR in SNS, namely the trustworthiness reflected by information publishers and the accuracy, completeness, currency and format of information perceived by information recipients.

Information Design in Markets

Sponsored: Auction and Market Design

Sponsored Session

Chair: Rachel Cummings, Georgia Tech, Atlanta, GA, 30332-0205, United States

1 - Algorithmic Price Discrimination

Rachel Cummings, Georgia Tech, Atlanta, GA, 30332-0205, United States, Nikhil Devanur, Zhiyi Huang, Xiangning Wang

We study the third degree price discrimination problem, where an intermediary between a buyer and a seller can design market segments to maximize any linear combination of consumer surplus and revenue, but the intermediary is only partially informed. We consider three informational models. First, we assume that the intermediary has a Bayesian prior of the buyer's value. Second, we consider the sample complexity model, where the intermediary only sees samples from this distribution. Finally, we consider an online learning model, where the intermediary only sees past purchase decisions of the buyer, not her value. For each model, we present algorithms to compute near optimal market segmentation.

2 - Algorithms for Multi-agent Persuasion with No Externalities

Haifeng Xu, University of Virginia, Charlottesville, VA, United States, hx4ad@virginia.edu, Shaddin Dughmi

We study the algorithmics of information structure design — a.k.a. persuasion or signaling — in a fundamental special case introduced by Arieli and Babichenko: multiple agents, binary actions, and no inter-agent externalities. We focus on two basic signaling models, i.e., public and private persuasion, and for each we design efficient algorithms that match complexity lower bounds. Our results reveal insights regarding when public or private persuasion is tractable and are built upon useful characterizations of the optimal signaling scheme which may be of independent interests. Based on joint work with Shaddin Dughmi.

3 - Disclosure and Pricing of Attributes

Alex Smolin, Toulouse School of Economics, Toulouse, 06511, France, alexey.v.smolin@gmail.com

A monopolist sells an object characterized by multiple attributes. A buyer is privately informed about his tastes and uncertain about the attributes. The seller can disclose attribute information to the buyer in a form of a statistical experiment. The seller maximizes revenue and offers a menu of options varying in upfront payments, experiments, and strike prices. I show that optimal experiments belong to a tractable class of linear disclosures and characterize optimal menus in various scenarios.

4 - Third-Party Data Providers Ruin Simple Mechanisms

Juba Ziani, Caltech, Pasadena, CA, 91106, United States, jziani@seas.upenn.edu, Yang Cai, Federico Echenique, Hu Fu, Katrina Ligett, Adam Wierman

We study mechanism design in the presence of a data provider. When no data provider is present, simple mechanisms achieve a constant fraction of the optimal revenue. We demonstrate that this is no longer true in the presence of a third party data provider. Even with a single seller, a single bidder, and a single item of uncertain type for sale, pricing each item-type separately and bundling all item-types under a single price can simultaneously be a logarithmic factor worse than the optimal revenue. Further, in the presence of a data provider, item-type partitioning mechanisms still cannot achieve within a $\log \log$ factor of the optimal revenue.

Optimization, Network

Contributed Session

Chair: Saeid Rasti, North Dakota State University, West Fargo, ND, 58078, United States

1 - Distributed Optimization of an Energy Distribution Network During Network Failure Using Blockchain Technology

Dustin Clasby, Colorado State University-Pueblo, Pueblo, CO, United States, Ebisa Wollega

The purpose of this research is to explore the state of the art in electrical distribution network optimization, specifically using alternating direction method of multipliers (ADMM) over a blockchain network, and then extend this work to include optimization during network uncertainty, including network failure. A simulated electrical network has been developed with nodes represented on a test Ethereum blockchain network.

2 - Robust Network Interdiction Considering Capacity and Resource Consumption Uncertainties

Darshan Rajesh Chauhan, Graduate Research Assistant and PhD Candidate, Portland State University, Portland, OR, United States, drc9@pdx.edu, Avinash Unnikrishnan, Stephen Boyles

The setting of the network interdiction problem is as follows: the goal of the adversary is to maximize the flow of a commodity through the network, and the goal of the interdictor is to minimize the maximum flow through the network by destroying arcs subject to the available interdiction resource. Uncertainties in the arc capacities and arc interdiction resource consumption are considered using a robust optimization framework. The final formulation is a mixed-integer program (MIP) and is solved exactly using Gurobi. A Benders' Decomposition based heuristic initialized with capacity and resource consumption cuts using Lagrangian Relaxation achieves high-quality results in a fraction of time.

3 - Dynamic Identification Method of Multi-bottleneck in Multimode Regional Rail Transit Interdependent Network

Su Liu, Southwest Jiaotong University, Chengdu, China, cdliusu@my.swjtu.edu.cn, Chengshuang Yin, Lin Wang

Adopting line load and network bottlenecks efficiency matrix, a multi-bottleneck dynamic identification model of regional rail transit network in stages is proposed based on the dynamic multi-Bottleneck transmission characteristics. Quantitative description and prediction of Multimode Regional Rail Transit Interdependent Network bottleneck under disturbance environment are realized. The validity of the model is verified by the calculation based on Chengdu-Chongqing Multimode Regional Rail Transit Interdependent Network.

4 - Network Optimization for Broadcast Services in Software Defined Networking

Ali Sarabi, Arizona State University, Tempe, AZ, United States, asarabi1@asu.edu, Arash Sarabi

These days, with increasing demands for streaming and broadcasting on the Internet, network service providers have been challenged to maximize their services in terms of quantity and quality. Software-defined network (SDN) is a computing approach that facilitates network management and enables efficient network configuration. In this study, we present a multi-commodity capacitated network flow model and train a neural network to learn traffic characteristics and optimize the network throughput in less execution time.

5 - Studying Essentiality in Protein Interaction Networks Using Centrality Metrics

Saeid Rasti, North Dakota State University, West Fargo, ND, United States, saeid.rasti@ndsu.edu

In this work, we propose a set of new group centrality metrics and show their performance in estimating protein importance in protein-protein interaction networks. We derive the computational complexity for each of the newly proposed metrics. Then, we provide mixed integer programming formulations to solve the problems exactly; due to the computational complexity of the problem and the sheer size of practical applications, using a commercial solver with the formulations is not a viable option. Hence, we also propose a column generation approach to solve the problems introduced.

Military DMSMS Applications

Sponsored: Military and Security

Sponsored Session

Chair: James Starling, University of Washington “

1 - Strategic DMSMS Management

Peter Sandborn, Professor, University of Maryland, College Park, MD, United States, sandborn@umd.edu

Reactive DMSMS mitigation focuses on minimizing the cost of resolving the unavailability of parts after it occurs. While reactive solutions always play a role in obsolescence management, a higher payoff is possible through strategic management approaches. Strategic management of DMSMS uses part availability data, logistics management inputs, technology forecasting, and business trending to enable strategic planning, life-cycle avoidance maximization, and business case development for the support of systems. The most common approach to DMSMS strategic management is Design Refresh Planning, which consists of choosing the best mix of reactive management approaches and design refreshes.

2 - A Bayesian Approach to Understanding System-level Obsolescence

Victoria Diaz, University of Washington, Seattle, WA, United States, Christina Mastrangelo

Understanding the risks associated to part obsolescence is imperative from both cost and logistical points of view. Questions in this field are usually concerned with the obsolescence risk of certain parts. Our research diverges from this approach by exploiting the structure of parts within a system in order to identify the impact of individual part obsolescence on the entire system.

3 - Optimization in Long Term Preventive Maintenance Planning for Military Aircraft

Sergio Rebouças, Technological Institute of Aeronautics, Sao Jose dos Campos, Brazil, reb@ita.br, Fernando Teixeira Abrahão

Aircraft maintenance activities have a significant impact on logistic costs. Currently, the preventive maintenance planning occurs only in medium to short-term horizon, which increases the potential for losses both in the fleet availability and logistic costs, either by the limited view provided by a restricted planning time horizon or by the solution found. This work proposes an optimization approach for long-term preventive maintenance plan for military aircraft, based on integer programming, in order to minimize logistics costs, in terms of downtime, therefore increasing the availability of the fleet. The model reached valuable savings in downtime compared to the conventional method.

4 - Modeling System Obsolescence via Simple Additive Bayesian Allocation Network Process

Tomi Adetunji, George Washington University, Washington, DC, United States

This work proposes a new application called the Simple Additive Bayesian Allocation Network Process (SABANP). SABANP uses a combination of Multi Criteria Decision-Making methodology and a Bayesian Belief Network to address the impacts of obsolescence on long-life systems. The results show that the application can address complex obsolescence decisions and enables the selection of the best system.

5 - Optimal Technology Refresh Strategies Using Infinite Horizon Optimization

James Starling, University of Washington, Seattle, WA, 98195, United States, jkstar@uw.edu, Christina Mastrangelo, Youngjun Choe

The research provides an application of strategic diminishing manufacturing sources and material shortages (DMSMS) management. For a strategic level decision, the question of when to schedule the first and successive technology refreshes is often difficult. Using an infinite horizon optimization model, this study identifies the optimal sequencing of technology refreshes taking into account various DMSMS associated costs. The optimal strategy can assist the DMSMS manager in scheduling successive technology refreshes.

Semiconductor Industry and Manufacturing

Contributed Session

Chair: Deepak Pahwa, North Carolina State University, 3520 Ivy Commons Drive, # 101, Raleigh, NC, 27606, United States

1 - Wafer-to-order Allocation in Semiconductor Back-end Production

Jelle Adan, Nexperia, Nijmegen, Netherlands, jelle.adan@protonmail.com

This work addresses the allocation of wafer to customer orders prior to assembly in a semiconductor back-end production facility with the aim to minimize overproduction. This study is motivated by and tested at Nexperia's assembly and test facilities, but its potential applications extend to many manufacturers in the semiconductor industry. Current practice is compared to existing heuristics and a commercial optimization solver. Experiments with real-world data sets show that significant improvements can be achieved. Furthermore, data processing steps and heuristics are presented to make the ILP applicable to real-world applications.

2 - Cascaded Convolutional Neural Network for Wafer Bin Map Defect Pattern Classification

Sun Geu Chae, Hanyang University, Seoul, Korea, Republic of, sgchae@psm.hanyang.ac.kr, Suk Joo Bae

Defect patterns on wafer maps provide useful information for identifying causes of failures in semiconductor manufacturing process. Since defect patterns represent specific root causes of failure, identifying the defect pattern is important. Recently, due to advances in image classification using Convolutional Neural Networks (CNN), various works have been conducted on wafer map defect pattern classification using CNN. However, in training the neural networks model, hyperparameter and network designs may have unintended issues such as overfitting. To overcome these risks, end-to-end trainable cascaded convolutional neural networks comprised of two stages is proposed in this research.

3 - Incorporating Assembly Line Balancing into Assembly Line Feeding Decision Making

Nico André Schmid, Ghent University, Ghent, Belgium, nico.schmid@ugent.be, Benoit Montreuil, Veronique Limere

Often, assembly line planning is exclusively associated with balancing, i.e., the distribution of tasks among workers. However, products are becoming more complex due to customization and accumulating part variants. The assembly line feeding problem aims to support managing this complexity by determining part provision, e.g., whether parts are sequenced or supplied in bulk. However, feeding decisions affect picking times and thus operators' workloads. Hence, we integrate assembly line balancing and feeding to minimize overall costs by means of a MIP model while maintaining a highly productive assembly system. Our findings are based on real world data from an automotive company.

4 - Order Acceptance Planning Using Markov Decision Process and Reinforcement Learning

Amirhosein Gholami, Binghamton University, Binghamton, NY, United States, Nasim Nezamoddini

The modern dynamic markets face a high level of variations in products and services. To sustain businesses in this highly volatile environment, supply chains should increase their flexibility by adopting make to order (MTO) systems for customized products. This research presents an application of Markov Decision Process (MDP) and Reinforcement Learning (RL) for optimizing order acceptance decisions in MTO supply chain systems. The technique is implemented on a 3-tiers supply chain. The efficiency of the technique is investigated by simulating different scenarios and risk analysis using statistical techniques.

5 - Using Deep Reinforcement Learning for Order Allocation in a Manufacturing-as-a-service Marketplace

Deepak Pahwa, North Carolina State University, Raleigh, NC, United States, dpahwa@ncsu.edu, Binil Starly

A two-sided manufacturing-as-a-service marketplace is a dynamic platform where orders and supplier capacities arrive stochastically over time. The platform needs to make two key decisions for optimal order allocation: how to allocate i.e. which orders to allocate to which suppliers and when to allocate i.e. how long the platform should wait to thicken the market before allocating. Reinforcement learning methods fail because of high dimensional state and action spaces. We use deep reinforcement learning (DRL) methods to estimate long term reward function for optimal order allocation. Our results prove the viability of DRL methods to solve this otherwise computationally intractable problem.

1 - Reinforcement Learning for Online Stochastic Optimization Problems

Anna Luo, Applied Scientist, Amazon.com, Seattle, WA, United States, Bharath Balaji, Jordan Bell-Masterson, Enes Bilgin, Andreas Damianou, Arpit Jain, Alvaro Maggiar, Pablo Garcia Moreno, Murali Balakrishnan Narayanaswamy, Chun Ye

We show that many online stochastic optimization problems in OR where the distribution of data is unknown is amenable to RL approaches. In particular, we study online stochastic versions of three canonical OR problems with a wide range of practical applications: Bin Packing, Newsvendor, and Vehicle Routing. We apply both well-known OR approaches and newer RL algorithms to these problems and analyze results. For each of these problems, we find that RL is competitive with or superior to the OR baselines.

2 - Reinforcement Learning for Spare Part Inventory Management

Sayak Roychowdhury, Assistant Professor, IIT Kharagpur, Kharagpur, India, sayakroychowdhury@gmail.com, Sarada P. Sarmah

Spare parts inventory management is an essential operation in different industry sectors, e.g. manufacturing, mining etc. Very often, there are dependencies among spare parts, that need to be ordered together to be utilized at the times of maintenance. The demand of such parts at any time maybe dependent on the frequency of scheduled and unscheduled maintenance, and longevity of the parts concerned. Here we propose a reinforcement learning method to determine the optimal order quantity of such spare parts, considering uncertainty in demand, and varying degrees of dependency. This has the potential to reduce inventory and opportunity costs related to availability of spare parts.

3 - A Reinforcement Learning Approach for Assigning Multiple Trucks to Multiple Orders

Yuncheol Kang, Hongik University, Seoul, Korea, Republic of, Daiki Min

We formulate a sequential assignment problem that matches multiple trucks to incoming multiple orders in the on-demand parcel delivery environment. Such problem, however, is highly likely to be intractable due to lots of factors and underlying complex dynamics of the environment. To tackle with this problem, we utilize a reinforcement learning algorithm along with a function approximation approach to deal with huge size of sequential decision making problems. Numerical illustrations will be provided by comparing the suggested algorithm with other related algorithms.

4 - Solving a Multi-item Capacitated Lot-sizing Problem with Reinforcement Learning

Lotte van Hezewijk, PhD Candidate, Eindhoven University of Technology, Eindhoven, Netherlands, Tom Van Woensel, Nico P. Dellaert, Noud Gademann

We study a multi-item, single-stage capacitated lot-sizing problem with stochastic demand. In this problem, the model incurs set-up costs, holding costs, and backorder costs. The objective is to determine the production lot-sizes in every period such that the total costs are minimized. This problem typically suffers from the curse of dimensionality and requires advanced heuristics to find solutions. We model the problem as a Markov decision process and learn optimal policies using reinforcement learning. We compare the results of applying this machine learning technique to existing solution heuristics.

5 - Deep Reinforcement Learning Approach for Metro Train Scheduling with Stochastic Passenger Demand

Chengshuo Ying, City University of Hong Kong, Hong Kong SAR, Hong Kong, cying9-c@my.cityu.edu.hk, Andy H.F. Chow, Kwai-Sang Chin

This paper presents an optimization method for metro timetabling over a double-track line with stochastic passenger demand. The problem is decomposed into many decision stages according to operation dynamics. With the aims to minimize passenger waiting time and operational cost, a learning agent is developed to find the quasi-optimal solution which is represented as a sequence of operational actions. The agent is trained with deep deterministic policy gradient algorithm and a case study supported by practical demand profile shows that the developed method outperforms classical heuristic algorithms in term of solution quality, computation time, and robustness under demand uncertainty.

Optimization & Sustainability

Contributed Session

Chair: Maneesh Reddy Ajjuguttu, Clemson University, Clemson, SC, 29631, United States

1 - Portfolio Optimization-based Approach for Optimal Capacity Utilization Using Less-than-truckload Carrier-to-carrier Collaborations Based on Freight Capacity Options

Choungryeol Lee, Research Assistant, Purdue University, West Lafayette, IN, United States, lee1210@purdue.edu, Srinivas Peeta

This study proposes a mean-risk portfolio optimization-based approach for optimal capacity utilization in the less-than-truckload carrier-to-carrier collaboration market. The proposed approach allows each collaborating carrier to optimally allocate its own capacity and invest excess capacity by considering the trade-off between return and risk. Results from numerical experiments show that the proposed approach enables the collaborating carriers to minimize risk for a specified level of expected return so as to enhance capacity utilization, profitability, and serviceability.

2 - Residential Stormwater Management: Promoting the Installation of Green Infrastructure Through the Optimal Distribution of Incentives

John Edgar Fontecha Garcia, University at Buffalo, Buffalo, NY, United States, Zhenduo Zhu, Alexander Nikolaev, Jose Luis Walteros

Several cities across the US have launched incentives programs to catalyze the adoption of green infrastructure in private property; nonetheless, identifying the most efficient incentives (and the distribution policy) to persuade residents is still a challenge. To strategically allocate the available budget and maximize the common good, it is critical to consider the government goal as well as each household's individual decision-making process. To tackle this challenge, we propose the design and implementation of a bi-level optimization problem to model the interaction between the decisions of both players.

3 - Institutional Investors and Green House Gas (GHG) Emissions

Jaeseog Na, KAIST, Seoul, Korea, Republic of, jsna@kaist.ac.kr, Bowon Kim

We examine how institutional investors affect the GHG emission rate. Based on the U.S. firms' GHG data from Trucost, we find that the presence of institutional investor reduces the GHG. Also, we try to investigate the heterogeneous effects of institutional investors. It appears that both short-term and long-term oriented institutions have incentives to reduce GHG. The institutions with short-term investment horizon tend to avoid a penalty, and the institutions with long-term investment horizon have incentives to push managers toward engaging in more environmental activities. It implies that institutional monitoring generally has a positive effect on reducing GHG emissions.

4 - Can Interest Rate Marketization Alleviate the Financing Constraints of R&D Investment? Evidence from China

Xinxin Zhao, Huazhong University of Science and Technology, Wuhan, China, zhaoxx20@163.com

This paper aims to examine the moderating effect of interest rate marketization on the relationship of the financing constraints and R&D investments. The interest rate marketization index is constructed using the interest rate determination ways, the interest rate fluctuation restrictions and the real interest rate level. Based on panel data of Chinese listed firms for 2007-2017 in manufacturing industry, using Euler-equation investment model, we find that interest rate marketization alleviates the financing constraints especially for non-state-owned enterprises.

5 - Operational Transparency and Slow Fashion

Maneesh Reddy Ajjuguttu, Clemson University, Clemson, SC, United States, majjugu@g.clemson.edu, Aleda Roth

This study addresses the effects of operational transparency on the fashion sector. In particular, we examine the consumer buyer behaviors on the emerging movement called "slow fashion." Slow fashion is a strategy that aims to reduce the toxic and non-toxic wastes that accrue through the supply chains, which are causing havoc to the environment.

OPT Interger/Global: New Relaxation Techniques for MINLPs

Sponsored: Optimization/Integer and Discrete Optimization

Sponsored Session

Chair: Taotao He, West Lafayette, IN, 47906, United States

1 - Optimization Problems Involving Matrix Multiplication with Applications

Burak Kocuk, Sabanci University, Istanbul, Turkey, burakkocuk@sabanciuniv.edu, Ali Rana Atilgan

We consider optimization problems which involve the multiplication of unknown matrices to be selected from a given finite family. Such nonlinear discrete optimization problems arise in applications from biology and material science among others, and are known to be NP-Hard even for a special case of interest. We propose compact-size mixed-integer programming formulations for these problems utilizing disjunctive arguments. Finally, we present the results of our computational experiments.

2 - Enhancing Relaxations for Nonconvex Mixed-integer Quadratically Constrained Quadratic Programs

Carlos Nohra, Carnegie Mellon University, Pittsburgh, PA, United States, cnohrakh@andrew.cmu.edu, Aida Khajavirad, Nick Sahinidis

This work addresses the global optimization of nonconvex mixed-integer quadratically constrained quadratic programs. We show how certain facets of the Boolean Quadric Polytope can be utilized in order to enhance factorable relaxations of MIQCQPs constructed by global optimization solvers. To illustrate the benefits of this approach, we propose an efficient implementation which integrates these facets as cutting planes into the branch-and-reduce global solver BARON. We demonstrate the impact of the proposed implementation by conducting an extensive computational study on a large collection of problems selected from publicly available test sets.

3 - Tight Piecewise Polyhedral Relaxations for MINLPs with Multilinear Intermediates

Harsha Nagarajan, Los Alamos National Laboratory, Los Alamos, NM, 87544, United States, harsha@lanl.gov

We present a MILP-based formulation of a piecewise, polyhedral relaxation of multilinear terms based on term-wise convex hull representations. We also present valid inequalities which tighten these relaxations for the summation of multilinear terms in a given constraint. Further, we present an adaptive discretization-based algorithm which efficiently solves MINLPs to global optimality. Finally, we present computational results showing the effectiveness of our formulation on various MINLPLib instances.

4 - Fractional 0-1 Programs: Links Between Mixed-integer Linear and Conic Quadratic Formulations

Andres Gomez, University of Pittsburgh, Pittsburgh, PA, 15217, United States, agomez@pitt.edu, Erfan Mehmanchi, Oleg A. Prokopyev

We focus on methods that improve the performance of solution approaches for multiple-ratio fractional 0-1 programs (FPs) in their general structure. In particular, we explore the links between equivalent mixed-integer linear programming and conic quadratic programming reformulations of FPs. Thereby, we show that integrating the ideas behind these two types of reformulations of FPs allows us to push further the limits of the current state-of-the-art results and tackle larger-size problems. We perform extensive computational experiments to compare the proposed approaches against the current reformulations from the literature.

Robust Optimization with Varying Uncertainty

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Kartikey Sharma, Northwestern University, Evanston, IL, 60208, United States

Chair: Omid Nohadani, Northwestern University, Northwestern University, Evanston, IL, 60208-3119, United States

1 - A Generalized Cutting Plane Algorithm for Robust Optimization with Decision-dependent Uncertainty Sets

Anirudh Subramanyam, Argonne National Laboratory, Lemont, IL, United States, Nikolaos Lappas, Chrysanthos Gounaris

There exist many optimization problems in which the decision-maker can affect the realization of the uncertain parameters (also known as endogenous uncertainty). Such settings can be addressed within the context of a robust optimization framework via the use of decision-dependent uncertainty sets. To that end, we propose a primal branch-and-bound algorithm that generalizes the well-known cutting plane method of Mutapcic and Boyd to the case of decision-dependent uncertainty sets. A comprehensive computational study showcases the advantages of the proposed algorithm over that of existing methods that rely on classical duality-based reformulations.

2 - Unit Commitment with Decision Dependent Uncertainty

Kartikey Sharma, Northwestern University, Evanston, IL, United States, kartikeysharma2014@u.northwestern.edu, Omid Nohadani

Unit commitment problems are an important category the area of Electricity production and distribution. When solving these problems we have to account for uncertainty in demand and generation. In this work we consider the UC problem under decision dependent uncertainty where the demand uncertainty can be affected by decisions for a price. We leverage an affine policy and provide a cut generation algorithm to solve this problem. We evaluate the performance of this model through numerical experiments.

3 - Optimization under Decision Dependent Uncertainty

Omid Nohadani, Northwestern University, Evanston, IL, 60208-3119, United States, nohadani@northwestern.edu, Kartikey Sharma

The efficacy of robust optimization spans a variety of settings with predetermined uncertainty sets. In many applications, uncertainties are affected by decisions and cannot be modeled with current frameworks. This talk takes a step towards generalizing robust optimization to problems with decision-dependent uncertainties, which we show are NP-complete. We introduce a class of uncertainty sets whose size depends on decisions, and proposed reformulations that improve upon alternative techniques. In addition, the proactive uncertainty control mitigates over conservatism of current approaches.

Recent Advances in Robust Optimization

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Guanglin Xu, University of North Carolina at Charlotte, University of North Carolina at Charlotte, Charlotte, NC, 28223, United States

1 - Semi-parametric Choice Model: Implications and Applications

Xiaobo Li, Assistant Professor, National University of Singapore, Singapore, Singapore, iselix@nus.edu.sg

In this talk, we present the modeling power of the semi-parametric model, a recently proposed choice model that is derived based on the distributionally robust bound on consumers' welfare. We reformulate some existing choice models and study their practical implications due to these reformulations. Applications in revenue management problems are also studied.

2 - Zeroth- and First-Order Stochastic Methods for Large-Scale Distributionally Robust Optimization

Guanglin Xu, University of North Carolina at Charlotte, 9201 University City Blvd., Cameron Hall - 204, Charlotte, NC, 28223, United States, guanglin.xu@uncc.edu

We introduce efficient first- and zeroth-order methods to solve large-scale distributionally robust optimization problems. We propose stochastic gradient-based and alternating direction method of multipliers-based algorithms in the case where gradient information is known, and propose zeroth-order methods in the case where the gradient information is not available. To enhance the convergence, we incorporate a stochastic variance reduction technique in our methods. Finally, we prove theoretical guarantee of our proposed algorithms and validate their effectiveness through various numerical experiments.

3 - Robust Optimization with Order Statistic Uncertainty Set

Pengfei Zhang, The University of Texas at Austin, Austin, TX, 78703, United States, Diwakar Gupta

We propose a new uncertainty set based on order statistics for robust optimization problems. We develop a tractable formulation of the robust optimization model with our new uncertainty set. We highlight the advantages of the new uncertainty set, and show that the interval uncertainty set, the budget uncertainty set and the demand uncertainty set can be obtained as special cases of the new uncertainty set. Finally, we report computational results on portfolio optimization problems with shortfall constraints, and show that the new uncertainty set has superior performance relative to common alternatives.

1 - Two Stages Stochastic Programming for Multi-echelon Multi-product Reverse Logistics Network Design with Lot Sizing

Vahid Azizi, Iowa State University, Ames, IA, United States, Guiping Hu

This study proposes an integrated model for a multi-period multi-product reverse logistics network design problem under uncertainty. The stochastic reverse logistics network is modeled as a two-stage stochastic program to make strategic and tactical decisions. The main uncertain parameters are the primary market return and secondary market demand. The model aims to determine the optimal number of sorting centers and warehouses, optimal lot sizes and optimal transportation plan that minimizes expected total system cost over the planning horizon. A case study has been conducted to validate the model. Numerical results are analyzed to illustrate the usefulness of the stochastic model.

2 - Modeling Lot-sizing and Cutting Stock Problem with Uncertain Material Batch Sizes

Hsueh-Chien Peng, National Chiao Tung University, Hsinchu, Taiwan, hcpeng.iem07g@nctu.edu.tw, Sheng-I Chen

This study considers the restrictions of equipment capacity and material availabilities for making production planning. Raw materials are received in batches, and each of them has uncertain quantity and can be used to fulfill orders with the same specifications. The decision is to satisfy demands with the objective to minimize the WIP levels, as well as excess supplies. To tackle the problem, we integrate capacitated lot-sizing and cutting-stock models with the development of stochastic mixed integer program to capture the uncertain batch size of materials. Sensitivity analysis is performed to assess the uncertain effect on productivity and loading for bottleneck stations.

3- Sample Efficient Q Learning for Generator Expansion Planning

Vijay Kumar, Pennsylvania State University, State College, PA, United States, vuk19@psu.edu, Mort Webster

The long-term Generator Expansion planning problem is a multi-stage decision to determine the optimal type, size, location and timing of new power plants to minimize the entire cost over the horizon. The conventional methodology of dynamic programming suffers from the curse of dimensionality and is computationally intractable. We propose a novel sampling algorithm, inspired from importance sampling for Multi-Stage Generator Expansion planning, under uncertainties in fuel and carbon prices.

4 - Stochastic Transmission Expansion Planning Using Randomization Policy

Minseok Ryu, University of Michigan, Ann Arbor, MI, United States, msryu@umich.edu, Ruiwei Jiang

We consider a stochastic transmission expansion planning (STEP) model that optimally expands a transmission grid to ensure reliable operations under uncertain input parameters. The STEP models are computationally challenging due to the binary recourse variables representing the number and location of the new circuits. In this talk, we propose a randomization policy to mitigate this challenge and provide an upper bound of the optimal value of STEP. We test the proposed solution approach in several numerical case studies.

Heuristic Programming and Traffic Management

Contributed Session

Chair: Yassine Ridouane, Georgia Institue of Technology, Atlanta, GA, 30318, United States

1 - Information Management under Strategic Inventory in Dual Channel Supply Chain

Jingjie Su, University of Texas at Arlington, Arlington, TX, United States, jingjie.su@mavs.uta.edu, Yan Lang, Kay-Yut Chen

We study the dual channel supply chain model with strategic inventory. The retailer gain advantage by using the strategic inventory. On the other hand, we also study if the asymmetric information will provide retailer with further advantage. We apply the game theory model and find the PBNE equilibrium of the model.

2 - A Substitution Based Model for Equipment Balancing Problem in Service Networks

Yassine Ridouane, Georgia Institute of Technology, Atlanta, GA, United States, yridouane@gatech.edu, Yu Yang, Natashia Boland, Alan Erera, Martin W. P. Savelsbergh

Logistics companies often operate a heterogeneous fleet of equipment to support their network operations. This poses a challenge as facilities need to be balanced with respect to total inbound and outbound equipment flows within a tactical planning horizon. We formulate an equipment balancing MIP model in which we seek to minimize the equipment imbalance by substituting the initial equipment assigned to a load with a compatible one. In a second phase, we seek to minimize the number of substitutions required. This problem can be proven to be NP-Hard. Computational experiments using realistic instances show that a significant reduction in the total equipment imbalance in the network can be obtained.

3 - Designing Locations and Capacities for Charging Stations to Support Intercity Travel of Electric Vehicles

wang chengzhang, Tsinghua university, Beijing, China, 875083229@qq.com

This study is devoted to designing locations and capacities of charging stations for supporting long-distance travel by electric vehicles. We first establish an expanded network structure to model the set of valid charging strategies for EV drivers, and then a variational inequality is formulated to capture the equilibrated route-choice and charging behaviors of EVs. Next, we formulate the problem of designing the locations and capacities of charging facilities under a fixed budget constraint and solve the optimization problem with a heuristic algorithm. Numerical examples with a toy network and a highway network are used to show the effectiveness of the proposed methodology.

Chair: Dimitri Papadimitriou, U Antwerpen, 24 rue du Charme, Brussels, 1190, Belgium

1 - Discrete Moment Problems with Log-concave and Log-convex Distributions

Talal Alharbi, PhD Student, Florida Institute of Technology, Melbourne, FL, United States, talharbi2015@my.fit.edu, Anh Tuan Ninh, Ersoy Subasi, Munevver Mine Subasi

We introduce new shape constraints (log-concavity and log-convexity) to discrete moment problems (DMP) for bounding the r-out-of-n type probabilities and expectations of discrete random variables with non-negative support. Numerical experiments show significant improvement in the tightness of the bounds. The proposed problem is expected to expand the scope of applications for both discrete moment problems and log-concavity and log-convexity.

2 - A Real-Time Optimization Scheme for Multi-Period AC Optimal Power Flow Problems

Youngdae Kim, Postdoctoral appointee, Argonne National Laboratory, Lemont, IL, United States, Mihai Anitescu

We present a real-time optimization strategy for a rolling horizon method applied to multi-period AC optimal power flow problems (MPACOPFs), where each of temporally interlinked MPACOPFs needs to be solved in every few minutes. An approximate tracking scheme combined with two warm-start methods will be described. Our method shows fast computation time while maintaining a good solution quality, which makes it best suitable to work under a real-time environment. Theoretical results bounding the tracking error to the second order of the parameter changes will be presented.

3 - A Direct Search Algorithm for Multi-objective Optimization in MATLAB

Adam Hug, The MathWorks, Natick, MA, United States

MATLAB's Global Optimization Toolbox now offers the paretosearch function: a direct search method that is designed to solve black box multi-objective problems. The algorithm uses an infinite barrier method and a direct search framework to obtain a set of Pareto optimal solutions. Coupled with this approach are several heuristics aimed at producing a wide sampling of the Pareto front. We will give an overview of the algorithm and discuss how it compares to metaheuristic approaches.

4 - Two Modified Trust Region Algorithms for Unconstrained Optimization

Mostafa Rezapour, PhD candidate, Washington State University, Pullman, WA, United States, mostafa.rezapour@wsu.edu, Thomas J. Asaki

We propose two modified trust-region algorithms for unconstrained optimization. These algorithms minimize a model of the objective function within the trust-region. Our modified algorithms are opportunistic in the sense that they explore outside of the trust-region if the boundary of the region prevents the algorithm to accept a more beneficial point. It occurs when there is very good agreement between the model and the objective function on the trust-region boundary, and we can find a step outside the trust-region with smaller value of the model objective while the agreement between the model and the objective function remains good.

Strategies in Supply Chain Network

Sponsored: Optimization/Network Optimization

Sponsored Session

Chair: Kedong Chen, University of Minnesota

1 - Identifying the Locus of Vulnerability to Supply Network Disruption

Hyunwoo Park, The Ohio State University, Columbus, OH, 43210, United States, park.2706@osu.edu, Yusoon Kim

We propose measures for node vulnerability in supply networks and compare their explanatory power in network-level disruptions using empirically observed supply networks. We also extend the notion of network-level disruptions incorporating multi-source multi-sink situations in supply networks. We discuss the implications of our study for managing managerial attention to monitor disruptions in supply networks.

2 - Distributionally Robust Inventory Network

Yun Zhang, Carnegie Mellon University, Pittsburgh, PA, 02139, United States, pyzhang@cmu.edu, Louis L. Chen

We consider a network version of newsvendor model. In period one, the network planner decides on the quantity of inventory to be placed at each node. In period two, demand materializes, the planner decides on allocation. Demand follows an adversarially chosen distribution from an ambiguity set, consisting of all joint demand distributions consistent with a set of marginal distributions. Via modern tools in discrete convex analysis, we precisely characterize the optimal inventory and allocation decisions. More interestingly, we are able to characterize the worst-case demand distributions. This allows us to provide managerial insights into the impact of network topology on inventory strategies.

3 - Supply Network Resilience Learning a Data-driven Exploratory Study

Yuhong Li, Old Dominion University, Norfolk, VA, 48084, United States, y9li@odu.edu, Kedong Chen, Kevin W. Linderman

When a disruption occurs, individual firms can learn from the disruption and reduce the risk of similar future disruptions, but what happens to the supply network? This study examines how the supply network learns from suppliers' disruptions to improve network resilience. It takes an agent-based perspective where suppliers act as agents within an ego network of a focal firm. Analytical analysis and data analytics are conducted to understand the condition under which supply network resilience learning improves more. Risk plays a contingent role in the cross-level learning effect. Data-driven propositions aim to make the most of limited resources and better facilitate supply network learning.

4 - Effect of Social Influencer on Crowdfunding Project Efficiency

Hung-Chung Su, University of Michigan-Dearborn, Dearborn, MI, 48126, United States, hcsu@umich.edu, Shih-Hui (Steven) Hsiao, Ta-Wei Kao, Chih-Hao Ku

Existing crowdfunding studies pay much attention to the influence of properties of the project (e.g., category and goal; the information content of the project) on crowdfunding success. In this project, we collect project creators' network data from Kickstarter and apply stochastic frontier analysis to understand how creators' network characteristics affect their project crowdfunding efficiency, the transformation of project inputs (properties) to output (the amount of funding). Our initial findings show that the backer's network centrality significantly influences crowdfunding efficiency.

Network Optimization for Resilience

Sponsored: Optimization/Network Optimization

Sponsored Session

Chair: Charles D. Nicholson, University of Oklahoma, Norman, OK, 73019, United States

1 - Community Resilience Analysis: Joplin, MO

Charles Nicholson, University of Oklahoma, Norman, OK, 73019, United States, cnicholson@ou.edu

Communities, such as cities and towns, are highly dependent on the built environment, including the building portfolio and the infrastructure networks (e.g., transportation, power, water), as well as existing social and economic networks and systems. This interdependent system of systems is, however, vulnerable to natural hazards. In May 2011, a catastrophic EF5 multiple-vortex tornado struck the community of Joplin, Missouri killing more than 150 people and causing billions of dollars in damage. In this presentation, we present a case study based on Joplin and the 2011 tornado to analyze issues, opportunities, and challenges for community resilience optimization.

2 - Facility Location and Restoration Games

Suzan Iloglu, Yale University, New Haven, CT, United States, Laura Albert, Carla Michini

We present a non-cooperative facility location and restoration game that considers infrastructure systems as a layered network with each system as a layer of the network. Players, infrastructure owners, locate facilities within their layer, and install edges within their own layer and between the layers to minimize the cost to satisfy their own demand. We prove the existence of Nash equilibria. We propose a mechanism using inverse optimization and an approximation primal-dual algorithm to decide fees that players should pay when sharing facilities to obtain the social optimal solution.

3 - An Approximate Dynamic Programming Approach for the Stochastic Two-level Integrated Inventory Problem: Applications in Battery Swap Stations

Amin Asadi, University of Arkansas, Fayetteville, AR, United States, asadi@email.uark.edu, Sarah Nurre

We present the class of stochastic two-level integrated inventory problems (TOLIPs) which we use to determine policies for the management of inventory at EV and drone battery swap stations. In a stochastic TOLIP, the use and replenishment of first-level battery charge is the direct cause of degradation in second-level battery capacity. Thus, when faced with uncertain demand for battery swaps, we determine policies for charging and discharging battery charge inventory and replacing battery capacity inventory over time. We model the stochastic TOLIP as a Markov Decision Process. Using approximate dynamic programming, we determine policies and deduce insights for the swap station application.

4 - Approximating Optimal Recovery of Infrastructure Networks via Distributed Percolation Processes

Bowen Fu, PhD Candidate, Rice University, Houston, TX, United States, Leonardo Duenas-Osorio

Optimization methods guarantee the optimality of network resilience under practical resource constraints, but become computationally intractable for realistic systems. In this talk, we propose a scalable method based on percolation theory that exploits the modularity of networks and embeds field-informed restoration processes, to approximate optimal repair sequences for resilience. Our approximations ensure low computational cost and acceptable accuracy as ongoing theoretical developments suggest. We show the merits of our proposed strategy to support community resilience by comparing against guaranteed-optimality recovery sequences for realistic utility networks.

5 - Interdependent Integrated Network Design and Scheduling Problems with Machine Movement: Application Post Disaster Infrastructure Restoration

Aniela Garay-Sianca, University of Arkansas, Fayetteville, AR, United States, Sarah G. Nurre Pinkley

Recent disasters have motivated many researchers to focus on post disasters infrastructure restoration models. Many of these models fail to account for infrastructure interdependency on the availability of the transportation network. We propose a new mixed integer optimization model that considers restoration interdependency among infrastructures, network optimization, and scheduling. We include the selection of damaged components, the assignment of these components to work crews, the sequence of the restoration, and the movement of work crews on the transportation network. We provide significant results and comparison with a current integrated network design and scheduling model.

Joint Session MCDM/ICS: New Research Directions in Multi-objective Integer Programming: Machine Learning and Multiplicative Programming

Sponsored: Computing

Sponsored Session

Chair: Hadi Charkhgard, University of South Florida, Tampa, FL, 33620-5350, United States

1 - A Criterion Space Search Algorithm for Mixed Integer Linear Maximum Multiplicative Programs: A Multi-objective Optimization Approach

Hadi Charkhgard, University of South Florida, Tampa, FL, 33620-5350, United States, Payman Ghasemi Saghand

We study a class of mixed integer optimization problems with linear constraints and a multi-linear objective function, the so-called mixed integer linear maximum multiplicative programs (MIL-MMPs). MIL-MMPs can also be viewed as special cases of the problem of optimization over the set of efficient solutions in multi-objective optimization. By using this observation, we develop a criterion space search algorithm for solving any MIL-MMP. An extensive computational study on around 2000 instances illustrates that the proposed algorithm significantly outperforms existing methods/solvers.

2 - Generalized Mixed Integer Linear Maximum Multiplicative Programs: Multi-objective Optimization Approaches

Payman Ghasemi Saghand, University of South Florida, Tampa, FL, 33559, United States, payman@mail.usf.edu, Hadi Charkhgard

We study Integer Linear Generalized Maximum Multiplicative Programs (IL-GMMP). An IL-GMMP can be reformulated as a mixed integer Second-Order Cone Program and can be solved by commercial solvers such as IBM ILOG CPLEX, Gurorbi, and FICO Xpress. By showing that IL-GMMPs are special cases of optimization over the efficient set problems, we develop three exact solution approaches which only solve a number of single-objective integer linear programs to compute the optimal solution. We also draw an extensive comparison using the three commercial solvers. The results show that, by the right choice of the commercial solver, our proposed algorithms are significantly faster than other approaches.

3 - A Branch-and-Bound Algorithm for a Class of Mixed Integer Linear Minimum Multiplicative Programs: A Bi-Objective Optimization Approach

Vahid Mahmoodian, University of South Florida, Tampa, FL, 33620-5350, United States, Hadi Charkhgard, Yu Zhang

The branch-and-bound algorithm has been used to solve different types of mixed integer linear and even non-linear programming problems for decades. In this research, a new algorithm is introduced to solve the minimum bi-linear multiplicative programs as well as two branch-and-bound algorithms to solve mixed-integer minimum multiplicative programs. Moreover, an extensive computational study is done to show the effect of several proposed enhancements and capability of algorithms which shows that both algorithms perform well but one of them significantly outperforms SCIP so that it is up to 50.34 times faster only on the instances which are solved by both to optimality.

4 - Learning to Project in Multi-Objective Binary Linear Programming

Sierra Altamiranda Alvaro, University of South Florida, Tampa, FL, 33620-5350, United States, amsierra@mail.usf.edu, Hadi Charkhgard, Iman Dayarian, Ali Eshragh, Sorna Javadi

We study the possibility of improving the performance of multi-objective optimization algorithms using machine learning (ML). We focus on binary linear programs and employ the so-called KSA, a criterion space search algorithm. KSA computes all nondominated points of a problem by searching on a projected space. We present a ML approach to identify on which space the KSA should be projected. We also present a biobjective optimization based heuristic for selecting the best subset of features to avoid overfitting. Through an extensive computational study, we show performance improvement achieved by our ML method compared to a random selection of the projected space over several instances.

1 - Exact and Heuristic Methods for Solving the Bi Objective Maximal Covering Minimal Tour Problem

Sanaz Goldani, Analytics Software Tester, SAS/IDeaS, Cary, NC, 27606-5803, United States, sgoldan@ncsu.edu
Sanaz Goldani, Analytics Software Tester, North Carolina State University, Raleigh, NC, United States, sgoldan@ncsu.edu, Yahya Fathi

The Bi-objective maximal-Covering minimal-Tour Problem is a variation of the Covering Tour Problem in which our aim is to simultaneously minimize the travel distance and maximize the total demand covered. We tackle this problem using a branch-and-cut algorithm and a heuristic procedure in the context of the - constraint method. We present the results of our computational study on benchmark instances adapted from the literature.

2 - Matroid Based Decomposition Algorithms to Estimate the Reliability of Large Scale Structured Linear Sensor Networks

Vishnu Vijayaraghavan, Texas A&M University, College Station, TX, United States, vishnunitr@tamu.edu, Kiavash Kianfar, Yu Ding, Hamid R. Parsaei

Determining the reliability of a linear sensor system is a crucial problem in data analytics which directly impacts the design and operation of such systems. The runtime and the accuracy of Recursive Variance Reduction (RVR) methods to estimate reliability depend on the approach by which the minimal cut sets are obtained. We propose two matroid decomposition based RVR algorithms in which we utilize the structural properties inherent in clustered linear sensor systems to propose decomposition theorems based on matroid theory allowing for the disintegration of the problem into smaller subproblems over which the computations are performed.

3 - Optimum Search Schemes for Approximate String Matching Using Bidirectional FM-Index

Bahman Torkamandi, Texas A&M University, College Station, TX, United States, Kiavash Kianfar, Haochen Luo, Knut Reinert, Christoper Pockrandt

Approximate search in a text is a key problem in bioinformatics. Bidirectional indices and search schemes have opened possibilities to speed up the search by starting within the pattern and extending in both directions. However, finding optimal search schemes is a difficult combinatorial optimization problem. For the first time, we propose a mixed integer programming to find the exact optimal solution to this problem for the Hamming distance. Our experiments show that approximate matching of 101-bp DNA reads (with two errors) becomes 35 times faster than standard backtracking and the running time of in-index search using our optimal schemes is comparable to the state-of-the-art aligners.

4 - The Bi-criteria Set Covering Problem with Conflict Constraints

Saeed Saffari, Grubhub Holdings Inc., New York City, NY, 27695, United States, ssaffar@ncsu.edu, Yahya Fathi

We consider the well-known set covering problem with additional constraints that represent incompatibilities between certain pairs of columns (variables). We introduce this problem in a bi-criteria context in which we simultaneously maximize the number of covered rows (elements) and minimize the number of selected columns (nodes). We propose several classes of valid inequalities for the corresponding IP model, and demonstrate their effectiveness in the context of a branch and cut algorithm.

1 - Implicit Regularization and Solution Uniqueness in Over-parameterized Matrix Sensing

Anastasios Kyrillidis, Assistant Professor, Rice University, 3119 Duncan Hall, 6100 Main Street, Houston, TX, 77005, United States, anastasios@rice.edu

We consider whether algorithmic choices in over-parameterized linear matrix factorization introduce implicit regularization. The algorithm we study is factored gradient descent, where we model the low-rankness and PSD constraints through matrix factorization. Surprisingly, recent work argues that the level of rankness is not pivotal: even setting the factors as full square matrices is sufficient to find the low-rank solution, which suggests that operating over the factors leads to an implicit regularization. We show that under certain conditions, the PSD constraint by itself is sufficient to lead to a unique low-rank matrix recovery, without implicit or explicit low-rank regularization.

2 - Green Simulation Optimization Using Likelihood Ratio Estimators

Ben Feng, University of Waterloo, Waterloo, ON, N2J 4Y3, Canada, ben.feng@uwaterloo.ca, David J. Eckman

Green simulation reuses past simulation outputs to enhance the efficiency of current and future simulation experiments. One application of green simulation is in simulation optimization, wherein outputs from past iterations can be reused in subsequent iterations. We draw attention to challenges that arise when green simulation likelihood ratio estimators are naively employed in simulation optimization. In particular, we show that for searches that identify new designs based on past outputs, outputs in different iterations are conditionally dependent. We demonstrate how this conditional dependence and bias can adversely affect the behavior of gradient-based optimization algorithms.

3 - Derivative Approximation of Some Model-based Derivative Free Methods

Liyuan Cao, Doctoral Student, Lehigh University, Bethlehem, PA, 18015, United States, lic314@lehigh.edu, Albert Solomon Berahas, Katya Scheinberg

To optimize a black-box function, gradient-based methods can be used in conjunction with finite difference methods. Alternatively, optimization can be done with polynomial interpolation models that approximate the black-box function. A class of random gradient-free algorithms based on Gaussian smoothing of the objective function was analyzed by Yurii Nesterov in 2011. Similar random algorithms were implemented and discussed in the machine learning community in more recent years. We compare these methods on their accuracy of gradient approximation and the overall performance.

4 - Reduced-space Methods for LP Regularized Problems

Hao Wang, Shanghai Tech University, Shanghai, China

We propose a general algorithmic framework for solving the unconstrained lp regularized problems and estimate the lower bounds of the nonzero components. We show that the proposed algorithm detects the zero components during iteration using these lower bound estimation, so that fast local convergence can be achieved. Global and local convergence are analyzed. Numerical experiments demonstrates the efficiency of the proposed method.

Novel Traffic Signal Control Approaches

Sponsored: Transportation Science & Logistics/Intelligent Transportation Systems (ITS)

Sponsored Session

Chair: Ali Hajbabaie, Washington State University, Pullman, WA, 99164-2910, United States

1 - Time-Dependent Area Traffic Signal Control against Uncertainty

Suh-Wen Chiou, Professor, National Dong Hwa University, Hualien, Taiwan, chiou@mail.ndhu.edu.tw

A time-dependent traffic signal control model is presented for dynamic traffic assignment with users route choice. In the presence of uncertain travel demands, a time-dependent stochastic mathematical program with equilibrium constraints (SMPEC) is proposed. A bundle-like data-driven approach is proposed to effectively solve the SMPEC. Numerical experiments are conducted and comparison are empirically made with existing methods. It indicates that proposed model can achieve reliably better system performance in reducing traffic congestion over periods as compared to those did recent alternatives.

2 - Deep Learning Methods for Real Time Traffic Volume Prediction for Signalized Intersections

Xuegang Ban, Associate Professor, University of Washington, Seattle, WI, United States, banx@uw.edu, Wan Li

We propose a deep learning based method to predict real time short-term traffic volumes for signalized intersections. The predicted volumes can be used for optimizing real time traffic signal timing optimization

3 - Stochastic Gradient-based Optimal Signal Control with Energy Consumption Bounds

S.M. A. Bin Al Islam, North Carolina State University, Raleigh, NC, 37830, United States, H.M. Abdul Aziz, Ali Hajbabaie

This study develops a stochastic approximation-based traffic signal timing optimization model with bounds on network-level energy consumption. Due to the non-convex and non-linear structure of the energy consumption function, we utilize a stochastic approximation algorithm. We incorporate a simultaneous perturbation gradient estimation for solving the optimization problem. Our proposed gradient approximation technique guides the search directly towards the optimal solution. Empirical results show that it is possible to achieve optimized signal settings at a desired energy consumption bound for a network without compromising mobility performance.

4 - A Scaleable and Real-time Approach for Optimal Signal Control in a Multi-modal Semi-connected Vehicle Environment

S.M. A. Bin Al Islam, North Carolina State University, Raleigh, NC, 37830, United States, sislam5@ncsu.edu, Ali Hajbabaie

This research develops a multi-modal cell transmission model and integrates it into a mixed-integer linear program (MILP) to optimize the timing of signalized intersections. The proposed formulation explicitly accommodates multiple transportation modes and different connected vehicle market penetration rates. The proposed model formulation can correctly estimate traffic flow dynamics of transit vehicles. We have incorporated the proposed formulation in a distributed optimization algorithm. The results indicate significant improvement in network performance under various CV penetrations rates compared to existing transit signal priority approaches in a simulated environment.

Vehicle Routing III

Contributed Session

Chair: Yajing Chen, Shanghai Jiao Tong University, Xuhui District, Shanghai, 200030, China

1 - Statistical Models in Vehicle Routing

Debdatta Sinha Roy, Robert H. Smith School of Business, University of Maryland, College Park, MD, United States, debsroy@rhsmith.umd.edu, Bruce L. Golden, Edward Andrew Wasil, Xingyin Wang, Adriano Masone

Delivery and service companies send out vehicles to deliver customer products and provide services. For the capacitated vehicle routing problem, we show that reducing route variability while generating the routes is an important consideration to minimize the total operating and delivery costs for a company when met with random traffic. Routing companies participating in competitive bidding might need to respond to a large number of requests regarding route costs in a very short amount of time. For the close enough traveling salesman problem with customer locations distributed randomly and all customers having the same radius, we estimate the route length using information about the instances.

2 - An Exact Algorithm for Electricity AGV Routing with Pickup and Delivery Time Windows

Wei Zhang, National University of Singapore, Singapore, Singapore, Chenhao Zhou

In the operations of modern ports, the electricity AGVs are broadly used for container transferring, as it can work more efficiently and save manpower. Besides the common constraints in the traditional vehicle routing problems, there is an additional limit for the electricity AGV on its travel distance before recharging. To reduce the charging time, the battery swap scheme is becoming a more attractive solution. Bearing this in mind, along with the pickup and delivery time windows, it is even more complicated than the general vehicle routing problem. To solve this problem, we utilize the Lagrangian relaxation method and a dynamic programming.

3 - Vehicle and Pedestrian Routing Problem with Parking Space in the Last Mile Logistics

Gitae Kim, Hanbat National University, Daejeon, Korea, Republic of, gitaekimemail@gmail.com

The difficulty of the problem is compounded when we think of it in an urban area. Over the years, the importance of the final leg of delivery to customers has increased through the realization that Vehicle Routing Problem constitutes a large part of logistics operations in terms of cost, time, and service level. Due to the complicated buildings and limitation of parking space, it is hard to estimate the travel time with only road network. Thus, this paper combines VRP with pedestrian routing problem in the last mile delivery. We consider the parking space when the vehicle arrives at each customer site. We propose a multi objective model for the problem and provide the numerical results to present the models.

4 - Data-driven VRP with Time Dependent Cost Function

Sami S. Ozarik, Eindhoven University of Technology, Eindhoven, Netherlands, s.s.ozarik@tue.nl, Lucas Petrus Veelenturf, Tom Van Woensel, Gilbert Laporte

The recent increase in online orders leads to logistical challenges such as low hit rates (number of successful deliveries) and unattended deliveries. In this paper, we consider exact and heuristic approaches in order to solve last mile delivery problems in which customers' attendance probability data is considered for each of the time buckets in the planning horizon. We aim to improve the hit rate by considering routing and scheduling decisions. We develop an efficient heuristic approach by iteratively solving routing and scheduling problems. Numerical results will be presented.

5 - Minmax Vehicle Routing Problem in a Megacity – Comparison Two Heuristics

Jihyun Jo, Pennsylvania State University, University Park, PA, United States, JZJ5077@psu.edu, Soundar Kumara

We consider the min-max vehicle routing problem for a large franchise system in a megacity. There are several characteristics of a megacity delivery network such as high node density, huge gaps between delivery locations and distribution centers and etc. To solve this routing problem, we proposed the "Route first - Partition second" method with genetic algorithm in the earlier study. In this study, we compare this method and another method which is a reverse way (Partition first - Route second). Due to the distinctive features of the megacity delivery network, we find out that our earlier method is better than the second method in both solution wise and CPU time wise.

6 - Two-sided Matching Model Between Surgeons and Patients in Elective Surgery Considering No Show and New Patient Arrival

Yajing Chen, Shanghai Jiao Tong University, Shanghai, China

With the reform of the medical system, people are getting more and more demanding on the quality of medical services. How to ensure that patients receive satisfactory service is a problem of great concern to hospitals.In real life, there is a situation of patients' no show which will lead to a waste of medical resources.How to improve the utilization rate of resources is also a matter of great concern to hospitals.In this paper, we give a two-sided matching model for surgeons and patients in elective surgery considering patients' no show and new patients' arrival.

Joint session TSL/OPT.under Uncertainty: ADP/Reinforcement Learning in Vehicle Routing II

Sponsored: Transportation Science & Logistics/Freight Transportation & Logistics

Sponsored Session

Chair: Jorge Mendoza

1 - A Dynamic Pickup and Delivery Problem with Transfers

Albert H. Schrotenboer, University of Groningen, Vlasstraat 19, Groningen, 7912KS, Netherlands, a.h.schrotenboer@rug.nl, Paul Buijs, Onur A. Kilic, Marlin Wolf Ulmer, Michiel uit het Broek

We study a dynamic pickup and delivery problem with transfers inspired on the daily operations of a bike courier company in Groningen, The Netherlands. Multiple couriers are managed dynamically to satisfy pickup and delivery requests. In addition, small city distribution centers are utilized to allow for the transfer of parcels between couriers. We present and compare different Approximate Dynamic Programming (ADP) approaches for modeling and solving the problem of managing this fleet of couriers most efficiently. In the context of ADP, we present different approaches for assigning requests to bike couriers and study how to ensure that parcels are transferred between couriers efficiently.

2 - Dynamic Repositioning in Free-floating Bike Sharing Systems Using Approximate Dynamic Programming

Xue Luo, Tsinghua University, Beijing, China, luoxue16@mails.tsinghua.edu.cn, Li Li, Lei Zhao

In bike sharing systems, bike flows are dictated by customers' travel patterns. As a result, the imbalance of customer flows leads to the shortage of bike supplies in some area and overage in some others. Repositioning must be performed to restore balance to the system, dynamically or statically. We present a stochastic dynamic program for dynamic repositioning, with explicit consideration of the characteristics of free-floating systems. We examine the effectiveness and efficiency of several approximate dynamic programming (ADP) algorithms. Highlighting the time-variance of stochastic demand and supply, we conduct extensive numerical experiments and gain useful managerial insights.

3 - Deep Q-learning for Same-day Delivery with a Heterogeneous Fleet of Vehicles and Drones

Xinwei Chen, University of Iowa, Iowa City, IA, 52242, United States, Marlin Wolf Ulmer, Barrett Thomas

As e-commerce continues to expand, retailers offer faster deliveries to stay competitive. Same-day and instant delivery are expected to reach a combined share of 15% of the market by 2020. To overcome the cost challenges in same-day delivery, companies have begun to use drones. We introduce a deep Q-learning (DQL) approach to study same-day delivery with a heterogeneous fleet of vehicles and drones. The DQL policy significantly outperforms benchmark policies. We will explore how feature selection impacts the learning, discuss the value of rejecting feasible requests, and illustrate the DQL policy with visualizations.

4 - Solving the Stochastic Vehicle Routing Problem with Reinforcement Learning

Tao Li, Lehigh University, Bethlehem, PA, United States, tal214@lehigh.edu, Larry Snyder, Martin Takac

We propose a reinforcement learning (RL) algorithm to solve the stochastic vehicle routing problem (SVRP), in which the demands and distances are related to features such as temperature and humidity. We compare the results with approximate and exact solutions coming from stochastic programming approaches. In SVRP, the optimal solution is highly dependent on the problem instance. Therefore, instead of predicting the demands and distances based on the features for each instance, we propose a structure to learn the input information, and the relationship between the inputs and the features. Then we use a pointer network, trained with an actor-critic algorithm, to make decisions in the RL framework.

5 - Atari-ing the Vehicle Routing Problem with Stochastic Requests

Jorge E. Mendoza, Visiting Professor, HEC Montréal, Montreal, QC, Canada, jorge.mendoza@hec.ca, Clément Grodecoeur, Nicholas D. Kullman, Martin Cousineau, Justin Goodson

Deep reinforcement learning (RL) has seen much recent success in solving tasks that involve sequential decision making under uncertainty. One of the most celebrated applications is gaming. Deep RL has been used to develop a single agent capable of outperforming humans on a majority of classic Atari 2600 games — considered a milestone in the progression towards more general artificial intelligence. In this work, we attempt to represent a classical logistics problem, namely the Vehicle Routing Problem with Stochastic Requests, as such a video game and employ deep RL tactics to solve it. We compare this approach to classical solution methods from approximate dynamic programming.

Inventory Management I

Contributed Session

Chair: Sangjo Kim, Shanghai University of Finance and Economics

1 - An Efficient Decomposition Method for the General-product Structure Assemble-to-order System

Mohsen Elhafsi, University of California-Riverside, Riverside, CA, United States, melhafsi@ucr.edu, Jinaxin Fang, Essia Hamouda

We consider a general-product structure ATO problem which we model as an infinite horizon discounted MDP. Obtaining the optimal control policy of such a system is computationally intractable. As such, we develop a heuristic policy (DHP) based on a decomposition of the ATO system into a series of two-component, multi-demand-class M-product structure ATO subsystems. Exploiting the structure of the optimal policy of such subsystems, we show that the DHP possesses many properties similar to those encountered in special-product structure ATO systems. Extensive numerical experiments show that the DHP is very efficient and compares favorably to other proposed heuristics in the literature.

2 - Risk Averse Inventory Management under Autocorrelated Log-log Demand Series

Ting Wang, University of Science and Technology of China, Hefei, China, sa172040@mail.ustc.edu.cn, Yugang Yu, Ye Shi

Motivated by the practice of a food manufacturer, we conduct predictive analysis on its data and find that the demand process of FMCG (Fast Moving Consumer Goods) can be well characterized by an autocorrelated log-log demand series. Under the new demand structure, we study a risk averse inventory management problem and examine the properties of the optimal order policy with respect to the degree of risk aversion, where the optimal order quantity does not necessarily increases as the degree of risk aversion increases. In addition, we also investigate the bullwhip effect under the autocorrelated log-log demand series and find that the risk aversion behavior may affect bullwhip effect.

3 - Clustering Retail Stores for Inventory Transshipment

Emily Barbee, University of Alabama, Tuscaloosa, AL, United States, ecbarbee@crimson.ua.edu, Burcu B. Keskin

We investigate a transshipment problem with a large network of retail stores. Specifically, we design clustering approaches for the efficient and effective transshipment of goods inside large networks. Using a large grocery retailing data set with multiple products across two large and closely located metropolitan areas, we derive product level and retailer level insights and investigate the validity of several common assumptions present in the literature.

4 - Optimal Consignment Stocking Policy under Uncertainty

Md Shahriar J. Hossain, Northwestern State University, Natchitoches, LA, 71457-5947, United States, msjhossain1@gmail.com, Bhaba R. Sarker

Consignment stocking is an effective approach to bring a product next to the door of a consumer. This supply chain system often encounters both demand and lead-time uncertainty, as well as space and shelf life constraints. In this paper, a joint total cost model is developed and solved to determine the optimum order quantity and reorder point for a single-vendor, single-retailer consignment stocking system. The solution procedure varies depending on the distribution of demand and lead time. For uniformly distributed demand and lead time a gradient method is applied with an iterative search procedure. In case of normal distribution, an exhaustive search procedure is followed within certain domains.

5 - The Optimal Policy for Periodic Stocking and Bundling

Sangjo Kim, Shanghai University of Finance and Economics, Shanghai, China, sangjo@sufe.edu.cn, Youyi Feng, Jianjun Xu

We investigate the optimal policy for joint inventory replenishment and bundling decisions, where a seller periodically replenishes individual products as well as bundles them to another selling item. The seller backlogs unmet demands and carries over unsold items aiming to minimize the total discounted cost over a finite horizon. We reveal that there exists an economic relationship such that each pair of the bundle and an individual product should be regarded as substitutes while each couple of individual ones as complements. We characterize the optimal policy and propose efficient algorithms to compute the policy as well as provide a myopic policy that may be optimal under certain regularities.

1 - Yard Crane Scheduling in a New Automated Container Terminal Design

Xin Jia Jiang, Nanjing University of Aeronautics and Astronautics (NUAA), Nanjing, China

To reduce the time wasted in the yard crane (YC) gantry moves, a new design has been proposed to install a rail-mounted ground trolley (GT) along each block for container delivery. The GT based Automated Container Terminal (GT-ACT) is proven to be very effective in operation, but the interaction between YC and GT increases the planning difficulty of container handling. At the operational level, the container handling efficiency highly depends on the YC scheduling decisions. An interesting YC scheduling problem with GT collaboration is formally discussed in this study. The VRP related modeling and solution approaches will be shared.

2 - Container Handling and Layout Optimization in Empty Container Depots

Erhan Karakaya, PhD Student, Auburn University, Auburn, AL, United States, erhan@auburn.edu, Julio Jiménez, Jimena Pascual, Alice E. Smith

We propose an analytical method and develop a simulation model to improve handling operations for empty container depots. We consider the design of the block layout of the depot to minimize the expected handling of containers due to retrievals and arrivals. Alternative policies regarding retrieval are assessed. Empty container depots are ubiquitous in the global supply chain but differ in significant ways from the more often studied maritime ports. This is one of the very few studies to specifically address empty container depots.

3 - Simulation Optimization Iteration Approach on Traffic Integrated Yard Allocation Problem in Transshipment Terminals

Qitong Zhao, National University of Singapore, Singapore,zhaoqitong@u.nus.edu, Loo Hay Lee, Ek Peng Chew

To improve the efficiency of the container terminals, we propose a simulation optimization iteration approach to integrate the yard allocation problem (YAP) with traffic system. YAP is formulated as a mixed integer programming model with the objective to reduce the total job travel time. A discrete event simulation model is developed to simulate traffic and the terminal operation. The approach solves two models iteratively to improve the allocation decisions. Experiment results show that this approach can generate yard allocation decisions to reduce the overall traffic time comparing with traditional intuitive rules.

4 - A Distributionally Robust Optimization Approach for Marine Search and Rescue Operations

Hassan Sarhadi, Assistant Professor, F.C. Manning School of Business, Acadia University, Wolfville, NS, Canada, hassan.sarhadi@acadiau.ca

Search and Rescue (SAR) operation is a critical component of marine activities as it reduces the loss of life, injury, and property damage following marine incidents, thereby mitigating the risks involved with marine activities. This research intends to formulate the problem of allocating SAR vessels to response stations by taking into account the uncertain nature of incidents. To this end, a distributionally robust optimization approach is proposed to model the underlying uncertainty of this problem.

Joint Session AAS/TSL Air: Deep Learning Technologies in ATM/UTM

Sponsored: Aviation Applications

Sponsored Session

Chair: Yulin Liu, University of California-Berkeley, University of California-Berkeley, Berkeley, CA, 94709, United States

1 - Autonomous Air Traffic Controller: A Deep Multi-Agent Reinforcement Learning Approach

Marc Brittain, Iowa State University, Ankeny, IA, 50021, United States, mwb@iastate.edu, Peng Wei

Ensuring high-density air transportation systems of the future are both safe and efficient is a top priority. With the growing air traffic complexity in traditional and low altitude airspace, an autonomous air traffic control system is needed to ensure safe-separation requirements. We propose a deep multi-agent reinforcement learning framework that is able to identify and resolve conflicts between aircraft in a high-density, stochastic, and dynamic en-route sector with multiple intersections. We show that our framework is both scalable and efficient for large number of incoming aircraft to achieve extremely high traffic throughput.

2 - Generative Adversarial Networks for Synthetic Generation of Tactical Reroutes

James Calvin Jones, MIT Lincoln Laboratory, Lexington, MA, 02140, United States, Changming Xu, Yan Glina

We propose the use of Generative Adversarial Networks (GANs) in the Air Traffic Management context for the generation of synthetic reroutes around convective weather areas. This talk explores the characteristics of tactical reroutes generated by the GAN framework for trajectories in the Northeast United States.

3 - Towards the Next Generation Airline Revenue Management: A Deep Reinforcement Learning Approach to Seat Inventory Control and Overbooking

Syed A.M. Shihab, Iowa State University, Ames, IA, United States, shihab@iastate.edu, Caleb Logemann, Deepak-George Thomas, Peng Wei

In this paper, the seat inventory control and overbooking problem of airline revenue management has been tackled by first casting it as a Markov Decision Process and then using Deep Reinforcement Learning with the goal of maximizing the revenue for each flight departure to find the optimal policy. To generate data and train the agent, a basic air-travel market simulator was developed. The performance of the agent in different simulated market scenarios was compared against theoretically optimal solutions and was found to be nearly close to the expected optimal revenue.

4 - Autonomous UAS Traffic Management System for Multi-aircraft Coordination

Xuxi Yang, Iowa State University, Iowa State University, Ames, IA, 50011, United States, xuxiyang@iastate.edu, Yulin Liu, Peng Wei

Flying with electrical vertical takeoff and landing (eVTOL) aircraft will bring fundamental changes to city infrastructures and daily commutes. To enable safe and efficient autonomous on-demand free flight operations for the eVTOL aircraft, a centralized computational guidance algorithm is proposed and analyzed for multi cooperative aircraft. By generating real-time actions for all the aircraft to follow, the algorithm can guide all the aircraft to their respective destinations while avoiding conflicts between them. For illustration, a free flight airspace simulator is created to test the performance of this algorithm.

Dynamic Pricing in Network Settings

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Yash Kanoria, Columbia Business School, New York, NY, 10027, United States

Chair: Pengyu Qian, Columbia University-Graduate School of Business, Columbia University-Graduate School of Business, New York, NY, 10027, United States

1 - Near Optimal Control of a Ride-hailing Platform via Mirror Backpressure

Pengyu Qian, Columbia University-Graduate School of Business, Columbia Business School, c/o PhD Office, New York, NY, 10027, United States, PQian20@gsb.columbia.edu, Yash Kanoria

Ride-hailing platforms need to match supply and demand so as to maximize payoff under the geographical flow constraints. We consider two platform control settings: joint entry-assignment (JEA) and joint pricing-assignment (JPA). We introduce a novel family of Mirror Backpressure (MBP) policies which are simple, practical, and do not require knowledge of the demand arrival rates. MBP generalizes Backpressure policy such that it executes mirror descent. MBP loses at most $O(K/T + 1/K)$ fraction of the achievable payoff in JEA and $O(\sqrt{(K/T + 1/K)})$ fraction in JPA, where K is the number of vehicles and T is the horizon. Simulation results in a realistic environment support our theoretical findings.

2 - Network Revenue Management with Online Inverse Batch Gradient Descent Method

Cong Shi, University of Michigan, 2257 Woodhaven Ct, Ann Arbor, MI, 48105, United States, Yiwei Chen

We consider a general class of price-based network revenue management problems that a firm aims to maximize revenue from multiple products produced with multiple types of resources endowed with limited inventory over a finite selling season. A salient feature of our problem is that the firm does not know the underlying demand function that maps prices to demand rate, which must be learned from sales data. We propose a novel nonparametric learning algorithm termed online inverse batch gradient descent (IGD) algorithm. For large scale systems, we establish a dimension-independent regret bound. This result is independent of the number of products and resources and works well for a continuum price set.

3 - Finite-time Analysis of Distributed TD(0) with Linear Function Approximation

Thinh Doan, Georgia Institute of Technology, Atlanta, GA, United States, thinhdoan@gatech.edu

We study the policy evaluation problem in multi-agent reinforcement learning, where a group of agents works cooperatively to evaluate the value function for the global discounted accumulative reward. For solving this problem, we consider a distributed variant of the popular TD methods. Our main contribution is providing a finite-time analysis for the convergence of this method. Our results mirror what we would expect from using distributed stochastic gradient descent for solving convex optimization problems.

4 - Menu Design of a Bipartite Matching Queueing System with Strategic Users

Lisa Hillas, University of Chicago, Chicago, IL, United States, Rene A. Caldentey, Varun Gupta, Christopher Ryan

In this talk, we explore the optimal design of matching topologies for a multi-class multi-server queueing system under a FCFS-ALIS service discipline. We investigate the performance of the system from the perspective of a central planner who must design a menu of service classes, which are defined by the subset of servers that can serve each class. Customers are heterogeneous on their preferences over servers and self-select the service class to join.

Managing On-demand Platforms

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Murray Lei

1 - Dynamic Pricing and Matching in Ride-hailing Platforms

Chiwei Yan, Uber Technologies, San Francisco, CA, United States, Nikita Korolko, Dawn Woodard, Helin Zhu

Advanced matching and dynamic pricing algorithms are the two key levers in ride-hailing platforms. We give a brief overview of state-of-the-art matching and pricing algorithms run by these platforms. We then demonstrate via a stylized model, calibrated with Uber data, that the synergy of these two levers can bring significantly more benefits. To be specific, we study a novel matching mechanism called dynamic waiting. We show that pricing and waiting could be jointly optimized in reducing rider and driving waiting times, lowering price volatility, and increasing trip volume and welfare.

2 - Charging Electric Vehicle Sharing Fleet

Long He, National University of Singapore, Singapore, Singapore, longhe@nus.edu.sg, Guangrui Ma, Wei Qi, Xin Wang

We develop models to jointly optimize the sites and sizes of charging stations, along with the coupled fleet charging and repositioning operations. Our nonlinear optimization model closely tracks EV energy levels and explicitly depicts stochastic charging operations. We conduct a case study with data sets of Car2Go's operations.

3 - Dynamic Labor Rebalancing for a On-demand Delivery Model

Murray Lei, Queen's University, 465 Goodes Hall, 143 Union Street W, Kingston, ON, K7L 3N6, Canada, yl64@queensu.ca, Stefanus Jasin, Jingyi Wang

We study a problem of incentivizing a proper number of workers to match with demand in the context of on-demand delivery. Demand for delivery during a specific time slot arrives sequentially over time. The firm sends multiple rounds of incentives to a finite pool of potential workers. At the beginning of each round, the firm decides how many incentives to send to which group of potential workers. Workers may respond positively or negatively, or simply don't respond. The objective is to minimize the regret, defined as the gap between the final number of workers and demand. We propose an algorithm that easily computes the number of incentives to send, and show that it achieves near-optimal regret.

4 - A Pricing Framework for the Multi-modal Mobility Marketplace

Chamsi Hssaine, Cornell University, Ithaca, NY, Siddhartha Banerjee, Ragavendran Gopalakrishnan

We study the problem of designing an efficient mobility marketplace: a centralized platform where private on-demand mobility providers and public transit can jointly offer hybrid multi-modal trips to commuters. Pricing such trips to maximize social welfare, while ensuring that both commuters and mobility providers enjoy weak Pareto improvement (compared to the status quo), is a hard problem. Our general approach is based on formulating a "shaded" welfare maximization program and yields a pricing policy with a constant-factor approximation guarantee, under an intuitive structural condition based on a notion of the "efficiency gains" from introducing multi-modal trips.

Operations, Revenue, and Learning Theory

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Rad Niazadeh, Stanford University, Stanford University, Stanford, CA, 94305, United States

1 - Selling to a No-regret Buyer

Seth Matthew Weinberg, Princeton, Princeton, NJ, 08540, United States, Mark Braverman, Jieming Mao, Jon Schneider

We consider the problem of a single seller repeatedly selling a single item to a single buyer (specifically, the buyer has a value drawn fresh from known distribution D in every round). Prior work assumes that the buyer is fully rational and will perfectly reason about how their bids today affect the seller's decisions tomorrow. In this work we initiate a different direction: the buyer simply runs a no-regret learning algorithm over possible bids. We provide a fairly complete characterization of optimal auctions for the seller in this domain.

2 - Efficient Learning in Online Auctions

Nika Haghtalab, Cornell University, Ithaca, NY, United States

We consider the design of computationally efficient online learning algorithms and their applications to auction design. We present an algorithm called Generalized Follow-the-Perturbed-Leader and provide conditions under which it is oracle-efficient while achieving vanishing regret. Our auction-design framework considers an auctioneer learning an optimal auction for a sequence of adversarially selected valuations with the goal of achieving revenue that is almost as good as the optimal auction in hindsight. We give oracle-efficient learning results fora number of commonly used auctions in practice.

3 - Semi-parametric Efficient Policy Learning with Continuous Actions

Vasilis Syrgkanis, Microsoft Research, Cambridge, MA, 02139, United States, vasy@microsoft.com

We consider off-policy evaluation and optimization with continuous action spaces. We focus on observational data where the data collection policy is unknown. We take a semi-parametric approach where the value function takes a known parametric form in the treatment, but we are agnostic on how it depends on the observed contexts. We propose a orthogonal/doubly robust off-policy estimate for this setting and show that off-policy optimization based on this estimate is robust to estimation errors of the policy function or the regression model. We provide an experimental evaluation of our method in a synthetic data example motivated by personalized pricing and resource allocation.

4 - Regret Analysis of Bayesian Multi-armed Bandit with Many Arms

Khashayar Khosravi, Stanford University, Stanford, CA, 94305, United States, khosravi@stanford.edu, Mohsen Bayati, Nima Hamidi, Ramesh Johari

We consider the Bayesian multi-armed problem in the presence of many arms and provide lower bounds on the regret of all policies. We also design and analyze algorithms that can achieve these regret bounds. Through simulations, we confirm our theoretical results and demonstrate that the proposed methods work well in practice.

RM from a Customer Lifetime Value Perspective

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Dragos Florin Ciocan, INSEAD, Fontainebleau, France

1 - Are Markets with Loss-averse Consumers More Sensitive to Losses?

Zhenyu Hu, National University of Singapore, 15 Kent Ridge Drive, Mochtar Riady Building, BIZ1 8-69, Singapore, 119245, Singapore, Javad Nasiry

Behavioral pricing and revenue management aim to incorporate realistic consumer behavior into firms' pricing and inventory models. The key input to these models is market demand, which is often assumed to inherit the characteristics of consumer behavior—as when, for example, one assumes that a market consisting of loss-averse consumers is more responsive to losses than to gains. The empirical evidences on loss-sensitive demand, however, are frustratingly mixed. We offer one explanation on why gain-sensitive demand and loss-averse consumers can coexist by accounting for the heterogeneity in consumer valuation and examine its implication on the firm's optimal pricing policies.

2 - RM with Repeated Interactions

Dragos F. Ciocan, INSEAD TOM Department, Fontainebleau, France, Andre Du Pin Calmon, Gonzalo Romero

Motivated by online advertising, we model and analyze a revenue management problem where a platform interacts with a set of customers over a number of periods. Unlike traditional NRM, we consider customers who dynamically change state between periods. Customer state depends on the quality of their past service and determines the amount of budget that they allocate to the platform. These dynamics create a tradeoff between the platform myopically maximizing short-term revenues, versus maximizing the long-term goodwill of its customers. We identify reasonable conditions under which myopic policies that ignore the budget dynamics are either optimal or near-optimal.

3 - Value of Promotions with Delayed Incentives: An Empirical Investigation of Gift Card Promotions

Ozalp Ozer, The University of Texas at Dallas, Richardson, TX, 75080-3021, United States, Bharadwaj Kadiyala, A. Serdar Simsek

Gift card promotions provide customers an incentive to spend more than an expenditure threshold on regularly priced (as opposed to discounted) products, by rewarding customers with a gift card. This type of promotion is gaining significant popularity among luxury fashion, department store, and consumer electronic industries. Using a proprietary data set from a large department store, we investigate how customers respond to these promotions as well as its effectiveness as a promotional vehicle for retailers. We find significant and positive effects on both purchase likelihood of customers and total sales of the retailer.

4 - Efficient Strategic-level Repositioning in Vehicle-sharing Networks

Gonzalo Romero, Rotman, University of Toronto, Toronto, ON, M4K 3H6, Canada, gonzalo.romero@rotman.utoronto.ca, Mahsa Hosseini, Joseph Milner

We study the dynamic problem of repositioning vehicles using steady-state behavior for a network with centralized control and uncertain, unbalanced demand. We provide interpretable strategic level reposition policies via absorbing Markov chain concepts. Specifically, we use the structure of the underlying transition matrix to estimate the relocation gradient as a function of the current number of vehicles in each location These gradients then provide a state-dependent heuristic for the dynamic vehicle repositioning problem.

Marketing III

Contributed Session

Chair: Ankita Sahai, IIM Indore, FPM Residence, Indore, 453556, India

1 - A Study on Saddle in New Product Diffusion Processes

Masahiro Ishii, Professor, Sophia University, Chiyoda-ku, Tokyo, Japan, Hideyuki Takenouchi, Yoko Sugitani, Ichiro Takahashi

After Bass (1969) applied a diffusion model to describe innovation adoption curves of eleven durable goods, a large number of papers has addressed the related issues. One of the main streams of literature has been emerged in modelling the spread of innovations throughout their entire life cycle. Then, we develop an extended Bass model to reflect complexities, especially saddles, in market penetration curves of new products. In the model, social factors such as social character, social networks, and network externalities etc. are employed as explanatory variables.

2 - Enhancing Return Flexibility Through the Cooperation Between Competitive Retailers

Yi Chen, Xi'an Jiaotong University, Xi'an, China, chenyic@stu.xjtu.edu.cn, Qin Su

Given the importance of return flexibility to consumer shopping experience, our study focuses on the cooperation between competitive retailers with the aim of higher return flexibility. We build an analytical model to explore whether and when two competing brick-and-mortar retailers should accept returns from their online competitor. When store traffic is valuable, we investigate how the cooperation with online retailer in handling returns changes brick-and-mortar retailers' pricing strategies and equilibrium outcomes.

3 - The Impact of Tourist's Level of Mindfulness on Tourism Satisfaction and Experience

Ankita Sahai, Indian Institute of Management Indore, Indore, India, f17ankitas@iimidr.ac.in, Rajendra V. Nargundkar

This study aims to explore the impact of level of mindfulness of a tourist on his/her level of satisfaction and experience with the tourism destination. In the literature, mindfulness has been linked with wellness, but linkages between mindfulness, tourist satisfaction and tourism experience remain unexplored. In the context of tourism in India, we investigate whether mindful tourists gain higher sense of satisfaction and better experiences with tourism. The results of the study may help in determining whether there exists the potential for creating a niche for mindful tourists within a destination. The destination may be branded as a mindful tourism destination.

Optimizing Public Policy

Sponsored: Public Sector OR

Sponsored Session

Chair: Nick Arnosti

1 - Designing Fair, Efficient, and Interpretable Policies for Prioritizing Homeless Youth for Housing Resources

Phebe Vayanos, University of Southern California, University Park Campus, USC, Viterbi School of Engineering, Los Angeles, CA, 90089, United States, phebe.vayanos@usc.edu, M.J. Azizi, Bryan Wilder, Eric Rice, Milind Tambe

We consider the problem of designing fair, efficient, and interpretable policies for prioritizing heterogeneous homeless youth on a waiting list for scarce housing resources of different types. We propose a data-driven mixed-integer optimization framework for designing point-based policies that use features of the housing resources and the youth to maximize the probability that the youth will have a safe and stable exit from the housing program. We evaluate our framework using real-world data from the United States homeless youth housing system.

2 - Analyzing the Effects of Judge Rotation and Judge Shopping on Criminal Sentencing

Lawrence M. Wein, Stanford University, Graduate School of Business, 655 Knight Way, Stanford, CA, 94305-5015, United States, lwein@stanford.edu, Can Wang

Motivated by data from South Carolina, which rotated judges throughout the state on a weekly basis, we analyze a model in which defendants wait for a lenient judge before plea bargaining. We look at the impact of four factors on the mean and variance of criminal sentences: the amount of judge rotation, the amount of allowable judge shopping, the transparency of the judges' schedules, and the capacity utilization of the judicial system.

3 - Redistricting Liver Allocation: A Simulation-optimization Approach

Theodore Papalexopoulos, MIT, Cambridge, MA, United States, tpapalex@mit.edu, Dimitris Bertsimas, Nikolaos Trichakis, Yuchen Wang, Ryutaro Hirose, Parsia Vagefi

We develop a simulation-based optimization algorithm for districting in deceased-donor liver allocation. The algorithm partitions the United States' 58 donor service areas to minimize a weighted sum of annual mortality and organ transport distance in simulation. Graph-based machine learning models capture the simulator's output and allow for an efficient local search procedure to select desirable districts. Our results are part of broader work analyzing efficiency and fairness tradeoffs in liver transplantation policy design.

4 - Jumping the Line, Charitably: Analysis and Remedy of Donor-priority Rule

Ronghuo Zheng, University of Texas at Austin, Austin, TX, 78723, United States, ronghuo.zheng@mccombs.utexas.edu, Tinglong Dai, Katia P. Sycara

We develop a parsimonious model of organ donation to analyze the welfare consequences of introducing the donor-priority rule. Assuming heterogeneity in the cost of donating only, we find introducing donor-priority rule improves social welfare. By incorporating heterogeneity in the likelihood of requiring an organ transplant and in organ quality, we show that introducing donor-priority rule can lower social welfare due to unbalanced incentives across different types of individuals. We then consider a freeze-period remedy and show this additional friction helps rebalance the incentive structure, and in conjunction with the donor-priority rule, can guarantee an increase in social welfare.

Humanitarian and Disaster Operations Management

Sponsored: Public Sector OR

Sponsored Session

Chair: Arian Aflaki

1 - Donations for the Refugee Crisis: Cash Versus In-kind Assistance

Telesilla O. Kotsi, Kelley School of Business, Indiana University, Bloomington, IN, 47401, United States, tkotsi@indiana.edu, Owen Wu, Alfonso J. Pedraza-Martinez

Motivated by our fieldwork during the humanitarian responses to the 2017 refugee crisis in north-western Greece, we analyze trade-offs between cash and in-kind assistance that a humanitarian organization offers to refugees. Our goal is to help humanitarian organizations and governments improve the mix of assistance to maximize the overall benefits to refugees, local business, and residents. Cash assistance allows refugees' spending flexibility and supports local economy, but is complicated by the presence of market power of the local retailer. We examine the impact of market structures, specifically the government's involvement, on the assistance decision of humanitarian organizations.

2 - Evaluating Strategies for Intraorganizational Information Management in Humanitarian Response

Erica L. Gralla, George Washington University, Washington, DC, 20052, United States, egralla@gwu.edu

Information management is critical in humanitarian response, but there is little guidance for humanitarian organizations on how to set up internal information management processes. We use an agent-based model to evaluate several strategies for intra-organizational information management. The results show that holding regular information-sharing meetings significantly reduces the time to acquire adequate information, but does not reduce information overload; however, deploying an information management specialist reduces both time required and information overload. We conclude with recommendations for humanitarian organizations setting up information management processes.

3 - Joining a Humanitarian Coalition: An Empirical Investigation

Maria Besiou, Kuehne Logistics University, Hamburg, 50100, Germany, Mahyar Eftekhar

This study examines the impact of supply availability, scale and magnitude of demand, and environmental conditions on humanitarian organizations' field coordination pattern. This empirical study is based on a unique data set of interactions among humanitarian organizations in 45 countries, during emergency relief operations, from 2006 to 2018.

4 - Evaluating Strategies for Intraorganizational Information Management in Humanitarian Response

Lauren Bateman

Information management is critical in humanitarian response, but there is little guidance for humanitarian organizations on how to set up internal information management processes. We use an agent-based model to evaluate several strategies for intra-organizational information management. The results show that holding regular information-sharing meetings significantly reduces the time to acquire adequate information, but does not reduce information overload; however, deploying an information management specialist reduces both time required and information overload. We conclude with recommendations for humanitarian organizations setting up information management processes.

5 - Reliable Transportation Procurement in Humanitarian Sector: A Data-driven Approach

Feyza G. Sahinyazan, Simon Fraser University, Vancouver, BC, Canada, feyza_sahinyazan@sfu.ca, Mare-Eve Rancourt, Vedat Verter

Aid organizations choose their service providers through reverse auctions to decrease their logistics costs. Most aid organizations award their contracts to the lowest bidders, which often yield aggressive bidding and eventually low quality of service. This problem is known as abnormally low bids (ALB) in public procurement. scrutinizing service levels. Current literature on ALBs is rather limited. In this study, we develop a data-driven contract awarding framework that estimates "reasonable" rates based on lane and contract specifications and eliminates ALBs. Our results demonstrate that service levels can be improved significantly with the suggested framework.

Vendor Tutorial

1 - A Closer Look: Launching your Optimization Application in Minutes

Filippo Focacci, Decision Brain, 18 rue Yves Toudic, Paris, 75010, France, Michael Eisenmann

This tutorial will show attendees an overview of the benefits of using DOC v4 /DecisionsBrain Gene to generate, build and run a complete application in minutes by: • Defining the business data model (entities and relationships) that will be used inside the application) • Generating the application using the Gene Command Line Interface (CLI) The created application will include: • Predefined projects to support the micro-services that will constitute the application • Project build configuration files (Gradle, Docker) • Application deployment configuration files (docker-compose) it is ready to be built and can be run on a stand-alone laptop immediately.

2 - Map-Reduce for Optimization: Build and Deploy Optimization Decomposition on Distributed Resources in the Cloud

Filippo Focacci, Decision Brain, 18 rue Yves Toudic, Paris, 75010, France

DecisionBrain Optimization Server (DBOS) seamlessly runs multiple CPU intensive computational jobs locally or remotely and provides administrative tools to easily monitor and manage them. Specifically designed to help build and deploy fully scalable optimization applications, it enables optimization developers to easily design parallel and distributed decomposition methods and large neighborhood search methods. In this workshop, we demonstrate how this technology can be used to solve a large-scale optimization problem by mimicking, in a very simple way, a Map-Reduce type of approach: split the problem into sub-problems, solve each sub-problem on a different distributed resource, and eventually, combine the different results.

Statistical Modeling and Inference in Smart and Connected Systems

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Changyue Song, Madison, WI, 53715, United States

Chair: Kaibo Liu, University of Wisconsin-Madison, Madison, WI, 53706, United States

1 - Identifying the Influential Inputs for Network Output Variance Using Sparse Polynomial Chaos Expansion

Zhanlin Liu, University of Washington, Seattle, WA, 98105, United States, zhanlliu@uw.edu, Ashis Banerjee, Youngjun Choe

Sensitivity analysis aims to identify system inputs that most influence the variance of system output. Existing approaches typically take the input-output relationship as a black-box and conduct extensive Monte Carlo sampling to identify influential inputs. For a class of input-output relationships expressed as directed acyclic networks, this study proposes a novel model that requires much fewer observations than Monte Carlo sampling to accurately identify influential inputs. Asymptotic properties of the model are established and two manufacturing examples are implemented for validation.

2 - Real-time Quality Monitoring of Supply Chains with Perishable Products

Weihong (Grace) Guo, Rutgers, The State University of New Jersey, Piscataway, NJ, 08854, United States, wg152@rutgers.edu, Mark Rodgers

This study focuses on the real-time monitoring and control of the quality of perishable products to mitigate against degradation as they are transported throughout a smart and connected supply chain network. Given the rising number of food waste and safety scandals in recent years, the quality of perishable products has important implications. In this work, environmental conditions and product quality characteristics are recorded during the transportation journey. These data are modeled to predict residual shelf life for any given conditions of the journey, which will help optimize the future journey in order to ensure an acceptable residual shelf life when the products reach its destination.

3 - Transfer Learning Between Material Systems for Laser Based Additive Manufacturing

Linkan Bian, Mississippi State University, Industrial and Systems Engineering Department, Mississippi State University, MS, 39762, United States, bian@ise.msstate.edu, Jack Francis, Arman Sabbaghi, Ravi Shankar, Morteza Ghasri-Khouzani

Distortion in additive manufacturing is a critical issue that adversely affects the geometric integrity of additively manufactured products. Current methods for investigating the distortion behaviors of different material systems typically involve Finite Element Analysis or a large number of experiments in an empirical study. We propose a Bayesian model transfer methodology that is both physics-based and data-driven to leverage past experiments on previously studied material systems for more efficient distortion modeling of new systems. We validate our methodology in a case study of distortion model transfer from Ti-6Al-4V disks to those manufactured using 316L stainless steel.

4 - Machine Learning and Artificial Intelligence for Long-term Fault Prognosis in Complex Manufacturing Systems

Kahkashan Afrin, Texas A&M University, College Station, TX, 77840, United States, afrin@tamu.edu, Satish Bukkapatnam, Darpit Dave, Soundar Kumara

Recent advances in sensors and streaming data sources of plant floor information systems open an exciting possibility to predict the fault risks over much longer time horizons than what was conceivable before. This work introduces a Manufacturing System-wide Balanced Random Survival Forest (MBRSF), a nonparametric machine learning approach that can fuse complex dynamics underlying these data streams to provide long-term fault prognosis. Experimental investigations with a 20 machine automotive manufacturing line suggest that MBRSF reduces prediction errors by over 90% compared to other contemporary methods.

1 - Research on Multi-stage and Multi-objective Production Planning Considering Decision Makers' Preference

Yanfeng Chu, Nanjing university of Aeronautics and Astronautics, Nanjing, China, yanfengc@nuaa.edu.cn

The purpose of the study is to resolve the problem on making production planning of the multi-product, multi-stage and small-batch products when information is uncertain. In this paper, the linear programming model of grey parameters is constructed. Compared with the traditional production planning optimization method, the effectiveness of the production planning is proved. The results will give a range of decision variables, and help decision makers arranging production planning to deal with unavoidable information uncertainty.

2 - Privately Detecting Changes in Unknown Distributions

Yuliia Lut, Georgia Institute of Technology, Atlanta, GA, United States, yuliia.lut@gatech.edu, Rachel Cummings, Sara Krehbiel, Wanrong Zhang

The change-point detection problem seeks to identify distributional changes in streams of data, and is increasingly studied in settings where data may be highly sensitive. Differential privacy is a powerful technique for enabling data analysis while preventing privacy leakage. All prior work on private change-point detection requires complete knowledge of the pre- and post-change distributions, but this assumption is not reasonable in practice. We develop differentially private algorithms for solving the change-point problem when the distributions of data are unknown. We also apply our algorithms to detect changes in the linear trends in data streams that change smoothly over time.

3 - Differentially Private Change-Point Detection

Wanrong Zhang, Georgia Institute of Technology, Atlanta, GA, United States, Sara Krehbiel, Rui Tuo, Yajun Mei, Rachel Cummings

The change-point detection problem seeks to identify distributional changes at an unknown changepoint k in a stream of data. This problem appears in many important practical settings involving personal data, including biosurveillance, fault detection, nance, signal detection, and security systems. The eld of dierential privacy oers data analysis tools that provide powerful worst-case privacy guarantees. We study the statistical problem of change-point detection through the lens of dierential privacy. We give private algorithms for both online and oine change-point detection, analyze these algorithms theoretically, and provide empirical validation of our results.

4 - Analysis and Forecasting of Mass Shootings Using Change Point Detection

Cameron MacKenzie, Iowa State University, 3029 Black Engineering, Industrial and Manufacturing Systems Eng, Ames, IA, 50011, United States, Xue Lei

The frequency with which active or mass shootings occur in the United States is increasing in each year. This research conducts statistical analysis on historical data to forecast the number of active or mass shootings occurring in the United States. Change point detection can be applied to historical mass shootings to understand how the frequency of shootings has changed over time. Change point detection also enables us to forecast how the number of shootings will change during the future. The results of this research can contribute to improving laws, preventing mass shootings, and responding to them.

5 - A Stochastic Assignment Problem with Unknown Eligibility Probabilities

Zhengyu Zhang, University of Southern California, Los Angeles, CA, United States, zhan892@usc.edu, Sheldon M. Ross, Gideon Weiss

Consider n initially empty boxes, numbered 1 through n. Balls arrive sequentially. Each ball has a binary vector I = (I1,...,In) attached to it, with the interpretation that the ball is eligible to be put in box i if Ii = 1. An arriving ball can be put in any empty box for which it is eligible. Assuming that components of the vectorare independent Bernoulli random variables with initially unknown probabilities pi = P(Ii= 1), i = 1, ..., n, our primary interest is to compare several policies to determine which leads to a stochastically smaller number of observed balls until all boxes are filled.

Sponsored Session

Chair: Chao Wang, University of Wisconsin Madison, University of Wisconsin Madison, Madison, WI, 53706, United States

1 - Stochastics Prognostics under Multiple Time Varying Stress Factors

Salman Jahani, University of Wisconsin-Madison, Department of Industrial/Systems Engineering, Madison, WI, 53706, United States, jahani@wisc.edu, Shiyu Zhou, Dharmaraj Veeramani

In this study, we present a new multilevel modelling framework for sensor-based degradation signals that predicts, in real time, the residual life time of individual components subject to a time varying environment. Unique to our methodology, additive effects of multiple time varying stress factors influences the degradation of individual components. The proposed framework updates degradation model and the residual life distribution of the components by combining the historical data with real-time sensor-based data through a Bayesian approach.

2 - Spatial-temporal Modeling of Cardiac Electrical Activity Based on Gaussian Process and Mechanistic Model

Zhiyong Hu, Texas Tech University, TX, 79415, United States

This study integrates Gaussian Process (GP) with electrophysiological model of cardiac tissue to provide an accurate estimation of spatial temporal variations of cardiac action potential. Specifically, the spatial temporal propagation of action potential is described using a GP, where the mean is modeled by a 2D reaction-diffusion model, and the covariance captures the correlation of model discrepancy in both temporal and spatial domains. The reaction-diffusion and the GP models are calibrated simultaneously using a small set of observations to identify optimal parameters. The hybrid model can significantly reduce computational time, thus has great potentials for practical applications.

3 - Functional Principal Component Analysis for Extrapolating Multi-stream Longitudinal Data

Seokhyun Chung, University of Michigan, Ann Arbor, MI, United States, seokhc@umich.edu, Raed Al Kontar

We propose a functional principal component (FPC) analysis based approach to predict the evolution of multi-stream longitudinal data for an in-service unit based on other historical units. Our approach first decomposes each stream into eigenfunctions and corresponding FPC scores. A Gaussian process prior for the FPC scores is then established based on a semi-metric measuring similarities between streams of historical units and the in-service unit. Finally, an empirical Bayesian updating strategy is derived to update the prior using real-time data obtained from the in-service unit. Strengths of the model are illustrated through numerical studies using synthetic and real-world data.

4 - Approximate Multivariate Distribution of Key Performance Indicators through Ordered Block Model and Pair-copula Construction

Chao Wang, University of Iowa, Iowa City, IA, 53706, United States, cwang436@wisc.edu

We propose to use ordered block model and pair-copula construction (OBM-PCC) to approximate the multivariate distribution of Key Performance Indicators (KPIs). The KPIs are treated as random variables in the OBM and studied under the stochastic queuing framework. The dependence structure of the OBM represents the influence flow from system inputs to KPIs. Based on the OBM structure, the PCC is employed to approximate the joint distribution represented by KPIs and quantify the KPI values. The OBM-PCC model removes the redundant pair copulas in traditional modeling, and enjoys the flexibility and analytical properties in KPI modeling, thus efficiently providing the accurate approximation.

Chair: Rui Tuo, College Station, TX, 77845, United States

1 - Gaussian Process Model Assisted Active Learning of Physical Laws

Lulu Kang, Associate Professor, Illinois Institute of Technology, Chicago, IL, 60616, United States, lkang2@iit.edu, Jiuhai Chen, Guang Lin

Discovering the governing equations from noisy data is an essential challenge in many areas of science and engineering. However, in many cases, experimental data are costly or time-consuming to obtain. This article provides an active learning approach to estimate the underlying PDE and ODE models. We propose an adaptive design criterion combining the D-optimality and the maximin space-filling criterion, and use the Gaussian process model and its derivatives to substitute the unknown functions and their derivatives. Variable-selection-based regression methods are used to learn the PDE or ODE models. The proposed active learning approach is entirely data-driven.

2 - A Clustered Gaussian Process Model with an Application to Solar Irradiance Emulation

Chih-Li Sung, Michigan State University, East Lansing, MI, 48824, United States, sungchih@msu.edu

A Gaussian process has been one of the important approaches for emulating computer simulations. However, the stationarity assumption for a Gaussian process and the intractability for large-scale dataset limit its availability in practice. In this article, we propose a clustered Gaussian process model which segments the input data into multiple clusters, in each of which a Gaussian process is performed. The stochastic expectation-maximization is employed to efficiently fit the model. In a simulation as well as a real application, our prediction had smaller mean square error than its main competitors, with competitive computation time.

3 - Uncertainty Quantification for Bayesian Optimization

Wenjia Wang, SAMSI, Durham, NC, 27713, United States, 1992wangwenjia@gmail.com, Rui Tuo

In this work, we propose a novel approach to assess the output uncertainty of Bayesian optimization algorithms, in terms of credible regions for the maximum value and the maximizer of the objective function. These regions can be computed efficiently, and the credible levels of these regions are guaranteed by newly developed uniform error bounds for Gaussian process regression. Our theory provides a unified uncertainty quantification framework for all sequential sampling policies in Bayesian optimization and arbitrary stopping criteria.

Empirical Study in Substance Misuse

Sponsored: Health Applications

Sponsored Session

Chair: Qiushi Chen, Penn State University, University Park, PA, 16802, United States

1 - The Impact of Substance Abuse Treatment Services Facilities in Combating the Opioid Epidemic

Liang Xu, Pennsylvania State University, 419A Business Building, Penn State University, State College, PA, 16801, United States, lzx103@psu.edu, Hui Zhao

Despite better treatments play a central role in combating the opioid epidemic, fewer than 10% of these patients are receiving these treatments. The low prevalence of treatments is largely due to the lack of access to treatment facilities. We investigate how an increased supply of treatment facilities could help to combat the epidemic, and find that, on average, a 1% increase in the number of treatment facilities in a state leads to a 1.848% decrease in the overdose death rate, as well as a 2.083% decrease in the opioid-related ED visit rate in the state. Furthermore, the increase of SATS facilities with MAT services is more effective in reducing opioid overdose death rate than the ones without MAT services.

2 - Analyzing Recent Trend of Massachusetts Opioid Prescribing Patterns Leveraging All Payer Claims Data

Muhammad Noor-E-Alam, Northeastern University, Boston, MA, MA 02115, United States, md.alam@neu.edu

This study, as part of an ongoing research investigates the recent trend of prescription opioids dispensed for Massachusetts residence. Results showed an increasing trend in the prescribing of suboxone—an opioid largely prescribed for managing opioid addiction. Such drug level analysis in different geographic regions by leveraging Massachusetts All Payer Claims Data (MA APCD) provides promising insights that can be exploited to design interventional strategies to combat opioid crisis.

3 - Opioid Related Adverse Drug Reactions Prediction with Machine Learning

Soundar Kumara, Pennsylvania State University, University Park, PA, United States, Dolzodmaa Davaasuren

Opioid analgesics are widely used in the treatment of chronic, cancer and non-cancer related pain. In the recent years, the opioid epidemic has evolved rapidly, starting with an increase in opioid prescription. Based on the FDA Adverse Event Reporting Data, we performed extensive investigation on the opioid related adverse events in terms of patients' demographic, disease and other commonly prescribed drugs along with opioids. Also, we propose a machine learning algorithm for predicting adverse reaction and outcome resulting from the potential interaction among prescribed drugs for the disease and opioids.

4 - Extracting Meaningful Features from Transaction Data

Ryan Sanders, University of Arkansas, Cave City, AR, United States, rpsander@uark.edu, Shengfan Zhang, Art Chaovalitwongse

The goal of this project is to develop an efficient methodology for extracting features from time-dependent variables in transaction data. Transaction data is collected at varying time intervals making feature extraction more difficult. Supervised representational learning techniques are investigated, and the results compared with those from other feature engineering techniques. This methodology is then applied to insurance claims data in order to find features to predict whether a patient is at risk of overdosing on opioids. This data covers prescription, inpatient, and outpatient transactions.

5 - Drug Arrests and Overdose Outcomes of Substance Abuse

Qiushi Chen, Pennsylvania State, University Park, PA, 16802, United States, Glenn Sterner, Joel Segel

To combat the opioid crisis, state and federal governments have implemented different policies, such as prescription drug monitoring programs and "pill mill" laws, which primarily focus on curbing the supply of prescription opioids. But less is known about supply of illicit substances, which is also a critical factor that has been fueling the epidemic. In this study, we collect illicit drug arrest data from an incident-based reporting system used by law enforcement agencies in the United States to describe the illicit drug availabilities, and examine the association between drug criminal activities and health outcomes including healthcare utilization and overdose death.

Scheduling in Healthcare Operations

Sponsored: Health Applications

Sponsored Session

Chair: Jin Qi, Hong Kong University of Science and Technology, Hong Kong University of Science and Technology, Hong Kong, Hong Kong

1 - Medical Appointment Overbooking and Optimal Scheduling

Yong-Hong Kuo, Assistant Professor, The University of Hong Kong, Dept. of Industrial and Manu. Sys. Eng., Pokfulam Road, Hong Kong, yhkuo@hku.hk, Hari Balasubramanian, Yan Chen

We propose a framework that utilizes a stochastic mixed-integer linear program for guiding scheduling decisions under a simulation environment. With this framework, we conduct a comprehensive analysis of the tradeoffs between schedule efficiency and accessibility to service. Our computational experiments suggest that a session capacity approximate to the request rate can balance the multiple conflicting objectives more effectively; a fixed capacity policy can be as effective as a dynamic overbooking policy under the setting of a constant request rate; and a dynamic overbooking policy leads to a slightly better performance under the setting of a non-homogeneous appointment request rate.

2 - When to Triage in Service Systems with Hidden Customer Class Identities?

Zhankun Sun, City University of Hong Kong, 7-268, 7/F, Academic 3, Tat Chee Avenue, Kowloon, Hong Kong, zhanksun@cityu.edu.hk, Sukriye Nilay Argon, Serhan Ziya

Motivated by patient triage, we consider a single server service system with Poisson arrivals and two types of jobs. The type identity of each job is initially unknown but can be revealed through triage. However, triage takes time and is error-prone. Hence, it is unclear when triage should be carried out. We formulate this problem as a Markov decision process and characterize the optimal policy on triage. We identify conditions under which triage should never be considered and when a state-independent policy performs sufficiently well.

3 - A Comparative Analysis of Scheduled- Versus Compassionate-dialysis for the Uninsured and Indigent

Farnaz Nourbakhsh, Southern Methodist University, Dallas, TX, 75243, United States, Olga Bountali, Sila Cetinkaya

Uninsured patients suffering from chronic diseases may have access to medical treatment under federal law, EMTALA, only after being evaluated as in ‘emergent, life-threatening condition’. In the case of ESRD patients who do not have access to regular treatment, the practice of offering dialysis conditional on a screening assessment in the ER is known as “compassionate dialysis”. In this paper, we pose the hypothetical question of “What if the uninsured ESRD patients had access to scheduled dialysis as an option?” Our goal is to offer a comparison of system and patient-centric performance criteria under the two options.

4 - Operating Theatre Scheduling under Uncertainty with an Entropic Index

Xiaojin Fu, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, Hong Kong, xfuab@connect.ust.hk, Jin Qi, Han Ye

We consider a surgery sequencing and scheduling problem in the Operating Theatre. From the data, “to follow” policy is observed, in which surgeries are conducted one after another and can start earlier than the scheduled time. Under this policy, we propose a mathematical framework to balance the idle and waiting risk with the Inbound Index. To find the optimal sequence and scheduled starting times, we develop an efficient algorithm based on Benders Decomposition. Moreover, for its practical use, we propose heuristics for sequencing decisions based on surgical time’s standard, forward and backward deviations. We further propose numerical studies to show the benefit of the model and the heuristics.

Healthcare Analytics in Emergency and Critical Care

Sponsored: Health Applications

Sponsored Session

Chair: Xiaolei Xie, Tsinghua University, Beijing, 100084, China

Co-Chair: Zhankun Sun, City University of Hong Kong, Kowloon, Hong Kong

1 - Dynamic Scheduling of Multi-priority Multi-class Patients with Wait Time Targets in a Tele-ICU: Case Study and Analysis

Xuanjing Li, Tsinghua University, ShunDe, Beijing, China, lixj15@mails.tsinghua.edu.cn, Dacheng Liu, Xiaolei Xie

This paper, motivated by the collaboration with a tele-ICU company, focuses on reducing the incidents of excessively long waits at any server in a tandem queue. We first conduct descriptive analytics of arrival data and service time of multi-priority multi-class patients. To improve the waiting time management, we consider the accumulating priority queue (APQ), where the priorities of patients are functions of their waiting time and initial class. Using empirical data from the tele-ICU company, we build simulation models to compare the performance of different scheduling policies, including policy derived from APQ, threshold-based policy and FIFS (First-In-First-Serve) policy.

2 - Who is Next: Dynamic Patient Prioritization in an Emergency Department

Wenhao Li, City University of Hong Kong, Kowloon, Hong Kong, wenhaoli6-c@my.cityu.edu.hk, Zhankun Sun, Jeff Hong

In the emergency department (ED), priority scores are assigned to patients at triage based on their acuity levels. However, using operational data from more than 150,000 patient visits, we find that doctors may deviate from this priority sequence, and within each priority class, patients may not be served in a first-come-first-serve manner. Our analysis shows that when selecting the next patient to treat, doctors prioritize patients who are more likely to be discharged after treatment at ED when many ED beds are occupied by boarding patients, in an effort to avoid further access block to the ED.

3 - Scheduling of Physicians with Time-varying Productivity Levels in Emergency Departments

Marco Bijvank, University of Calgary, Calgary, AB, T2N 1N4, Canada, marco.bijvank@haskayne.ucalgary.ca, Farzad Zaerpour, Zhankun Sun

Traditionally, physicians are assigned to shifts based on preferences or other conditions like fairness or ergonomics. As a result, physicians are considered interchangeable. However, each physician has a different productivity (measured as the number of new patient assessments in an hour, or PPH rate). Ignoring the heterogeneity between physicians can lead to congested EDs. We show with a regression analysis that the PPH rate is a physician characteristic independent of the congestion level at the ED. Next, we solve the physician rostering problem with a two-stage stochastic program formulation, where we incorporate the stochastic nature of both patient arrivals and physician productivity.

4 - Physician Scheduling for Emergency Department with Time-varying and Stochastic Demand

Ran Liu, Associate Prof., Shanghai Jiao Tong University, Shanghai, China, liuran2009@sjtu.edu.cn, Xiaolan Xie

The patient arrival rates to emergency department (ED) during one day is strongly time-varying. Such fluctuation is one main cause of long waiting times, and ED staffing is one key driver of service quality improvement. Based on data from a large hospital of Shanghai, China, we model the service of ED as a non-stationary M(t)/M/C(t) queuing system. Based on Markov chain model and uniformization, system is analyzed and the physician scheduling problem is formulated as a MIP model. An heuristic algorithm is designed to the problem. Experiments show the algorithm has good performances. Compared with scheduling used in the hospital, our solution can reduce patient waiting time and physician working time.

5 - The Operational Effectiveness of a Full Capacity Protocol to Ease the Crowding at an Emergency Department

Lu Wang, University of Kansas, Lawrence, KS, 66045, United States, lu.wang@ku.edu, Mazhar Arikan, Suman Mallik

The Full Capacity Protocol (FCP) is a set of guidelines that coordinate the patients flow when the emergency department (ED) is overcrowded. Utilizing data from a large urban teaching hospital, we characterize its impacts on the operational performance of the ED.

Decision and Data Analytics for Healthcare Service Operations

Sponsored: Health Applications

Sponsored Session

Chair: Zhan Pang, PhD, Purdue University, West Lafayette, IN, 47907, United States

1 - Discrete Convexity Results for Coordinated Scheduling for In-clinic and Virtual Medicine Patients in an Integrated Practice Unit

Douglas Morrice, University of Texas-Austin, IROM Department, Austin, TX, 78712-1750, United States, douglas.morrice@mccombs.utexas.edu, Jingyao Huang

Coordinated services and virtual medicine are two innovative concepts being employed in value-based, patient-centered care. In this paper, we develop discrete convexity results and heuristics for coordinated scheduling of both in-clinic and virtual medicine patients in an Integrated Practice Units (IPU). An IPU is a co-located, multi-disciplinary team of providers that delivers a full care cycle.

2 - Risk-sensitive Appointment Scheduling

Shuming Wang, University of Chinese Academy of Sciences, Beijing, China, wangshuming@ucas.edu.cn, Zhan Pang

We study a joint sequencing and scheduling problem with uncertain service times and multi-class patients in the framework of stochastic optimization with risk measures. We minimize the overtime risk and constrain the delay risk for each patient scheduled. We focus on the problem with the popular coherent risk measure CVaR. In particular, for the case of single-class of patients, we show the problem under CVaR measure is $L^\natural$-convex, which enables us to design polynomial time algorithms to solve the problem efficiently and practically. As for the multi-class case, we show that the problem in sample formulation can be transformed into a mixed integer linear program.

3 - Managing Quality of Care in Competitive Healthcare Markets: A Rational Expectations Equilibrium Approach

Linggang Qi, City University of Hong Kong, Hong Kong, China, lingganqi2-c@my.cityu.edu.hk, Zhan Pang, Sergei Savin

Our work investigates the effects of social learning on hospitals' quality decision in a competitive healthcare market. We consider a duopoly where hospitals are competing on quality, which may be inferred from online patients' reviews when it is unknown and patients are sensitive to quality-of-care, waiting times and traveling cost. We analyze the rational equilibrium behavior of patients and Nash equilibrium quality decisions of hospitals. We find that hospitals' quality decision is decreasing in traveling cost. Also, we find that hospitals' quality decision is decreasing with the accuracy of information that can be acquired by patients.

Socially Responsible Supply Chains: Auditing and Competition

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Rodney Parker

Co-Chair: Han Zhang

1 - A Balancing Act of Regulating On-demand Ride Services

Jiayi Joey Yu, University of California, Berkeley, Berkeley, CA, 94720, United States, yujiayijoey@gmail.com, Christopher S. Tang

Regulating on-demand ride-hailing services requires a balance of multiple competing objectives. This study is motivated by a regulatory policy implemented by the Chinese government in 2017 and a similar policy approved by the New York City Council in 2018. We examine the impact of these policies on the welfare of different stakeholders. By analyzing a two-period dynamic game, we find that relative to no regulations and a complete ban policy, a carefully designed regulatory policy can strike a better balance of multiple competing objectives. Finally, if a government can reform the taxi industry by adjusting the taxi fare, then lowering the taxi fare can improve the total social welfare.

2 - Supplier Centrality and Auditing Priority in Socially-responsible Supply Chains

Jiayu Chen, The University of Texas at Dallas, Richardson, TX, 75080, United States, Anyan Qi, Milind Dawande

Most supply networks are characterized by firms that source from multiple suppliers and suppliers that serve multiple firms, thus resulting in suppliers who di er in their degree centrality, i.e., the number of firms they supply to. In such networks, negative publicity from suppliers' noncompliance of socially-responsibility can damage the buying firms' brand. To mitigate this, firms audit suppliers, although resource and time considerations restrict the number of audited suppliers. A key question is whether firms should prioritize the auditing of suppliers with low or high centrality. We explore how supplier centrality affects socially-responsible supply chains and offer useful insights.

3 - Supplier Audit Information Sharing and Responsible Sourcing

Yunjie Wang, Renmin University of China, Zhongguancun Street, Beijing, 100080, China, ywangbm@connect.ust.hk, Albert Y. Ha, Weixin Shang

We develop a game-theoretic model to study the incentive for competing manufacturers to share supplier audit information in a market with some consumers who boycott a manufacturer if supplier responsibility violations occur. Based on the audit information, each manufacturer either continues to source from an existing common supplier who has uncertain responsibility risk, orswitches to a new supplier who has no responsibility risk but charges a higher price. We characterize the manufacturers' equilibrium audit information sharing decisions and sourcing strategies, and show how they depend on the model parameters.

4 - Social Responsibility Auditing in Supply Chain Networks

Han Zhang, student, Indiana University Bloomington, Bloomington, IN, 47405, United States, hz8@iu.edu, Goker Aydin, Rodney P. Parker

We study a buyer's problem of auditing suppliers in a generalized three-tier supply network with the intention of verifying their social responsibility compliance. The buyer suffers economically if a non-compliant supplier's violation is exposed. To avoid such damages, the buyer dynamically chooses which suppliers to audit. If a supplier fails an audit, the buyer chooses whether to rectify the supplier or drop the supplier from the supply network entirely. Dropping a supplier (and its dependents) lessens the buyer's profit due to reduced competition. We characterize the price/quantity equilibrium of production activities in the supply network and the buyer's optimal auditing strategy.

Supply Chain Management VII

Contributed Session

Chair: Chun Cheng, Polytechnique Montreal, Montreal, QC, H3S1T1, Canada

1 - The Impact of Relative Performance in a Supply Chain with Multiple Retailers

Xifei Liu, Peking University, Beijing, China, liuxifei@pku.edu.cn, Shuxiao Sun

This paper studies the impact of relative performance (RP) on the equilibrium quantities and profits in a supply chain consisting of one manufacturer and multiple retailers. The manufacturer decides the wholesale price and the retailers engage in quantity competition. We assume that some of the retailers have relative preferences when they make their decisions, i.e., maximizing a weighted sum of profits and their relative performances.

2 - Strategic Overcapacity in Platform Selling under Asymmetric Information

Liqun Wei, Tianjin University, Tianjin, China, lqwei@tju.edu.cn, Jianxiong Zhang

In this paper, we study the optimal capacity strategy of manufacturer who sells product on platform. The platform has the leadership of pricing and more demand information about the market. We build a signaling game model where the manufacturer can learn the demand information disclosured from the platform's commission fee decision to more properly set retail price, and investigate the interactions between the manufacturer's capacity decision and the retailer's signaling. Interestingly, we find that the manufacturer may strategically set the overcapacity decision, that is, he could gain more profit by investing in a high capacity level which always exceeds the actual demand.

3 - Learning Asymmetric Forecast Preferences in Supply Chain Forecast Sharing

Lin Zhao, Tsinghua University, Beijing, China, zhaolin14@mails.tsinghua.edu.cn

Forecast sharing has been widely adopted to coordinate production planning in supply chains. However, the effectiveness of forecast sharing can be hindered by forecast inflation caused by the forecaster's asymmetric preference toward over-and-under-forecast. We present two optimization models for the supplier to recover the asymmetric forecast preferences. We apply the models in a case study concerning a real-world forecast sharing practice in a PC manufacturing supply chain. The results show that there exists significant forecast inflation in the shared forecasts. We also investigate the supplier's benefit from learning the manufacturer's forecast preference.

4 - How National Culture Moderates the Effect of Supply Chain Integration on Flexibility Performance: Evidence from Multi-country Data

Jing Tan, Xi'an Jiaotong University, Xi'an, China, xjtutj@stu.xjtu.edu.cn, Shan Liu, Hongyi Mao, Jinlong Zhang, Yajun Zhang

Although global supply chain (SC) is widespread, the role of national culture in SC management is poorly understood. This study examines how the effect of SC integration on flexibility performance is contingent on critical national culture dimensions. Based on 121 pair-wised survey data from SC managers and senior managers of retail firms from 31 countries, results corroborate that SC integration has a positive effect on the flexibility performance of firms. Such effect decreases in individualism but increases in high uncertainty avoidance culture. Our findings contribute to the literature to global SC management by integrating the contingency view and cultural perspective.

5 - A Process View on Managing Supply Chain Disruptions

Iana Shaheen, University of South Florida, Tampa, FL, United States, ianalukina@usf.edu, Arash Azadegan, Kevin Linderman

Viewing a major SC in disruption as an organizational change process, we develop and test a series of propositions. First, we look at patterns of leadership behavior during 41 SC disruptions in the supply network of a global automotive firm. Second, we use vignette-based experiments to offer support for some of the propositions developed in the first study.

6 - Robust Facility Location under Disruptions

Chun Cheng, Polytechnique Montreal, Montreal, QC, Canada, chun.cheng@polymtl.ca

We study a fixed-charge location problem that considers the risk of disruptions. We adopt a two-stage robust optimization method, where facility location decisions are made here-and-now and recourse decisions to reassign customers are made after the uncertainty information on the facility availability has been revealed. We implement a column-and-constraint generation algorithm to solve the robust models exactly. We further develop an approximation scheme for instances of a realistic size; it requires the adjustable decisions to be an affine function of the uncertain parameters.

1 - Towards Next Generation of Manufacturing Smart Devices - Insights from Customer Reviews

Suchithra Rajendran, University of Missouri, Columbia, MO, United States, suchithra.rajendran@gmail.com, Emily Pagel

In the era of web 2.0, with the introduction of smart devices, consumers are inviting technology into their home in pursuit of a more efficient lifestyle. Although these gadgets' performances are quite impressive, there remains a need for continuous improvement. To fully evaluate the market's perception of each applicable smart device, in this study, text analytics tools were used to analyze customer reviews and perform SWOT analysis. Based on our analysis, several next-generation manufacturing design insights are provided that can be adapted by most of the smart devices.

2 - A Machine Learning Approach for Analyzing Microstructure on Fiber Reinforced Materials

Zimo Wang, Texas A&M University, College Station, TX, United States, zimowang@tamu.com

Natural Fiber reinforced Plastic (NFRP) composites offer tremendous ecological advantages for sustainable manufacturing because of their degradability and recyclability. However, the heterogeneity of the NFRP leads to variations of material removal mechanisms over time which adversely impacts the surface finish. We present an in-process monitoring approach for characterizations for machining Natural Fiber Reinforced Plastic (NFRP) materials manufacturing processes. The presented machine learning approach allows the estimation of the localized fiber packing density (FPD) and resultant the surface integrity using extracted features from implemented sensors.

3 - The Impact of Patents on American Manufacturing Productivity

Anand Kandaswamy, Economist, NIST, Washington, DC, United States, anand.kandaswamy@nist.gov

The economics literature on the topic of productivity stresses the importance of innovation along with traditional factors like capital and labor investments. Using patents activity as a proxy for innovation, we statistically model just how important innovation is in driving gains in certain key American manufacturing industries.

4 - The Impact of IT Investment and Worker Composition on Manufacturing Worker Productivity: The Moderating Effect of IT Usage

Changqin Yin, Huazhong University of Science and Technology, Wuhan, China, yinchangqin2015@163.com

In this study, two types of manufacturing enterprises with significant differences in the use of IT were selected to examine the impact of IT investment and worker composition on worker productivity. The results show that in enterprises with a high degree of IT use, IT investment positively impact worker productivity, the decrease of professional and civilian worker has a positive effect on the improvement of worker productivity, while the decrease of managerial worker negatively impacts worker productivity. In a manufacturing company with a low level of IT use, the result is the opposite.

1 - Using Spreadsheet Maps for the Optimal Placement of Low Altitude Platform (LAP) Wireless Network Nodes for Disasters

Michael Bartolacci, Professor of Information Sciences and Technology, Penn State University - Berks, Reading, PA, 18017, United States, mbartolacc@aol.com, Larry J. LeBlanc, Thomas A. Grossman

Low Altitude Platform (LAP) architectures are an emerging architecture platform for providing wireless network connectivity to areas with a damaged fixed wireless network infrastructure. The most common reason for such damage is weather-related, but could also be due to terrorism, sabotage, or human errors. The authors propose a spreadsheet-based approach for practitioners to locate LAP nodes in the field. We suggest a new spreadsheet-based approach that will appeal to practitioners by providing graphical visualizations of potential solutions.

2 - Optimization of the Supply Chain in Healthcare

Albena Mihovska, Associate Professor, Aarhus University BSS, Birk Centerpark 15, Herning, 7400, Denmark, amihovska@btech.au.dk, Alexander Bødker Andersen

Disruptive innovations through the digitalization of processes and emerging new technologies are all part of the fourth industrial revolution - called Industry 4.0. This research focuses on the potential impact and benefits Industry 4.0 could cause in the supply chain for a large Danish healthcare technology company. The research is conducted as an explorative case study which investigates how the transportation and implementation of high-technological and complex healthcare technology in the Danish hospitals can be mapped and potentially optimized. Furthermore, is it analyzed how Industry 4.0 concepts and technologies can be utilized by the company in a cost-efficiency perspective.

3 - Purposeful Internet Use in the United States: Geodemographics of Internet Access, Use, and Impact

Avijit Sarkar, University of Redlands, Redlands, CA, United States, avijit_sarkar@redlands.edu, James B. Pick

As internet penetration rates have steadily increased in the United States across dimensions such as education, gender, age, race/ethnicity, income, and employment, the span of purposeful internet usage has diversified as well. This paper examines socioeconomic aspects and geographic patterns of purposeful internet use in US states for hedonic and non-hedonic, contemporary activities such as engaging in e-commerce, e-health, and telework. Implications for the US digital divide are discussed, in light of an increasing focus on digital innovation driven by a sophisticated digital workforce.

2 - Share Repurchases and Market Returns

Hariprasad Bellamkonda, Associate Professor, IIM Indore, Indore, India, hariprasad@iimidr.ac.in

The investor reaction to actual share repurchases is examined in the Indian context. It is observed that the firms engage in buybacks when the share price exhibit a declining trend, consistent with price support hypothesis. The price patterns around share repurchases by smaller firms is consistent with signalling the undervaluation. When the percentage of share buyback is low, the results however confirm the price support hypothesis.

3 - Adjusted Portfolio Selection Model Reflecting the End of the Year Effect of Global Economic Growth

Jihye Yang, Yonsei University, Seoul, Korea, Republic of, jihyeyang89@gmail.com, Hongseon Kim, Seongmoon Kim

This study suggests improved investment strategy based on Markowitz's portfolio selection model reflecting the End-of-the-Year Effect. The proposed model includes additional constraints reflecting GDP adjusting the proportion of capital invested in risk assets and risk-free assets according to end of the year global economic growth. We empirically evaluate the performance of the proposed model in U.S, Germany, Korea, and Hong Kong stock markets. The proposed model achieved substantially higher returns, lower risk, and thus superior Sharpe ratio and Rachev ratio compared with other benchmarks.

4 - Dynamic Portfolio Selection with Linear Control Policies for Coherent Risk Minimization

Yuichi Takano, University of Tsukuba, Tsukuba, Japan, ytakano@sk.tsukuba.ac.jp, Jun-ya Gotoh

This talk is concerned with developing a linear control policy for dynamic portfolio selection where a coherent risk measure is minimized. We formulate this problem as a scenario-based optimization model. We then apply robust optimization techniques to our optimization model to improve the out-of-sample investment performance. Specifically, we prove that the worst-case coherent risk measure can be decomposed into the empirical risk measure and the regularization term. The efficacy of our method is assessed through numerical experiments with historical data on actual stock returns.

5 - Asset Allocation Model Using Asset-class-based and Factor-based Risk Parity Approaches

Norio Hibiki, Professor, Keio University, Yokohama, Japan, hibiki@ae.keio.ac.jp, Hirotaka Kato

In recent years, the risk parity strategy has become attractive to academics and practitioners. We propose a methodology of constructing the well-balanced portfolio by the mixture of asset-class-based and factor-based approaches. We also show the method of determining the weight of two approaches using the diversification index. We examine the characteristics of the model through the numerical tests with seven financial indices and three factors. We implement the backtest from 2005 to 2018, and the performances are measured on a USD basis. We find our method decreases risks, and it has a higher Sharpe ratio than other portfolio strategies. The results show our new method has practical advantages.

Sponsored Session

Chair: Kenneth Schultz, Xenia, OH, 45385, United States

1 - Last Place Aversion in Queues

Ryan Buell, Harvard Business School, Boston, MA, 02163, United States, rbuell@hbs.edu

Every line has an end, and with it, a person who is in last place. This paper documents the effects of last place aversion in queues on customer experiences and behaviors, as well as for operating performance. The results demonstrate that last place aversion harms customer experiences and can lead to maladaptive behaviors - switching that increases wait times, and abandoning when the benefits of waiting are most pronounced. The paper also documents the detrimental effects of last place aversion for queuing capacity. When the effects of last place aversion are addressed, overall abandonment decreases, such that with equivalent arrival and service rates, total service capacity can be increased.

2 - Structural Estimation of Intertemporal Externalities on ICU Admission Decisions

Fanyin Zheng, Columbia University, Columbia Business School, New York, NY, 10027, United States, Yiwen Shen, Carri Chan

The Intensive Care Unit (ICU) in a hospital often has the highest cost and the highest congestion level. Our study focuses on the intertemporal externalities in physicians' ICU admission decisions and their impact on patient outcomes and system performance. In particular, we study how admitting a patient in the current period affects the system status, and, in turn, its ability in admitting another patient with possibly more severe conditions in the next period. We take the structural estimation approach which allows us to estimate how much the physicians internalize the intertemporal externalities in their decision making from data.

Economic Value of Digital Platforms and Artificial Intelligence

Sponsored: Information Systems

Sponsored Session

Chair: Shan Huang, University of Washington, Seattle, WA, 98195, United States

1 - The Value of Artificial Intelligence in Drug Development

Bowen Lou, University of Pennsylvania, Philadelphia, PA, United States, Lynn Wu

We examine how artificial intelligence (AI) can influence the drug development process. Despite an enormous amount of time and financial resources invested in developing drugs, pharmaceutical firms experience declines in novelty for drugs they produced. As AI becomes an important general purpose technology (GPT), it could be used to address some known challenges in the drug development process. Using a number of large-scale datasets that contain detailed historical records of global patents as well as drug development, we identify firms' AI capabilities and construct a relatively new metric to measure drug novelty, based on a novel backtracking graph matching algorithm to pinpoint the maximum common substructure in chemical graph representations of drugs. By differentiating multiple stages in the drug development process, we investigate where AI is most effective in developing new drugs. We find that AI can primarily affect the earliest stage in drug discovery when tasks are heavily dependent on automatic data processing and reasoning. However, it may not necessarily help with the more expensive and risky clinical trial stages that require substantial human engagements and interventions. Additionally, AI can facilitate the development for drugs at the medium level of chemical novelty but is not helpful with drugs at the extreme ends of the spectrum, those that are entirely novel or incremental me-too drugs. Our study sheds light on the understanding of the roles and limitations modern technology can have on drug development, one of the most complex innovation processes in the world.

2 - GDP-B: Accounting for the Value of New and Free Goods in the Digital Economy

Avinash Collis, Massachusetts Institute of Technology, Cambridge, MA, United States, Erik Brynjolfsson, Erwin Diewert, Felix Eggers, Kevin Fox

The welfare contributions of the digital economy, characterized by the proliferation of new and free goods, are not well measured in our current national accounts. We derive explicit terms for the welfare contributions of these goods and introduce a new metric, GDP-B which quantifies their benefits, rather than costs. We apply this framework to several empirical examples including Facebook and smartphone cameras and estimate their valuations through incentive-compatible choice experiments. For example, including the welfare gains from Facebook would have added between 0.05 and 0.11 percentage points to GDP-B growth per year in the US.

3 - The Contagion of Online Gift Giving

Yuan Yuan, Massachusetts Institute of Technology, Cambridge, MA, 110819, United States, Tracy Liu, Chenhao Tan, Jie Tang, Alex Pentland

Pay-it-forward behavior is a type of contagion of prosocial behavior. Existing empirical evidence of pay-it-forward behavior has been largely based on laboratory experiments, which are limited in sample size and external validity. Extending this research, our study uses a natural experiment to examine pay-it-forward reciprocity in a real-life context with a large-scale dataset of 3.4 million users of an online platform. Our natural experiment is enabled by the randomness in the mechanism that WeChat, a Chinese online social networking platform, uses to split an online monetary gift (also known as a "red packet") to its recipients. Our results show that recipients on average pay forward 10.34% of the amount they receive. We further find that "luckiest draw" recipients, or those who obtain the largest shares of their corresponding red packets, are 1.5 times more likely to pay it forward than other recipients. Our analyses indicate that in a multiple recipient setting, users' pay-it-forward behavior is enforced by a group norm that luckiest draw recipients should send the first subsequent gift and promoted by their distributional social preferences of the random amounts split by the platform. Finally, our study shows that those recipients without any in-group friends do pay it forward, even though their pay-it-forward behavior is less likely to be driven by their reputational concerns among acquaintances. Overall, our work provides insights into mechanisms and conditions that encourage pay-it-forward reciprocity, which have implications for fostering prosocial behavior.

Auctions/Mechanism Design

Contributed Session

Chair: Wei Chen, University of Kansas, Lawrence, KS, 66049, United States

1 - Truthful Mechanisms for Location Games of Dual Role Facilities

Minming Li, City University of Hong Kong, Hong Kong, Hong Kong, minming.li@cityu.edu.hk, Xujin Chen, Changjun Wang, Chenhao Wang, Yingchao Zhao

This paper is devoted to the facility location games with payments, where every agent plays a dual role of facility and customer. In this game, each selfish agent is located on a publicly known location in a metric space, and can allow a facility to be opened at his place. But the opening cost is his private information and he may strategically report this opening cost. Besides, each agent also bears a service cost equal to the distance to his nearest open facility. We are concerned with designing truthful mechanisms for the game. The objective is to minimize (exactly or approximately) the social cost (the total opening and service costs) or the maximum agent cost of the outcome.

2 - Value Mutation and the Information Disclosure in Sponsored Search Advertising

Yun Zhou, School of Management, Zhejiang University, Hangzhou, China, zhouyun2015@zju.edu.cn, Weihua Zhou, Mingzheng Wang

In Sponsored Search Advertising (SSA), ad slots placed at higher rank may mysteriously possess lower click value than those at lower rank. This phenomenon, defined as Value Mutation (VM), will fairly distorts advertisers' bidding behavior. Using a game-theoretic model, this study thoroughly investigates the impact of VM and propose insights for Search Engine. A Decision Tree of Search Engine is constructed sequentially including disclosure of VM's information and VM modification. Search Engine always prefers to release the information. Counterintuitively, Search Engine is probably favored by the existence of Value Mutation, under specified conditions.

3 - Information Platforms for Congestible Goods

Hamidreza Tavafoghi, University of California-Berkeley, Berkeley, CA, United States, tavaf@berkeley.edu, Akhil Shetty, Kameshwar Poolla, Demosthenis Teneketzis, Pravin Varaiya

We study information disclosure mechanisms for congestible goods with unknown (uncongested) valuations. We show that a social planner can improve the outcome by providing either a public imperfect information signal about the goods' valuation or coordinated private recommendations to each agent. The welfare gain is increasing in prior uncertainty about the valuations and decreasing in the prior expected difference in the valuations. We consider two extensions of the basic model. First, we analyze the outcome in an environment with a single or multiple revenue-maximizing platforms. Second, we investigate the outcome in a dynamic two-step case where agents learn from their past experience.

4 - Optimal Periodic-Review Policies for Repeated Awards of Non-monetary Rewards

Wei Chen, Assistant Professor, University of Kansas, Lawrence, KS, United States, wei.chen@ku.edu, Milind Dawande, Ganesh Janakiraman

In practice, there are many situations where a principal reviews an agent's performance periodically, and awards him non-monetary rewards if his past performance is satisfactory at the time of each review. These non-monetary rewards motivate the agent to exert costly efforts to achieve good performance outcomes. Agent's efforts are not directly observable by the principal, while performance outcomes of the agent are directly observable. In this paper, using long-run average utilities as objectives, we study optimal period-review policies for the principal, and agent's best effort exertion under such policies.

1 - Media Health Literacy Plays Critical Role of Shared Decision Making: Mediating Or Moderating?

Chi-Chang Chang, chungshan medical university, Taichung, Taiwan, changintw@gmail.com, Chalong Cheewakriangkrai, Ying-Chen Chen

Media health literacy have proven to be associated with health information seeking and with health literacy may be predicted by patient's Shared Decision Making. The mediation models and mediating hypotheses were tested by applying hierarchical multiple regression analyses. The finding suggests that e-health literacy has fully mediating effects between health literacy and shared medical decision making. Overall, it is important for health providers to consider the notion that more ehealth literacy may sometimes, but not always, be better.

2 - Model Exploration of an Information-based Healthcare Intervention Using Parallelization and Active Learning

Chaitanya Kaligotla, Postdoctoral Scientist, Argonne National Laboratory, Chicago, IL, United States, ckaligotla@anl.gov

This paper describes the application of a large-scale active learning method to calibrate a computational agent-based model developed to investigate the impact of a clinical information-based health intervention that provides patients with personalized information about local community resources to meet basic and self-care needs. The diffusion of information about community resources and their use, is modeled via networked interactions and their subsequent effect on agents' use of community resources across an urban population. We demonstrate the feasibility of using active learning model exploration techniques on an HPC to characterize large parameter spaces.

3 - Multi-game Modeling for Counter-smuggling

Craig Bakker, Pacific Northwest National Laboratory, Richland, WA, United States, craig.bakker@pnnl.gov, Jennifer B. Webster, Kathleen E. Nowak, Samrat Chatterjee, Casey J. Perkins, Robert T. Brigantic

Trade provides an avenue for terrorists to smuggle illicit materials into a target country. Policymakers need models and decision support tools to inform their responses to this. To that end, we have developed a multi-game model that considers security and economic aspects of counter-smuggling interdiction efforts. Here, we demonstrate the model's capabilities on a representative system of ports, trade routes, and commodities. We find that economic factors play a large role in the interdiction task and provide correspondingly important tools for deterrence.

4 - Optimal Facility Sequencing When Deploying A New Clinical Information System

Nathaniel Horvath, BC Cancer, Vancouver, BC, Canada

This case study presents the problem of replacing the clinical information system in use across cancer centres in British Columbia, Canada. Since centres cannot undergo replacement at the same time, executives must plan a deployment sequence. If two centres are using different information systems, operational overhead increases, as a patient may travel to different facilities in the network for different parts of their treatment. A method is presented to identify such connections between centres. This is combined with a network modelling framework to determine optimal centre pairs for system replacement. These findings informed the organization's current replacement strategy.

5 - Model Predictive Control with Gaussian Process Nonlinear Autoregressive Model and its Application to Energy Storage System Control

Jinkyoo Park, Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of, jinkyoo.park@kaist.ac.kr

This paper discusses a data-driven model predictive control (MPC) approach to optimize the operation of an energy storage system (ESS). For every time step, the MPC optimizes a sequence of control actions over a finite horizon using the state transition model and executes only the first action. The performance of the MPC is thus strongly dependent on the predictive accuracy and reliability of the state-transition model (i.e., dynamic model) of a target system. In this paper, we used a Gaussian Process Nonlinear Autoregressive model to predict the distribution on the future state trajectory given the historical state data and use the distribution to optimize the future sequence of control inputs.

6 - Minimizing Radiology Errors Using Discrete System Simulation

Mahdi Nasereddin, Penn State- Berks, Reading, PA, United States, mxn16@psu.edu, Michael Bartolacci

Health care is one of the biggest industries in the United States. To combat increasing costs, the health care industry have emphasized increasing efficiency and reducing errors. One such area that needs improvement is radiology. Missed or delayed diagnostics often results in substantially higher costs later. In medicine, fatigue has been well-documented as a source of medical errors. One of the main sources of fatigue is excessive workload. In this paper we explore using discrete system simulation to predict demand to minimize radiologist fatigue.

7 - On Delivering Fast in Online Luxury Retail

Catarina Pinto, INESC TEC / FEUP, Porto, Portugal, cppinto@fe.up.pt, Pedro Amorim

Despite relying on operational excellence to survive, online grocers often fail by delivering orders that mismatch the ones requested. Few studies have evaluated how customers respond to such events in short-term. By analyzing the changes between subsequent orders, we quantify how customers defect. Our results show a reduction in spending immediately after a failure that increases with the number of failed items. We show the impact of failures depends on the type of failure, customer, and product category. Understanding the magnitude and timing of this reaction leads to personalized inventory management and compensation strategies with important consequences for customer satisfaction.

8 - Fractal Methodology to Explore the Long-Term Memory Behavior to Time Series of Space Data, Using the Hurst Index

Francisco Gerardo Benavides Bravo, Tecnológico Nacional de México, Guadalupe N.L., Mexico

When performing meteorological time series analysis, an important issue is the information underlying these. We use the Rescaled Range (R / S) methodology to explore the behavior of rainfall stations in the San Juan River basin (data provided by the National Water Commission (CONAGUA)) using the fractal exponent. The purpose is to explore the long-range condition, using different Hurst indicators to perform a classification.

Chair: Panagiotis Andrianesis, Boston University, Brookline, MA, 02446, United States

1 - Exploring a Farmer's Production Scheme under Production-dependent Contract Farming

Li-Ming Chen, National Chengchi University, Taipei, Taiwan

Farmers under poverty have the increasing desire of exploiting the new opportunity by farming for those who are socially responsible and willing to source from the poor. This work studies a poor farmer's production decision under production-dependent contract farming from which a farmer prioritizes the supply of goods to a responsible buyer. In return, he benefits from a high premium and guaranteed minimum of the buyers' procurement quantity. We formulate our problem as stylized periodic-review, finite-horizon dynamic programming models and analyze the model structure. We further conduct the numerical study to investigate a farmer's improvement on profitability.

2 - Corporate Social Responsibility and Firms' Resilience to Natural Disasters

Po-Hsuan Hsu, National Tsing Hua University, HSin Chu, Taiwan, pohsuanhsu@mx.nthu.edu.tw, Hsiao-Hui Lee, Long Yi

We propose that corporate social responsibility (CSR) serves as an intangible investment in stakeholder relationships to guard against natural disasters. We develop a stylized model to show that CSR investment, while costly, helps firms recover from natural disasters, thanks to customers' and employees' preferences for CSR. Using factory location data from the toxic release inventory database to specify firms' geographic distribution, we find that firms with higher CSR ratings are much less affected by natural disasters. We then examine the customer and employee mechanisms through which CSR engagement shields firms against natural disasters.

3 - How Does Range Limit Influence the Adoption and Expansion of Electric Vehicles? Evidence from a Commercial Operating Platform

Jingying Ding, Shanghai Jiao Tong University, Shanghai, China

Commercial vehicles such as taxis and buses have significant longer annual ranges than usual household vehicles, which also cause more environmental pressure. Electric vehicles (EVs) could address this problem effectively by reducing the emission of greenhouse gases but there are some difficulties in EVs expansion and development. We study whether range limits or range anxiety have an influence on drivers' adoption of EVs and withdrawal behaviors using a dataset from a commercial operating platform.

4 - Green Fleet Sizing and Routing for Profit Maximization

Isil Koyuncu, University of Alabama, Tuscaloosa, AL, United States, ikoyuncu@crimson.ua.edu, Mesut Yavuz

This talk presents a maximum profit mixed-fleet electric vehicle routing problem with traditional and electric vehicles. A set of customers are willing to pay a green premium to reduce their supply chain carbon footprint. We formulate the emerging rich VRP as a mixed integer linear program, and investigate its exact solution.

5 - Dynamic Pricing in Electricity Distribution Networks; New Business Model

Panagiotis Andrianesis, Boston University, Brookline, MA, 02446, United States, panosa@bu.edu, Michael C. Caramanis

Electricity distribution utilities are confronted today with great challenges resulting from the rapid introduction of Distributed Energy Resources (DERs). DER scheduling is bound to have a profound impact on the adequacy of assets, efficient grid operation, reliability, and security of supply. We claim that the spatiotemporal dynamics of the value of DER interactions with the grid is the key driver of optimal DER scheduling. We present a new business model based on dynamic pricing and optimal DER scheduling, which will bring about fundamental changes in distribution network investment planning, operation, and in current and future power markets.

Production and Scheduling

Contributed Session

Chair: wenjie Liu, Nanjing University of Aeronautics and Astronautics, Jiangning District, Nanjing, 210006, China

1 - Logic-based Benders Reformulations for Integrated Process Configuration and Production Planning Problems

Karim Perez Martinez, HEC Montreal, Montreal, QC, Canada, karim.perez-martinez@hec.ca, Yossiri Adulyasak, Raf Jans

This research addresses production planning problems where products of different types can be produced simultaneously according to a specific process configuration or pattern. The problem consists of determining the configurations to be used and the production level of each configuration to fulfill the demand at the minimum total cost, which typically includes setup costs, inventory holding or overproduction costs. We propose logic-based Benders reformulations and algorithms to optimally solve this problem in two industrial contexts: the steel industry and the printing industry. The proposed methods outperform the benchmark approaches in the tested problems.

2 - Optimal Sampling Plan of a Multistage Production System with Competing and Propagating Random Shifts

Sinan Obaidat, University of Arkansas, Fayetteville, AR, United States, sfobaida@uark.edu, Haitao Liao

This presentation addresses the problem of finding the optimal sampling policy of a multistage production system subject to competing and propagating random quality shifts. A two-unit serial production system that produces one type of product with a constant production rate is studied. The optimal sampling parameters: sample size, sampling interval, and acceptance threshold are determined by minimizing the long-run cost rate subject to the average time to signal a true alarm, effective production rate, and system's availability constraints.

3 - The Multi-Period Cutting Stock Problem with Diameter Conversion in the Construction Industry

Deniz Altinpulluk, Wayne State University, Detroit, MI, United States, deniz.altinpulluk@gmail.com, Haldun Sural

One-dimensional cutting stock problem has been widely used for reinforcement steel bar in the construction industry. Diameter size of a rebar is determined by structural designer to provide tensile strength to the structure and it can be changed if cross-section area per concrete area stays constant. We study the cutting stock problem that decides diameter size and cutting time and cutting patterns to minimize usage of raw material and holding cost. It differs from classical cutting stock as it is not known how many pieces should be cut until diameter sizes are chosen. We propose a pseudo-polynomial formulation and a genetic algorithm to solve the problem. Computational results are provided.

4 - Scheduling Optimization on Flexible Flow Shop Scheduling Based on a Hybrid Genetic Algorithm with Matrix Coding

wenjie liu, College of Economics and Management, Nanjing University of Aeronautics and Astronautics, Nanjing, China

Flexible flow-shop scheduling problem (FFSP) is a key issue for electronic assembly industry. To solve it, a scheduling optimization model is constructed first. A hybrid genetic algorithm (GA) adopting matrix coding is proposed to solve it by combining a GA with a heuristic rule of First In First Out. Finally, the proposed model and algorithm are used to a case of printer enterprise. Research results show: (1) Order completion time are shortened by more than 20%; (2) Equipment utilization rate rises sharply and exceed 85%. Main contribution of this paper is to yields an effective decision-making tool for FFSP in electronic assembly industry, and to provide an accurate and efficient scheduling solution.

1 - Auto Recognition with DNA Data for Stages of Osteosarcoma

Yuchen Wang, University of North Texas, Denton, TX, United States, yuchen.wang@unt.edu, Foad Hassanmirzaei, Robert Pavur

Osteosarcoma is the most common bone cancer, yet research on osteosarcoma stages prediction is scarce. The goal of this research is to simplify the diagnostic process using gene testing. For the business disciplines, this research optimizes diagnostic procedures by developing machine learning algorithms to identify cancer stages. The preliminary study uses DNA and clinical data sets from the TARGET database. The five predictive models developed in this study are highly precise. The results show that certain chromosomes are recognized as potential indicators of the cancer stages. These results could improve health management and lower costs.

2 - Big Data Excellence: A Framework for Sustained Performance

Mark Rodgers, Rutgers Business School, Newark, NJ, United States, mrodgers@business.rutgers.edu, Ajai Kapoor, Alok Baveja, Sayan Mukherjee

Businesses rush to implement big data and AI initiatives, often, without clarity on their business problems and the appropriate methodologies to deploy. Anchored in Information theory and relevance of a practitioner's quest for solving a business problem, we present a systematic framework to help managers identify the right question, find the relevant data, choose the appropriate methodology to extract information from data, and find actionable solutions. We also provide a prescriptive, Methodology-choice framework based on the predictability and adaptability of the system. Eleven case studies from various industries show the validity and applicability of the proposed framework.

3 - Leveraging Device Fingerprint Solution for Account Protection Service

Justin Wang, Microsoft, Redmond, WA, United States, justwang@microsoft.com, Jay Pillai

Device fingerprinting is a technique which is used by eCommerce merchants to recognize which devices their traffic is coming from. The technology is wildly used in account protection to prevent fraud. In practice, device fingerprinting solutions need to be implemented close to real time. With internet volume, matching one eCommerce event with the existing thousands of million devices in a few milliseconds is almost impossible. This talk we introduce a hierarchical partition design which can limit the number of matches needed to be evaluated for a given event, discuss how machine learning technology can be applied to improve decision quality and how we select data to train the machine learning models.

4 - Distributed Tensor Principal Component Analysis

Davoud Ataee Tarzanagh, University of Florida, Gainesville, FL, United States, Tarzanagh@ufl.edu, George Michailidis

Tensor PCA is a widely used dimension reduction technique with an extensive range of applications. In this paper, a distributed algorithm is proposed for recovering the principal eigenspaces. We further establish its rate of convergence and show how it relates to the number of nodes employed in the distributed computation, the effective rank of the data tensor under consideration, and the gap in the spectrum of the underlying population covariance tensor. The proposed algorithm is illustrated on low-rank approximation tasks. The numerical results show a substantial computational speed-up vis-a-vis standard tensor PCA algorithms, without compromising learning accuracy.

1 - Communication-constrained Expansion Planning for Resilient Distribution Systems

Geunyeong Byeon, University of Michigan, Ann Arbor, MI, United States, gbyeon@umich.edu, Pascal Van Hentenryck, Russell Bent, Harsha Nagarajan

Distributed generation and remotely controlled switches have emerged as important technologies to improve the distribution grids' resiliency against extreme weather events. Thus it is important to study how best to place them on the grid to meet resiliency criteria, while capturing their dependencies on communication systems. To address the need, this study introduces the Optimal Resilient Design Problem for Distribution and Communication Systems (ORDPDC) and proposes a Branch and Price algorithm (BP) for the ORDPDC. The ORDPDC and BP were tested on various test cases, and the results demonstrate the impact of network topologies on expansion plans and costs, and computational benefits of the BP.

2 - Multi Objectives Online Scheduling in a Vehicle to Grid System

Zihao Jiao, Beijing Institute of Technology, Beijing, China, Yanzi Zhang

In this paper, we study how to further improve the effectiveness of the vehicle-to-grid (V2G) system as a promising sustainable, flexible operation for the future by integrating energy-storage devices into a charging station with V2G function. Specifically, an integrated multi-objective optimization model is proposed to handle the charging station location, energy-storage device allocation, Electric vehicle charge and discharge scheduling problem in V2G operations. For motivating drivers to sell electricity, we also explore the effect of applying a flexible price framework in V2G operation.

3 - Strategic Microgrid Scheduling with DER to Enhance the Distribution Network Resiliency

Farhad Angizeh, PhD Student, Rutgers, the State University of New Jersey, Piscataway Township, NJ, United States, farhad.angizeh@rutgers.edu, Khashayar Mahani, Mohsen Jafari

In this research work, we aim at developing an operation scheduling model for microgrids with locally-owned distributed energy resources (DER) to enhance the distribution network resiliency. The proposed model, which is developed as a mixed-integer linear programming model, co-optimizes the operation schedules of various DERs, including emergency diesel generator (EDG), PV, combined heat and power (CHP), and energy storage system (ESS), to supply the microgrid demand under both normal and island operation modes. The proposed model enables the microgrid operators to capture flexibilities of DERs to enhance the network resiliency once the upstream grid reliability is jeopardized.

4 - Energy Consumption Based Rendez-vous Problem for Mobile Robots

Nazli Dolu, METU, Ankara, Turkey, ndolu@metu.edu.tr, Mustafa Kemal Tural

We study the problem of finding individual meeting (rendez-vous) points for a group of mobile robots to meet with the tanker robot for recharging by taking the energy consumption of the robots into account. The problem is examined under two different objective functions, one of them is minimizing the total energy consumption and the other is minimizing the total time spent until all the robots are recharged to a predetermined energy level. The energy consumption function of the robots cannot be formulated linearly so that we provide a second order cone programming (SOCP) formulation for the problem.

5 - Money Market for Energy Efficiency

Burcu E. Kose, Rutgers University, New Brunswick, NJ, United States, burcu.kose@rutgers.edu

Promoting energy efficient behavior in commercial and office buildings is a challenge for many building managers. This study explores incentivizing energy efficiency by creating a money market and awarding energy efficient behavior.

Simulation and Optimization I

Contributed Session

Chair: Debdatta Sinha Roy, University of Maryland, College Park, MD, 20742, United States

1 - Lightning Decisions: The United States Marine Corps F-35 Lightning II Maintenance Manning Dilemma

Matthew Hawks, Assistant Professor, US Naval Academy, Annapolis, MD, United States, mhawks@usna.edu

The United States Marine Corps is in the process of integrating the F-35B Lightning II to its fleet of war fighting platforms. Currently, there are questions about the manning of maintenance crews. We focus on optimizing the manning for the Marines attached to the squadrons by simulating maintenance events with current and variable crew allotments. The goal is to optimize maintenance crew numbers while completing required maintenance to maximize mission completion and overall operational readiness of the USMC.

2 - Shicap: A Methodology for Shipyard Facilities Capacity Planning Using DES

Alejandro Garcia del Valle, University of A. Coruna, A. Coruna, Spain, alejandro.garcia.delvalle@udc.es, Rouco Couzo Marcos, Quiroga Pazos Marta, Javier Faulin

The aim of the present work is to establish a methodology, using discrete event simulation, that will be used to determine the required capacity of a shipyard, currently planning to upgrade its facilities. Simulation proves that the existing premises are not sufficient to accommodate for future demand and therefore the required capacity is calculated. Additionally, a sensitivity analysis is conducted to evaluate how variability on critical activities durations would impact on the reliability of the results. Results will be showed for a real shipyard in Spain.

3 - Tree-search Based Bayesian Optimization Algorithms for Stochastic Simulations

Szu Hui Ng, National University of Singapore, Singapore, Singapore, isensh@nus.edu.sg, Songhao Wang

Bayesian optimization is an increasingly popular approach in stochastic simulation optimizations. In this work, we combine this approach with a tree-search partitioning technique. This helps to eliminate the non-trivial optimization of an acquisition function, which is important when we have time constraints on decision making with simulation. We propose a general framework and algorithm with convergence and finite-time regret guarantees. Different from the deterministic cases, here, decision on which node to expand and how to allocate computing budget to the nodes are necessary, and we discuss how these decisions affect the performance.

4 - Simulation Platform to Evaluate the Performance of Sorting and Retrieval Policies in a Logistic Services Container Terminal.

Juan Pablo Cavada, PhD Candidate, Universidad de Chile, Santiago, Chile, jucavada@ing.uchile.cl, Cristian Eduardo Cortes, Pablo Andres Rey

We present a type of depot for containers not commonly studied in the literature, which we call Logistic Services Container Terminal (LSCT).These are inland terminals where full and empty containers are not only stored by clients but also they require service to either the cargo or to the containers themselves. In this paper, we use a stochastic simulation framework to evaluate sorting policies in a LSCT, some of them taken from the literature and other proposed by us, ad-hoc to the features of these terminals and their peculiarities.

5 - Data Driven Optimization and Statistical Modeling to Improve Meter Reading for Utility Companies

Debdatta Sinha Roy, Robert H. Smith School of Business, University of Maryland, College Park, MD, 20742, United States, debsroy@rhsmith.umd.edu, Christof Defryn, Bruce L. Golden, Edward Andrew Wasil

Utility companies collect usage data from meters on a regular basis. Each meter has a signal transmitter that is automatically read by a receiver within a specified distance using radio-frequency identification (RFID) technology. In practice, there is uncertainty while reading meters from the planned routes of the vehicles. The RFID signals are discontinuous, and each meter differs with respect to the specified distance. These factors can lead to missed reads. We use data analytics, optimization, and Bayesian statistics to address the uncertainty. Simulation experiments using real data show that a hierarchical Bayesian model performs the best by designing improved routes for the vehicles.

Sustainability I

Contributed Session

Chair: Navid Sabbaghi, Saint Mary's College of California, Martinez, CA, 94553, United States

1 - The 'Degree-of-Health' Concept: Providing the Healthiest Route Through a City

Ben Desmet, Ghent University, Ghent, Belgium, bendsmet.desmet@ugent.be, Nils Van den Steen, Dirk Van den Poel

As urban living is slowly regaining popularity, cities have become ground zero for the struggle between on the one hand a desire for improved mobility and on the other hand increased attention for sustainability. We take a first step to address this. In order to stimulate active transport and inform about the healthiest route, we introduce degree-of-health as a concept. We show this metric is predictable over different timeframes by using sensor data from one of Belgium's largest cities. As proof of concept, the degrees of health of routes are calculated in a small, fictitious case study.

2 - Pricing-newsvendor Problem with Quality-sensitive Demand and Donations

Armagan Ozbilge, PhD Candidate, McMaster University, Hamilton, ON, Canada, ozbilgea@mcmaster.ca, Elkafi Hassini, Mahmut Parlar

Each year, millions of tonnes of foods are wasted causing economic, environmental and social misfortunes. Besides expired items, edible foods are often deliberately disposed of to attract quality sensitive consumers. In this paper, we introduce a quality-dependent newsvendor problem which takes true (effective) quality of the products into account to help food retailers reduce the food spoilage while retaining the profits. We discuss two cases: (1) joint ordering and pricing at the beginning of the period and (2) donation and repricing during the period. We show that donation can reduce waste and increase retailer's profits, with proper incentive mechanism.

3 - Sustainability-oriented Innovation Capabilities in Manufacturing Organisations

Budi Harsanto, University of Liverpool Management School, Liverpool, United Kingdom, harsanto.id@gmail.com
Budi Harsanto, Universitas Padjadjaran, Bandung, Indonesia, harsanto.id@gmail.com, Niraj Kumar, Yuanzhu Zhan, Roula Michaelides

Many companies recently giving increased attention to sustainability-oriented innovation (SOI) in response to a combination of stakeholder pressure and opportunity for growth (Geradts and Bocken, 2019). The aim of this study is to understand the capabilities needed to become a more sustainable innovator. A case study-based approach is employed by using the case of multi-industry manufacturing companies in Indonesia.

4 - Research on Stakeholders Identification and Analysis in Urban Low Carbon Development Project Based on Social Network Analysis Method

Fang Peng, College of Economics and Management, Nanjing University of Aeronautics and Astronautics, Nanjing, China

Urban Low Carbon Development Project(ULCDP) is rapidly advancing on a global scale which is comprehensive involving lots of stakeholders. Their cooperation directly contributes to the success of project. However, these stakeholders have different interest and positions, which leads to hierarchical influence in those projects. This paper proposes a systematic method for evaluating and analyzing the process of ULCDP from the perspective of stakeholders using Social Network Analysis method, and validates the feasibility of this method through case analysis.

5 - Community Contracts

Navid Sabbaghi, Faculty in Business Analytics, Saint Mary's College of California, Moraga, CA, United States

We consider a supply chain setting with a supplier and retailer where the economic benefits of the supplier's production are obtained by one community and where a separate community funds those benefits. We introduce and analyze the effect of contracts that enable the downstream community of consumers to also benefit.

Carbon Pricing in Electricity Markets

Sponsored: Energy, Natural Res & the Environment/Environment & Sustainability

Sponsored Session

Chair: Mort David Webster, Pennsylvania State University, University Park, PA, 16802, United States

1 - Carbon Pricing on Border Power Flows: The Impact on Investment, Operation and Emission Reduction

Qingyu Xu, Johns Hopkins University, Baltimore, MD, 21218, United States, qxu25@jhu.edu, Jing Peng, Benjamin Field Hobbs

To mitigate carbon leakage, jurisdictions with carbon pricing mechanisms can establish rules governing interactions with other jurisdictions. In the power sector, this usually involves pricing carbon on border flows. Different options for pricing have been proposed or implemented: based on the source, on the marginal emission rate (internal or external), or a fixed or time-varying deemed emission rate. Using JHSMINE, a generation-transmission expansion planning model, we explore the impact of such options on investment, operation, and emission reduction in the western US power system.

2 - Effect of Carbon Pricing on the Generation Investment Decisions of a Strategic Producer

Brayam Valqui Ordonez, M.S., Pennsylvania State University, State College, PA, 16801, United States, bdv3@psu.edu

This paper presents a bi-level optimization model to study the generation investment problem of a strategic producer under different carbon taxes. The upper level, which represents the strategic expansion decisions of a single producer, solves for the optimal investment and the lower level, which represents the ISO's problem, solves for the economic dispatch problems under different scenarios. This model is transformed into an MPEC and solved under different carbon taxes to determine how they impact strategic investment decisions.

3 - Multi-agent Reinforcement Learning for Evaluating Renewable Energy Policies: Impact of Energy Producer's Characteristics

Masaaki Suzuki, Tokyo University of Science, Chiba, Japan, m-suzuki@rs.tus.ac.jp, Mari Ito, Ryuta Takashima

Even as governments combat greenhouse emissions through a range of initiatives, research has not yet clarified how renewable energy policy, energy market structure, and number of energy producers impact social welfare. We model a deregulated market for electricity as a blind single-price call auction and construct a multi-agent system with reinforcement learning that facilitates more realistic market evaluations and observation of equilibrium processes. We then assess the market dynamics that specifically consider the diversity of agents' characteristics.

1 - Cyber Threats for Urban Distribution Systems: A Case of Manhattan

Yury Dvorkin, New York University, Metrotech Center, Fay Street, New York, NY, 11201, United States, dvorkin@nyu.edu

The roll-out of electric vehicles paves the way to a new cyber-physical attack vector that can be exploited by various state and non-state actors. Using the Borough of Manhattan, New York City, as our case study we demonstrate that malicious actors can collect sufficient information from open-source EV and power grid data sets and design a covert, dynamic cyber attack that is capable of causing instability in the 345 kV transmission network. Using a control- and system-theoretic framework, we analytically demonstrate that such attacks are robust to partial observability of the power system by the attacker and inaccurately approximated power system parameters.

2 - Transmission Expansion Model Considering Flexible Assets Based on AC OPF

Hrvoje Pandzic, University of Zagreb, Unska 3, Zagreb, 10000, Croatia, hrvoje.pandzic@fer.hr

The proposed methodology for transmission expansion planning problem considers investments in flexible assets, i.e. battery energy storage systems and thyristor controlled series compensators, and in traditional assets, i.e. transmission power lines. The proposed model uses a linearized form of AC OPF under Benders decomposition taking the perspective of the system operator.

3 - Robust Stability in Uncertain Power System Optimization Problems

Jianzhe Liu, Argonne National Laboratory, Lemont, IL, United States, jianzhe.liu@anl.gov, Chen Chen, Bo Chen

There is significant uncertainty in power systems where stability and constraint satisfaction are important concerns. Most existing optimization problems that involve uncertain power flows cannot provide stability guarantees. In contrast, our work studies a robust optimization formulation aiming to make both stability and other constraints satisfied. The need to consider uncertainty in the formulation results in a challenging semi-infinite program (SIP). The proposed algorithm reformulates the SIP into a computationally amenable form whose solution provides a feasible point for the SIP. The proposed algorithm is demonstrated using various modified IEEE test cases.

4 - Resilient Network Design of Electricity and Gas Networks

Russell Bent, Los Alamos National Laboratory, Lanl, Los Alamos, NM, 87545, United States, Pascal Van Hentenryck, Seth Blumsack

Recent trends in gas-fired power plant installation has increased the connections between the electric power and natural gas industries. Despite these dependencies commercial, political, operational and technical requirements can sometimes force these industries to plan and operate in isolation. As a result, undesired situations may arise where both systems experience simultaneous high demand that place unexpected stress on the systems (i.e., extreme cold weather events). In this talk, we discuss the technical challenges and present a combined network design planning model to improve the resilience of both system.

Learning and Control of Demand Response (DR) and Distributed Generation (DG)

Sponsored: Energy, Natural Res & the Environment/Energy

Sponsored Session

Chair: Andrew Liu

1 - Learning and Selecting Users for Achieving Reliability in Demand Response: A Multi-armed Approach

Yingying Li, Harvard University, Cambridge, MA, United States, yingyingli@g.harvard.edu, Qinran Hu, Na Li

Major challenges of residential demand response (DR) lie in the uncertainty and randomness of customer behaviors. To learn and select the right customers, we formulate the DR problem as a combinatorial multi-armed bandit (CMAB) problem with a reliability goal. We propose a learning algorithm: CUCBAvg (Combinatorial Upper Confidence Bound-Average), which utilizes both upper confidence bounds and sample averages to balance the tradeoff between exploration (learning) and exploitation (selecting). We study both time-invariant target and time-varying target and proves that CUCB-Avg achieves O(log T) and o(T) regrets respectively. Simulations further show the effectiveness of our algorithms.

2 - Decentralized Demand Response in Electricity Markets

Andrew Lu Liu, Purdue University, School of Industrial Engineering, West Lafayette, IN, 47907, United States, andrewliu@purdue.edu, Zibo Zhao

There has been a rapid growth of distributed energy resources (DERs) in power systems, which cannot be centrally controlled by a system operator. While real-time electricity pricing (RTP) could entice the DERs to act properly, since all DERs would receive the same price signal, naïve response would cause significant price volatility and system instability in real time. To avoid such a “herding” effect, we propose a multiarmed bandit (MAB) game framework in which each consumer employs a policy to minimize cumulative regret. Numerical results show fast convergence to a steady-state of the MAB game with much reduced price volatility and higher social welfare than the naïve-response case.

3 - Optimal Electricity Distribution Pricing under Risk and High Photovoltaics Penetration

Xinyue Song, Johns Hopkins University, Baltimore, MD, United States, xsong11@jhu.edu, Maxim Bichuch, Benjamin Hobbs, Yijiao Wang

We consider a reverse Stackelberg game in the electricity market between a centralized regulator and rational consumers with stochastic demand. A typical consumer is allowed to generate PV electricity to offset his power demand (and sell the excess back), and optimizes this decision to maximize his total utility from the income or bills. He affects the bulk market price, and hence all consumers, by contributing to the overall market demand. The regulator sets up distribution fees so as to recover grid maintenance costs and encourage PV penetration. We study the Nash equilibrium of generation decisions, and present data calibrated results on the coupled decision making of the consumers and regulator.

4 - Valuation of Flexible Energy Resources in a Nonbinding Commitment Transactive Energy Market

Somayeh Moazeni, Stevens Institute of Technology, Babbio Center, Hoboken, NJ, 07030, United States, smoazeni@stevens.edu, Boris Defourny

Current distribution systems cannot support simultaneous and identical actions of a large number of distributed flexible energy resources reacting to an identical signal. This talk presents a transactive energy market framework when their access to transactions is restricted. A nonlinear pricing structure incentivizes small transactions spread out among arrivals of operation opportunities. A self-exciting point process expresses operation permissions. The problem of optimal operations in this market to maximize the cumulated revenue is modeled as a piecewise deterministic Markov decision process. Various properties of the optimal value and sensitivity to market parameters are studied.

Chair: Saurabh Kumar, Indian Institute of Management Indore

1 - Extended Similarity Measures to Predict High Cost Patients in USA Medicare Advantage Plans

Michael Mannino, University of Colorado Denver, Denver, CO, United States, Michael.Mannino@ucdenver.edu, Joel Fredrickson

This research proposes similarity measures to predict high cost patients in USA Medicare Advantage plans. Classification of high cost patients helps determine cost reimbursement, target effort for care management, and identify patients with most serious conditions. We design and test nearest neighbor algorithms employing similarity measures derived from patient attributes and abstracted claims histories. The novel similarity measures use claims cost, partial matching of diagnosis codes, and diagnosis severity for each encounter in a claims history. We evaluate this new method against the CMS-HCC model, commonly used to perform large population risk prediction and cost adjustment.

2 - A Novel Metric for Search Engine Evaluation

Aarushi Jain, PhD Student, Indian Institute of Management-Indore, Indore, India, f17aarushij@iimidr.ac.in, Rajhans Mishra

Several researchers have compared various search engines and identified how one search engine is superior to others. In this work, a performance evaluation metric is prepared for three search engines i.e., Google, Yahoo, and Bing. Using the performance evaluation parameters Content Similarity, Domain Similarity, Structural Similarity, and Sequential Similarity, we found out which search engine provides better information on the basis of their similarity of content, their sequence of information, the positioning of websites on the internet, and the positioning of the anchor texts within a website.

3 - Read the News, Not the Books: Predicting Firms Financial Health

Sophie Zhai, Iowa State University, Ames, IA, United States, Drew Zhang

In this paper, we show that mining firm-related events in public news can effectively predict various firm financial ratios. By exploiting state-of-the-art neural architectures including pseudo-event embeddings, Long Short-Term Memory Networks, and attention mechanisms, our news-powered deep learning models are shown to outperform standard econometric models operating on precise historical accounting data. We also observe forecasting quality improvement in multi-task learning settings. Our forecasting models (and byproducts such as attention maps and firm embeddings) benefit various stakeholders with not only quality predictions but also explainable insights.

4 - Multivariate Adaptive Regression Splines Knot Selection and Global Optimization

Xinglong Ju, The University of Texas at Arlington, Arlington, TX, United States, xinglong.ju@mavs.uta.edu, Victoria C.P. Chen, Jay Michael Rosenberger, Feng Liu

Multivariate adaptive regression splines is a popular statistical modeling method. In the MARS model building process, knot positioning is a critical aspect that potentially affects the accuracy of the final MARS model. By exploring the lack-of-fit (LOF) function within MARS, we find that local optima from previous model building iteration are very close to those of the current iteration. In our approach, this prior LOF information is used to warm start a local optimization algorithm for knot positioning. A novel method is proposed to do global optimization analytically on two-way interaction truncated linear MARS by using mixed integer quadratic programming.

5 - Privacy Preserving Recommender Systems in Mobile Context Using Privacy Dashboard

Saurabh Kumar, Indian Institute of Management Indore, Indore, India, saurabhkumar@iimidr.ac.in, Mukul Gupta

The paper proposes a Privacy Preserving Recommendation Systems (PPRS) which focuses on providing the customised recommendations to the smartphone users without hampering the privacy of the users with the aid of privacy dashboard techniques. PPRS investigates how the location data of users is processed for generating personalised contents and advertisements for mobile devices. But the users will also have access to the information which they wish to share with the service providers. Together with the data practices and opt-out option, a simplified Privacy-Dashboard is proposed which have the option of controlling the access of information to any other third party.

Modeling and Control of Smart Manufacturing Systems I

Emerging Topic: Advanced Manufacturing

Chair: Feng Ju, Arizona State University, Tempe, AZ, 85281, United States

1 - The Joint Cognitive Work of Production Scheduling

Peter O. Denno, Researcher, NIST, Gaithersburg, MD, United States, peter.denno@nist.gov

Humans provide at least two unequaled abilities: a circumspect ability to interpret situations, and a generative ability to hypothesize about causality in the system. We use these abilities to step in when system behavior goes awry and to devise plans for a better system. Can we build systems around these abilities? I will take up this question in the context of production scheduling at small and medium-sized manufacturers, and discuss a methodology and tools to enable SMEs to pursue increasingly effective solutions to production scheduling problems.

2 - Real-time Control for Multi-stage Serial Production Line with Residence Time Constraints

Feifan Wang, Arizona State University, Tempe, AZ, 85281, United States, feifan.wang@asu.edu, Feng Ju

Potential quality problem may occur, and production cost may increase, if residence time of intermediate products is left uncontrolled. The real-time production control that guarantees a high production rate and small scrap rate is beneficial in practice. However, such a production control is difficult to derive due to the large state space of this problem. In this study, we propose a novel aggregation-based method for production control, and simulation study suggests that the proposed method can improve system performance with small computational cost.

3 - Throughput Improvement of Serial Production Lines via Downtime Reduction

Mengyi Zhang, Politecnico Di Milano, DIP. Meccanica, Milano, Italy, Andrea Matta

Throughput is one of the key performance indicators for manufacturing systems, and its improvement remains an interesting topic in both industrial and academic field. One way to achieve improvement is reducing downtime of unreliable machines. Under integrated simulation optimization framework, this paper develops Mixed Integer Linear Programming (MILP) models to improve system throughput by reducing downtime in the case of multistage serial lines. A variant of the proposed MILP can be used for the downtime bottleneck detection. Comparison with state-of-the-art approaches shows the effectiveness of the approach.

4 - Performance Evaluation of Queueing Networks with Nonstationary Demand, Part Priorities and Finite Buffers

Ronald G. Askin, Arizona State University, School of Computing, Informatics Engineering, Ira A. Fulton Schools of Engineering, Tempe, AZ, 85287-8809, United States, Ron.Askin@asu.edu, Girish Jampani Hanumantha

Manufacturing systems can be modeled as networks of queues, however models typically assume stationary arrival and processing rates. In this talk we present a computationally efficient approximation method for performance evaluation of queueing networks with known nonstationary arrival rates, controllable processing times (speeds and number of machines), part type priorities at workstations and finite staging buffers at workstations. Empirical results are shown for accuracy and computational time.

Chair: Tannaz Khaleghi

1 - Improving Surgical Service Operations Using Predictive Analytics

Tannaz Khaleghi, Wayne State University, Detroit, MI, 48201, United States, fj6710@wayne.edu

Surgery, intrinsically inherited by a set of vital activities which can be characterized by single or multiple codes, so-called Current Procedure Terminologies (CPT), that are maintained by the American Medical Association. CPT code identifies to insurance companies what type of care was provided. The surgery scheduler also forms the daily schedule based on case CPTs. In this study, we share our experience of an ongoing research to develop predictive models by text mining and machine learning tools to clean the unstructured surgery text, extract text features and predict the CPTs. We further highly value CPT codes as a key factor in estimating surgery duration more accurately.

2 - Prescriptive Analytics for Dynamic Task Assignment and Coordination of Inpatient Operations in Hospitals

Najibesadat Sadatijafarkalaei, Wayne State University, Detroit, MI, 48201, United States

Most hospital systems in the U.S. have employed some form of an Electronic Health Record (EHR) system in recent years to improve information flow and health outcomes. The information available in EHR systems can play a significant role in providing better coordination between different departments/services in the hospital through optimized task/resource allocation. We present a dynamic real-time coordination framework for resource and task assignment to establish automated coordination of health operations across emergency department (ED) and inpatient unit (IU) network. This research is in collaboration with Henry Ford Health System of SE-Michigan.

3 - Integrating Process Knowledge into Change Point Detection in Healthcare Systems

Suleyman Yildirim, Wayne State University, Detroit, MI, 48201, United States, suleymanyildirim@wayne.edu, Alper E. Murat, Murat Yildirim

Increasing complexity of modern systems require dynamic simulation models that update based on real-time data. The primary goal of this research is to propose a simulation framework that discovers and adapts to dynamic process knowledge of complex healthcare systems. We develop machine learning based discovery and calibration methods that integrate time series based Artificial Neural Network with Change Point Detection algorithms. The proposed framework achieves significant improvements in prediction accuracy, and provides an extensive basis for automated discovery of process knowledge in a general class of complex systems.

1 - Bootstrap-Based Exploration for Continuous Space Reinforcement Learning

Mohamad Kazem Shirani Faradonbeh, University of Florida, Gainesville, FL, United States, mfaradonbeh@ufl.edu, Ambuj Tewari, George Michailidis

In decision making problems for continuous state and action spaces, linear dynamical models subject to quadratic cost functions capture a large number of applications. Recent approaches in reinforcement learning employ randomized policies to address the trade-off between exploration and exploitation. One such policy prescribes to do the exploration through bootstrapping observed states and actions. We show that bootstrap-based policies achieve a square root scaling of regret with respect to time, and also specify the accuracy of learning the model. Further, we study robustness of the proposed adaptive policy to unknown and sudden changes in the dynamical model.

2 - Interior Point Methods with Adversarial Networks

Rafid Mahmood, University of Toronto, 3831 Janice Drive, Toronto, ON, L5M 7Y6, Canada, rafid.mahmood@mail.utoronto.ca, Aaron Babier, Adam Diamant, Timothy Chan

We consider a data-driven framework for learning to generate decisions for continuous optimization problems containing constraints that: (i) are not a priori specified, and (ii) vary with an instance-specific input. Our approach uses two machine learning models. The first is a feasibility classifier; we use it as a barrier function in an interior point method (IPM) to train the second model to generate decisions. In this work, we first develop optimality theory for IPMs when given a barrier that relaxes the feasible set, which we extend to probabilistic guarantees for learning. Finally, we implement our methods to predict personalized radiation therapy treatment plans in head-and-neck cancer.

3 - A Hierarchical Framework for Fair Data-driven Decisions

Mahbod Olfat, PhD Student, University of California-Berkeley, Berkeley, CA, 94702, United States, molfat@berkeley.edu, Anil Aswani

A trend in recent approaches to algorithmic fairness has been to make modifications to the optimization through which training is done itself, as opposed to modifying the data inputs or predictions output. We argue that all major notions are actually forms of robust conditional independence, and design a hierarchical optimization framework that can approximate such independence constraints using existing optimization tools. We also provide mechanisms for efficiently solving lower orders of the hierarchy, and present empirical results on a number of datasets.

4 - Safety Evaluation of Black-box Prediction Models via Rare-event Simulation

Zhiyuan Huang, University of Michigan, Ann Arbor, MI, United States, zhyhuang@umich.edu, Ding Zhao, Henry Lam

We study the design of good importance samplers to simulate the probability that a black-box predictor, built for instance from machine learning tools such as neural networks and random forests, outputs an exceedingly high prediction value. This problem is motivated from robustness and safety estimations that arise in recent applications of autonomous vehicles and other physical systems. Our approach utilizes mixed integer programming and a "cutting plane" approach to sequentially locate dominant points that guide the tilting of distributions in the importance samplers.

1 - Socially Optimal Contracting Between a Regional Blood Bank and Hospitals

Tharanga Kumudini Rajapakshe, University of Florida, Gainesville, FL, 32608, United States

Motivated by the operational challenges faced by a Regional Blood Bank (RBB) in distributing the blood among the hospitals in its service area, we study socially optimal contracting decisions of an RBB serving multiple hospitals. In the face of supply uncertainty, hospitals tend to over-order to compensate for a potential supply shortfall. We model the blood bank as a social planner with the objective of minimizing the total cost of shortages and outdates throughout the supply chain. We show that if the blood bank offers a suitable per unit subsidy for every unit of shortage experienced by a hospital, then hospitals would be induced to report demand to the blood bank without inflation.

2 - Analysis of Hospital-physician Gainsharing Contracts

Mili Mehrotra, University of Illinois at Urbana Champaign, Champaign, IL, 55455, United States

Under Episode-based Payment Models (EPMs), CMS allows a hospital to share gains/losses from reconciliation process and/or from its internal operations to incentivize physicians to select a treatment option that will improve quality and reduce cost. In this paper, we consider a class of linear gainsharing functions and study the impact of the stop-loss and stop-gain provisions imposed by CMS, the maximum savings potential, and the risk preferences of the hospital and physicians on gainsharing and the choice of treatment options.

3 - Designing Safe and Scalable Precision Medicine Supply Chain: Evaluating the Implementation of Guidelines

Jingwen Yang, PhD Student, Carlson School of Management, University of Minnesota, Minneapolis, MN, United States, yang5435@umn.edu, Anant Mishra, Kingshuk Sinha

Motivated by the challenges of integrating precision medicine based care into routine clinical practices, we empirically examine the effect of CPIC guidelines on building a safe and scalable precision medicine supply chain. The analysis is based on a sample of 26 FDA approved psychiatric precision medicine drugs. The results indicate that CPIC guidelines are associated with increased safety and scalability of precision medicine supply chain for psychiatric care delivery.

4 - Models for understanding Benefits-Value-Advisor (BVA) Program

Jingyao Huang, University of Texas at Austin, Austin, T X. 7870, Austin, TX, 78705, United States, jingyao.huang@mccombs.utexas.edu, Diwakar Gupta

We use a game-theoretic model to investigate providers' price and quality decisions under the Benefits-Value-Advisor (BVA) program, which is aimed at reducing the cost to self-insured employers of shoppable medical services. Under BVA, patients can call a consultant to get cost and quality information about in-network providers. BVA adds value by lowering members' search costs and by lowering insurer's cost via price transparency and gentle nudging. We are interested in two questions: (1) How will providers set price and quality levels in response to the BVA program? (2) What combinations of incentives, penalties, and payment regimes should the insurer use to lower cost and improve quality?

1 - Brand Personality Congruity on Social Media: The Impact of Brand-Consumer Personality Distance on Electronic Word-of-Mouth (eWOM)

Arnold Dongwoo Chung, The University of Texas at Austin, Austin, TX, United States, adwc86@utexas.edu, Yoonhi Sung, Hyunsang Son, Joshua Ryoo

This study explored messages both from brands and consumers on Facebook based on Aaker's (1997) brand personality dimensions and to look into the impact of brand-consumer personality congruity on electronic word-of-mouth. All of the existing brand messages were collected from the 2015 Interbrand 100 brands' Facebook pages. For the consumer-generated messages, messages of the top 25 comments of each brand message were collected. The findings showed the extent to which brand messages were congruent with consumer comments for each brand. In addition, the results suggested that congruity between brand messages and consumer comments was positively correlated with the total number of comments.

1 - Energy Exchange Traded Funds Jump Effects with Hawkes Processes

Steve Yang, Stevens Institute of Technology, Babbio Center, Hoboken, NJ, 07030, United States, steve.yang@stevens.edu

In this study, we focus on the Exchange Traded Funds (ETFs) in the energy sector and conduct a high frequency data modeling on their return jumps based on Hawkes Processes. It is known in the current literature that energy ETFs returns are highly correlated with equity market performance in general. We construct two multivariate Hawkes processes to examine the self and cross excitation effects of future indices and three different types of ETFs. We show that both the oil and S&P 500 future indices lead the ETFs return jumps. Moreover, the Master Limited Partnership (MLP) ETFs have least influence from the future indices compared with other energy ETFs.

2 - The Primacy of Numbers in Financial and Accounting Disclosures: Implications for Textual Analysis Research

Federico Siano, Boston University - Questrom School of Business, Boston, MA, United States, fsiano@bu.edu

Numbers are central to financial and accounting disclosures, yet current textual analysis research dissociates words and numbers, or ignore numbers altogether, within disclosures. We hypothesize and show that the prevalence of numbers within a corporate disclosure is highly correlated with the readability of the disclosure. More importantly, we show that prior findings on the links between disclosure readability and various economic outcomes are explained by the prevalence of numbers within the disclosures. We discuss implications for past and future research that attempts to analyze the determinants, attributes and outcomes of financial and accounting disclosures.

3 - Trader Behavior Detection Using Reinforcement Learning

Xiaodi Zhu, Assistant Professor, New Jersey City University, Jersey City, NJ, 07030, United States, xzhu@njcu.edu, Xugong Li

Stock traders apply different strategies to make trading decisions. However, some traders try to make profit by manipulating the price of securities, such as spoofing and pinging trading. Detecting improper trading behaviors is crucial to brokers and regulators. This paper considers trading behavior as a Markov decision process and applies reinforcement learning framework to analyze different behaviors. We further distinguish normal trading and improper trading behaviors using clustering algorithm. This model tends to contribute to automatic trading behavior detection system that benefits market regulators and broker companies.

1 - A General Dual Sourcing Inventory Model: Trading Off Lead Time and Cost Differences

Zhe Liu, Imperial College London, 3022 Broadway, London, 10027, United Kingdom, Awi Federgruen, Lijian Lu

We study a single product, periodic review inventory system with two suppliers and salvage options. A regular supplier has a longer lead time but is cheaper than an expedited supplier. Salvage options allow for bilateral inventory adjustments. All inventory adjustments involve a fixed cost component in addition to variable costs or revenues and may be capacitated. We show that the optimal order sizes and/or salvage quantity follow a relatively simple structure. This applies when the lead times of the two suppliers differ by a single period. However, our structural results suggest effective heuristics for general lead times and demonstrate the significant benefits of dual sourcing.

2 - Learning-based Approach for Combined Set Covering and TSP

Yuwen Yang, University of Pittsburgh, Pittsburgh, PA, 15213, United States, yuy49@pitt.edu, Bo Zeng, Jayant Rajgopal

Last-mile vaccine delivery can be complex in regions with geographically dispersed and nomadic populations, and outreach is utilized to raise immunization rates. A set of population centers is chosen, and over a suitable time horizon, clinicians are sent from a depot to set up mobile clinics to vaccinate surrounding areas. The optimization model for this results in a combination of a Set Covering problem and a TSP. Repetitively solving this via MIP could be computationally expensive, and we explore Machine Learning as a way to effectively deal with the problem. The proposed framework is to establish supervised models that generate solutions with minimum total cost.

3 - Dynamic Car Planning

Huichiao Jen, CSX, 500 Water St, Jacksonville, FL, 32202, United States, Jerry Kam

Rail car planning is a challenge problem for railroad. Railroad would like to know how many cars will arrive in each station in order to have better resource planning especially at the interchange stations. Rail cars come from foreign railroad to CSX network with very short notification before they enter CSX network. This study uses offline event data that receive from foreign railroad to build a machine model which estimate travel time between foreign (intermediate) location and CSX interchange location once the rail cars depart from foreign original locations and toward to CSX interchange location.

4 - Forecasting Statistical Distribution of Retail Demand by Pattern Mining of Historical Prediction Residuals and Modeling Error

Kin Ming Kam, JD.com, BDA, Beijing, 100176, China, jerrykam@hotmail.com

This presentation is about a data mining research on distribution forecasting which supports inventory management in a retail giant in China. The inventory replenishment and reallocation do not only need the most probable demand but also the statistical distribution of the demand. In the tasks of inventory optimization, we want to have enough safe stocks to avoid out-of-stock while keeping the inventory level at the minimum. So, instead of the most probable value, we in fact want a percentile, e.g. 95th percentile, of the prediction based on the uncertainty of the prediction result. To forecast the future distribution of the forecast, we leverage the historical residual and training error.

1 - A General Theory of Non-Markovian Consistent Planning

Camilo Hernández, Columbia University, New York, NY, United States, camilo.hernandez@columbia.edu

We develop a theory for continuous-time non-Markovian stochastic control problems which are time-inconsistent (P). For these problems the classical dynamic programming principle (DPP) do not hold. We a sophisticated agent seeking for consistent plans. We introduce a new definition of equilibrium that allows us to prove an extended DPP. Consequently, we pose a system of BSDEs (H) and obtain a verification result. Moreover, (H) is also necessary for (P). This is, given an equilibrium it must necessarily maximise the Hamiltonian of (H) and the associated value function induces a solution to (H). We also provide a well-posedness result in the case of uncontrolled volatility.

2 - Contract Theory in a VUCA World

Nicolás Hernández, University of Michigan, Ann Arbor, MI, United States, nihernan@umich.edu, Thibaut Mastrolia

In this paper we investigate a Principal-Agent problem with moral hazard under Knightian uncertainty. We extend the seminal framework of Holmström and Milgrom (1987) by combining a Stackelberg equilibrium with a worst-case approach. We study a general model in the spirit of Cvitani , Possamaï, and Touzi (2017). We show that optimal contracts depend on the output and its quadratic variation by extending Mastrolia and Possamaï (2018) and Sung (2018). We compute the optimal effort of the Agent through the solution to a second order BSDE and we show that the value of the problem of the Principal is the viscosity solution of a Hamilton-Jacobi-Bellman-Isaacs equation, by using stochastic Perron's method.

3 - Rational Inattention and Dynamic Discrete Choice

Hao Xing, Boston University, Boston, MA, United States, haoxing@bu.edu, Jianjun Miao

We adopt the posterior-based approach to study dynamic discrete choice problems with rational inattention. We show that the optimal solution for the Shannon entropy case is characterized by a system of equations that resembles the dynamic logit rule. We propose an efficient algorithm to solve this system and apply our model to explain phenomena such as status quo bias, confirmation bias, and belief polarization. A key condition for our approach to work in dynamic models is the convexity of the difference between the discounted (generalized) entropy of the prior beliefs about the future states and the entropy of the current posterior.

4 - Demand-response Management for Mean-field Electricity Consumers

Dylan Possamaï, Assistant Professor, Columbia University, New York, NY, United States, dp2917@columbia.edu

We study the problem of demand response contracts in electricity markets, considering a mean-field of consumers. We formulate the problem as a Principal-Agent problem with moral hazard in which the Principal is an electricity producer who observes continuously the consumption of a continuum of risk-averse consumers, and designs contracts in order to reduce her production costs. We prove that the producer can benefit from indexing contracts on the consumption of one Agent and aggregate consumption statistics from the distribution of the entire population of consumers. In the case of linear energy valuation, we provide closed-form solutions.

1 - A Closed-loop Stencil Printing Control System Using a Hybrid Online Learning and Heuristics Approach

Hongya Lu, Binghamton University, Binghamton, NY, United States, hlu26@binghamton.edu, Haifeng Wang, Sang Won Yoon, Daehan Won

This research aims to develop a dynamic optimization model performing real-time control of a stencil printing process (SPP) by maintaining optimal printer parameter settings. To improve the SPP system performance in a dynamic environment, this research proposes an online optimization model by using online learning to predict real-time SPP status and the Evolutionary Search (ES) to determine optimal settings. From the model selection from the online based learning, a multi-layer Online Sequential Extreme Learning Machine shows high accuracy. From the real implicational results, the proposed SPP system shows outstanding results in Cpk, promising the potential of online learning in SMT control.

2 - Predicting Combat Outcomes in Real-time Strategy Games Using Deep Learning

In Sung Baek, Korea University, Seoul, Korea, Republic of, insung.baek01@gmail.com, Seoung Bum Kim

Predicting intermediate combat results in real-time strategy games such as StarCraft II is one of the most important issues because the combination of various battle outcomes eventually determines the final winner of the game. However, in StarCraft II, it is difficult to predict battle outcomes because of numerous factors including the diversity of units, the diversity of unit combinations, and unit upgrades. In this study, we propose a game result prediction model based on deep learning approaches.

3 - Breaking Through Barriers to Deep Learning Adoption in Customer Behavior Modeling

Mustafa Murat Arat, University of Tennessee, Knoxville, Knoxville, TN, United States, marat@vols.utk.edu, Michel Ballings, George Miller Moore

The purpose of this study is to subject to scrutiny commonly held beliefs that are precluding the adoption of deep learning in customer behavior modeling. We provide the following collection of conjectures: deep learning methods (i) will fit spurious relationships, (ii) are better at predicting than standard linear models, (iii) are black box and cannot be used for explaining, (iv) they cannot do joint estimation or fit random effects, and (v) are too expensive and difficult to make them work. We provide mathematical, visual, and textual explanations to refute these beliefs and deliver a proof of concept in the form of a case study on customer lifetime value modeling using deep learning.

4 - Using Artificial Intelligence and Natural Language Processing to Predict Alzheimer's Disease

Maryam Zokaeinikoo, Pennsylvania State University, State College, PA, United States, mzz30@psu.edu

Automatic diagnosis of Alzheimer's disease and dementia can help with early detection of these diseases. We propose different neural network models based on Long Short Term Memory networks (LSTM) to detect the onset of Alzheimer's early in the course of the disease using textual data from both healthy subjects and patients. These models include LSTM networks, bidirectional LSTM (BLSTM), bidirectional LSTM with attention layer (Attention-BLSTM), Multi-head attention, Adversarial and bidirectional LSTM with conditional random fields layer (CRF-BLSTM).

5 - Surface Roughness Prediction Modelling for 3d Printed Parts

Md Shahriar J. Hossain, Assistant Professor, Northwestern State University, Natchitoches, LA, United States, msjhossain1@gmail.com, Jafar Al-Sharab, Curtis Desselles

Surface roughness (SR) is viewed as a crucial quality aspect of 3D printed models in fused deposition modeling (FDM) technology. In FDM, SR depends on several system parameters including build angle, layer thickness, temperature, % infill and feed rate. An efficient prediction model is required for presetting the parameters that can result a desired SR. In this research, a data driven artificial intelligence-based prediction model is proposed. Taguchi design of experiment is followed in data collection. These data are further used for training ANN, ANFIS and multiple regression models. The best model is selected based on minimum mean square error generated in the k-fold cross validation.

1 - Personalize Weight-loss Goals on Online Healthcare Platforms: A Multi-arm Bandit Approach with Dynamic Discrete Choice Scheme

Tongxin Zhou, University of Washington, Seattle, WA, 98105, United States, Yingfei Wang, Lu Yan, Yong Tan

Many online healthcare platforms provide patients with healthcare interventions. However, implementing healthcare interventions is still challenging in practice. First, healthcare intervention needs to be assessed for each individual as healthcare is highly personal. Second, adequate information is required in order to deliver effective interventions, which brings challenge to newly-started platforms. To address these challenges, in this study, we propose a Multi-armed bandit (MAB) approach for offering healthcare interventions. In evaluating the effectiveness of the MAB approach, we further establish a structural model to depict individuals' healthcare decision making.

2 - understanding and Predicting Individuals' Future Success – A Social Capital Perspective

Zhiya Zuo, City University of Hong Kong, Kowloon, 52240, Hong Kong, zhiyazuo@gmail.com, Kang Zhao

In this study, we investigate individuals career success trajectories from a social capital perspective. For early- and mid-career professionals: (i) experience with high-standing colleagues is a consistent predictor for future attainments; (ii) being a broker who connects various communities, though no immediate effects, is a signal of long term success. For senior professionals, building new ties with high-standing colleagues is a minute yet significant predictor for future impact. Findings provide implications for hiring organizations and individuals strategically planning career paths.

3 - Online Interactions and the Spatial Diffusion of Crowdfunding

Keongtae Kim, Chinese University of Hong Kong, Shatin, Hong Kong, keongkim@cuhk.edu.hk, Jooyoung Park, Sunil Mithas

This study documents the role of online social interactions in the diffusion of crowdfunding. Using the data on the creation of crowdfunding projects from 2009 to 2013 and Facebook Social Connectedness Index Data, we find that the number of crowdfunding projects in an area is positively associated with the number of prior crowdfunding projects from areas that are online socially connected. The association is stronger when considering large, successful projects. The peer effect from the socially connected areas becomes larger as the crowdfunding adoption from geographically proximate areas increases. Last, the influence of virtually connected areas is stronger for areas that are well off.

4 - Against Voting? The Crowd Classification Problem

Joshua Becker, Kellogg School of Management, Evanston, IL, United States, joshua.becker@kellogg.northwestern.edu, Douglas Guilbeault, Edward Smith

Decades of research has shown that information exchange improves group judgments. However, we show both theoretically and experimentally that this effect is limited to numeric judgments. In discrete choice estimates, also known as classification tasks—e.g. yes/no decisions, or selecting between two options—social influence simply amplifies the majority, regardless of accuracy. Thus inaccurate groups become less accurate but show greater consensus. Surprisingly, even when people exchange numeric estimates before voting, the vote becomes less accurate even as the average estimate becomes more accurate. These results point to the need for a contingency theory of collective intelligence.

1 - Influence Maximization with Stubborn Agents under Time-varying Dynamics

David Scott Hunter, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States

We consider the problem of optimizing the placement of stubborn agents in a social network in order to maximally influence the population. To model the opinion of the agent's in the network, we propose a new opinion dynamics model that is motivated by research in psychology. Under this model, we consider maximizing the mean opinion and also maximizing the number of individuals whose opinion exceeds a fixed threshold. We consider applying our methods on real social network in Twitter with hundreds of thousands of individuals.

2 - Assessing the Impact of Bots on Opinions in Social Networks

Nicolas Guenon des Mesnards, Massachusetts Institute of Technology, 143 Albany St, Cambridge, MA, 02139, United States

We develop a method to assess the impact of bots in social networks. We assume user opinions are in an equilibrium based on a generalized opinion dynamics model with stubborn users who have immutable opinions. We use an algorithm based on the Ising model to identify bots in networks and calculate the equilibrium mean opinion with and without the bots. The shift in this mean provides a measure of the impact of the bots. We apply our method to Twitter users discussing Brexit and the Gilets Jaunes protests. We find that the bot impact varies greatly in these datasets.

3 - Running Influence Campaigns on Social Media

Tauhid Zaman, MIT, Boston, MA, 02114, United States

We conduct a field experiment in Twitter to understand how to influence users on the topic of immigration. We consider to what degree the opinions of Twitter users can be influenced by mutual followers. We consider how the effectiveness of influencers vary across several dimensions including race, shared group identity, and social rapport between users. We measure influence through the change of language used by the subjects on social media. Through this, we draw conclusions on the effectiveness of peer influence on Twitter in changing opinions on a politically heated topic.

4 - Twitter-based Cyber Security Warning and Prioritization System

Enhao Liu, Graduate Research Associate, Ohio State University, Columbus, OH, United States

Cyber vulnerability management continues to be an important topic in companies even with the emphasis on resilience. Using Twitter predictions of local incident counts in advance are possible from time series models. Also, classification models can identify the likely key vulnerabilities involved. We describe briefly the models, features, and implications.

Queueing Approximations and Strategic Queues

Sponsored: Applied Probability

Sponsored Session

Chair: John Hasenbein, University of Texas-Austin, Austin, TX, 78712-0292, United States

1 - A Fluid-diffusion-hybrid Limiting Approximation for Priority Systems with Fast and Slow Customers

Lun Yu, Northwestern University, Evanston, IL, 60208, United States, Seyed Iravani, Ohad Perry

Motivated by emergency departments, we consider a priority queueing system with two customer classes; the first class (of "high acuity") requires long service times and receives priority over the second class (of "low acuity"), whose average service times are substantially shorter. Unfortunately, the dynamics of such a system are intractable, and existing heavy-traffic regimes cannot capture the fact that, in practice, a non-negligible proportion of the arrivals from either class must wait for service. We propose a Fluid-Diffusion Hybrid limit to approximate the two queues, and demonstrate how it can be employed to study the benefits of de-pooling (namely, of having a "fast-track").

2 - Dynamic Pricing in a Robust Naor's Model

John Hasenbein, University of Texas-Austin, 1 University Station Stop C2200, Department of Mechanical Engineering, Austin, TX, 78712-0292, United States, jhas@mail.utexas.edu

We investigate a version of Naor's model with dynamic pricing, heterogenous customers, and an uncertain arrival rate. We solve the pricing problem from a robust viewpoint, in the process developing robust Bellman equations and a modified value iteration algorithm.

3 - The Supermarket Game with Finitely Many Servers

Ran Snitkovsky, Tel Aviv University, Tel Aviv, 6997712, Israel, ransnit@gmail.com, Hassin Refael

Homogeneous customers with exponentially-distributed service demand arrive following a Poisson process at a service facility with N different single-server queues. Upon arrival, each customer randomly inspects a given number out of the N queues and joins the shortest one. Customers incur a fixed inspection cost per queue and linear waiting costs, and wish to minimize their total expected cost. Xu and Hajek (2013) named this model the Supermarket Game and applied a mean field approach to study the game when the number of servers, N, approaches infinity. We discuss the case of finite N and in particular, derive analytic results for N=2.

4 - Effects of Patient Heterogeneity on the Patients' Choice in a Transplantation System

Chia-Hao Chang, The University of Texas at Austin, Austin, TX, United States, chchangkh@utexas.edu, John Hasenbein

In this work, we study the patient's strategic behavior in a transplantation system. Specifically, we model the system as an M/M/1 queue, where both patients and organs arrive as a Poisson process. Each patient is allowed to accept or decline an organ offer in his own interest. In this regard, the problems is modeled as a Markov decision process. We study how the patient's heterogeneity may influence each individual's decision. We also compare how different system parameters may affect the patient's choice.

Stochastic Networks Asymptotics

Sponsored: Applied Probability

Sponsored Session

Chair: Rami Atar, Technion, Haifa, 32000, Israel

1 - Heavy Traffic Limit for Ridesharing Systems

Amir A. Alwan, PhD. Student, University of Chicago Booth School of Business, Chicago, IL, United States, amir.alwan@chicagobooth.edu, Baris Ata

We model a ridesharing system as a queueing network with service and travel nodes, where service nodes correspond to regions of the city and travel nodes help model travel time between service nodes. We establish a heavy traffic limit for the system state.

2 - Many-server Asymptotics for Join-the-shortest-queue: Large Deviations and Rare Events

Eric Friedlander, University of Chicago, 110A Crest Street, Chicago, IL, 27510, United States, efriedlander@uchicago.edu, Amarjit Budhiraja, Ruoyu Wu

We study the Join-the-Shortest-Queue load balancing policy in an asymptotic regime where the number of processors, n, scales with the arrival rate. Letting Xin(t) denote the proportion of queues with i or more jobs at time t, we establish a large deviation principle (LDP) for Xn=(X1n, X2n, ...), as n ∞. Some of the technical obstacles in the proof will be discussed, as well as implications of the result. In particular, we address how the LDP can be used to estimate rates of decay for probabilities of rare-events, such as long-queues.

3 - Functional Limits for Markov Modulated Stochastic Fluid Flow Models

Harsha Honnappa, Purdue University, West Lafayette, IN, 47906, United States, honnappa@purdue.edu, Prakash Chakraborty

We propose a model of a stochastic fluid flow system where the cumulative stochastic fluid input is modeled by the integrated number of occupied servers of a loss model with non-stationary and Markov modulated arrivals. General service times and the fixed system size pose serious challenges in analyzing server occupation, and forms a complicated interacting particle system. Under mild conditions we obtain functional fluid and diffusion limits as the system size scales to infinity for the number of occupied servers in the loss system and the corresponding integrated process. Our results also suggest a propagation of chaos type result suggesting asymptotic independence of the servers.

4 - Robustness via Renyi Divergence, with Applications to Queueing

Rami Atar, Technion, Department of Electrical Engineering, Haifa, 32000, Israel

This talk describes a recently developed approach to large deviation (LD) estimates on probabilistic models that are uniform within families of underlying probabilistic primitives. The approach is based on defining these families in terms of Renyi divergence. Advantages of the approach are that it (1) provides effective bounds on hard models (including ones for which the LD principle is not known to hold), (2) explicitly quantifies robustness of these estimates to distributional perturbations. After the introduction of the main ideas, the talk will focus on applying them to queueing models. The talk is based on joint work with Amarjit Budhiraja, Paul Dupuis and Ruoyu Wu.

1 - Non-parametric Up-and-down Experimentation Re-revisited

F. M. Spieksma, Leiden University, Leiden, Netherlands, Sheldon M. Ross, Michael N. Katehakis

We consider an experiment that can be run at levels 1, 2, ..., n. When it is run at level i it is a success with probability p_i, where the p_i are increasing in i, and unknown. In applications, p_i might be the cure probability when i units of a medication are used. We are interested in the smallest dosage i^* with a cure probability that is greater than a fixed target value. We discuss alternative sequential estimation methods of i^* with fast convergence properties.

2 - Some New Policies for Selecting the Best Population

Sheldon M. Ross, Universit of Southern California, Los Angeles, CA, 90089, United States, M. Javad Azizi, Y. .Cao

We consider the problem of selecting the best population, both in the Bernoulli and normal case. One objective considered is to minimize the expected selection time subject to an upper bound on the probability of making a wrong choice; another is to maximize the probability of correct choice when the time horizon is fixed.

3 - Fatou's Lemma in its Classic Form for Varying Measures with Applications to MDPs

Yan Liang, University of Toronto, Toronto, ON, Canada, Eugene A. Feinberg, Pavlo O. Kasyanov

This paper provides sufficient conditions when Fatou's lemma holds in its classic form for a sequence of weakly converging measures. In general, Fatou's lemma for a sequence of weakly converging measures states a weaker inequality than the classic one because the integral of the lower limit should be replaced with the integral of the lower limit in two parameters, where the second parameter is the argument of the functions. The obtained results are used to prove broad sufficient conditions for the validity of optimality equations for average-cost Markov decision processes. In particular, these conditions hold for classic inventory control problems.

4 - Accelerated Linear Convergence of Stochastic Momentum Methods in Wasserstein Distances

Mert Gurbuzbalaban, Rutgers University, Newark, NJ, United States, Bugra Can, Lingjiong Zhu

Momentum methods such as Polyak's heavy ball (HB) method, Nesterov's accelerated gradient (AG) as well as accelerated projected gradient (APG) method have been commonly used in machine learning practice, but their performance is quite sensitive to noise in the gradients. We study these methods under a first-order stochastic oracle model where noisy estimates of the gradients are available and obtain a number of fast convergence results in the Wasserstein metric for both stochastic convex and strongly convex optimization.

Adaptive Analytics: Effects on Business and the Supply Chain

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Clark C Pixton, Brigham Young University, Brigham Young University, Provo, UT, 84601, United States

1 - Variance-Damping or Variance-Amplifying? A Look at Analytics in the Supply Chain

Clark C. Pixton, Brigham Young University, Provo, UT, 84601, United States, cpixton@byu.edu

We introduce a framework, based on the stochastic optimization paradigm, which allows for analysis of the externalities of implementing adaptive analytics. Specifically, we show that when feature-based prediction becomes an input into a decision process, such as an order quantity or pricing decision, it may have either a positive or negative effect on upstream decisions. We discuss operational and strategic implications.

2 - Double Dipping of Two-Sided Platform Economy

Satyanath Bhat, National University of Singapore, Singapore, satya.bhat@nus.edu.sg, Jussi Keppo, Chung Piaw Teo

The role of platforms in breaking traditional monopolies, creating new markets, and resulting increase in social welfare is overwhelmingly positive. We examine a two-sided platform economy against a more stricter benchmark —- an open platform that discloses its proprietary information. We show that, due to the big proprietary data the platforms control, they can be detrimental to both sides of the market resulting in social welfare losses compared to the benign open platform.

3 - Menu Costs and the Bullwhip Effect: Supply Chain Implications of Dynamic Pricing

Ioannis Stamatopoulos, University of Texas at Austin, McCombs School of Business, 2110 Speedway B6000, Austin, TX, 78705, United States, yannis.stamos@mccombs.utexas.edu, Robert Louis Bray

We study the supply chain implications of dynamic pricing. Specifically, we estimate how reducing menu costs — the operational burden of adjusting prices — would affect supply chain stability.

Decision Analysis I

Contributed Session

Chair: Alireza Lari, Wake Forest University, Cary, NC, 27518, United States

1 - Extracting Latent Information Sources from Dependent Distributional Forecasts

Yuanyuan Lei, Tsinghua University, Beijing, China, leiyy17@mails.tsinghua.edu.cn

Traditional aggregation in forecasts often ignores the judges' correlation, which can be attributed to the shared-information problem. In this study, we propose a functional analysis model about quantile predictions on a continuous uncertain quantity, in which the predictive function is represented by a Gaussian process and its mean is a linear combination of independent and orthogonal cues function. The estimated weights reveal information utilizing and can be used to group experts. Thus we can explore the relationship between experts and construct an optimization for the expert grouping and weight assigning to groups (if historical data is available), which is more stable for aggregating.

2 - A Two Phase Framework of Project Portfolio Selection and an Empirical Study in the Integrated Circuit Design Company

Kang-Ting Ma, National Tsing Hua University, Hsinchu, Taiwan, Chen-Fu Chien

The semiconductor industry is capital intensive, and Integrated Circuit design company plays an important role in leading the industry chain to migrate to new technologies and to develop variety of applications. Project portfolio selection in Integrated Circuit design company is important to maintain the competitiveness by considering profitability, and resources utilization. This paper aims to propose a two phase framework, which incorporates the project evaluation phase by the data envelopment analysis, and project portfolio selection phase by a mathematical programming. An empirical study is conducted in a Integrated Circuit company, and results show the decision quality is improved.

3 - Analysis and Prediction of Airline Delay

Alok Dand, Wichita State University, Wichita, KS, United States, axdand@shockers.wichita.edu, Khawaja Saeed, Bayram Yildirim

Supply chains are impacted greatly by airline delays and cancellation. With around 20% of domestic flights being impacted each year, the costs to passengers, airline companies and the economy are in billions of dollars each year. With an estimated 50% increase in the people traveling via airlines in the next 2 decades, a thorough examination of the different trends and impact of different airline company controlled variables and uncontrollable variables is essential. Different machine learning algorithms are then used to predict delays which are compared using recall rates and ROC-AUC score.

4 - Opportunities and Challenges for Cost Management by Optimizing Benefits of Workers of a Collective Agreement

Rodrigo Barraza, Universidad Santo Tomas, Santiago, Chile, rodrigobarrazaal@santotomas.cl, Juan Venegas

This article proposes a framework consisting of an optimization model and an application that allows designing and executing instances of analysis to optimize the benefits of union workers in a company providing services to the mining industry. However, both collective bargaining processes and the execution of collective bargaining agreements over time present fluctuations in costs, which have a negative impact on the management of the collective bargaining agreement and, finally, on the appropriate allocation of benefits for workers. We purpose a framework to analyze optimal instances of collective bargaining agreements of a worker's union.

5 - Which Channel Improvement Project to Invest In? A Case Study

Yasamin Salmani, Bryant University, Smithfield, RI, United States, Fariborz Partovi, Avijit Banerjee

In this study, an investment model towards improving channel structures, in a multi-channel multi-product setting, is reviewed. The focus of this study is the application of the proposed methodology in a U.S. manufacturing company.

6 - Introducing Business Analytics in an Overseas Car Manufacturer to Improve Business Processes

Alireza Lari, Teaching Professor, Wake Forest University, Winston Salem, NC, United States, Nasim Lari

To improve process efficiency and data-driven decision-making, PKH committed to leveraging business analytics. This required establishing data governance best practices, data architecture, introduction of analytics methods, and management science. Preliminary evaluations demonstrate improved process optimization, prediction of equipment failure and production breakdowns, reduction of quality costs, and increase in customer and employee satisfaction. This paper highlights the successful implementation of analytics in an environment with significant limitations.

Innovations in Teaching Service Operations

Sponsored: Manufacturing & Service Oper. Mgmt/Service Operations

Sponsored Session

Chair: Ryan Buell, Harvard Business School, Boston, MA, 02163, United States

1 - Finding Your Teaching Style in the MBA Classroom

Maria R. Ibanez, Kellogg School of Management at Northwestern University, 2211 Campus Drive, Evanston, IL, 60208, United States

We will discuss teaching methods and experiences, including tips for future MBA instructors.

2 - Bringing Experiential Learning into The Classroom

Amrou Awaysheh, Indiana University, Indianapolis, IN, 28006, United States, awaysheh@iu.edu

Experiential Learning (EL) gives students the opportunity to learn through doing. We will discuss some strategies for incorporating EL in the MBA classroom.

3 - Incorporating Research into Teaching

Yasin Alan, Vanderbilt University - Owen Graduate School of Management, 401 21st Avenue South, Nashville, TN, 37203, United States, yasin.alan@owen.vanderbilt.edu

In this talk, I will discuss my efforts to incorporate research findings into case discussions. I will provide a few specific examples from the MBA-level courses I teach at Vanderbilt.

4 - Teaching Experimentation in Service Operations

Ryan Buell, Harvard Business School, Boston, MA, 02163, United States

In 2017, Commonwealth Bank of Australia was seeking to differentiate itself from other banks, and to improve the financial wellbeing of its customers. To that end, managers had developed a provocative experiment dubbed "The Good and the Bad." Rather than just presenting the strengths of its credit card offerings, they proposed also promoting each credit card's drawbacks. Being transparent with customers might help them make better choices, but would those choices come at the expense of bank performance? The case helps students think through the process of incorporating experimentation into service operations - from idea generation, to execution, to evaluation.

Sponsored Session

Chair: Nicholas A Arnosti, Columbia Business School, New York, NY, 10027, United States

1 - Optimal Commissions and Subscriptions in Networked Markets.

Hongfan Chen, University of Chicago, Chicago, IL, 60615, United States, hongfan.chen@chicagobooth.edu, John R. Birge, Ozan Candogan, Daniela Saban

Two salient features of most online platforms are that they do not dictate the transaction prices, and use commissions/subscriptions for extracting revenues. We shed light on how these commissions/subscriptions should be set in networked markets. We provide a tractable convex optimization formulation to calculate the revenue-maximizing commissions/subscriptions. Motivated by simpler schemes used in practice, we show that the revenue loss can be unbounded when all traders on the same side are charged the same commissions/subscriptions. Charging only buyers or only sellers leads to at least half of the optimal revenues, when different types on the same side can be charged differently.

2 - Food waste

Elena Belavina, Cornell University, Ithaca, NY, United States

Roughly 1/3 of all food produced in the world is wasted. All this wasted food represents carbon emissions that could have been avoided. In this talk we will explore the biggest culprits and what could be done to reduce food waste.

3 - On the Optimal Design of a Bipartite Matching Queueing System

Philipp Afeche, University of Toronto, Rotman School of Management, 105 St. George Street, Toronto, ON, M5S 3E6, Canada, afeche@rotman.utoronto.ca, Rene A. Caldentey, Varun Gupta

We study the design of optimal matching topologies between customer classes and servers for a multi-class multi-server queueing system with a FCFS-ALIS service discipline. We aim to identify topologies that optimize - in a Pareto efficiency sense - the trade-off between two competing objectives: (i) minimizing customer waiting times and (ii) maximizing matching rewards generated by pairing customers and servers. To this end we show that in heavy traffic, for any matching topology the scaled steady-state waiting times are determined via an intuitive partition of interconnected subsystems, and the matching rates are very well approximated via a quadratic flow maximization program.

4 - A Continuum Model for Stable Matching with Finite Capacities

Nick Arnosti, Columbia Business School, New York, NY, 10027, United States

Stable matching algorithms are used to clear many markets — most notably, for residencies and public schools. However, the literature relating outcomes to market primitives is sparse, and often makes very restrictive assumptions such as uniform random preferences. We introduce a continuum model that allows for arbitrary capacities, preferences, and priorities, and show that it always has a unique stable outcome. The model accurately predicts simulation outcomes from the literature, even for markets with as few as ten or or twenty participants on each side. We illustrate the usefulness of the model by proving several new results.

Joint Session MSOM/SC/Practice Curated: Omni-channel Retail Operations

Sponsored: Manufacturing & Service Oper. Mgmt/Supply Chain

Sponsored Session

Chair: Stanley Lim, University of San Diego, Tempe, AZ, United States

Chair: M. Serkan Akturk, Clemson University, Clemson University, Clemson, SC, 29631, United States

1 - The Effect of Offering Additional Fulfillment Options

Chloe Kim Glaeser, University of North Carolina, Kenan-Flagler Business School, 714 Greenwood Rd, Chapel Hill, NC, 27514, United States, chloe_glaeser@kenan-flagler.unc.edu, Kenneth Moon, Xuanming Su

We partner with an online grocery retailer to answer the practice-based question of the optimal mix of delivery zones and fulfillment options using data-driven analytics. We investigate how consumers respond to the locally tailored fulfillment options made available to them by the online grocer. We employ a geographical regression discontinuity design to find the causal effect of delivery introduction.

2 - Should Omnichannel Retailers Allow in Store Returns of Online Purchases?

Punya Chatterjee, Penn State University, University Park, PA, United States, pxc85@psu.edu, Aydin Alptekinoglu, Nicholas C. Petruzzi

We investigate when an omnichannel retailer should allow in-store returns of online purchases. The retailer has two substitutable products to offer, both available online, that differ by the uncertainty consumers have over their valuation. The retailer sets prices and store assortment in addition to the store return policy.

3 - Lead Time and Demand Sensitivity: Implications for Omni-channel Facility Network Design

Stanley Lim, University of San Diego, San Diego, CA, United States, stanleylim@sandiego.edu, Fei Gao, Fangyun Tan

Previous research on showrooms in retailing typically differentiates the showroom channel from the online channel only in terms of information delivery. It implicitly assumes that consumers have homogeneous preference in product fulfillment across channels. That is, the showroom demand is assumed to have the same elasticity/sensitivity to delivery lead time as demand in the other channels. We empirically examine this assumption and the channel-specific effects of lead time on demand. We further incorporate our findings into the design of an omni-channel retailer's facility network in terms of decisions about the quantity and size of the showrooms.

4 - Assessing the Value of Launching Omnichannel Retailing Practices

M. Serkan Akturk, Assistant Professor, Clemson University, Department of Management, Sirr 374A Sirrine Hall, Clemson, SC, 29631, United States, makturk@clemson.edu

Recent changes in the shopping journey of customers arising from technological advancements, increasing use of smartphones, and continuous access to internet force retailers to integrate their existing channels by offering omnichannel service processes such as buy-online and pick-up-in-store or ship-to-store. Using a proprietary transaction level dataset from a U.S. based retailer, we explore the impact of launching omnichannel service offering across both online and offline channels. Our findings are extensive and provide managerial insights in the omnichannel retail operations domain.

1 - Air Pollution and Green Consumption of Consumers in China's Urban Areas: A Norm Activation Perspective

Ruiju Yang, University of Science and Technology of China, Hefei, China, yangruij@mail.ustc.edu.cn

This study explores how consumers' psychological factors affect their green purchasing behaviors during a city smog. Using a questionnaire survey involving 1124 participants living in the Beijing-Tianjin-Hebei region of China, we found the following results. First, product knowledge, smog knowledge, risk perception, and systematic processing positively influence consumers' purchase intentions of green anti-smog products. Second, consumers' personal norms significantly affect their green purchase decisions. This study provides practical guidance for marketing management and helps managers gain accurate insight into consumer behavior in a crisis situation.

2 - Team Composition Considering Individual Differences in Pacing Styles

Tianchen Sun, University of Washington, Seattle, WA, United States, Ji-Eun Kim

Pacing style refers to the distribution of individuals' efforts over time as deadlines approach; some individuals start their work early, while others do not start their work until the deadline. Researchers have conceptualized and modeled individual differences in pacing styles (IDPS); however, effective composition of teams accounting for such differences have not been clearly identified. In this study, we collected students' online activities on course websites and explored the relationship between the level of pacing style diversity within individual teams of students and team performance. This research elucidates improved practices for team formation.

3 - How to Develop Effective Systems Engineers?

Morteza Nagahi, Mississippi State University, Starkville, MS, United States, mn852@msstate.edu, Niamat Ullah Ibne Hossain

This research introduces a new system engineering instrument that assesses the performance of systems engineers based on the set performance indicators of six fundamental system engineering attributes. This instrument would serve a baseline to understand the current state of the skill of individual system engineers. The paper is structured to explore four primary areas. First, we examine why there is a need to develop effective systems engineers. Second, we proposed a novel tool that could aid in developing effective systems engineers. Next, we present an examination of the individual performance of induvial systems engineers, followed by the implications of the proposed instrument.

4 - Productivity Implications of Diversity of Experience in Fluid Teams

Antti Tenhiala, IE Business School, Madrid, Spain, antti.tenhiala@ie.edu, Constantin Alba, Fabrizio Salvador

How does team diversity in past work experience influence project productivity? We study this question using work assignment data from a multinational software services firm. We operationalize diversity of experience along three dimensions: the variety of specializations, separation of experience profiles, and disparity of expertise. We hypothesize and observe distinct curvilinear productivity effects for each dimension. We further theorize that project complexity moderates the hypothesized relationships and observe differences in each dimension up to the reversal of the productivity effect between projects of low and high complexity.

5 - Resilience Assessment in Social Systems: Applications in Communities, Sports and Education

Daniel Hernando Romero, Universidad Del Norte, Barranquilla, Colombia, hromero@uninorte.edu.co, Weimar Ardila, Alex Savachkin

Resilience assessment in social, physical and cyber systems has offered multiple metrics, definitions and dimensions, but there is still a lack of consensus in how to capture it. This presentation offers an overview of resilience measurements and drivers identification in social systems. A community affected by pandemic influenza, teams abilities to comeback when facing a scoring disadvantage in sports, and students ability to recover when the cumulative grade is not satisfactory to pass a grade, are three applications to showcase different settings where resilience can be explored.

Using OR/Analytics Methods to Assess and Improve Performance of Higher Education

Contributed Session

Chair: Philip Schuyler Baxa, United States Coast Guard, Gales Ferry, CT, 06335, United States

1 - Artificial Intelligence and its Applications in Higher Education: A Synthesis

SeokJoo Kwak, University of Michigan, Ann Arbor, MI, United States, seokjook@umich.edu, Joi-Lynn Mondisa

Current issues of formidable inequities in the quality of higher education are matters of institutional and system reform of our society which are directly connected with future employment and generations. Furthermore, future generations will be significantly impacted by technological advances such as Artificial intelligence (AI). The purpose of this paper is to synthesize details about the evolution and development of AI, identify the role and impact of AI in higher education, and speculate about the future of AI in higher education.

2 - Managing Yield-uncertainty Caused by Randomness and Subsequent Withdrawals in Academic Admissions

Subhamoy Ganguly, University of Auckland, Auckland, New Zealand, s.ganguly@auckland.ac.nz, Ranojoy Basu, Viswanathan Nagarajan

Admissions to academic programs often involve filling seats by making offers to a rank-ordered list of applicants, but only a fraction of those receiving offers end up enrolling. We develop an analytical model to arrive at the number of offers to make while considering the expected costs of exceeding or falling short of the target enrollment. The model generates interesting insights and is validated using a large multi-year empirical data set of applications and admission offers for an MBA program.

3 - Performance Evaluation and Enrollment Quota Allocation for Higher Education Institutions in China

Ganggang Zhang, University of Science and Technology of China, Hefei, China, ggz1616@mail.ustc.edu.cn

The rapid economic growth has brought China's higher education into a new stage. However, the uneven development of higher education in different provinces has become a critical factor restricting China's overall progress. We propose a Data Envelopment Analysis approach to evaluate the efficiency of higher education resource utilization in provinces of China. We assess the productivity changes of each province with the help of the Malmquist productivity index. By considering the enrollment quota as a resource, we construct a reasonable allocation scheme. Suggestions are put forward to help the Chinese government better solve the unbalanced development of higher education among provinces.

4 - Predictive Modeling of the U.S. Coast Guard Academy Graduating Class

Philip S. Baxa, Mathematics Instructor, United States Coast Guard Academy, New London, CT, United States

The U.S. Coast Guard Academy (USCGA) has developed leaders of character who embody Coast Guard values since 1876. This project assessed the USCGA's training and education program by analyzing historical cadet data to forecast the composition of the graduating class by analyzing the attributes of the incoming class, and attributes (e.g. GPA, demerits, physical fitness scores, and athletic, clubs and activity participation) that are accumulated over the course of a cadet's career. This research supported the USCGA's Strategic Plan and analyzed the relationship between the intended majors of applicants, the migration of cadets between majors, and the degree a cadet ultimately completes.

Systemic Risk

Sponsored: Finance

Sponsored Session

Chair: Mike Ludkovski, University of California-Santa Barbara, Santa Barbara, CA, United States

Chair: Nils-Christian Detering, University of California-Santa Barbara, University of California-Santa Barbara, Santa Barbara, CA, 93106-3110, United States

1 - Incorporating Confidence into Systemic Risk

Maxim Bichuch, Johns Hopkins University, Dept of Applied Mathematics and Statistics, Johns Hopkins University, Baltimore, MD, 21218, United States, Ke Chen, Zachary Feinstein

In a crisis, to raise funds, banks can sell their shares in the market and borrow money. We propose a simple model that incorporates market confidence to find the maximum amount of new funds the banks can raise in this way. Additionally, for a given shortfall, we find the optimal mix of borrowing and stock selling. We show the existence and uniqueness of Nash equilibrium strategy, and calibrate this model to market data. In a related model of financial contagion in a network subject to fire sales and price impacts, we give sufficient conditions for existence and uniqueness of the clearing solutions (i.e. the Nash equilibrium of an aggregation game).

2 - Numerical Methods in Mean-field Game for Large Banking System with Defaults

Tomoyuki Ichiba, University of California-Santa Barbara, South Hall 5607A, Santa Barbara, CA, 93106, United States, ichiba@pstat.ucsb.edu

We consider the dynamics of the cash reserves of an interconnecting banking system. Whenever a bank defaults (by letting its reserve reach a given threshold), each bank is impacted negatively, via an instantaneous jump on its reserve level. We also take into account the arrival of new financial institutions in the system. Under such setup, we discuss numerical methods to solve the mean-field game and identify the resulting dynamics as the equilibrium among banks in interaction. Part of research is joint work with R. Elie and M. Lauriere.

3 - Suffocating Fire Sales

Nils Detering, University of Califnornia-Santa Barbara, Santa Barbara, CA, United States

In this paper we develop models that allow us to investigate central characteristics that drive the propagation of distress through fire sales in financial systems. We investigate single systems as well as ensembles of systems that are alike, where similarity is measured in terms of the empirical distribution of defining properties of a system. A natural characterization of systems resilient to fire sales emerges. We propose minimal capital requirements, investigate the effect of portfolio diversification and quantify the trade-off between objectives for classical single firm risk management and those for systemic risk management.

4 - Measuring Risks in Hedge Funds: Evaluation and Usefulness of Exposure Data in Form PF

Stathis Tompaidis, University of Texas-Austin, McCombs School of Business, IROM Department, Austin, TX, 78712-1179, United States, Stathis.Tompaidis@mccombs.utexas.edu, Phillip Monin, Matthew Pritsker

We use data from a new regulatory filling for large hedge funds, Form PF, to evaluate the accuracy of reported stress test exposure information and to construct measures of hedge funds' aggregate risk. At the individual fund level, we find the exposure information has weak power to explain individual fund returns. However, aggregating the reported stress test results by groups or for the entire set of reporting funds improves the situation significantly. We build two aggregate measures of risk and decompose the contributions to these measures by fund strategy and fund liquidity. Our results can be used to improve the form and to monitor aggregate risk across reporting funds.

CC- Room 310

Topics in Sustainable Operations

Sponsored: Manufacturing & Service Oper. Mgmt/Sustainable Operations

Sponsored Session

Chair: Ximin Huang, University of Minnesota, Minneapolis, MN, 55455, United States

1 - Fleet Refresh Decisions in Car-sharing Business Models

Ximin Natalie Huang, Assistant Professor, University of Minnesota, 321 19th Ave S, Ste 3-150, Minneapolis, MN, 55455, United States, huangx@umn.edu, Vishal Agrawal, Ioannis Bellos

We study how car-sharing service offerings should be managed along with produce sales. We focus on an important decision, namely how often to refresh the car-sharing fleet, as it influences both the primary and secondary market. We also explore these decisions for a third-party car sharing provider competing with sales.

2 - We Are on the Way: Analysis of On-demand Ride Hailing Platforms

Guiyun Feng, Singapore Management University, Singapore, Singapore, Guangwen Kong, Zizhuo Wang

The rapid rise of on-demand ride-hailing platforms has raised questions about how such a new matching mechanism will affect the efficiency of the transportation system. In this paper, we shed light on this question by building a stylized model of a circular road and comparing the average waiting times of passengers under various matching mechanisms. We discover the inefficiency in the on-demand ride-hailing system when the en route time is long, and find that the on-demand matching mechanism could result in lower efficiency than the traditional street-hailing mechanism in some scenarios.

3 - Green Farming: the Interaction of New Technologies, Consumer Preferences and Contract Choices

LI Dong, Lingnan (University College), Sun Yat-Sen University, Guangzhou, China, lidong9@mail.sysu.edu.cn, Saif Benjaafar, Niyazi Taneri

Over half of all farmland in some US states are operated by farmers who are not the landowner. New technologies such as sensors, drones, satellite imaging, and cloud computing promise to enable the landowner to monitor farmers' efforts and alleviate the hidden action problem. In the context of green farming, we generate analytical insights that result from the interaction of consumer preferences, contracting decisions and these emerging technologies.

Advances in Decision Modeling

Sponsored: Decision Analysis

Sponsored Session

Chair: Ahti Salo, Aalto University, Aalto University, Aalto SCI, 00076, Finland

1 - A Multi-objective Decision Support Tool for Cooperative Duty Rostering

Antti Punkka, Aalto University, Systems Analysis Laboratory, Aalto SCI, 00076 Aalto, Espoo, Finland, antti.punkka@aalto.fi, Aleksi Porokka

We develop a rostering tool, which produces cost-efficient, personalized, 3-week long rosters for Finnish train drivers. The optimization model for producing the rosters is based on maximizing additive multi-attribute value subject to constraints set by law, collective bargaining, equal treatment of drivers and their personal competences and preferences. The model considers many aspects of drivers' well-being, which makes trade-offs between cost-efficiency and drivers' well-being transparent. We discuss how the tool improved the rosters' cost-efficiency and enhanced the interaction between the driver representatives and the roster planners through cooperative, iterative planning.

2 - Decision Programming for Optimizing Multi-Stage Decision Problems under Uncertainty

Fabricio Oliveira, Aalto University School of Science, Espoo, Finland, fabricio.oliveira@aalto.fi, Ahti Salo, Juho Andelmin

We develop the Decision Programming approach for solving multi-stage decision problems which can be represented as extended influence diagrams where the 'no forgetting' assumption need not hold. This approach can handle multiple objectives and different risk measures, including VaR and CVaR. It can also be viewed as an extension of Contingent Portfolio Programming (Gustafsson and Salo, Oper. Res., 2005) for selecting projects which can influence scenario probabilities. We show that problems of realistic size can be efficiently solved as mixed-integer linear programs strengthened by probability cuts.

3 - The Efficient Frontier Based on Second- and Third-order Stochastic Dominance

Juuso Ilari Liesio, Aalto University School of Business, Finland, juuso.liesio@aalto.fi

Stochastic dominance provides decision recommendations among portfolios of assets with uncertain outcomes (e.g., investments, projects or stocks) without requiring exact specification of risk preferences. We develop models to identify the set of portfolios that are efficient in the sense of second- or third-order stochastic dominance. These models provide novel insights into the composition of portfolios belonging to the efficient frontier. Moreover, the identification of the efficient frontier makes it possible to utilize additional information on the decision maker's risk preferences to further reduce the set of admissible portfolio alternatives.

4 - Analytic Method for Identifying and Visualizing a Diverse Set of Plausible Scenarios for Strategic Planning

Teemu Seeve, Aalto University School of Business, Espoo, Finland, teemu.seeve@aalto.fi, Eeva Vilkkumaa

In uncertain future operational environments, consideration of alternative scenarios can support strategic planning of organizations. Scenarios can be modeled as combinations of levels on multiple uncertainty factors describing, e.g., technological and economic developments. We develop an efficient algorithm to filter the most plausible out of exponentially many candidate scenarios, and a visualization method to support the identification of a diverse set of plausible scenarios. This method is applied to a real case in developing scenarios for the National Emergency Supply Organization in Finland.

Decision and Risk Analysis in a Digital Era

Sponsored: Decision Analysis

Sponsored Session

Chair: Jun Zhuang, University at Buffalo, SUNY, Buffalo, NY, 14260, United States

1 - Cognitive Consistency and Confirmation Bias in Deception Detection of False Information in Social Media Following Extreme Events

Richard S. John, Professor, University of Southern California, Dept of Psychology MC 1061, Los Angeles, CA, 90089-1061, United States, richardj@usc.edu, Katie Byrd

Social media has become a critical source of information following extreme events. Such communication is often hindered by false and deceptive posts. I report behavioral research on detection of false information in social media immediately following natural disasters and soft target terrorist attacks. Detection performance is evaluated within a Signal Detection Theory (SDT) framework by manipulating both base-rates and error penalties. Detection biases are identified and related to individual cognitive, motivational, and personality factors. Both utcome feedback and critical thinking training are evaluated independently and jointly as possible interventions to improve performance.

2 - A Blockchain Framework to Improve Emergency Communications

Kyle J. Hunt, Student and Research Assistant, University at Buffalo, Buffalo, NY, 14221, United States, kylehunt@buffalo.edu, Jun Zhuang

In recent years, research has studied the spread of fake news and misinformation during natural disasters, elections, and terrorist events across social media and even emergency alert systems. Besides the worries regarding content veracity, the timeliness of information is of the utmost concern in crisis communications and emergency management. In this work, we study the application of blockchain to improve crisis communications. We propose a framework to create safer, quicker, and more reliable communication networks in times of natural disasters, terrorism events, and other hazardous situations.

3 - Estimating Strategic Catastrophe Insurance Demand with Social Media Data Analysis

Shenming Song, Tsinghua University, Beijing, 100084, China, Chen Wang, Shu Huang

We consider the leader insurers who are involved in the risk sharing partnership mandatorily but require the additional regulatory cost, and the follower insurers who choose to join the partnership voluntarily but probably need incentive. To deal with the fluctuations in catastrophe insurance demand, this research proposes a social learning model to elicit the time-varying purchase utility by using repost and review data in online social networks. We then characterize the government dynamic schemes about whether targeting on the leader or follower insurers given the population dynamics.

4 - Application of Social Media Image Classification to Detect Infrastructure Damage During Natural Disasters

Ridwan Al Aziz, State University of New York-Buffalo, Buffalo, NY, 14260, United States, ridwanal@buffalo.edu, Puneet Agarwal, Nafisa Mahbub, Qing He, Jun Zhuang

During natural disasters, it generally takes a substantial amount of time for humanitarian organizations to assess the damages caused by them. As image-based social media platforms like Instagram and Flickr have become very popular to the mass people, they can be viewed as a fast and easily accessible source for image data at a relatively lower cost. In this paper, different machine learning algorithms are applied to a dataset developed by retrieving infrastructure damage related images during disasters. Among the five approaches, Convolutional Neural Network is identified as the most efficient approach and hence, provides an inexpensive and faster alternative in real time damage detection.

5 - Understanding Information Diffusion in Social Media in a Hurricane Evacuation Context

Kamol Chandra Roy, University of Central Florida, Orlando, FL, United States, Samiul Hasan

Using online social network, one can now communicate with thousands of other people that may shape their evacuation decisions. In this study, we use Twitter data to study the dynamics of warning information propagation through social media. We also study how information propagation affects individual evacuation decisions. Finally, we jointly model the information propagation and evacuation decision dynamics using an epidemic modeling approach. The findings of our study will reveal the effects of network structure and initial adoption strategy on warning propagation and evacuation decision-making.

CC- Room 401

Revenue Management, Pricing III

Contributed Session

Chair: Ozden Engin Cakici, American University, NW, Washington, DC, 20016, United States

1 - Distribution Free Algorithms for Network Revenue Management

Jonathan Z. Amar, Massachusetts Institute of Technology, Cambridge, MA, United States, amarj@mit.edu, Nikolaos Trichakis

We consider a canonical network revenue management model (NRM) in which a decision maker offers multiple products, which consume capacitated resources. We focus on environments where demand is highly uncertain, and the decision maker needs to make sales decisions in an online fashion. We provide a distribution-free online algorithm for NRM and analyze its performance and establish that the proposed algorithm is asymptotically optimal, by achieving the best possible competitive ratio. By analyzing special relevant network structures, we show how to tune our algorithm in an intuitive way. Computational experiments demonstrate the proposed algorithm to outperform existing methods.

2 - Price Markdowns to Induce Customers to Opt Out of Free Returns

Sajjad Najafi, Ross School of Business, University of Michigan, Ann arbor, MI, United States, snajafi@umich.edu, Izak Duenyas

We study a newly emerging product return policy in the retail e-commerce industry. Alongside the conventional free return option, consumers are offered an additional return alternative called opt-out of free return (FO). If consumers forego free return and pick FO, the firm offers them a price markdown, and they can still return the product during the grace period, but they will have to pay a fixed penalty and a variable penalty proportional to the product’s purchase price. We model this return policy with the aim of deriving managerial insights on when offering FO would be beneficial to firms, and if they offer it, how the firm can set the optimal markdown level.

3 - Dynamic Learning and Pricing with Time-inconsistent Customer Behavior

Belleh Fontem, Assistant Professor, University of Massachusetts Lowell, Lowell, MA, United States, Canan G. Corlu

We study a learning and pricing problem for an online seller who begins a sequence of transactions with a customer despite possessing zero information on the customer’s true valuation for an item that the seller peddles. To complicate matters, the customer’s purchasing decision criterion is modulated by a Markov process with two disparate states that are hidden from the seller. The seller’s goal is to price the item in such a way as to efficiently elicit the buyer’s true valuation, while at the same time maximizing discounted expected revenue. We design a recursive filtering pricing algorithm, and using ideas from martingale theory, prove that it eventually elicits the customer’s valuation.

4 - Cross Channel Fulfillment in Omni Channel Network

Ting Luo, California State University Fullerton, Fullerton, CA, United States

Omni-channel retailing creates seamless shopping experience for consumers and lucrative sales opportunities for retailers. But how to price and fulfill the order is always not an easy decision for the retailer under dynamic environment, especially with a network of brick-and-mortar stores. Using a choice model for consumer channel, we frame the retailer’s problem as an MDP, with real time decisions of pricing and cross-fulfillment. We find we can use cross-fulfillment to replace dynamic pricing decision. We also find an optimal strategy to utilize inventory resource on a network .

5 - Optimal Pricing in Markets with Non-Convex Costs

Navid Azizan, California Institute of Technology, Pasadena, CA, United States, Yu Su, Krishnamurthy Dvijotham, Adam Wierman

We consider a market (such as an electricity market) run by an operator, who seeks to satisfy a given consumer demand by purchasing it from a group of suppliers with nonconvex cost functions. The operator knows the cost functions and announces a price function for each supplier. Each supplier then makes an individual decision about how much to produce. We propose a new pricing scheme, which is applicable to general nonconvex costs, and allows using general parametric price functions. Our scheme allows finding prices that are economically more efficient and less discriminatory. We supplement the proposed method with a polytime approximation algorithm for finding the optimal quantities and parameters.

6 - Coordinating Procurement and Distribution Decisions of Brokers

Ozden Engin Cakici, Assistant Professor, American University, Washington, DC, United States, ozdengin@gmail.com, Itir Z. Karaesmen

Bidding decisions to procure goods in B2B markets are made under uncertainty and resemble pricing decisions to sell goods in B2C markets. We develop and analyze analytical models to determine the optimal bid values for a broker in the first stage and the optimal shipping decision in the second stage.

Joint Session Serv Sci/Practice Curated: Machine Learning in Service Science

Joint Session

Chair: Xinying Hao, University of Texas, Austin, TX, 78731, United States

1 - Evaluation of Multiple Machine Learning Methods on Prediction of Users' Rate Based on Yelp Challenge Data Set

Aidin Tamhidi, UCLA, Los Angeles, CA, United States, aidintamhidi@ucla.edu, Rio Sonoyama

We aimed to predict the star rating that a Yelp user would probably assign to a business such as a Restaurant, a Hair salon, etc. which they have never met. The dataset which contains observations from users' rating to the businesses and their features is provided by the Yelp Dataset Challenge. Through dividing it into two parts, train dataset and validation data set, we fit models for this multi-class classification task and evaluate each of them based on their prediction accuracy on validation data set. Eventually, we compared models according to their results such as Root Mean Squared Error (RSME) and other evaluation criteria to suggest the best model for the prediction.

2 - A Deep Learning Based Approach for Consumer Complaint Analysis

Xiaoguang Tian, Purdue University Fort Wayne, Fort Wayne, IN, United States, Wen Fu

Complaint analysis allows firms to learn in a continuous manner to adapt their products and services to customer preferences. However, analyzing consumer complaints confronts several big data challenges: volume, velocity, variety, veracity, efficiency, and effectiveness. This study proposes a comprehensive customer-oriented model to tackle difficult tasks. The automated text mining and machine learning process could help firms respond quickly to demanding customers and support an enterprise level textual contents analysis.

3 - Optimizing Email Marketing Through Deep Reinforcement Learning.

Senne Van Steelandt, University of Tennessee, Knoxville, TN, United States, svanstee@vols.utk.edu, Michel Ballings, Dirk Van den Poel

A long-standing goal in Marketing Analytics is to devise an algorithm that learns superhuman proficiency in selecting the next best direct marketing action. It has long been considered an intractable problem owing to its massive search space, and the stochastic and delayed nature of action evaluation. Using data provided to us by a US online retailer, we introduce a deep RL framework to efficiently learn next best email actions. After pre-training the model on historical data, we employ it in a real-life experiment, where results show it outcompetes human-guided decision making.

4 - A Study on Big Data Business Analytics System, Value Creation, and Triple-A in Firm's Supply Chain Management

Peter Wui, Professor, University of Arkansas-Pine Bluff, Pine Blufff, AR, United States, wuiy@uapb.edu

The purpose of this paper was to identify the value creation of the BDBA system and to understand how such a value creation affects the Triple-A of SCM. In order to accomplish the purpose, the literature was reviewed and a research model was devised with the two main hypothesis. The hypothesis on whether a BDBA system affects its value creation was adopted. The hypothesis that the BABD's created value affects the Triple-A of SCM was also adopted in a high level significance. The created value of the BDBA system has a positive significant influence on the agility, adaptability, and alignment of the SCM with the highest impacts on agility performance.

5 - Emoji as a New Targeting Language: A Multi-modal Emoji Mining Approach

Xinying Hao, University of Arizona, Tucson, AZ, United States, xyhao@email.arizona.edu, Vijay Mahajan

Emoji targeting has made its debut in marketing practice. In this paper, we develop a multi-modal emoji-mining approach and examine the incremental effect of using emojis in targeted messages. To overcome the technical challenge that no emoji-mining approach is currently available in the marketing literature, we leverage state-of-the-art deep learning tools by training on a large Twitter dataset. We develop a multi-modal approach that combines both the visual and textual features, and we fuse the information from both modalities to decode the emoji representation. We validate our approach by investigating the incremental effect of emoji use on targeting outcomes (e.g. CTR) via experiments.

6 - A Study on Big Data Business Analytics System, Value Creation, and Triple-A in Firm's Supply Chain Management

Sungho Kim

The purpose of this paper was to identify the value creation of the BDBA system and to understand how such a value creation affects the Triple-A of SCM. In order to accomplish the purpose, the literature was reviewed and a research model was devised with the two main hypothesis. The hypothesis on whether a BDBA system affects its value creation was adopted. The hypothesis that the BABD's created value affects the Triple-A of SCM was also adopted in a high level significance. The created value of the BDBA system has a positive significant influence on the agility, adaptability, and alignment of the SCM with the highest impacts on agility performance.

Food Waste in the Grocery Retail Industry

Sponsored: Service Science

Sponsored Session

Chair: Astashkina Ekaterina

1 - Optimal Issuing Policy for Perishables with Deteriorating Quality

Jae Hyuck Park, Stanford University, Stanford, CA, 94305, United States, jaehyuck@stanford.edu, Erica Plambeck, Dan Andrei Iancu

We consider a retailer who sells a perishable product whose quality deteriorates over time. The retailer maximizes the long-run average customer welfare by jointly deciding whether to issue the oldest or newest stock first to consumers and when to remove unsold items from the shelf. As the deterioration rate and the salvage value increase, it is optimal to issue the newest available item first and salvage items earlier. We show that the retailer can simultaneously improve profitability and customer welfare while reducing food waste by converting unsold inventory into by-product.

2 - Buy-one-Get-one-Free: Impact on Profit and Waste

Dorothee Honhon, Associate Professor of Operations Management, University of Texas at Dallas, Richardson, TX, 75080, United States, dorothee.honhon@utdallas.edu, Qi Wu

We study how Buy-One-Get-One-Free (BOGOF) promotions for perishable items affect a retailer's profits and the amount of waste, both at the store and the consumer levels. We compare the traditional BOGOF campaign in which the consumer immediately gets two items for the price of one to a promotion where the consumer receives a coupon for a free item on her next store visit. We show that in some cases, choosing the proper promotion strategy can lead to more profits and less waste.

3 - Reducing Food Waste at Grocery Stores Through Omni-channel Retailing

Chokdee Siawsolit, Drucker School at Claremont Graduate University, 839 Endicott Drive, Claremont, CA, 91711, United States, csiawsolit@yahoo.com, Gary M. Gaukler

The USDA estimates that roughly 10% of our food supplies are lost at the retail level, costing major national chains nearly 15% in revenue and 43 billion pounds of discarded food annually. To address this pressing matter, we develop an MDP-based inventory model to compare and contrast two strategies that an omni-channel grocery retailer can deploy to reduce food waste, including accepting online orders in advance and allowing backlog order placements on out-of-stock items.

Enhancing Cyber-Physical Security and Resilience of Smart Grid

Sponsored: Service Science

Sponsored Session

Chair: Wei Sun, PhD, University of Central Florida, FL, United States

1 - Moderator

Wei Sun, University of Central Florida, Orlando, FL, 32816, United States, wei.sun@ucf.edu

This panel will host five talks on enhancing cyber-physical security and resilience of smart grid. First talk will introduce a generative adversarial network-based approach to defend smart grid against cyber data attacks. Second talk will discuss about how to enhance cyber-physical security using power electronic devices. Third talk will introduce how to recover from cyber-physical attacks, and fourth talk will be focused on improving smart grid resilience using simulation-based optimization approach. Last talk will cover state-of-the-art research and testbed on cyber-physical security of smart grids.

2 - Cyber-physical Security of Power-electronics Enabled Power Systems

Yunhe Hou, University of Hong Kong, Hong Kong, yhhou@eee.hku.hk

3 - A Simulation-based Optimization Approach to Improve Power Grids Weather Resilience

Jie Xu, George Mason University, Fairfax, VA, 22030, United States, jxu13@gmu.edu

4 - Cyber-physical Attacks Recovery for Self-healing Smart Grids

Wei Sun, Assistant Professor, University of Central Florida, Orlando, FL, 32816, United States, wei.sun@ucf.edu

5 - Measuring and Enabling Cyber-Physical Resiliency of the Electric Grid

Anurag Srivastava, Washington State University, EME 102 Spokane St, Pullman, WA, 99164, United States

6 - Protecting CPS/IoT from End to End

Xinwen Fu, University of Central Florida, Orlando, FL, United States

CC- Room 4C-4

Fair Division Session

Sponsored: Auction and Market Design

Sponsored Session

Chair: Shai Vardi, Purdue University, Caltech, West Lafayette, IN, 91125, United States

1 - Communication Complexity of Cake Cutting

Simina Branzei, Noah Nissan, Purdue University, West Lafayette, IN

We study classic cake-cutting problems, but in discrete models rather than using infinite-precision real values, specifically, focusing on their communication complexity. Using general discrete simulations of classical infinite-precision protocols (Robertson-Webb and moving-knife), we roughly partition the various fair-allocation problems into 3 classes: “easy” (constant number of rounds of logarithmic many bits), “medium” (poly-logarithmic total communication), and “hard”. Our main technical result concerns two of the “medium” problems (perfect allocation for 2 players and equitable allocation for any number of players) which we prove are not in the “easy” class. Our main open problem is to separate the “hard” from the “medium” classes.

2- An Improved Approximation Algorithm for Maximin Shares

Jugal Garg, Univ of Illinois At Urbana Champaign, Urbana, IL, United States, Setareh Taki

We study the problem of fair allocation of m indivisible items among n agents with additive valuations using the popular notion of maximin share as our measure of fairness. The maximin share (MMS) of an agent is the maximum she can guarantee herself if she is allowed to choose a partition of items into n bundles, with the condition that all other agents get to choose a bundle before her. An MMS allocation provides each agent a bundle worth at least her maximin share. While it is known that such an allocation need not exist, a 3/4 MMS allocation always exists in which each agent receives a bundle worth at least 3/4 times her maximin share. We present a strongly polynomial algorithm that obtains a 3/4 MMS allocation.

3 - How to Make Envy Vanish Over Time

Gerdus Benade, Carnegie Mellon University, Pittsburgh, PA, United States, Ariel Procaccia, Aleksandr M. Kazachkov, Christos-Alexandros Psomas

We study the dynamic fair division of indivisible goods. Suppose at every time step an item arrives online and must be allocated to an agent, and agents have heterogeneous values for the items. Our goal is to design allocation algorithms that minimize envy, defined as the maximum difference between any agent’s overall value another agent’s allocation and his own. We design asymptotically optimal allocation algorithms with vanishing envy.

4 - Fair Bandwidth Allocation

Shai Vardi, West Lafayette, IN, 47906, United States, Benjamin Moseley

We study the fair allocation of bandwidth to users in a geometric space, using a new scheduling model.

Decision Support Systems I

Contributed Session

Chair: Rodrigo Ulloa, Arizona State University, Tempe, AZ, 85281, United States

1 - An Effective Marketing Promotions Policy to Maximize Profits

Srikanth Vadde, Director of Data Science, Kaizen Analytix, Atlanta, GA, United States, srikanth.vadde@kaizenanalytix.com, Tom Tang, Anand Srinivasan

Marketing teams often face the challenge of designing an effective promotion policy to maximize return-on-investment without exceeding the allocated budget. Firms often fall short of designing effective promotion programs due to the inherent complexity of understanding their customers willingness-to-pay a price. This work presents a framework to design an effective promotions program considering customer willingness-to-pay using optimization. A case study is presented to demonstrate the approach and its effectiveness.

2 - Intelligent Automation - Automobile Insurance Fraud Detection

Xi Liu, The University of Manchester, Manchester, United Kingdom, Kennedys Law LLP, Manchester, United Kingdom

In this presentation, we will introduce a transparent intelligent automation system which can provide a decision on detecting fraudulent claims by considering complex experienced-based rules and by analysing & managing a large amount of insurance data. In this system, a rule-based inference methodology is developed by pre-defining optimal relationships between inputs and outputs through probabilistic inference and prediction. The whole system can be fine-tuned by combining expert knowledge and insurance data. This intelligent automated decision-making system not only reduces underwriters decision cycle time but also improves the quality of decision making.

3 - A Prediction-optimization Framework for Site-wide Process Optimization

Xiang (Claire) Ma, Senior Data Scientist & Managing Consultant, IBM Canada, Vancouver, BC, Canada, claire.ma1@ibm.com, Dharmashankar Subramanian, Pavankumar Murali, Nianjun Zhou, Giovane Cesar Da Silva, Raju Pavuluri, Jayant Kalagnanam

A multi-plant production site is a complex network of process plants and storage tanks with continuous flows of materials and products. Optimizing production and managing inventories in real time have been challenging for operations managers as there are various local breakdowns at different plants and shifting economic objectives. To help improve the production planning decision, we present a novel solution based on the use of machine learning to learn process relationships from sensor data and converting the process network into a prediction-optimization framework using segmented linear models and couple them with mixed-integer linear programming for site-wide production optimization.

4 - A Flexible Packing Optimization Approach to Improve Product Quality and Worker Training

Roshanak Akram, Graduate Research Assistant, The University of Tennessee, Knoxville, Knoxville, TN, United States, roshanak@utk.edu, Rapinder Sawhney, Ninad Pradhan

Product life cycles in industries using flexible packing materials have reduced. Ad-hoc packing strategies result in loss of product and package quality. The packing strategy must be dynamic, standardized, and must integrate worker training to address these challenges. This paper presents an optimization-based strategy rooted in Industry 4.0 goals of ``quality” and ``worker well-being”. The proposed intelligent automation model allows packing facilities to be responsive to product innovations and resultant packaging changes. The integrated SOP generation and worker training framework has direct benefit to workers as well as managers.

5 - Integrated Stochastic Planning Platform for Small Agricultural Growers with an Application to Arizona and New Mexico

Rodrigo Ulloa, Arizona State University, Tempe, AZ, United States, rulloa1@asu.edu, Hector Flores, J. Rene Villalobos

We propose a decision-making support platform for small farmers in their process of planning the next season. We consider farmers location, resources availability and operational costs; also random parameters such as weather conditions and products prices. We developed a tactical stochastic planning optimization model, which outputs are crop selection, planting/harvesting schedules, resources allocation, and logistic decisions as well. We added a machine learning component to the algorithm to get insights from the information of intermediate solving stages. Furthermore, we present an application of this planning tool to local growers in Arizona and New Mexico.

1 - Why Won't They Use My Model? Difficulties in Implementing Optimal Scheduling Models

Walt DeGrange, CANA Advisors, Chapel Hill, NC, 27517, United States, wdegrange@canallc.com

What if someone were to furnish you with a Ferrari and pay for all the fuel, tires, insurance, and maintenance. How would you drive the car? Surprisingly this is what happens in the United States military when the services provide forces to operational commanders. The Replenishment at Sea Planning (RASP) tool schedules supply ships using an optimization that solves the traveling salesman problem with moving cities (customer ships). Even though the tool reduced hours of planning to a few minutes, it took years for implementation. This brief covers why it took so long, why change is so hard, and what we did to improve the implementation process.

2 - MS Excel - The Multitool of Analysis

Joseph Lindquist, Program Director, US Military Academy, West Point, NY, United States, joseph.lindquist@westpoint.edu

While specialized tools exist to conduct most operations research analysis, a common tool across the entire DoD Enterprise, available on virtually every computer system no matter where an analyst finds themselves is a spreadsheet. This chapter will demonstrate how this common analytical tool can be used to conduct analysis on the following classes of problems: Statistical analysis (to include summary statistics, regression, data exploration, and visualization). A subset of linear and non-linear optimization problems Simulation for use in queuing models (to include creation of empirical distribution functions).

3 - From Bogsat to Turboteam: Collaboration for National Security Teams in the Age of Analytics

Freeman Marvin, Executive Principal, Innovative Decisions, Inc., Broad Run, VA, 20137, United States, ffmarvin@innovativedecisions.com

Recent experience with a range of national security and public safety team meetings has shown that there are new ways to combine process facilitation, analytic techniques, and computer software right in the meeting room to improve the quality of problem solving and decision making. The Analytic Collaboration approach builds on a foundation of process facilitation and structured analytic techniques with Simple Analytic Models (SAMs). This chapter describes the Analytic Collaboration process and how six national security and public safety teams used SAMs to improve meeting effectiveness. The chapter illustrates this approach using three common team tasks: deciding, diagnosing, and designing.

Spatial Analysis

Contributed Session

Chair: Sepideh Yazdekhasti, Xylem Inc

1 - Growth Process Modeling of Carbon Nanotubes: A Hierarchical Physical-statistical Model

Mengqi Fan, Tsinghua University, Beijing, China, fmq15@mails.tsinghua.edu.cn

In scaling-up Carbon Nanotubes (CNTs) array manufacturing, the uniformity of CNTs' height, or flatness of array needs to be properly controlled. This research work aims to model the growth process based on a hierarchical physical-statistical model. This model consists of two major components: morphology and local variability. The morphology component represents the overall trend characterized by the physical model. The area-specific variability is less understood in nanophysics due to complex spatial correlation, characterized by the Kriging model. Simulation and validation are provided to verify the performance of the proposed model.

2 - Prediction of Water Main Failures with the Spatial Clustering of Breaks

Thomas Ying-Jeh Chen, University of Michigan, Ann Arbor, MI, United States, tyjchen@umich.edu

Due to limited budgets and an aging system, infrastructure managers have increasingly sought cost-effective means to evaluate asset condition. A spatial clustering of pipe breaks fits well into a wider asset management framework. The information about spatial clusters identified using historical breaks, if and where they exist, can potentially improve predictions on the location of future breaks. In this research, we present three algorithms for scanning and clustering pipe break data and demonstrate its application on a real pipeline network. We also explore whether the use of spatial clusters as an explanatory variable can improve the accuracy of pipe break machine learning models.

3 - Estimation of Monetary Damages in a Water Network During Pipe Failure

Sepideh Yazdekhasti, Xylem Inc, Columbia, MD, United States, Karl Ivan San Luis, Amin Ganjidoost, Craig Daly

Monetary estimation of damages arising from pipe failures is an evolution from a factor based approach which aids in prioritizing million dollar capital improvement planning projects for water utilities. An innovative, monetized consequence of failure approach is presented where it follows a three-step process of data gathering, quantifying the customers affected and quantifying the monetary impact for each affected customer. The results lead to a continuous scale distribution which is closer to an exponential distribution rather than a centrally weighted distribution. This approach forms a solid foundation in optimizing the best return on investment for capital projects.

Reinforcement Learning for Scheduling

Contributed Session

Chair: Mohammad Dehghanimohammadabadi, Northeastern University, Boston, MA, 02115, United States

1 - Multipriority Patient Scheduling in the Emergency Room Using a Reinforcement Learning Approach

Seonghyeon Park, Yonsei University, Seoul, Korea, Republic of, s.park10@yonsei.ac.kr, Young Hoon Lee

To establish a effective scheduling, it is important to know the operation sequence of jobs in advance. However, the operation sequence of patients in the emergency room appears in a stochastic pattern. This leads to the unique problem that represented by a dynamically changing graph in which the next process is determined stochastically. We propose a patient scheduling model that minimizes the tardiness of multi-priority patients in the emergency room using a reinforcement learning approach. The proposed model is shown to yield an improved result than existing ones in a less computational effort.

2 - A Reinforcement Learning Based Algorithm to Schedule Multi-category Patients at a Multi-facility Hospital

Varun Jain, Tiger Analytics, Chennai, India, varunjain.vj.5@gmail.com, Usha Mohan

One of the key operational decisions faced by hospitals is the choice of the patient category to serve for a test. We include health check-up patient category who need to be served for a sequence of tests as against the other categories of patients (Outpatient and Emergency Patients) who usually are served at one test. We use Markov Decision Process (MDP) to capture the system dynamics with the objective of maximizing net revenue. We factor the MDP formulation to a decentralized MDP, and we propose a reinforcement learning based heuristic to solve it. We show the efficiency of the proposed heuristic through numerical experiments.

3 - Robotic Cell Scheduling with a Reinforcement Learning Approach

Hyun-Jung Kim, Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of, kim.hj@skku.edu, Jun-Ho Lee

A robotic cell scheduling problem is addressed with a reinforcement learning approach. There are two part types processed on a different set of machines, and a material handling robot transports each part between machines. Processing times on machines have a variation, and the objective is to find an efficient robot task sequence in order to minimize makespan. The experimental result shows that the proposed algorithm performs better than a dispatching rule.

4 - Reinforcement Learning for the Vehicle Routing Problem with Time Windows

Yanfei Huang, Eindhoven University of Technology, Eindhoven, Netherlands, y.huang1@tue.nl, Virginie Lurkin, Tom Van Woensel

Following the development of computer technology and digitization, machine learning algorithms outperform classical approaches in solving various models. In this paper, the vehicle routing problem with time windows is formulated as a Markov Decision Process and a Reinforcement Learning model is developed. Unlike other kinds of heuristic methods, reinforcement learning model learns from the data generated during the training so that no heuristic rules need to build up.

5 - Online Operation of Electric Automated Taxi Fleets

Xindi Tang, Tsinghua University, Beijing, China, Meng Li, Xi Lin, Fang He

It is foreseeable that electric automated taxis will play an important role in future transportation systems for serving diverse travel demands. In this study, we propose a two-stage methodological framework to solve the online operation problem of electric automated taxi fleets with combinatorial optimization <and> reinforcement learning. A centralized control system dynamically manages taxis to be assigned to serve demands, dispatched to eliminate supply-demand imbalance <and> forced to charging stations to get refueled. The experiments show that our method outperforms the myopic model in realistic cost where the taxis can be dispatched to the zone with peak-hour demands in advance.

CC- Room 604

Mixed Integer Optimization

Contributed Session

Chair: Azadeh Ahkamiraad, SUNY at Binghamton, Binghamton, NY, 13905, United States

1 - Shorter Automatic Extremality Proofs for Cut-generating Functions

Yuan Zhou, University of Kentucky, Lexington, KY, United States, yuan.zhou@uky.edu

We present a new implementation of our automatic theorem proving technique in the domain of cut-generating functions for integer programs. The new implementation uses a more powerful representation of proof cells as half-open basic semialgebraic sets. It employs strategies that lead to larger proof cells and thus shorter proofs. We use our implementation to automatically prove cutting-plane theorems from the literature.

2 - Strong Valid Inequalities for the Survivable Multi-Module Network Design Problem

Haochen Luo, Texas A&M University, College Station, TX, 77843-3131, United States, Kiavash Kianfar

Capacitated survivable network design (SND), i.e., designing a network that can survive edge failures with minimum flow-routing plus capacity-installation cost, is a fundamental problem in network science and its applications. We study a highly applicable form of SND, referred to as the multi-module SND (MM-SND), in which transmission capacities on edges can be sum of integer multiples of differently sized capacity modules. We formulate MM-SND as a mixed integer program (MIP) and derive several classes of valid inequalities for this MIP, and show that the valid inequalities previously developed in the literature for the single-module SND are special cases of our inequalities. Furthermore, we show that our valid inequalities are facet-defining for MM-SND in many cases. Our computational results, using a heuristic separation algorithm, show that these inequalities are very effective in solving MM-SND.

3 - Matrices with Lexicographically-ordered Rows

Gustavo Angulo, Pontificia Universidad Católica de Chile, Santiago, Chile, gangulo@ing.puc.cl

The lexicographic order can be used to force a collection of decision vectors to be all different, i.e., to take on different values in some coordinates. We consider the set of fixed-size matrices with bounded integer entries and rows in lexicographic order. We present a dynamic program to optimize a linear function over this set, from which we obtain a compact extended formulation for its convex hull.

4 - Team Formation on Social Networks

Nihal Berktas, Bilkent University, Ankara, Turkey, nihal.berktas@bilkent.edu.tr, Hande Yaman

We study the Team Formation Problem (TFP) in which the quality and cost of communication is taken into account using the proximity of the potential members in a social network. Given a set of required skills, TFP aims to construct a capable team that can communicate effectively. To solve larger sizes, we propose a novel branch and bound approach: we formulate the problem as a constrained quadratic set covering problem, use the reformulation-linearization technique and relaxation to be able to decompose it into a series of linear set covering problems and impose the relaxed constraints through branching. The algorithm is capable of solving large sizes that are intractable for the solver.

5 - Generating Effective Constraints for Bilevel Mixed Integer Linear Programming

Wei Wang, University of Pittsburgh, Pittsburgh, PA, United States, w.wei@pitt.edu, Bo Zeng

Generally, bilevel mixed integer linear programming (BMILP) problems are difficult to solve and the traditional high point relaxation is often weak. In this study, we generate strong constraints, which can be adopted in a branch-and-cut frame work, to remove bilevel infeasible solutions. Computational experiments on testing problems will be presented to demonstrate the effectiveness of our constraints.

6 - Time Based Electric Demand Response for Smart Homes with Electric Vehicles and Renewables

Azadeh Ahkamiraad, SUN Y. at Binghamton, Binghamton, NY, United States, Arefeh Mohammadi

It is expected that micro-grid solutions will provide fundamental changes in energy consumption behavior. While the tendency toward intermittent energy storage systems is growing considerably, this study introduces an intelligent home demand-side model for households empowered by electric vehicles, storage facilities, and renewables as local resources. With the objective of minimizing the energy cost, a mixed-integer linear program is proposed to maximize the use of renewables while scheduling the operation of home appliances under varied pricing strategies. The model is carried out in Lingo and simulation results under varied scenarios demonstrate the effectiveness of the technique.

Stochastic Nonlinear Mixed-Integer Problems: Conic Programming Approaches

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Janiele Custodio, George Washington University, DC, United States

1 - A Two-stage Distributionally Robust Chance-constrained Model for Humanitarian Relief Network Design

Ran Ji, Assistant Professor, George Mason University, Fairfax, VA, 22030, United States, rji2@gmu.edu, Zhenlong Jiang

We study a distributionally robust chance-constrained optimization problem for pre-disaster relief network that determines facility locations and capacities, their inventory level and distribution of relief supplies under uncertainty of post-disaster demands and facility conditions. By leveraging Bonferroni and worst-case CVaR approximation, we develop conic representable formulations. Computational studies on real-world applications are conducted to demonstrate the performance of proposed models.

2 - Conic Reformulations of Queuing Stochastic Location-Allocation Models with Decision-Dependend Uncertainty

Janiele Custodio, George Washington University, Washington, DC, 20011, United States, janiele@gwu.edu, Miguel Lejeune

This research presents a new class of stochastic location allocation optimization models. The uncertainty is modeled using queuing theory and the parameters of the system are determined endogenously. We explicitly consider the minimization of the response time of a drone network delivery system. We present an equivalent convex reformulation of the model based on conic programming. We present an application to a discrete facility location model and also to a continuous facility location on the plane model.

3 - On Risk-averse Optimization in Discrete Systems

Pavlo A. Krokhmal, Professor, University of Arizona, Department of Systems & Industrial Engineerin, 1127 E. James E. Rogers Way, Tucson, AZ, 85721, United States

In this talk we discuss risk-averse stochastic optimization in discrete systems, such networks or graphs. In particular, we consider identification of minimum-risk structures in stochastic networks. A family of certainty equivalent coherent/convex measures of risk is employed, resulting in mixed-integer conic programming with non-symmetric cones. Among applications, we consider determining the systemic risk of a networked system.

4 - Approaching Probability Computation of Implicit Sets by Algebraic Means

Ruediger Schultz, University of Duisburg-Essen, Department of Mathematics, Thea-Leymann-Str. 9, Essen, D-45127, Germany, ruediger.schultz@uni-due.de

In stochastic programming, computing probabilities of implicitly given sets has been a research focus since the advent of chance constraints. Recently, this development received another boost by capacity optimization under uncertainty in various industrial endeavours. In the talk we discuss steady state equations for gas flow arising from Kirchhoff's Laws. We arrive at a system of multivariate polynomials of order two. This system is easy to handle for gas networks with at most one cycle. If there are two or more cycles pairwise sharing edges the theory of ideals offers reduction techniques allowing for model streamlining and parametric solution of the system of polynomial equations.

Robust Optimization of Machine Learning Models

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Dimitri Papadimitriou, Brussels, 1190, Belgium

1 - The Stochastic Multigradient Algorithm and its Application to Supervised Machine Learning

Suyun Liu, Lehigh University, Bethlehem, PA, United States, Luis Nunes Vicente

We study the stochastic multi-gradient (SMG) method, seen as a natural extension of the classical stochastic gradient method from single to multi-objective optimization (MOO). We establish the convergence rates to compute a point in the Pareto front. The analysis handles the bias in the multi-gradient and the unknown a priori weights of the limit Pareto point. The SMG method is framed into a more general algorithm for the computation of the entire Pareto front. It can be applied to any stochastic MOO problem arising from supervised machine learning, and we report results for logistic binary classification where multiple objectives correspond to distinct-sources data groups.

2 - Integrating Benders' Decomposition and Piecewise Linear Approximation for Support Vector Machines

Yang-Chieh Ho, National Chiao-Tung University, Hsinchu, Taiwan, daisyhoho1105@gmail.com, Lo-Min Su, Sheng-I Chen

Machine learning optimization problem is to determine the parameters of a model to minimize errors based on the training data set. In the aspect of support vector machines, the problem is to obtain parameters of a linear system defined on feature space. The goal maximizes the distance between two parallel hyperplanes and minimizes classification errors. Such a model has been broadly utilized for data scientists to classify either labeled or unlabeled data. We integrate Benders decomposition and linear approximation for solving the primal problem of support vector machines. The results display computational performance and solution quality between the proposed method and existed algorithms.

3 - Physics-driven Regularization of Deep Neural Networks

Mohammad Amin Nabian, PhD Candidate, University of Illinois at Urbana-Champaign, Urbana, IL, United States, mnabia2@illinois.edu, Hadi Meidani

We introduce a physics-driven regularization method for training deep neural networks (DNNs) for engineering design and analysis. In particular, we focus on prediction of a physical system, for which in addition to training data, information on the governing laws is also available. These laws often appear in the form of differential equations derived from first principles. We propose a training approach that regularizes data-driven DNN models by penalizing divergence form the governing laws. As an application, we study metamodeling for aerodynamic design optimization of vehicles, where we demonstrate the superior accuracy of the proposed method compared to other common alternatives.

4 - Simple Estimators of Value of Data and Price of Data for Data-Driven Distributionally Robust Optimization

Jangho Park, Lawrence Berkeley National Laboratory, Berkeley, CA, 43210-1271, United States, janghopark@lbl.gov, David Love, Guzin Bayraksan

This paper investigates the value of additional data in a distributionally robust optimization (DRO). Such notions have been used in decision analysis and stochastic programming since the 50s. We extend it to the DRO setting. The change in the optimal value due to a specific additional observation of a scenario is called the value of data (VoD). The average change in the VoD is called the price of data (PoD). Additional optimization problems should be solved to calculate the VoD and estimate the PoD. This is computationally expensive. The paper provides estimators of VoD and PoD without solving any additional optimization problems and showcases how they can be used by decision makers to gain insight.

1 - Iterative Algorithms for Risk-averse Stochastic Combinatorial Optimization

Jaehyeon Ryu, Korea Advanced Institute of Science & Technology, Daejeon, Korea, Republic of, jhryu034@kaist.ac.kr, Sungsoo Park

We study risk-averse stochastic combinatorial optimization problems. The mean-standard deviation objective is defined to measure a risk that a linear cost function with independently distributed random coefficients becomes too large. Our problem is equivalent to a robust optimization problem with an ellipsoidal uncertainty set, and we approximate it by polyhedra. We solve the resulting approximate problem by solving some deterministic problems repeatedly. As a result, a (1+)-approximation algorithm, solving at most O(n^1.5/√) nominal problems is obtained. Moreover, we develop a practically fast convergent exact algorithm by adjusting and solving approximate problems iteratively.

2 - Risk-averse Bilevel Stochastic Linear Programs

Matthias Claus, University of Duisburg-Essen, Essen, Germany, matthias.claus@uni-due.de, Johanna Burtscheidt, Stephan Dempe

Two-stage stochastic programs and bilevel problems under stochastic uncertainty bear significant conceptual similarities. However, the step from the first to the latter mirrors the step from optimal values to optimal solutions and entails a loss of desirable analytical properties. The talk focuses on mean risk formulations of stochastic bilevel programs where the lower level problem is linear. Structural properties as continuous differentiability of the objective function are established. Furthermore, based on a growth condition, stability with respect to perturbations of the underlying measure is derived.

3 - Finite Time Analysis of Q Learning with Linear Function Approximation

Zaiwei Chen, Georgia Institute of Technology, Atlanta, GA, United States, Sheng Zhang, Thinh Doan, Siva Theja Maguluri, John-Paul Clarke

We consider in this paper the popular Q-learning method with linear function approximation for finding the optimal policy of a Markov decision problem. Our main contribution is, to provide a finite-time bound for the convergence rate of Q-learning with constant step sizes, without requiring the critical conditions on the i.i.d. sampling and impractical projection steps as often assumed in the existing literature. As a by-product, we provide sufficient conditions for the convergence of linear Q-learning with diminishing step sizes. We also performed comprehensive analysis, both theoretically and numerically, on the conditions needed for convergence.

4 - Integrating Benders Decomposition and Pure Cutting Plane Method for Solving Stochastic Integer Program

Yen-Ting Wu, National Chiao Tung University, Hsinchu, Taiwan, 0113304jason@gmail.com, Sheng-I Chen, Cheng-Yu Rao

Benders decomposition is a commonly-used approach for solving large-scale programs. The application in stochastic program is known as L-shaped method proposed for solving two-stage stochastic programs. However, it may not converge to optimal with integer recourse. This study focuses on a general case of two-stage stochastic programs, in which both stage problems are integer programs. We integrate the L-shaped method and Gomory cutting plane to obtain an approximate solution. A finite cutting plane method is proposed to the second-stage problem to obtain a lower bound of the recourse function. The computational result shows that the integrated method is capable to yield quality solutions.

5 - Investigating Aggregate vs Separate Service Level Constraints in the Stochastic Lot Sizing Problem

Narges Sereshti, HEC Montréal, Montréal, QC, B3H 3M9, Canada, Yossiri Adulyasak, Raf Jans

An efficient approach to deal with demand uncertainty in the multi-item lot-sizing problem is the stochastic programming models which generally consider the uncertainty in the forms of probabilistic distribution functions or probabilistic scenarios. These models are used to determine production plans which minimizes the expected total operating costs while ensuring that a predefined service level constraint for each product is satisfied. We extend and investigate these stochastic models of the multi-item lot-sizing to a more practical setting where multiple service levels can be used in conjunction across multiple products to ensure that the business requirements are satisfied on an aggregate level.

1 - Unsupervised Anomaly Detection with Data-describing Deep Neural Network

Hyungrok Do, Korea University, Seoul, Korea, Republic of, hyungrok@korea.ac.kr, Seoung Bum Kim

Data description methods concern the characterization of a data set. A good description of data can be used to detect novel data or outliers. In this study, we propose a neural network-based data description algorithm, named neural data description (NDD). The proposed NDD algorithm simultaneously learns feature mapping from data and constructs compact hypersphere that encloses data points in the feature space. We demonstrate the effectiveness and applicability of the proposed algorithm through real-world data sets.

2 - Missing Data Imputation with Cycle-consistent Adversarial Networks

Hyungu Kahng, Korea University, Seoul, Korea, Republic of, hgkahng@korea.ac.kr, Seoung Bum Kim

We extend the recently proposed generative adversarial imputation networks (GAIN) framework for missing data imputation by introducing an additional regularization term to induce cycle consistency. The generator learns to predict the missing values and uses the predicted values to reconstruct the observed values. The discriminator attempts to determine which components are actually observed. Experiments on various datasets demonstrate that the proposed algorithm outperforms the GAIN and other imputation methods for various missing rates.

3 - Automatic Insect Count from Incomplete Scenes Using Convolutional Neural Networks

Jose Azucena, Ph. D. Student, University of Arkansas, Fayetteville, AR, United States, jch051@uark.edu, Haitao Liao

For geographical areas intended to be used for agricultural endeavors, an estimate of the size of existent insect populations can be of interest. A method capable of identifying and counting different species without manual or expert input is a valuable tool for population monitoring. This work proposes the use of Convolutional Neural Network models to learn from incomplete scenes. ResNet architecture is used to achieve robust estimations under variable specimen deformation. Simulated datasets of insect images are created, and the model is evaluated under various scenarios.

4 - Increasing Traffic Management Efficiency for Highway Authorities

Zainab Riaz, Assistant Professor, LUMS, Lahore, Pakistan, zainab.riaz@lums.edu.pk, Zeeshan Aziz

Decisions taken in early stages of Traffic Management planning have a huge influence on downstream implementation and in determination of road user impact. Given increasing demands and expectations from Road Network operators, decision-making will become more complex in years ahead. In this context, it is important to leverage existing data to drive efficiencies. In this paper, Traffic Management incursions and accident data sets were analysed with a view to drive insights and patterns from existing data sets, to ensure organisation is yielding benefits from data that is being collected and to demonstrate benefits that could be achieved by analysing the collected data.

5 - Adaptive Traffic Signal Control for Intersection Networks

Myungeun Eom, POSTECH, Pohang, Kyungbuk, Korea, Republic of, meeom@postech.ac.kr, Byung-In Kim

Adaptive traffic signal control is necessary to reduce traffic congestion at intersections. However, adaptive control for a network of intersections is challenging because the characteristics of the intersections and the network are unique and complicated, and traffic flows are highly stochastic. This talk proposes a simulation based optimization algorithm, which is applicable to various network types, to determine the optimized signal plan. The algorithm considers various objectives of the traffic signal control corresponding to principles of intelligent transportation systems.

6 - Examining the Spatiotemporal Trend of Left-turn Crashes with Multidimensional Panel Data At Intersections

Mengqing Xu, Southwest Jiaotong University, Chengdu, China, xumengqing1@163.com, Yingfei Fan

Based on 13-year multidimensional panel data (i.e., crash counts, geographical and spatial characteristics, traffic features, and economic variables) in Michigan, the paper adopts the support vector machine model to compare the spatiotemporal associations, including the independent-over-time random variation with the fixed spatial correlation, the fixed-over-time-space correlation, and the varying coefficient between time and space. Significantly explanatory variables are also identified.The results show that 1) three types of left-turn crashes show different spatiotemporal trends and 2) the spatiotemporal associations are correlated with the variation of economic variables.

1 - Learning-based Optimal Solution Prediction for Mixed Integer Programming

Jian-Ya Ding, Zhejiang Cainiao Supply Chain Management Co., Ltd., Hangzhou, China, jianya.djy@cainiao.com, Lei Shen, Peng Fei, Bing Wang, Yinghui Xu

Mixed Integer Programming (MIP) is a widely used modeling technique for combinatorial optimizations. In most applications, a similar MIP model is solved on a regular basis, maintaining the same form but differing in data. This allows the use of Machine Learning method to explore underlying information in MIP structures. In this paper, we present a solution predicting method to add initial cuts to the MIP model. Rather than treating each decision variable isolatedly, we view coefficients matrix in MIP as a graph and use graph embedding to analyze variable connections. Numerical evaluations show significant improvements in several different MIP problems, including two Cainiao online applications.

2 - Mixed-Integer Multi-Objective Optimization through Multiparametric Programming

Styliani Avraamidou, Texas A&M University, College Station, TX, United States, styliana@tamu.edu, Iosif Pappas, Burcu Beykal, Baris Burnak, Justin Katz, Metin Turkay, Efstratios Pistikopoulos

Optimization problems involving more than one objective function are referred to as Multi-Objective Optimization (MOO) problems. In this work, we present an algorithm for the exact explicit derivation of the Pareto front of mixed-integer linear MOO problems based on multi-parametric programming. The -constraint approach is used to transform the MOO problem into a single objective multi-parametric mixed-integer linear problem where the tunable suboptimality variables (resulting from the -constraints) are considered as parameters. The proposed approach is illustrated through a set of numerical examples and its capabilities are demonstrated in a computational study.

3 - A Multi-parameter Sensitivity Analysis of Linear Integer Program

C Y. (Chor-yiu) Sin, National Tsing Hua University, Hsinchu, Taiwan, cysin@mx.nthu.edu.tw

A stochastic programming with P states can well be formulated as a deterministic programming with P-1 probabilities. In this and the case with non-linearity in parameters, when one parameter changes the others may also change. Consequently the existing sensitivity analysis in the linear integer program may not be applicable, as it confines the attention to one-parameter change. This paper considers a special type of Lagrangian dual function which renders strong duality. Using this Lagrangian dual function, we first generalize the result in Shapiro (1977) to multi-parameter cases. Further, we show with synthetic data that our analyses save a lot of computer time in large-scale optimization.

4 - Weapon-target Assignment Problem: Exact and Approximate Solution Algorithms

Konstantin Pavlikov, University of Southern Denmark, Odense M, Denmark

The Weapon-Target Assignment (WTA) problem aims to assign a set of weapons to a number of targets, such that the expected value of survived targets is minimized. The WTA problem is a nonlinear combinatorial optimization problem known to be NP-hard. We employ several techniques to linearize the WTA problem, which makes the problem more tractable from computational point of view. Mixed integer linear reformulations of the WTA problem are solved using state of the art optimization software. Numerical experiments demonstrate that problem instances of size of up to 250 weapons and 500 targets can be solved to optimality and larger instances to suboptimality with small gaps within reasonable amount of time.

1 - Structural Embeddedness and Efficiency of Warehouse Inventory Management: a Network Perspective

Kedong Chen, University of Minnesota, Minneapolis, MN, 55414, United States, chen3548@umn.edu, Hung-Chung Su, William Li, Kevin W. Linderman

Inventory efficiency is a key performance indicator for warehouse managers when companies increasingly rely on intricate networks of warehouses to satisfy customer demands. Facing demand and product variabilities, How can warehouse managers take advantage of the network structure to better handle variabilities and improve inventory efficiency? The concept of structural embeddedness captures the focal warehouse's connections with other warehouses in the network. Through a two-stage least-square fixed-effects model on a panel dataset, we examine the effects of structural embeddedness and how it interacts with product and demand variabilities to affect inventory efficiency of a warehouse.

2 - Modeling Uncertain and Dynamic Interdependencies of Infrastructure Systems with Stochastic Block Model

Jin-Zhu Yu, Vanderbilt University, Nashville, TN, United States, yujinzhu88@gmail.com, Hiba Baroud

Modeling the resilience of interdependent critical infrastructure (ICI) requires a careful assessment of interdependencies as these systems become interconnected. The interdependency across ICIs are often subject to uncertainty due to lack of data. This paper develops an approach to modeling the interdependency of ICIs with probabilistic graphical models. Specifically, the approach estimates the probability of links between individual systems considered as blocks in the stochastic block model. The proposed model uses several nodal attributes as predictors. The proposed approach is illustrated with a case study of the interdependent water and power networks in Shelby County, Tennessee.

3 - The Role of Structural Characteristics of Entities in Explaining Firm Performance in Inter-firm Networks

Gyusuk Lee, Michigan State University, East Lansing, MI, United States, leegyus1@broad.msu.edu, Srinivas Talluri

The research objective of this study is to investigate the impact of supply network structures on performance of different supply chain entities in various settings. The structural characteristics of supply network and its entities will be modeled through social network analysis. The role of different supply network structures and structural positions of supply chain participants in explaining firm performance will be empirically tested utilizing panel network data.

4 - How Do Technological Characteristics of a Firm's Supply Network Drive its Innovativeness?

Shubhobrata Palit, Student, Georgia Institute of Technology, 8 00 West Peachtree NW, Atlanta, GA, 30308, United States, Manpreet Singh Hora, Soumen Ghosh

We examine how the technology characteristics of a firm's supply network drive its innovation capability. Using the innovation and the supply chain relationship data, we find empirical support for hypotheses linking technology characteristics of a firm's supply network and the firm's innovation capability. This study has important managerial implications for sourcing and innovation strategy.

1 - Two-stage Robust Minimum Cost Flow under Demand Uncertainty

Sabrina Schmitz, RWTH Aachen University, Aachen, Germany, Christina Büsing, Arie M.C.A. Koster

In this talk, we introduce a minimum cost flow model where on the one hand demand and supply are subject to uncertainty and on the other hand flow values of a predetermined set of arcs have to be equal in all demand and supply realizations. The integration of these aspects is motivated by, for example, long-term contracts in logistics where the transportation volumes of subcontractors need to be determined before the number of shipments are known. In the case of a discrete set of scenarios, we derive structural results, study the problem's complexity, and analyze first algorithms.

2 - Cell-based Dynamic Evacuation Traffic Management under Risk and Resource Allocation Considerations

Vedat Bayram, Assistant Professor, TED University, Ankara, Turkey, vedat.bayram@tedu.edu.tr, Hande Yaman

In this study, an evacuation management problem based on cell transmission model (CTM) is presented. Although cell-based approach models the traffic phenomenon in the most realistic way, it can hardly handle realistic-size instances due to excessive memory and/or CPU time requirements. We transform the original road network to a cell network and the cell network to a time expanded network to efficiently solve realistic instances. We consider hazard values of road segments that change dynamically over time. We also study the optimal dynamic resource allocation strategies to enable efficient use of road capacities. We present methodologies to efficiently solve the problem.

3 - An Exact Bidirectional Pulse Algorithm for the Constrained Shortest Path Problem

Andres L. Medaglia, Universidad de los Andes, Cr 1 este #19 A. 40, Ingenieria Industrial, ML711, Bogota, 111711, Colombia, amedagli@uniandes.edu.co, Nicolás Cabrera, Leonardo Lozano, Daniel Duque

A constrained shortest path is a minimum-cost sequence of arcs on a directed network that satisfies knapsack-type constraints on the resource consumption over the arcs. We propose an exact method based on a recursive depth-first search procedure known as the pulse algorithm. One of the key novelties of the proposal lies in a bidirectional labeling strategy leveraged on parallelism. In addition, we developed a pulse-based heuristic that quickly finds near-optimal solutions and shows great potential for column generation schemes. We present computational experiments over large real-road networks with up to 6 million nodes and 15 million arcs.

4 - Large-Scale Network Design with Application to Carbon Capture and Storage

Navid Matin Moghaddam, Arizona State University, Tempe, AZ, 85281, United States, nmatinm@asu.edu, Jorge A. Sefair

We study a fixed charge network design problem with application to carbon capture and storage (CCS). Motivated by the emerging need of climate stabilization, CCS seeks to prevent carbon emissions from entering the atmosphere by capturing, compressing, and transporting CO2 from sources (e.g., oil refineries) to geologic reservoirs (e.g., depleted oil wells) for its long-term storage. To find the least-cost network of pipelines able to transport a target amount of CO2, we propose an optimization model and an exact decomposition algorithm that takes advantage of the optimal solution sparsity and the problem's cost structure. We illustrate the performance of our methods on a set of real instances.

1 - Coordinated Logistics with a Truck and A Drone

John Gunnar Carlsson, University of Southern California, Los Angeles, CA, 90089, United States

We determine the efficiency of a delivery system in which an unmanned aerial vehicle (UAV), or a fleet of UAVs, provides service to customers while making return trips to a truck that is itself moving. In other words, a UAV picks up a package from the truck (which continues on its route), and after delivering the package, the UAV returns to the truck to pick up the next package. We conclude that the improvement in efficiency due to introducing a UAV is proportional to the square root of the ratio of the speeds of the truck and the UAV.

2 - Data-driven Optimization Approach for Inventory Planning

Hoda Bidkhori, University of Pittsburgh, Dept of Industrial Engineering, Pittburgh, PA, 15206, United States, bidkhori@pitt.edu, Ke Ren, Max Shen

We present a data-driven continuous-review inventory problem for a warehouse facing unknown non-stationary demands. We learn and update the inventory policies using both historical and daily observed demand data. We present four approaches, where two are Bayesian-based approaches and the other two are lasso-based. The Bayesian-based algorithms integrate both the inventory parameters and observed demands to identify the optimal inventory policies, whereas the lasso-based algorithms use the consistency between demands. Finally, we discuss how practitioners should choose the best approach based on their product data environments.

1 - Optimizing Conservation Planning for Multiple Cohabiting Species

Hayri Onal, University of Illinois, Agr. & Consumer Economics, 305 Mumford Hall, Urbana, IL, 61801, United States, h-onal@illinois.edu, Yicheng Wang

We introduce a linear MIP model for designing a spatially coherent nature reserve system that provides protection to multiple cohabiting species. When selecting reserve sites, we consider a conservation resource limitation, interdependencies between the species' habitat needs, and spatial characteristics of the available habitat sites. We present an empirical application to the joint protection of two cohabiting species in a military installation in Georgia, USA. We test the computational efficiency of the model and investigate the trade-offs between spatial attributes and habitat quality.

2 - Modern Portfolio Theory to Formalize Diversification as an Explicit Strategy for Managing Risk in Climate-driven Reserve Design

Zulqarnain Haider, University of South Florida, Tampa, FL, 33613, United States, zulqarnain@mail.usf.edu, Mitchell J. Eaton, Simeon Yurek, Julien Martin, Fred Johnson, Bradley Udell, Hadi Charkhgard, Changhyun Kwon

Climate change and urban growth impact habitats, and species. Uncertainty regarding the scale of landscape change complicates reserve planning. We use principles of Modern Portfolio Theory, to formalize diversification as an explicit strategy for managing risk in climate-driven reserve design. Evaluating several climate risk profiles for a case study in South Carolina, our results suggest that budgets will likely be important determinants of conservation planning strategies, particularly when considering divestment. Optimal reserve design solutions are determined to improve expected losses while considering risk associated with sea level rise and urbanization.

3 - Optimizing Search and Control of EAB in Canadian Forests

Sabah Bushaj, New Jersey Institute of Technology, Newark, NJ, United States, sb2386@njit.edu, Esra Buyuktahtakin Toy, Denys Yemshanov, Robert Haight

Emerald ash borer (EAB) is one of the most damaging invasive species ever to reach the United States, killing millions of ash trees. In this study, we present a multi-stage stochastic mixed-integer programming (M-SMIP) formulation to minimize the damage caused by EAB in Canadian Forests. Our results provide insights into optimal timing and location of EAB surveillance and control strategies.

4 - A Network-based Approach to Assess the Trade-off Between Forest Management and Wildlife Protection Goals in Boreal Landscapes

Denys Yemshanov, Natural Resources Canada, Sault Ste. Marie, ON, P6A2E5, Canada, denys.yemshanov@canada.ca, Robert G. Haight, Mark-Andre Parisien, Ning Liu, Frank H. Koch, Quinn Barber, Cole Burton, Fabio Campioni, Salimur Choudhury

Wildlife protection is a critical priority in the areas of active forest management. We link a network-flow habitat connectivity model with a harvest scheduling model which finds optimal harvest regimes under the habitat connectivity objective. The model maximizes the amount of connected wildlife habitat while satisficing the forest harvest objective, subject to even harvest flow, harvested timber volume target and sustainability constraints. We apply the model to explore the trade-off between caribou protection measures and harvest in Canadian boreal forests - areas of prime caribou habitat.

1 - A Doubly-randomized Block-coordinate Primal Dual Method for Large-scale Convex Concave Saddle Point Problems: Acceleration via Variance-reduction

Necdet Serhat Aybat, Penn State University, Penn State University, University Park, PA, 16802, United States, nsa10@psu.edu

We consider computing a saddle point (x*,y*) of convex-concave L(x,y)=\sum_{n=1}^N Phi_n (x,y). To contend with the challenges in computing full gradients, we employ a primal-dual scheme in which randomly selected primal and dual variable blocks, x_i and y_j, are updated at every iteration. When N is large, we can utilize an increasing batch-size of the gradients of Phi_n, to achieve the optimal rate of O(1/k) in terms of L(x^k,y*)-L(x*,y^k). This problem class includes convex optimization with a large number of constraints, and preliminary results on QCQPs with many constraints look promising.

2 - Learning via Non-convex Min-max Games

Meisam Razaviyayn, University of Southern California, Los Angeles, CA, 90089, United States, Maher Nouiehed, Maziar Sanjabi, Jason Lee

Recent applications that arise in machine learning have surged significant interest in solving min-max saddle point games. This problem has been extensively studied in the convex-concave regime for which a global equilibrium solution can be computed efficiently. In this talk, we study the problem in the non-convex regime and show that an ϵ—first order stationary point of the game can be computed when one of the player's objective can be optimized to global optimality efficiently. We discuss the application of the proposed algorithm in defense agains adversarial attacks to neural networks, generative adversarial networks, and generative adversarial imitation learning

3 - A Unified Analysis of Extra-gradient and Optimistic Gr adient Descent Ascent Methods for Saddle Point Problems: Proximal Point Approach

Sarath Pattathil, MIT, Cambridge, MA, United States, sarathp@mit.edu

In this work we study saddle point problems, and, in particular, we focus on two variants of Gradient Descent-Ascent algorithms, Extra-gradient (EG) and Optimistic Gradient Descent Ascent (OGDA) methods. We show that both of these algorithms admit a unified analysis as approximations of the classical proximal point method for solving saddle point problems. This viewpoint enables us to develop a new framework for analyzing EG and OGDA for bilinear and strongly convex-strongly concave settings. Moreover, we use the proximal point approximation interpretation to generalize the results for OGDA for a wide range of parameters.

4 - Negative Momentum for Improved Game Dynamics

Ioannis Mitliagkas, Université de Montréal, Montreal, QC, Canada

Games generalize the single-objective optimization paradigm by introducing different objective functions for different players. Differentiable games often proceed by simultaneous or alternating gradient updates. In machine learning, games are gaining new importance through formulations like generative adversarial networks (GANs) and actor-critic systems. However, compared to optimization, game dynamics are more complex and less understood. Our analysis shows that a negative momentum term can improve convergence. Our empirical results show that alternating gradient updates with a negative momentum term achieve convergence on the notoriously difficult to train saturating GANs.

1 - Lane-based Alternating Control Scheme: An Innovative Intersection Control Scheme Achieving Near-Optimal Throughput

Xi Lin, Tsinghua University, beijing, China, ghtttaifeng@126.com, Xiangdong Chen, Fang He, Yafeng Yin, Meng Li

This research proposed an intersection control scheme that achieves maximum throughput under mild assumption, called Lane-based Alternating Control Scheme (LACS). The control scheme assigns pre-set lane-based time windows to vehicles for entering an intersection, which allows the vehicle movements in all directions to work simultaneously without collisions. To further adapt the LACS to handle imbalanced demands, a hybrid scheme combining LACS with traffic signals (LA-TS) is proposed. Numerical experiments are implemented to compare the performances of LACS and LA-TS with some existing control schemes, and the results show that proposed schemes work well under various settings.

2 - Autonomous Intersection Management Applied to Realistic T raffic Scenarios

Aaron Parks-Young, Texas A&M, College Station, TX, United States, aaron.parks-young@tamu.edu, Guni Sharon

By relying on the fine and accurate control of connected and autonomous vehicles along with communication capabilities, intersection management protocols coordinate multiple vehicles simultaneously across an intersection. Previous publications have shown such protocols have potential to significantly reduce traffic delay for stylized traffic scenarios. In the proposed talk we will discuss adaptations to the known AIM simulator allowing it to simulate more real-to-life traffic scenarios as well as performance trends that arise from these scenarios.

3 - A Novel Trajectory Control Logic for Intersections with a Mix of Connected Human-driven and Automated Vehicles

Ramin Niroumand, Washington State University, Pullman, WA, United States, Mehrdad Tajalli, Leila Hajibabai, Ali Hajbabaie

This study proposes a new mathematical formulation to optimize the trajectory of connected human-driven and automated vehicles through traffic intersections. The underlying concept is to use traditional green and red signals under low connected and automated vehicle (CAV) market penetration rates. When the CAV market penetration rate is high enough, CAVs act as moving signals and control the movement of human-driven vehicles. Results indicate that the proposed method can work efficiently under various CAV market penetration rates.

4 - A Data-Driven Optimization Based Online Predictive Optimal Signal Control Model for Connected Signalized Intersections

Kuilin Zhang, Michigan Technological University, Civil and Environmental Engineering, 870 Dow Environmental Sciences, Houghton, MI, 49931, United States, klzhang@mtu.edu, Qinjie Lyu

We propose a data-driven optimization based online predictive traffic signal optimization model using real-time high-frequency connected vehicle data received at signalized intersections via vehicle-to-infrastructure communication technologies. An online learning algorithm is used to predict future traffic dynamics at signalized intersections using real-time mobile sensing data generated from connected and automated vehicles. The predicted traffic dynamics will be integrated into a data-driven optimization based control model for a robust optimal signal control under traffic uncertainty.

5 - A Lagrangian-based Signal Timing and Trajectory Optimization in a Mixed Connected and Automated Vehicle Environment

Mehrdad Tajalli, North Carolina State University, Raleigh, NC, 99163, United States, mtajall@ncsu.edu, Ali Hajbabaie

This study presents a mixed integer nonlinear program for integrated signal timing and trajectory optimization of connected and automated vehicles at signalized intersection to minimize total travel time and harmonize speeds. A lagrangian relaxation-based solution technique is developed that decomposes the problem into lane-group-level sub-problems. Numerical results show that the algorithm is capable of finding optimal solutions efficiently and improves traffic operations at signalized intersections.

Vehicle Routing IV

Contributed Session

Chair: Xingyin Wang, Singapore University of Technology and Design, Singapore, 487372, Singapore

1 - An Efficient Approximation Algorithm for Large-scaled Stochastic Combinatorial Optimization Problems

Yoko Ide, Mitsubishi Heavy Industry, Kanagawaken, Japan, yoko1_ide@mhi.co.jp, Kazuhisa Makino, Yo Morimoto

We propose an efficient approximation algorithm for large-scaled stochastic combinatorial optimization problems. Specifically, we focus on the vehicle allocation and production planning problems with uncertainty characterized by probability distributions for travel time and production lead time of the problems. Our algorithm makes use of a few scenarios to efficiently construct an approximate solution. We implement our algorithm by using Gurobi optimizer to demonstrate the effectiveness of the algorithm for large-scaled real-world problems.

2 - Impact of Drone Failures on the Drone Flight Schedule in a Delivery Application of Drones

Maryam Torabbeigi, University of Houston, Houston, TX, United States, maryam.torabbeigi@gmail.com, Gino J. Lim, Navid Ahmadian, Seon Jin Kim

One of the growing application of drones is in the parcel delivery. This study aims to provide flight paths for a group of drones such that the amount of demand that can be lost due to drones failures, will be minimized. Therefore the expected loss of demand (ELOD) is introduced here to obtain a more reliable flight schedule. A mixed integer programming (MIP) problem is provided that minimizes the ELOD and determines the assignment of customers to drones and the sequence of visiting them by drones. A SA heuristic algorithm is proposed to solve the large-size problems. The results show the impact of including drone failures in the scheduling.

3 - A Universal Routing Algorithm Including Parking Probabilities and Historic Travel Time Data

Mareike Hedderich, Bundeswehr University Munich, Munich, Germany

The daily challenges for an urban driver are finding a free on-street parking spot and meeting an arrival deadline at their destination. To overcome those problems, this paper presents an approach to combine two routing algorithms. The combination is called the universal routing algorithm and involves a park spot route using on-street parking information and a stochastic route using historic travel time data on street links. The result is a route that leads the driver through streets with high parking probabilities close to the destination and maximizes the probability of arriving on time. This paper presents a method on how to combine the two algorithms and shows some simulation results.

4 - Speed-up Heuristic for an On-demand Ride-pooling Algorithm

Roman Engelhardt, Bundeswehr University Munich, Neubiberg, Germany, roman.engelhardt@unibw.de, Florian Dandl, Klaus Bogenberger

Real-time assignments for large scale on-demand ride-pooling fleets is a challenging problem until today. In this study we compare a insertion heuristic algorithm with a state-of-the-art multi-step matching algorithm on trip data for Munich, Germany. Results indicate by using the multi-step algorithm up to 8% additional requests could be served while also 10% additional driven distance could be saved. To decrease computational time for the advanced algorithm, a vehicle selection heuristic is presented, which can speed up the most cost intensive algorithm step by a factor of 8, while keeping the number of served requests almost constant and maintaining 70% of the driven distance saved in the system.

5 - A Two-stage Solution Approach for the Directed Rural Postman Problem with Turn Penalties

Xingyin Wang, Singapore Univeristy of Technology and Design, Singapore, xingyin_wang@sutd.edu.sg, Carmine Cerrone, Benjamin Dussault, Bruce L. Golden, Edward Wasil

We consider the Directed Rural Postman Problem with Turn Penalties (DRPP-TP). A solution is a tour that traverses all required arcs of the graph. The cost of the tour is the sum of the lengths of the traversed arcs plus the penalties associated with the turns. An Eulerian tour-first turn-second approach has been proposed in the literature. In the first part of this paper, we identify several characteristics of an input instance that make the two-stage approach effective. In the second part of this paper, we describe an integer linear program that is combined with a local search algorithm. This combination produces high-quality solutions to the DRPP-TP in a reasonable amount of computing time.

Dispatching, Delivery, & Assignment

Sponsored: Transportation Science & Logistics/Freight Transportation & Logistics

Sponsored Session

Chair: Lei Zhao, Tsinghua University, Beijing, 100084, China

1 - Coordinated Delivery for Shopping Malls with Limited Docking Capacity

Ruidian Song, Tsinghua University, Tsinghua Student Building, No.15, Beijing, China, srd13@mails.tsinghua.edu.cn, Hoong Chuin Lau, Lei Zhao

Shopping malls can be densely located in major cities such as Singapore and Hong Kong. Due to limited docking capacity, uncoordinated deliveries to the tenants tend to result in congestion. A delivery coordination platform centrally schedules vehicle routes for multiple logistics providers, and simultaneously reserves dock timeslots for the deliveries. These decisions need to be made jointly against the backdrop of travel and service time uncertainty. We model this problem as a two-stage stochastic mixed integer program, and develop an adaptive large neighborhood search (ALNS) algorithm. Extensive numerical experiments demonstrate the effectiveness and efficiency of our approach.

2 - Dispatching in Liquefied Natural Gas Road Transportation

Yilei Wan, Tsinghua University, Beijing, China, wan-yl17@mails.tsinghua.edu.cn, Xue Luo, Lei Zhao

A liquefied natural gas (LNG) road transportation platform purchases LNG and dispatches a fleet of vehicles to load LNG at suppliers (e.g., liquefaction plants, storage terminals) and to deliver to customer sites (e.g., fuel stations). On each day, the platform dispatches and registers available vehicles to suppliers by a specified deadline. On the next day, the customer demands reveal and the platform dispatches loaded vehicles to satisfy these demands to maximize the overall profit. We model this problem as a two-stage stochastic mixed integer program, and develop an efficient algorithm based on adaptive large neighborhood search (ALNS).

3 - Heuristic Methods for the Locomotive Assignment Problem with DP

Camilo Ortiz-Astorquiza, Pontificia Universidad Javeriana, Bogota, Colombia, camiloortiz@javeriana.edu.co, Jean-Francois Cordeau, Emma Frejinger

In this talk, we present various algorithmic refinements on an IP formulation for a general variant of the Locomotive Assignment Problem at the tactical level in which the operating mode i.e. distributed power or conventional, is part of the decision-making problem. We also present two heuristic methods to obtain near optimal solutions. We discuss the potential benefits of the model and solution methods based on computational experiments from a case study for Canadian National Railways.

4 - Compact Routes in Vehicle Routing Problem with Time Windows in Postal Services

Alexis Bretin, Polytechnique Montreal & Gerad, Dept Math and Industrial Engineering, C. P. 6079 Succ Centre-Ville, Montreal, QC, H3C 3A7, Canada, alexis.bretin@polymtl.ca, Guy Desaulniers, Louis-Martin Rousseau

We will present a Branch-and-Price-Based Large Neighborhood Search algorithm to solve the Vehicle Routing Problem with Time Windows that arises in postal services (parcel deliveries). In this field, time window density happens to be sparse, as commercial customers have some, while personal customers may be visited without any time window restriction. Classic constraints and specific ones, such as minimum feeding curves of the sorting machines, have to be handled, as well as preferences for compact routes. Constraint Programming is used for pre-processing purpose.

5 - Same-Day Delivery using a Heterogeneous Fleet

Dirk C. Mattfeld, Technische Universität Braunschweig, Wirtschaftsinformatik, Braunschweig, 38106, Germany, d.mattfeld@tu-braunschweig.de, Jeannette Hermanns, Barrett Thomas, Marlin Wolf Ulmer

Due to cost pressure, environmental restrictions, and workforce shortages, service providers are testing a variety of different vehicle types to satisfy deliveries in urban areas. In this talk, we consider a fleet of different vehicle types to serve dynamically requesting customers for urban operational delivery. Each customer expects delivery from a depot before a deadline. Our objective is to minimize the expected third party delivery costs. We present a heuristic method that exploits the individual features of the vehicle types to determine good assignment strategies of customers to vehicles. Results indicate that the combination of vehicle and geography attributes drive assignments.

Inventory Management II

Contributed Session

Chair: Yan Liang, University of Toronto

1 - Dynamic Capacity Allocation under Lost Sales and Service Dependent Demand

Govind Lal Kumawat, Indian Institute of Management Ahmedabad, Ahmedabad, India, Debjit Roy, Felix Papier

We study the capacity allocation problem faced by a supplier under lost sales and service dependent demand. The supplier allocates a limited production capacity to heterogeneous customers. Any unmet customer demand is lost and impacts the future demand. Our research is motivated by a component supplier that supplies components to original equipment manufacturers in a heavy commercial vehicle market. We formulate the problem as a Markov decision process and derive optimal capacity allocation policies and structural results.

2 - On the Complexity of the Periodic Joint Replenishment Problem

Liron Yedidsion, Senior Research Scientist, Amazon, Seattle, WA, United States, yedidsion.liron@gmail.com, Alexander Tuisov

The Continuous Periodic Joint Replenishment Problem (CPJRP) has been one of the core and most studied problems in supply chain management for the last half a century. Nonetheless, despite the vast effort put into studying the problem, its complexity has eluded researchers for years. Although the CPJRP has one of the tighter constant approximation ratio of 1.02, a polynomial optimal solution to it was never found. Recently, the discrete version of this problem was finally proved to be NP-hard. In this research, we extend this result and prove that the CPJRP problem is also strongly NP-hard.

3 - Trade Credit Insurance: The Purchase Necessity and the Premium Cost-sharing Mechanism

Hongping Li, University of Science and Technology of China, Hefei, China, hpli@mail.ustc.edu.cn

We consider a supply chain consisting of an insurer, a manufacturer, and a capital-constrained retailer who get trade credit from the manufacturer. To avoid the default risk caused by demand uncertainty, the manufacturer and the retailer jointly consider the purchase of insurance. We explore decisions of each participant, the role of insurance and premium cost-sharing mechanism. Our results show that insurance is adopted by the manufacturer alone when she is highly sensitive to risk, which benefits all partners and partly coordinates the supply chain. Insurance impels more financing with lower wholesale price, and promotes higher order level. However, the retailer's default risk increases.

4 - On Average-cost Periodic-review Inventory Models with Lost Sales and Quasiconvex Costs

Yan Liang, University of Toronto, A-149, Math Tower, Toronto, ON, 11794, Canada, yan.liang@rotman.utoronto.ca, Eugene A. Feinberg

In this talk we discuss a stochastic periodic-review setup-cost inventory control model with lost sales and holding/shortage cost function satisfying quasiconvexity assumptions. We show that the family of discounted relative value functions is equicontinous and that this model satisfies sufficient conditions for the validity of the average cost optimality equations. This implies the average cost optimality of (s,S) policies and the pointwise convergence of the discounted cost value functions to the average cost value function as the discount factor increases to 1.

1 - Nationwide Passenger Migration Forecasting: A Spatio-temporal Deep Learning Approach

Yuxin He, City University of Hong Kong, Hong Kong, Hong Kong, yuxinhe2-c@my.cityu.edu.hk, Yang Zhao, Kwok Leung Tsui

Forecasting passenger migration by exploring nationwide migration pattern is vital for migration management and effective allocation of national transportation resources. However, it is challenging as nationwide migration is affected by complex factors including spatial and temporal dependencies, and external factors. Using migration data from Tencent Location Big Data, this paper employs the deep spatiotemporal residual network (ST-ResNet) to simultaneously forecast inflow and outflow of migrants of cities in China. The experimental results show that ST-ResNet can well capture the spatiotemporal dependencies and outperforms state-of-art baselines in terms of forecasting accuracy.

2 - Co-evolution of Electric Vehicle Adoption and Charging Infrastructure Expansion Using Agent-based Modeling

Yan (Joann) Zhou, Group Leader, Mobility and Deployment, Argonne National Laboratory, Lemont, IL, United States, yzhou@anl.gov, Marianne Mintz, Charles M. Macal

We developed an agent-based model, Compass, to model short to long-term co-evolution of electric vehicles adoption and charging infrastructure expansion by quantifying the energy consumption, spatiotemporal charging demand and unmet demand/trips in Chicagoland. Compass models decisions of three agents, driver, household and investors through daily and annual simulation modules. Compass uses both bottom-up and top-down approach by 1) capturing the charging demand at given location/time based on travel pattern and number of vehicles, and 2) identifying the relationship between the density of charging stations and vehicle stocks using empirical data. Case studies will be presented.

3 - Collaboration in the Urban Solid Waste Collection Design

Alejandro Lamas, NEOMA Business School, Rouen, France, alejandro.lamas@neoma-bs.fr, Carola A. Blazquez

Collaboration between supply chains aims to gain from the synergies arising from collaborators. An extension of such initiative for the public sector is the design of the collection of the urban solid waste. District authorities design this collection independently between each other so a joint planning that enables sharing resources (e.g. vehicles, workers, etc.) may lead to more efficient collection. We propose a framework for jointly design the collection in such a way we minimize the global cost while meeting the individual goals of the participants. Due to the combinatorial nature of the problem, we propose a Benders decomposition approach for addressin real-life size instances.

4 - A Cost Reduction Model for the Management of Pipe Cars in the Brazilian Northeast.

Reinaldo Crispiniano Garcia, Operations Research Laboratory (www.orlab.com.br), Brasilia, Brazil, rcgar@yahoo.com, Magno Gonçalves da Costa, Diogo Samy, Ana Luisa Oliveira, Clovis Neumann, Rodrigo de Morais Balduíno Oliveira, Álvaro Café

The problem of delivering water in the Brazilian Northeast is a challenging one, with 30,000 communities and 4,000 reservoirs to deliver it. Some of the reservoirs have a limited capacity, mainly the water treatment plants (WTP), even though they have priority due to their water quality. The no. of reservoirs and communities change every month, since depending on the rainfall, either a reservoir can become dry or a community will not request water by the pipe cars in the next month. This work implements a model of the VRP, taking into account the communities demands, the reservoirs capacities and their water quality. The developed model shows an annual savings of US$ 100 million, about 25% of the total cost.

5 - A Method to Quantify the Impacts of Charging Infrastructure on Passenger Vehicle Market in China

Shiqi(Shawn) Ou, Research Staff, Oak Ridge National Laboratory, Knoxville, TN, United States, ous1@ornl.gov, Zhenhong Lin, Xin He, Steven Przesmitzki, Jessey Bouchard

This study integrates the charging infrastructure analysis into the market dynamics analysis tool - New Energy and Oil Consumption Credits model to assess the charging infrastructure (home parking ratio, public charging opportunity, and charging costs) impacts on PEV ownership costs and analyze how the PEV market shares may be affected by attributes of the current charging infrastructure in China. Parameter sensitivity analysis on industry profits is conducted. The simulation results support that the public charging infrastructure has more effectiveness on promoting the PEV sales in the PEV emerging market than it is in the PEV mature market.

Joint Session AAS/TSL Air: Dynamic decision-making Models in AAS Operations and Revenue Management

Sponsored: Aviation Applications

Sponsored Session

Chair: Marla Lavanya

1 - Managing Airline Delay Uncertainty by Adjusting Connection Slacks: A Stochastic Programming Approach

Sujeevraja Sanjeevi, Team Lead Operations Research, Sabre, Southlake, TX, United States, sujeev.sanjeevi@gmail.com

Adjusting flight connection time slacks is a popular strategy among airlines to hedge against uncertainty in flight delays. We propose a 2-stage stochastic programming model that makes controlled adjustments to flight departure times to minimize the expected value of excessive flight delays. We solve this model using an integrated framework that uses Benders decomposition and column generation. Our computational results show that such adjustments can help airlines make significant improvements in reducing propagated delays and improving on-time performance. Our talk includes implementation techniques for drastic reductions in run times of integrated frameworks like ours.

2 - Efficient Performance Bounds for Dynamic Airline Recovery Models

Lavanya Marla, University of Illinois at Urbana-Champaign, Urbana, IL, 61801, United States, lavanyam@illinois.edu, Jane Lee

We introduce an information-relaxation-based approach to bounding the performance of airline recovery models. In a multi-stage dynamic programming, we construct an omniscient ops controller with full information, and penalize this controller based on the additional information that is not available to a real-world controller who cannot know future disruptions. Our approach reveals practical bounds on recovery approaches that are tighter than full-information-based regret bounds.

3 - A Model to Incorporate Dynamic Offer Generation Into Airline Revenue Management Systems

Kevin Wang, Graduate Research Assistant, MIT, Cambridge, MA, United States, kevini@mit.edu

Dynamic offer generation tailors offers to different demand segments by bundling ancillary services with flight purchases. We formulate a revenue-maximizing algorithm that dynamically prices flight and ancillary offers based on passenger willingness-to-pay, combining dynamic pricing and ancillary-aware RM. We show how this algorithm integrates with traditional RM systems. The PODS simulator is used to illustrate the source and magnitude of potential revenue gains from dynamic offer generation. The results provide insights about the benefits, drawbacks and competitive effects of ancillary bundling.

4 - Dynamic Pricing Recommendations for Airline Ancillaries with Customer Context

naman shukla, University of illinois, Urbana, IL, United States, namans2@illinois.edu, Arinbjörn Kolbeinsson, Lavanya Marla, Kartik Yellepeddi

Ancillaries have become a major source of revenue and profitability in the travel industry. Yet, conventional pricing strategies are based on business rules that are poorly optimized. We present a pricing model that provides dynamic pricing recommendations specific to each customer interaction and optimizes expected revenue per customer. We propose a meta-learning approach for synchronous deployment of multiple models. We describe the performance of these models based on both offline and online evaluations. We also measure the real-world business impact of these approaches by deploying them in an A/B test on an airline's internet booking website.

1 - The Leland Toft Optimal Capital Structure Model under Poisson Observations

Kazutoshi Yamazaki, Kansai University, Suita, Japan, kyamazak@kansai-u.ac.jp, Zbigniew Palmowski, Jose Luis Perez, Budhi Surya

We revisit the optimal capital structure model with endogenous bankruptcy first studied by Leland (1994) and Leland and Toft (1996). Differently from the standard case, where shareholders observe continuously the asset value and bankruptcy is executed instantaneously without delay, we assume that the information of the asset value is updated only at intervals, modeled by the jump times of an independent Poisson process. Under the spectrally negative Lévy model, we obtain the optimal bankruptcy strategy and the corresponding capital structure. A series of numerical studies are given.

2 - Dynamic Optimal Placement in a Limit Order Book under Variance Constraint

Hyoeun Lee, University of Illinois at Urbana-Champaign, Champaign, IL, United States, Jose E. Figueroa-Lopez, Raghu Pasupathy

We study the optimal placement problem of a stock trader who wishes to clear her inventory by a predetermined time horizon by using a limit order or a market order while controlling the variance. For a diffusive market, we characterize the optimal limit order placement policy under a variance constraint using two strategies: static and dynamic order placement strategy. We show that in the presence of a negative drift, there exist optimal placements for both cases. We also propose a simple method to approximate the optimal order placement with regard to the given variance constraint.

3 - Measuring the Endogeneity of the Cryptocurrency Market

Michael Mark, EPFL, Cugy(VD), Switzerland, Thomas A. Weber

To measure the self- and cross-dependence of the limit-order books for major cryptocurrencies, we estimate a nonparametric, mutually exciting Hawkes process. As the corresponding price processes are highly volatile and sensitive to news releases, we extend the standard law of motion for the arrival intensities by a kernel matrix representing the news impact. Using a hitherto untapped source of high-frequency cryptocurrency data, we construct a dynamic measure of the endogeneity of cryptomarket transactions.

4 - Uncertainty in Operating Leverage – A Foster Hart Risk Perspective

Ravi Prakash Ranjan, Eindhoven University of Technology, Eindhoven, Netherlands, miracle.ranjan@gmail.com, Shaunak Dabadghao, Arun Chockalingam

In this paper, we study the uncertainty in operating leverage and relate it to stability of heterogeneous set of firms. We define a coefficient of contribution margin (G) for a firm and understand its variation with degree of operating leverage. We quantify uncertainty in operating leverage using Foster-Hart (FH) risk where the fixed costs denote the threshold wealth in FH framework. We use the FH risk to assess whether the firm is in i) Safe Zone ii) Profit Making Zone with Risk, iii) Threat Zone and iv) Hazard Zone. Our subsequent analysis involves understanding how FH risk in operating leverage gets affected by firm's Cash Conversion Cycles and presenting empirical evidence for the proposed framework.

5 - Integrated Optimization of Maintenance Interventions and Spare Part Selections for a Partially Observable Multi-component System

Oktay Karabag, Postdoctoral Researcher, Eindhoven University of Technology, Eindhoven, Netherlands, o.karabag@tue.nl, Ayse Eruguz, Rob Basten

We consider a multi-component system in which a single condition parameter (e.g., vibration or temperature) is monitored. The outcome of monitoring indicates whether the system is functioning properly, is defective, or has failed. However, the condition signal does not reveal which component in the system is defective or has failed. The decision maker infers the exact state of the system from the current condition signal and the past data, in order to decide when to intervene for maintenance and which spare parts to take along. We model this system as a POMDP and examine the value of having better sensors in the system and the value of the optimal policy compared to more naive policies, numerically.

6 - Optimal Maintenance Policies of Partially Observable Systems with Costly Multi-sensor Observations

Heletje E. van Staden, PhD student, KU Leuven, Leuven, Belgium

Industry 4.0 technologies, including the Internet of Things, allows for increased access to the real-time monitoring of complex systems. In particular, it allows, by means of sensors, for the monitoring and fusion of data from multiple variables of complex systems, enhancing deterioration modeling. The different sensors may be deployed by different firms, such that the data may only be accessed at a fee. We investigate the effect of such costly multi-sensor data with uncertainty on the maintenance optimization problem. Using partially observable Markov decision processes, we derive insights into when costly sensor data should be acquired by developing optimal maintenance policies.

Joint Session RMP/Practice Curated: Market Design and Pricing for Ride-sharing

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Hamid Nazerzadeh, USC Marshall School of Business, Los Angeles, CA, 90089, United States

1 - Competition in Ride-hailing Markets

Amin Saberi, Stanford University, San Francisco, CA, 94105, United States, saberi@stanford.edu, Amir Ahmadinejad, Hamid Nazerzadeh, Nolan Skochdopole, Kane Sweeney

We present a model with two competing ride-hailing platforms. Riders choose the platform that maximizes their utility which is decreasing in price and waiting time. The drivers can accept trips from both platforms. We investigate whether competition can lead to a ``tragedy of the commons" and market failure as the platforms compete over the shared resource of open cars. We present a combination of theoretical results and numerical case studies, using parameters estimated from Uber data.

2 - Designing the Multi-modal Transit Marketplace

Chamsi Hssaine, Cornell University, Ithaca, NY, 90025, United States, ch822@cornell.edu, Siddhartha Banerjee, Samitha Samaranayake, Ragavendran Gopalakrishnan

We study the of design of a mobility marketplace: a centralized platform offering multi-modal trips that combie private firms like Lyft and Uber with public transit. We develop a framework for pricing multi-modal trips, with the objective of maximizing social welfare conditioned on ensuring that all commuters and transportation firms enjoy a weakly Pareto-improving outcomes. Our framework exposes tradeoffs between efficiency and fairness. Our results extend to incorporate common choice-models like the Multinomial Logit, marketplace subsidization, multiple mobility providers, and constraints on travel times and transit capacity.

3 - Incentivizing Optimal Locations in a Model of Spatial Competition with Stochastic Demand

J Massey Cashore, Cornell University, Ithaca, NY, United States

We study Nash equilibria in a stochastic strategic version of the facility location problem, modeling ridesharing and other two-sided marketplaces over networks. Specifically, given an assignment of agents to nodes, we study whether a payment mechanism exists under which the assignment is an equilibrium. Using a simple LP-based approach, we show that the welfare-optimal locations are incentivizable when the LP relaxation of the welfare optimization problem is integral. Finally, we study the efficacy of these payments using simulations based on the NYC taxi dataset.

4 - Dynamic Pricing for Ride Hailing Marketplaces

Hamid Nazerzadeh, USC Marshall / Uber Technologies, Los Angeles, CA, 90089, United States

Uber is running one of the largest marketplaces in the world that matches millions of riders and drivers together. One of the key features of Uber's marketplace is dynamic pricing, so called surge, that balances the demand for trips and the supply of available cars. The surge pricing also motivates drivers to relocate to parts of the city with higher demand. In this talk, I'll discuss the design and implementation of Uber's new driver surge mechanism.

Personalized Pricing and Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Sumit Kunnumkal, Indian School of Business, Hyderabad, 500032, India

1 - Dynamic Pricing with Demand Learning and Reference Effects

N. Bora Keskin, Duke University, Fuqua School of Business, Durham, NC, 27708-0120, United States, bora.keskin@duke.edu, Arnoud Victor den Boer

We consider a dynamic pricing problem with demand learning and reference effects. Customers are loss averse: they have a reference price that can vary over time, and the demand reduction when the selling price exceeds the reference price dominates the demand increase when the selling price falls behind the reference price by the same amount. Consequently, the demand function has a time-varying "kink" and is not differentiable everywhere. The seller neither knows the underlying demand function nor observes the reference prices. We consider several variants of this problem and design asymptotically optimal pricing policies.

2 - Pricing and Waiting Behavior of Individual Sellers in Electronic Marketplaces

Shweta Singh, University of Minnesota-Twin Cities, Minneapolis, MN, 55455, United States, shwetawipro@gmail.com, Guyves Achtari, Guang Li, Mikhail Nediak

We present an empirical study of the pricing and waiting behavior of individual sellers in an electronic marketplace and discuss its implications for design of price recommendation systems that target seller trade-off between revenue and time to sell.

3 - Prophet Inequalities on the Intersection of a Matroid and a Graph with Application to Network Revenue Management

Will Ma, Columbia University, 71 School Street, New York, NY, 02139, United States, Jackie W. Baek

We consider prophet inequalities on the intersection of a matroid and a graph, which improves approximation ratios in network revenue management. Our results generalize to the setting where personalized assortments are offered to each customer.

4 - Assortment Planning and Revenue Management with Customer "Inertia"

Sumit Kunnumkal, Indian School of Business, Ac 4 Level 1 4116, Hyderabad, 500032, India, sumit_kunnumkal@isb.edu, Sridhar Seshadri

We consider a situation where customers have a tendency towards sticking to their previously purchased item. We analyze the assortment decisions for a firm that has access to its customers' purchase history.

Chair: N. Bora Keskin, Duke University, Durham, NC, 27708-0120, United States

Co-Chair: Nur Sunar, UNC, Chapel Hill, NC, 27517, United States

1 - Pricing Itineraries and Laminar Bayesian Selection

Rad Niazadeh, Stanford University, Stanford, CA, 94305, United States, rad@cs.stanford.edu, Nima Anari, Amin Saberi, Ali Shameli

In this talk, I consider matroid Bayesian online selection, with applications to selling flight itineraries. The goal is to find a pricing algorithm for serving a sequence of arriving buyers that maximizes the expected welfare (or revenue), where the allowable subsets of served buyers are characterized by a laminar matroid with constant depth. We give the first Polynomial-Time Approximation Scheme (PTAS) for the above problem. Our approach is based on rounding the solution of a hierarchy of LP relaxations that can approximate the optimum online solution with any degree of accuracy as well as a concentration argument that shows our rounding does not have a considerable loss in the expected welfare.

2 - Pricing and Assortment Optimization of Horizontally Differentiated Products with Incomplete Information

Boxiao (Beryl) Chen, University of Illinois-Chicago, Chicago, IL, 60607, United States, bbchen@uic.edu, Arnoud Victor den Boer

We consider a decision maker selling multiple horizontally differentiated products. Customers are heterogeneous in their preferred location, of which the distribution is unknown. We develop a nonparametric data-driven algorithm that learns the unknown customer information only from historical sales data.

3 - Optimal Bayesian Price Fine-tuning

Jue Wang, Smith School of Business, Queen's University, ON, K7L 3N6, Canada, jw171@queensu.ca

We consider the problem of optimally fine-tuning the price near a historically fixed price (incumbent price) to maximize the expected revenue over a finite horizon. We formulate the problem as a discrete-time Bayesian dynamic program and connect it to the Gauss-Weierstrass Transform through a reformulation. We prove that the optimal pricing policy has a simple and intuitively appealing structure. Incomplete learning is absent from the optimal policy if the belief precision stays under a switching curve, but may emerge when the belief precision jumps above that curve, especially near the end of the horizon. We also develop an efficient algorithm using the fast Gauss transform.

4 - The Effects of Dynamic Pricing on Upstream Decisions

Clark C. Pixton, Brigham Young University, Provo, UT, 84601, United States, cpixton@byu.edu

We consider dynamic pricing in a setting where price adjustments are made in response to a dynamic, feature-based demand forecast. We show that while the implementation of dynamic pricing increases the long-run average profit from the pricing decision, it has mixed effects on the firm's other related decisions (such as inventory policy) and the customers' welfare and operational decisions.

1 - Agency Selling or Reselling? The Impacts of Data-driven Marketing in a B2C Platform

Yan Xiaoyu, Tianjin University, Tianjin, China, tjuyanxiaoyu@163.com, Liu weihua

This paper studies a B2C platform's preferences between agency selling and reselling considering the option of DDM. Conclusions are as follows. First, the platform prefers agency selling only when the market size is moderate.This contrasts with the traditional view that agency selling will make the platform more profitable by mitigating the double marginal effect. Second, the sales mode with higher sales volume may not be more profitable within a certain market size. This also explains the phenomenon in practice that the platform with high sales volume generates low profit. Finally, in more cases, the platform adopting a reselling mode has a higher profit growth rate.

2 - Market Foresight of the Platform Economy - Incorporating Stakeholders Into Scenarios

Jiawei Gao, Hitotsubashi University, Kunitachi, Tokyo, Japan, gaojiaweijp@hotmail.com

The platform economy is facing opportunities and challenges in the future market. Moreover, multiple stakeholders are involved in the market foresight for the platform economy: company, service/product provider, customer, government, community, etc. A stakeholder analysis embedded scenario planning is proposed to addressing the following questions: what will platform economy market looks like in the next 5 years from the perspective of stakeholders. The key focal issue of concern for the stakeholders are going to be interrogated and the role-play is going to be performed in the experimental design.

3 - Informing Marketing Decision by the Use of FMRI

Josephine S. Akosa, Visiting Assistant Professor, University of Notre Dame, Notre Dame, IN, United States, jakosa@nd.edu, Melinda McCann

A reliable and valid application of functional brain imaging techniques to understand consumer behavior can help inform marketing decisions. In this study, we discuss a bootstrap-based false discovery rate (FDR) controlling procedure suitable for functional magnetic resonance imaging (fMRI) data analysis by incorporating a generally valid null distribution and shrinkage estimation into the original procedures of Benjamini and Hochberg (1995) and Benjamini et al. (2006). Our goal is to provide the consumer researcher novel ways of using fMRI data analysis to inform marketing strategies and maximize profits.

4 - Finding Best Alternative Brand Based on Perceived Quality and Perceived Value Before Purchasing

Satanik Mitra, IIT Kharagpur, Kharagpur, India, satanikmitra@iitkgp.ac.in

Perceived quality and Perceived value of a brand traditionally measured using primary surveys. In this work, we propose a methodology to estimate these values from online consumer reviews using aspect-based sentiment analysis techniques. We first clean the crawled data; extract the aspects using a semi automatic approach using dependency parser and analyze sentiment scores. The aspects are categorized into five clusters. TOPSIS, a multi criterion decision making algorithm, is used to rank the brands based on perceived quality scores.

5 - Prataap Snacks: Journey from Back Alleys to National Markets

Bhavani Shankar Saripalli, Assistant Professor, Indian Institute of Management Indore, Indore, India, bhavanishankar@iimidr.ac.in

Emerging markets present peculiar situations to marketers. Those who can identify right opportunities and introduce products gain success. Prataap Snacks (PS) is one such market player from India. PS succeeded in subsistence markets by introducing snacks in tea stalls located in back alleys of small towns of Madhya Pradesh state in India. Most subsistence customers who aggregate for daily wage work require a snack at lower cost. PS expanded its network to cater to children's market with variety of confectionery. TV advertising helped improve market share, but PS has to focus on innovation to attract more customers. This paper is a case study analysis.

Topics in Humanitarian Operations

Sponsored: Public Sector OR

Sponsored Session

Chair: Seyma Guvan Kocack

1 - Interdicting Reconfiguring Networks with Applications in Human Trafficking

Daniel Kosmas, RPI, Troy, NY, United States, kosmad@rpi.edu, Thomas Sharkey, John E. Mitchell, Kayse Lee Maass

We consider the problem of disrupting networks that will reconfigure themselves based on our selected interdiction problem. The objective of the interdictor is to minimize the maximum flow in the reconfigured networks. The motivating application is in disrupting human trafficking networks where the reconfigurations helps to model the consequences, included unintended ones, of selected interdiction decisions. We discuss structural properties of the network that result in not choosing any interdictions is optimal and what this means in the context of human trafficking.

2 - Analysis of Food Security and Market Participation for Farmer Households in Uganda

Jarrod D. Goentzel, Massachusetts Institute of Technology, 7Cambridge, MA, 02139, United States, Micaela Wiseman, Courtney Blair, Tim Russell

We randomly surveyed 498 smallholder farmers in regions across Uganda to inform market facilitation efforts supported by development organizations. Results indicate that food security is not a prerequisite for market participation, indicating that market development activities will reach this vulnerable population. We also find that distance to roads and markets does not affect market participation but does affect the intensity of farmer engagement.

3 - Prescriptive Analytics for Post-disaster Inspection Operations

Mathieu Dahan, Georgia Institute of Technology, Atlanta, GA, United States, mdahan@mit.edu, Andrew Lee, Saurabh Amin, Georgia Perakis

We present a prescriptive analytics approach for localizing failures in the aftermath of a natural disaster. We utilize the information provided by failure prediction models to calibrate the generic formulation of a stochastic team orienteering problem. We derive a compact mixed-integer programming formulation of the problem that computes an optimal a-priori routing of the inspection teams. We illustrate our approach using the data from (i) Houston's drainage network inspection after Hurricane Harvey, and (ii) SF Bay area's gas pipeline inspection after an earthquake.

4 - Gift-in-kind Acceptance Strategies Based on Institutional Mission

Michael H. Veatch, Gordon College, Department of Mathematics, Wenham, MA, 01984, United States, mike.veatch@gordon.edu

Corporate Gifts-in-Kind (GIK) to relief and development NGOs benefit the donor and the recipients; however, the transport/logistics cost falls on the NGO. We develop a strategy for accepting/declining GIK that captures its value to the NGO's mission based on current conditions of demand, inventory, and freight budget. A case study with World Vision's GIK program demonstrates how the strategy can in implemented in the donation process.

5 - Meeting Demand with Multiple Resources Geographically and Over Time

Arden Baxter, Georgia Institute of Technology, Atlanta, GA, United States, abaxter8@gatech.edu

Allocation of limited resources (e.g., in an emergency or during disaster response) is a complex task, especially when demand is spread geographically and over time, and may require the simultaneous presence of multiple resources. We model this coordinated resource allocation problem as an integer program, present complexity results, and share results from a computational study on various graph structures.

Resilient Infrastructure and Community Networks

Sponsored: Public Sector OR

Sponsored Session

Chair: Gabriela Gongora Svartzman, PhD Candidate, Stevens Institute of Technology, Hoboken, NJ, United States

1 - Trade-off Analysis Between the Vulnerability and Recoverability Investments for Interdependent Infrastructure Networks

Kash Barker, University of Oklahoma, Norman, OK, 73019, United States, Deniz Berfin Karakoc

Communities become more dependent on the critical infrastructure networks to exist and operate. However these networks become more interdependent on each other to function and more vulnerable against stressors. Thus studying their (i) preparedness and (ii) recovery become crucial especially due to the increasing frequency of natural disasters. We extend a resilience-driven multi-objective mixed-integer programming model for interdependent infrastructure network restoration scheduling such that it performs a trade-off analysis between the resource investment through recovery and preparedness planning. The approach is illustrated on the critical infrastructures in Shelby County, TN.

2 - A Simulation-based Approach to Modelling Disruptions and Quantifying Uncertainties in a Large-scale Urban Transit System

Steffen O.P. Blume, Doctoral Researcher, ETH Zürich, Zürich, Switzerland, steffen.blume@frs.ethz.ch, Michel-Alexandre Cardin, Giovanni Sansavini

Expanding complexity is taking its toll on the resilience of public transit systems. Despite many operational and technological improvements, disruptions are inevitable and growingly catastrophic to the ever-increasing urban population. In this work, we present a simulation testbed that captures the complexity and uncertainties associated with large-scale urban transport system disruptions. The testbed provides estimates of the expected variability of the system performance during the disruption and recovery cycle and enables flexible system designs that take into account the uncertainties associated with network operations and passenger demand.

3 - Machine Learning and Data Mining in Identification of Unhappy Communities

Alexander Gilgur, PhD Student, Stevens Institute of Technology, Hoboken, NJ, 07030, United States, agilgur@stevens.edu, Jose Emmanuel Ramirez-Marquez

Happiness is a complex phenomenon. However, it is important to identify unhappy communities that need improvement and contented communities to compare them with. Subjective well-being surveys have an intrinsic selection bias, excluding the depressed and suicidal population. Medical records too have a selection bias. Suicide attempt rate answers the question of general contentment, and we used it to separate counties into "unhappy" and "contented". We then analyzed metadata and sentiment of NYT readers' responses to articles mentioning such counties. This paper outlines our findings.

4 - Multifaceted Modeling for Smart Urban Systems

Renee Obringer, Purdue University, West Lafayette, IN, United States, robringe@purdue.edu, Roshanak Nateghi

Modeling urban resilience will become crucial as urban populations grow and the climate continues to change. The theorists among the urban resilience community have been aware of the multifaceted nature of urban systems for quite some time. However, the models currently put into practice often only include a single facet of the complex urban networks they seek to model. This may have led to some misrepresentations of the resilience of various urban systems, especially when those systems are highly interconnected. Here we present a novel framework to simultaneously model multiple performance metrics of urban systems and analyze their resilience to various shocks.

5 - Visual Resilience Evaluation in Multiple Public Transportation Systems

Gabriela N. Gongora Svartzman, Stevens Institute of Technology, Hoboken, NJ, 07030, United States, ggongora@stevens.edu, Jose Emmanuel Ramirez-Marquez

Public transportation systems are core infrastructures to cities and can be subject to unforeseen events. The novelty of this research resides in evaluating the resilience of public transportation (buses, subway, railroad) as a multi-layered and interdependent systems. Visual resilience of disruptions (different degrees) due to weather conditions, police events or even sports, are developed. Real and simulated behavior of multiple modes of transportation are compared, through their aggregated commuting times, the surrounding areas affected and the transportation alternatives they offer. Data visualization and urban computing are employed to analyze New York City as a case study.

Vendor Tutorial

1 - MemComputing's MemCPU(tm) SaaS Application Tutorial

Fabio L. Traversa, MemComputing, Inc., La Jolla, CA, United States

MemComputing will provide a tutorial on the MemCPU™ SaaS application for solving Integer Linear Programming problems. The MemComputing technology represents a completely new computational paradigm that is fine tuned to solve exponential combinatorial optimization problems in polynomial time. The MemCPU SaaS is in beta test. Beta testers are given free access to the service for testing out their own problems. Come along to see if this has applicability in your environment.

2 - Accelerate your business insights with Azure and PowerBI

Daniella Mark, ProCogia, Bellevue, WA, United States

Organizations today are struggling with generating valuable insights as the data gathering and wrangling processes get more involved and complex. In order to make sense of ever-changing business requirements, analysts must source data from multiple end points and build a cohesive understanding. To tackle this problem, we have developed an automated Azure solution with a data pipeline capable of listening to multiple sources. The implementation then interacts with a PowerBI front end which presents the results in a multi-dimensional way. The solution is totally customizable to work with any API. This solution speeds up the delivery time of insights generation.

Advanced Maintenance Models

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Yisha Xiang, Texas Tech University, Lubbock, TX, 79409, United States

Chair: Zhicheng Zhu, Lubbock, TX, 79415, United States

1 - Opportunistic Condition-based Maintenance for a Degrading System with Individually Repairable Components

Nooshin Yousefi, Rutgers University, Piscataway, NJ, United States, no.yousefi@rutgers.edu, David Coit

An opportunistic condition-based maintenance is proposed for multi-component systems where each degrading component has competing failure modes of degradation and random shock. For systems functioning for a long time, components have been replaced several times and their initial degradation reaches a steady state behavior. For systems with high downtime costs, it is prudent to avoid system failure. When the maintenance team are sent to replace any component due to failure or on-condition replacement, there is an opportunity for other components to be preventively replaced. The optimal on-condition and opportunistic thresholds and inspection interval are found simultaneously.

2 - New Perspectives on Age Replacement under Non-stationary Replacement Costs

Shadi Sanoubar, University of Pittsburgh, Pittsburgh, PA, United States, SHS204@pitt.edu, Lisa M. Maillart, Oleg A. Prokopyev

In many equipment replacement settings, replacement costs increase in the age of the component, e.g., due to decreasing salvage value. We present analytical and numerical results that explore the effect of such age-dependency on the long-run cost rate and optimal replacement time under both cost rate-minimizing and availability-maximizing criteria. Additionally, for seasonal replacement costs, we compare a non-stationary myopic heuristic replacement policy to an optimal stationary replacement policy obtained via simulation.

3 - Selective Maintenance of Multicomponent Systems with Multiple Dependent Failure Modes

Cesar Ruiz, University of Arkansas, Fayetteville, AR, United States, caruizto@email.uark.edu, Haitao Liao, Edward A. Pohl

We propose a condition-based selective maintenance optimization framework for maximizing the reliability of a system with multiple components subject to multiple failure modes. In particular, we classify these failure modes into soft failures and hard failures. For the soft failures, we model the evolution of each performance measure as a stochastic degradation process. In addition, the hard failures depend on the degradation processes that change the parameters of failure-time distributions. We solve the optimization problem using a Differential Evolution (DE) heuristic.

4 - Condition-based Maintenance for Multi-component Systems: Modeling, Structural Properties, and Algorithms

Zhicheng Zhu, Texas Tech, Lubbock, TX, 79415, United States, Yisha Xiang

Condition-based maintenance (CBM) is recognized as a cost-effective maintenance strategy. However, most research on CBM focuses on single-component systems. Limited research has considered CBM for multi-component systems. In this paper, we study the CBM optimization problem for multi-component systems. We first develop a multi-stage stochastic integer model over a finite planning horizon. We then design two efficient algorithms to solve the two-stage model based on the structural properties. Our computational studies show that Algorithm 1 obtains optimal solutions to the majority of test cases in a reasonable amount of time and Algorithm 2 can find high-quality solutions quickly.

5 - Investigation of System Transient Behavior under Imperfect Maintenance

Suzan Alaswad, Zayed University, Khalifa City A, Abu Dhabi, United Arab Emirates, salaswa@gmail.com, Sinan Salman

This paper studies the impact of imperfect maintenance on the limiting availability of repairable systems. The imperfect repair is modeled using Kijima Type II virtual age model. The specific interest of this study is to investigate the transient behavior of the repairable system. While the results show that using preventive maintenance improves the steady-state availability of the system, it takes longer to achieve higher values of the limiting availability with more fluctuating transient behavior. This paper studies the tradeoff between higher steady state availability with longer fluctuated transient behavior, or a faster way to stabilize the system with lower steady-state availability.

1 - A Hybrid Approach of Machine Learning Methods with Genetic Algorithm Optimization for Improving Prediction Accuracy

Fatemeh Amini, Iowa State University, Ames, IA, United States, famini@iastate.edu

Compared with conventional datasets where the number of features are many fewer than the number of observations, today, data scientists often encounter ultra-high-dimensional datasets in which the number of features exceed number of observations. Genetic algorithms can be used as a feature selection method to select the best subset of features in order to predict the response variable as accurate as possible. In this paper, the focus is on regression datasets in which using genetic algorithms in conjunction with machine learning techniques, almost always provide us with higher prediction accuracy in comparison with just applying machine learning methods with regularization inside.

2 - A Data Analytic Framework for Breast Cancer Survivability

Zahra Sedighi Maman, Adelphi Univeristy, Garden City, NY, United States, zmaman@adelphi.edu, Alexa Mondello

Breast Cancer is the most common cancer diagnosed in women worldwide. With the advent of technology such as machine learning, and artificial intelligence, medical data can be further analyzed in addition to the manual analysis performed by medical professionals, which can lead to a more accurate prognosis. This paper lays out a framework to model breast cancer survival using Surveillance, Epidemiology, and End Results (SEER) data from 2004 to 2016 to predict survival in Females affected with breast cancer. Based on input data, the framework establishes criteria for unbalanced data, feature and machine learning algorithm selection for survival prediction.

3 - Opioid Related Adverse Drug Reactions Prediction Based on FDA Adverse Event Reporting Database

Dolzodmaa Davaasuren, The Pennsylvania State University, State College, PA, United States, Soundar Kumara

Opioid analgesics are widely used in the treatment of chronic, cancer and non-cancer related pain. In the recent years, the opioid epidemic has evolved rapidly, starting with an increase in opioid prescription. Based on the FDA Adverse Event Reporting Data, we performed extensive investigation on the opioid related adverse events in terms of patients' demographic, disease and other commonly prescribed drugs along with opioids. Also, we propose a machine learning algorithm for predicting adverse reaction and outcome resulting from the potential interaction among prescribed drugs for the disease and opioids.

4 - Community Structure and Sentiment Related to Brazilian Election Twitter Networks

Camila Pereira dos Tautenhain, Universidade Federal de São Paulo, São José dos Campos, Brazil, camila.p.san@gmail.com, Rodrigo Francisquini, Mariá Cristina Nascimento

Twitter is a platform widely used to express political opinions. In this study, we employed community detection methods to analyze networks constructed from tweets related to the Brazilian presidential elections. We verified that tweets that receive most of the retweets in these networks were viral and spread across several communities. The remaining tweets were trapped within the communities. Moreover, an analysis of the sentiments associated with the tweets revealed that words related to positive sentiments were more often in the communities. However, words associated with the highest negative sentiment scores were offensive.

5 - Smart and Context-aware Energy Demand Management: Data-driven Modeling for Automation in Buildings

Milad Afzalan, Virginia Tech, Blacksburg, VA, United States, afzalan@vt.edu

The adoption of data analytics and machine learning methods for management of infrastructures have received attention during recent years. Specifically, the technological advances in integration of distributed sensors and control systems are providing a large amount of data with opportunities for the formation of smart cities. In this work, through developing data mining and machine learning methodologies, I present my work on (1) autonomous systems for estimating energy information of buildings and (2) leveraging the impact of human-building interaction for improved distributed demand management. The findings shed light on adopting automation platforms for emerging smart buildings.

1 - Structured Point Cloud Data Analysis via Regularized Tensor Regression for Process Modeling and Optimization

Kamran Paynabar, Georgia Tech, Atlanta, GA, United States, kamran.paynabar@isye.gatech.edu, Hao Yan, Massimo Pacella

Advanced 3D metrology technologies such as coordinate measuring machine and laser 3D scanners have facilitated the collection of massive point cloud data, beneficial for process monitoring, control and optimization. However, due to their high dimensionality and structure complexity, modeling and analysis of point clouds are still a challenge. In this article, we use multilinear algebra techniques and propose a set of tensor regression approaches to model the variational patterns of point clouds and to link them to process variables. The performance of the proposed methods is evaluated through simulations and a real case study of turning process optimization.

2 - Data-driven Sem Image Enhancement for Nanomaterial Analysis

Yanjun Qian, Assistant Professor, Virginia Commonwealth University, Richmond, VA, 23221, United States, Yu Ding

We propose a data-driven super-resolution (SR) algorithm to recover a high-resolution (HR) electron microscopic (EM) image from its low-resolution (LR) counterpart, saving time and efforts for high-quality imaging of nanomaterial. To recover the information loss between the resolution levels, a patch-based library is learned from a captured HR image of a partial area and its corresponding LR region. Our work is focusing on the properties of the EM image data and its differences from natural optical images. The proposed method improves the quality of input EM images, while other generic SR methods fail to do so. Our method also increases the accuracy of further analysis of the processed images.

3 - Defect Detection for Surfaces with Random Texture

Anh Tuan Bui, Virginia Commonwealth University, Technological Institute, Richmond, VA, 60208, United States, Daniel Apley

We develop an approach for detecting local defects in surfaces that have random texture (e.g., textiles or material microstructures). We first use generic supervised learning methods to characterize the stochastic behavior of "normal" in-control samples of the surfaces. Based on the residuals of the supervised learning model applied to new samples in a statistical process control context, we propose two spatial moving statistics for detecting local aberrations in the surfaces. We illustrate the approach using simulated and real examples.

4 - A Deconvolution Approach to Learn 3d Shape Distortion Mechanism

Mingdong Lyu, University of Southern California, Los Angeles, CA, United States, mingdonl@usc.edu, Qiang Huang

To achieve prediction and control of 3D printing accuracy, it is important to understand the mechanism of the layer-by-layer build-up effect and its impact on the 3D shape distortion. Given input layer geometries, a novel deconvolution learning framework is proposed to capture layer interactions and deviation accumulation. Experimentation in stereolithography (SLA) and Fused Deposition Modeling process are conducted to demonstrate the proposed approach.

Predictive Modeling and Optimization in Reliability Analysis and Complex System Control

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Dongping Du, Texas Tech University, Texas Tech University, Lubbock, TX, 79409, United States

Chair: Chen Kan, University of Texas-Arlington, Euless, TX, 76039-6215, United States

1 - A Condition-based Predictive Maintenance Optimization for Multi-component Systems Subject to a System Reliability Requirement

Yue Shi, Texas Tech University, Lubbock, TX, 79415, United States, Yisha Xiang, Weihang Zhu

In this paper, we develop a condition-based predictive maintenance decision-framework for a multi-component system. The proposed framework joins the long-term system inspection schedule based on historical data and the short-term dynamic grouping based on newly observed information. More accurate predictive reliabilities are obtained via Bayesian updating, and an efficient algorithm is developed to identify groups of components for preventive maintenance to meet the reliability requirement. Numerical results show that the proposed model can lead to significant cost savings and improved system reliability, and can incorporate dynamic information.

2 - Model Identification and Physical Exercise Control Using Nonlinear Heart Rate Model and Particle Filter

Zhiyong Hu, Texas Tech University, Lubbock, TX, 79415, United States, Dongping Du

This study presents a Heart Rate -based modeling and control framework to monitor physiological changes during exercise and optimize exercise intensity to capitalize exercise outcomes. Particle filter (PF) is used to identify HR model parameters and optimize the intensity of exercise, e.g., walking or running speed, based on the calibrated model. HR prediction is calculated from the calibrated model, and the treadmill speed is optimized by minimizing the difference between predictions and target HR. The modeling and control framework is validated with different case studies. The results demonstrate the advantageous of the proposed framework for personalized HR modeling and exercise control.

3 - Failure Event Prediction Based on Time-to-event Data with a Deep Learning Model

Congfang Huang, UW-Madison, Madison, WI, United States, chuang286@wisc.edu, Shiyu Zhou, Akash Deep

Although statistical models have been developed to predict system failures in the design of maintenance policies, they are not flexible with time-variant covariates. We propose a deep learning model which utilizes Recurrent Neural Network to deal with the time-to-event sequence data and relates the time information to event type by adding a time entry to the one-hot encoded event vector. Compared with conventional methods, our deep learning model performs better on both simulated data and real world log files data.

4 - Fault Detection Using Deep Semi-supervised Feature Extraction with Positive and Unlabeled Data

Xiaomeng Peng, Northeastern University, Boston, MA, 02148, United States, peng.x@husky.neu.edu, Xiaoning Jin

In this research, we propose a novel semi-supervised fault detection methodology for a vehicle suspension system with positive and unlabeled (PU) samples. Fault detection with PU data aims build a classifier to assign samples to two classes, i.e., healthy class and faulty class. A deep semi-supervised learning method integrated with physical-based domain knowledge is applied for feature extraction. The suspension system for a full car model is modeled using a simulation tool, SIMPACK to generate the synthetic multi-sensor data. Our results show the effectiveness of the proposed in fault detection with PU data.

1 - A Machine Learning-enabled Partially Observable Markov Decision Process Model Prediction Framework

Zeyu Liu, University of Tennessee, Knoxville, TN, United States, zliu65@vols.utk.edu, Anahita Khojandi, Xueping Li, Rishikesan Kamaleswaran

Markov decision process models are commonly used in sequential decision making. In this work, we use this method to develop a novel predictive modeling framework. Specifically, we incorporate a machine learning method into an optimal stopping partially observable Markov decision process (POMDP) model to make predictions. We implement the framework for early predictions of sepsis, a life-threatening condition. The problem is solved using a modified Point-Based Value Iteration algorithm. Results show that the framework outperforms benchmark machine learning models.

2 - EEG/MEG Source Imaging with Probabilistic Hierarchical Graph Prior

Feng Liu, Massachusetts General Hospital, Harvard Medical School

Brain source imaging is an important method for noninvasively characterizing brain activity using Electroencephalogram (EEG) or Magnetoencephalography (MEG) recordings. Traditional EEG/MEG Source Imaging (ESI) methods usually assume that either source activity at different time points is unrelated, or that similar spatiotemporal patterns exist across an entire study period. The former assumption makes ESI analyses sensitive to noise, while the latter renders ESI analyses unable to account for time-varying patterns of activity. To effectively deal with noise while maintaining flexibility and continuity among brain activation patterns, we propose a novel probabilistic ESI model based on a hierarchical graph prior. Under our method, a spanning tree constraint ensures that activity patterns have spatiotemporal continuity. Comprehensive numerical studies using synthetic data on a real brain model are conducted under different levels of signal-to-noise ratio (SNR) from both sensor and source spaces. We also examine the EEG/MEG data under auditory and visual stimuli, in which our ESI reconstructions are neurologically plausible. Our method also shows accurate result for epilepsy patients. All the results demonstrate significant improvements of the proposed algorithm over the benchmark methods in terms of source localization performance, especially at high noise levels.

3 - Topological Pattern Recognition of Severe Alzheimer's Disease via Regularized Supervised Learning of EEG Complexity

Miaolin Fan, Northeastern University, Boston, MA, 02115, United States, fan.mi@husky.neu.edu

Alzheimer's disease is a progressive brain disorder with gradual memory loss that correlates to cognitive deficits in the elderly population. In this study, we aim to discover the altered spatio-temporal patterns of EEG complexity associated with AD pathology in different severity levels. Multiscale entropy is used as the complexity measure to characterize the nonlinear dynamics at multiple temporal scales. Further, we experimented on the EEG recordings collected from 123 participants and fed them to multivariate machine learning algorithms. The results showed that temporal and occipitoparietal brain regions were more discriminative for classifying severe AD cohort versus normal controls.

4 - Detecting Chronic Ankle Instability Using Koopman Operator-based Features of Gait Data

Chun-An Chou, Northeastern University, Boston, MA, 02115, United States

Up to 70% of individuals don't fully recover from single ankle sprains and eventually develop chronic ankle instability (CAI). Current diagnosis of CAI is manly based on self-report rather than objective biomechanical measures. The goal of this study is to analyze body movements as a dynamic system based on sensors on bilateral hip, knee, and ankle joints. By combining Koopman Operator and Dynamic Mode Decomposition, we can approximate the nonlinear dynamics of human movement for both CAI and healthy subjects through an infinite but linear space of observations and verify the information contained in Koopman Modes.

5 - Machine Learning Approach to Discover Circadian Rhythmicity Patterns from Telemetric Activity Data

Lin Ying, University of Houston, Houston, TX, United States, ylin58@uh.edu

Understanding the circadian rhythm regulations and their relevance to human health is critical for many chronic diseases prevention and treatment. Recent advances in sensing technology provides abundant of self-monitoring data that promotes the discovery of disease associated circadian rhythm patterns. However, characterizing the circadian patterns is challenged by the noisy monitoring data, individual-to-individual variations and patients' unknown health conditions. To mitigate these challenges, we developed a collaborative learning based hidden Markov model to discover the circadian patterns from patients' actigraphy data and validate their associations with disease.

6 - Detecting Chronic Ankle Instability Using Koopman Operator-based Features of Gait Data

Shaodi Qian

Up to 70% of individuals don't fully recover from single ankle sprains and eventually develop chronic ankle instability (CAI). Current diagnosis of CAI is manly based on self-report rather than objective biomechanical measures. The goal of this study is to analyze body movements as a dynamic system based on sensors on bilateral hip, knee, and ankle joints. By combining Koopman Operator and Dynamic Mode Decomposition, we can approximate the nonlinear dynamics of human movement for both CAI and healthy subjects through an infinite but linear space of observations and verify the information contained in Koopman Modes.

Ujjal Kumar Mukherjee, University of Illinois, Urbana-Champaign, 306 Wohlers Hall, 1206 South Sixth Street, Champaign, IL, 61820, United States, ukm@illinois.edu

In this paper we present a data driven framework for implementation of of precision medicine related to proteasome inhibitor treatment of multiple myeloma. We use genetic data from real patients to test the decision framework.

2 - Drivers of Drug Quality Failure

In Joon Noh, Ohio State University, 2100 Neil Avenue, Columbus, OH, 43210, United States, noh.69@osu.edu, John Gray, Hyunwoo Park, George Ball

Using novel and comprehensive drug-level data obtained from the FDA and other publicly available sources, this study empirically examines the various factors that relate to quality failures of drugs in the pharmaceutical industry context. We investigate first-order drivers and moderators.

3 - Effect of Mass Gathering on Hospital Admission

Tiancheng Zhao, University of Illinois at Urbana-Champaign, Champaign, IL, 61820, United States, tz14@illinois.edu, Ujjal Kumar Mukherjee, Dilip Chhajed, Han Ye

Mass gathering refers to an event where a large number of people gather in one location for a short period. Due to increased population intensity, this may create critical health risks. In this paper, we use admission data from an Indian hospital during regular times and the Kumbh Mela, a massive religious gathering, to study the effect of mass gathering on hospital admissions. The result of our spatial-Poisson arrival model shows that the effect of mass gathering on hospital admissions is heterogeneous on different disease groups, and regions with different geographical and socioeconomic parameters. We use the results of our study to provide insights which can be useful for future events.

4 - An Economic Analysis of Patient Compliance Programs under a Risk-sharing Agreement for Chronic Disease

Hui Zhang, Lakehead University, 950 Oliver Rd., Faculty of Business Administration, Thunder Bay, ON, P7B 5E1, Canada, hzhang2@lakeheadu.ca

Risk-sharing agreements have been used by drug makers and payers to control uncertainties in drug usage. One innovative form aims to address the concerns of low adherence, in which the drug maker reduces the price for the payer if the adherence exceeds a prespecified threshold. I compare this form with a traditional one in which the drug maker reduces price if the health outcome is lower than a threshold. Patient compliance program is used to improve the adherence. I thus investigate who should run the program under both forms of risk-sharing agreements and how the program should be run.

5 - New Tools for Predicting a Hospital Readmission

Stacey Mumbower, University of South Carolina, 1014 Greene Street, Columbia, SC, 29208, United States, stacey.mumbower@moore.sc.edu, Ronda Hughes, John Brooks, Neset Hikmet, Benjamin Schooley

Utilizing a hospital's electronic health record platform, we added three risk assessment tools for nurses to use to standardize and improve the discharge planning process. Hospital readmissions were then predicted with the additional information, using both a standard approach and a machine learning approach to compare predictive ability.

1 - Consistent Nursing Home Staff Scheduling under Heterogeneous Service Demand

Lingling Zhang, Dalian University of Technology, Dalian, China, zhangll0519@mail.dlut.edu.cn, Nan Kong, Mingyang Li, Mingzheng Wang

The demand for nursing home care is growing rapidly. High staff turnover and assignment inconsistency have limited the delivery of quality care, partially due to lack of intelligent demand forecasting and adaptive staff scheduling. We formulate a two-stage mixed-binary stochastic problem with integer recourse for integrated optimization of nursing staff scheduling and assignment under demand uncertainty. We select promising scheduling patterns from a large set while adjusting the service duration to improve consistency staff assignment to residents. We apply progressive hedging to solve large-size instances and provide insights into the planning operations.

2 - Transient Modeling of Handoff Process in Hospital Emergency Department

Wenjun Zhu, University of Wisconsin-Madison, Madison, WI, United States, wzhu83@wisc.edu, Jingshan Li

The handoff process in hospital emergency department refers to the transitions of patient from ED to hospital floor. Due to congestion or coordination issues, delays in handoff processes are not uncommon, which may lead to adverse events. Thus, substantial attentions have been paid to improvement in these transitions. Most of them are either qualitative or case study based, or addressing the steady state performance only. However, the handoff process needs to be carried out in a fast and safe manner. Studying the transient behavior of the process is more important. In this talk, a Markov chain based transient analysis model of handoff process is presented to analyze the dynamic behavior of the process.

3 - Frequent Pattern Mining from Multivariate Time Series Data

Meserret Karaca, University of Florida, Gainesville, FL, 32607, United States, mkaraca@ufl.edu, Michelle M. Alvarado, Panayote (Panos) M. Pardalos

Frequent temporal pattern mining (FTPM) is the problem of detecting frequently appearing events from multivariate time series data. This is a recently emerging problem with applications in medical event detection, equipment malfunction detection, environmental monitoring, etc. This study proposes a hybrid pattern mining approach for the FTPM problem. The FTPM problem has two steps: (i) generating patterns known as candidates, (ii) identifying the frequently occurring patterns. The goal of the study is to create a faster FTPM algorithm by preventing the generation of redundant candidates.

4 - Chance-constrained Stochastic Programming Model for Reducing Hospital Readmissions

Behshad Lahijanian, University of Florida, Herbert Wertheim College of Engineering, Industrial and Systems Engineer, Gainesville, FL, 32611, United States, b.lahijanian@ufl.edu, Michelle M. Alvarado

In response to the Hospital Readmission Reduction Program (HRRP), hospitals are seeking care strategies to reduce their readmission rates. We develop a scenario-based stochastic model as a multi-condition care strategy with probabilistic constraints to help hospitals prioritize treatment plans. The hospital aims to identify care strategies that provide a confidence level that the target readmission probability will be achieved. We explored the trade-off between the cost of care, probability of readmission, and confidence levels.

5 - Sequential Clinic Scheduling with Reentrance for Mohs Micrographic Surgery

Michelle M. Alvarado, Assistant Professor, University of Florida, Gainesville, FL, 32611-6595, United States, alvarado.m@ufl.edu, Haolin Feng, Mark Alan Lawley

Mohs Micrographic Surgery (MMS) is a surgical method used for the excision of skin cancers in areas of cosmetic importance, but is burdened by long in-clinic wait times due to the stochastic nature of layer removal. We develop a sequential stochastic scheduling method that balances patient wait time, clinic overtime and revenue while considering stochastic complications such as no-shows, processing time variance and reentrance. On average, simulation results indicate an approximate 34.6% improvement in objective function value over current practice, and a 24.6% improvement over models that ignore re-entrance.

1 - Optimizing Patient Flows in the Intensive Care Units - Downstream Wards Network

Silviya D. Valeva, Rice University, Houston, TX, 77098, United States, silviya.valeva@rice.edu, Guodong Pang, Andrew J. Schaefer

Intensive care units (ICUs) are expensive and high-demand resources treating critically ill patients that often act as a bottleneck in the hospital system. Coordinating the transfer of patients from ICUs to downstream units is usually handled by a single person and can cause significant delays and consequently block ICU bed access for incoming patients. We propose decision models and efficient solution approaches for the transfer and allocation of patients that maximize total ICU utility. Our models further incorporate flexible capacity, staffing, and fairness allocation as measures to hedge against peak demand and stress on the ward. We offer managerial insights based on simulation studies.

2 - Data Driven Inpatient Bed Assignment: AP Model Approach to Boarding and Overowing

Shasha Han, National University of Singapore, NUS Business School, Biz 2 Building B1, 1 Business Link, Singapore, Singapore, shashahan@u.nus.edu, Shuangchi He, Hongchoon Oh

We study inpatient bed assignment to shorten boarding times without excessive patient overflowing. We provide a practicable approach to solving the bed assignment problem. This data-driven approach captures critical features of patient flow management, while the resulting optimization problem is practically solvable. The proposed approach is a useful tool for the control of queueing systems with time-sensitive service requirements.

3 - Inpatient Overflow: An Approximate Dynamic Programming Approach

Pengyi Shi, Purdue University, Krannert School of Management, Kran 472, West Lafayette, IN, 47907, United States, shi178@purdue.edu, Jim Dai

Due to the inherent variations in arrivals and discharges, hospital managers may assign a patient to a non-primary inpatient ward, especially when the patient has boarded in the Emergency Department (ED) for several hours. Such overflow practice helps alleviate ward congestion but may compromise the quality of care. We formulate this overflow decision problem as a Markov decision process (MDP) within a multi-class, multi-pool queueing network setting. To overcome the curse-of-dimensionality, we develop an approximate dynamic programming (ADP) algorithm, where we use a novel combination of a fluid control model and an integrated single-pool model to guide the choice of the basis functions.

4 - Joint Capacity and Pricing Design for a Telehealth Network Model

Lan Jin, Pennsylvania State University, University Park, PA, 16803, United States, lxj84@psu.edu, Guodong Pang, Hui Zhao

We develop an optimal joint capacity design and pricing scheme for the operations management of a tele-health network. This network comprises local hospitals and a center. Local hospitals consider joining the network according to their utility and the costs including membership fee and service payment. The center decides the sta ng and prices to charge simultaneously. Within this framework, we consider small and large demands, which are motivated by two applications: sexual assault tele-center and tele-imaging diagnosis center. We discuss two variations of the current model: one di erentiating internal and external hospitals and the other di erentiating large and small scale hospitals.

5 - Supply Disruptions in Competing Drug Supply Chain

Parshuram Hotkar, University of Texas-Austin, McCombs School of Business, Austin, TX, 78712-1277, United States, Diwakar Gupta

We study the impact of information sharing in a competing drug supply chain where the firms are susceptible to a supply disruption. We find that the firms benefit from the visibility of the supply disruption as the firms can utilize their capacities efficiently. However, in equilibrium, the firms will invest in lower capacities which will result in lower drug supply.

1 - Integrated Equipment and Storage Design and Maintenance Policy Design Optimization for Reliable Air Separation Units Based on Markov Decision Process

Yixin Ye, Carnegie Mellon University, Pittsburgh, PA, United States, Ignacio E. Grossmann, Jose M. Pinto, Sivaraman Ramaswamy

Gas supply interruptions to customers can cause economic losses in Air Separation Units. As opposed to commonly used discrete event simulations, we propose an MILP model to simultaneously select equipment redundancy, storage, and maintenance policy optimizing the economic performance, where the degradation and maintenance activities are modeled as Markov Decision Processes. The resulting optimization model is solved through decomposition by processing stages to form a team game, where the stages (players) contribute individually to the system economic objective under the impacts of other players.

2 - Multi-objective Optimisation for Fault Tolerant Railway Network Design

Claudia Fecarotti, Eindhoven University of Technology, Eindhoven, Netherlands, c.fecarotti@tue.nl

This talk focuses on developing design strategies to improve the fault tolerance of railway networks. Crossovers improve the flexibility of the network by enabling trains to switch track, but they also contribute to failures occurrence and related risks. The problem of determining the optimal number and location of crossovers to achieve the required level of network availability under budget and performance constraints is formulated as a bi-objective nonlinear mixed-integer model based on the Set Partitioning. Solutions are addressed for a worst case and an average case disruption scenarios, where the maximum and average flow loss due to sections unavailability is minimized respectively.

3 - Discretizing Continuous-time Continuous-state Deterioration Processes, with an Application to Condition-based Maintenance Optimization

Bram De Jonge, Assistant professor, University of Groningen, Groningen, Netherlands, b.de.jonge@rug.nl

We present an approach for discretizing stationary continuous-time continuous-state non-decreasing deterioration processes. This results in a discrete-time Markov chain that is represented by its transition probability matrix. We consider the gamma deterioration process as a special case and use the discretization approach combined with matrix algebra to optimize condition-based maintenance for a continuously monitored single-unit system.

4 - Joint Effects of Local and Global Load Redistribution Model on Mixed Cascading Failures in Network Systems

Jian Zhou, PhD Candidate, Rutgers University, Piscataway, NJ, United States, zhoujian977913@gmail.com, David W. Coit, Frank A. Felder

A new model has been developed to analyze the impacts of network load redistribution on cascading failures in network systems. It provides distinct advantages in investigating the effects of combined load redistribution through system overloaded failures. Network load can be redistributed in the neighborhood of failed system components and globally based on system dependency. The new model extends previous research by taking both local and global load redistribution into account. Simulation of cascading failures is conducted on western U.S. power transmission grid topology for validation. The proposed model provides insights on load dynamics on system robustness against cascading failures.

5 - Research on Technical Framework of Helicopter Transmission System Reliability

Huichao Liu, Beihang University, Beijing, China, Wei Wang

Based on the analysis of the functional structure of helicopter transmission system, this paper constructs a technical framework for reliability design analysis and verification, which can guide the development of helicopter transmission system reliability and improve its reliability level. The results have certain reference value and guiding significance for the development of helicopter transmission system reliability and the improvement of its level, and are conducive to the improvement of helicopter transmission system reliability.

1 - Solving an Integrated Coverage Problem for Heterogeneous Sensor Networks

Mumtaz Karatas, Assoc. Prof., National Defense University, Naval Academy, Istanbul, Turkey, mumtazkaratas@hotmail.com, Ertan Yakici

Coverage is the most important performance metric for sensor networks. In this study, we consider an integrated area, point and barrier coverage problem in which a decision-maker seeks to locate a number of heterogeneous sensors along a two-dimensional belt-shaped region. We formulate the location problem as an integer non-linear program and an equivalent integer linear program. We, then, develop a heuristic approach to solve the problem and compare their performances in terms of solution quality and computation time.

2 - Optimizing the Ordered Recommendation List in E-commerce Sites via Quadratic Assignment Problem

Ayaka Shigematsu, Osaka University, Osaka, Japan, Naoki Nishimura, Shunji Umetani

Some of the recent recommender systems do not focus on increasing only the accuracy of listed items for matching the users' interests but their diversity. We consider specifying the ordered recommendation list to avoid the similar items placing in the neighborhood, and formulate this problem as the quadratic assignment problem. To improve computational efficiency, we develop a two-stage algorithm that selects top-N recommendation items and specifies their order to maximize its diversity. We have tested our algorithm for a real recommender system and obtained reasonable recommendation lists.

3 - A SHOT at Nonconvex MINLP

Andreas Lundell, Åbo Akademi University, Turku, Finland, andreas.lundell@abo.fi, Jan Kronqvist

The Supporting Hyperplane Optimization Toolkit (SHOT) is an open-source, polyhedral outer approximation-based, state-of-the-art software originally developed for solving convex mixed-integer nonlinear programming (MINLP) problems. Until recently, it had no specific support for solving also nonconvex problems. In this talk features such as convexity detection, automatic reformulations, infeasibility repair, and objective cuts, recently added to SHOT are described. These additional features make SHOT a heuristic solver for nonconvex problems. In addition, SHOT can also guarantee the globality of the obtained solution in some special cases.

4 - Minimal Quadratic Unconstrained Binary Optimization (QUBO) for Max 3-SAT

Amit Verma, Assistant Professor of Supply Chain Management, Missouri Western State University, Saint Joseph, MO, United States, averma@missouriwestern.edu, Mark Lewis, Gary Kochenberger

Max 3-SAT is a well-known and important problem with wide applicability. Quadratic Unconstrained Binary Optimization (QUBO) has received much attention recently as a unifying framework for modeling a wide range of problems that can be solved with a generic approach such as quantum annealing hardware. In this paper, we investigate the use of penalty functions to model Max 3-SAT as a QUBO. We employ a cubic-to-quadratic transformation that minimizes the number of additional variables required in the QUBO and then preprocess the QUBO using a set of logical inference rules for further reduction prior to solution. Empirical testing illustrates the efficacy of the approach.

1 - A Sequential Value Correction Heuristic for a Two Dimensional Cutting Process with Defective Plates

Andrea Pizzuti, Università Politecnica delle Marche, Ancona, Italy, a.pizzuti@pm.univpm.it, Fabrizio Marinelli

Industrial cutting problems are generally complicated by several details related to the type of material being cut and the characteristic of the cutting machines. In this work we deal with a three-stage two-dimensional cutting stock problem where parts must be obtained by plates with defects and according to a given

partial order. We proposed a sequential value correction heuristic that computes profitable cutting patterns by a dynamic beam search strategy. The performance of the proposed algorithm is evaluated on a set of real-world instances provided by a prominent glass manufacturer.

2 - A Robust Optimization Model for the Assortment and Cut of Defective Sheets in Glass Production

Fabrizio Marinelli, Associate Professor, Universita' Politecnica delle Marche, Ancona, Italy, fabrizio.marinelli@staff.univpm.it, Claudio Arbib, Mustafa C. Pinar

A cutting process in the production of automotive glass parts is organized in two phases: (1) an assortment of large rectangular sheets is obtained by cutting a ribbon of melted glass after cooling, (2) small rectangular items are cut from large ones, and then bent and refinished. We address the problem of fulfilling given requirements by choosing and cutting a limited assortment of large sheets with a minimum trim loss, under unpredictable defects (e.g., bubbles) occurring in the sheets. To this aim we use a robust optimization model based upon a suitable Bertsimas-Sim uncertainty set.

3 - An Optimization Model for Automated Guided Vehicle (AGV) Scheduling with Battery Charging Systems

Minsoo Kim, KAIST, Daejeon, Korea, Republic of, minsookim92@kaist.ac.kr, Young Jae Jang

Recently, the manufacturing systems often utilize Automated Guided Vehicles (AGVs) to return logistics. These systems include battery points in the AGVs path to supply the power of the vehicles. However, this is prone to congestion because AGVs interfere with each other at the battery points. We propose an optimization model for AGV scheduling with battery charging systems. We, then, compare the performance of the policy obtained by the model with that of different various policies using simulation. Finally, we analyze the effect of AGV battery charging policy on AGV operational efficiency.

4 - Distance and Matching-induced Search Algorithm for the Multi-level Lot-sizing Problem with Substitutable Bill of Materials

Mingyuan Wei, Tsinghua University, Beijing, China

This study examines the multi-level capacitated lot-sizing problems with a special focus on item replaceability. A matching-induced search algorithm to solve the problem is proposed, which leverages the matching between the rounded relaxation and the incumbent solution values. The algorithm is further enhanced by using both the matching information of historical feasible solution values and the distance between the relaxation and incumbent solution values. Extensive computational experiments are conducted to test the efficiency of algorithms. Experimental results show that the proposed enhanced algorithm can perform better than some other heuristics in the literature.

5 - A Study on the Cutting Force Prediction Model of Milling Process

Jeongin Koo, Korea Institute of Industrial Technology, Cheonan, Korea, Republic of, jikoo@kitech.re.kr, Dongil Kim

Predicting the cutting force of milling processes is important because it is connected with machining quality such as surface roughness. This study presents the cutting force prediction model based on machine learning approaches. To build models, we collect the data from cutting experiments by CNC machine and the pre-cutting simulation model. Using those data, we develop a cutting force prediction model and conduct experiments how the model predicts cutting forces. Experimental results show that the model can predict cutting forces depend on process conditions such as rpm, feedrate, and the depth of cut.

6 - Sequential Acceptance Sampling Using Reinforcement Learning as a Critical Success Factor for Lean Six Sigma

Hani Khalil, PhD Candidate, University of Wisconsin-Milwaukee (UWM), Milwaukee, WI, United States, Dr. Wilkistar A. Otieno, Mark Halstrom

The successful implementation of lean six sigma - LSS is highly dependent on the critical success factors-CSFs. The literature review on the CSFs of LSS have not shown any work that studied whether acceptance sampling plans can be considered as a CSF for LSS (particularly sequential sampling). Reinforcement learning-RL is different from the other types of machine learning, it is a method of self-learning and acting based on observed data. The aim of this work is to develop a model based on coupling RL and sequential sampling to improve LSS in process and product monitoring. The result will show the integration of sequential sampling and RL as a key CSF for LSS implementation in the manufacturing industry.

Joint Session Telecom & Network Analysis/Practice Curated: Topics in Telecommunications and Network Analytics

Sponsored: Telecommunications and Network Analytics

Sponsored Session

Chair: Austin Buchanan, Oklahoma State University, Stillwater, OK, 74078, United States

1 - Smart Ports (in Maritime Shipping): Is It a Case for Telecommunications?

Stefan Voss, University of Hamburg, Hamburg, Germany, Leonard Heilig, Adriana Moros

Digital transformation in maritime shipping subsumes smart port initiatives, which are related to connected platforms, mobile devices and apps, cloud-based services, IoT technologies, augmented reality etc. Real-time monitoring of almost every part of todays supply chains is becoming reality and only very short time is needed to react to or anticipate any sort of changes, disturbances and alike. We survey the trend of smart port initiatives and show how telefommunications helps in an indispensable way.

2 - New Models and Preprocessing Techniques for Segment Routing Optimization

Bernard Fortz, Université libre de Bruxelles, CP 212 Bld Du Triomphe, Bruxelles, 1050, Belgium, bernard.fortz@ulb.ac.be

Segment routing is a modern variant of source routing in computer networks. In a segment routed network, an ingress node may prepend a header to packets that contains a list of segments, which are instructions that are executed on subsequent nodes in the network. Such an instruction may be an instruction to forward a packet to a specific destination.

We present models for traffic engineering in a network implementing segment routing on top of shortest paths routing protocols. We also present some preprocessing techniques that allow to decrease significantly the size of the resulting models, and present numerical experiments validating the approach on a large set of test instances.

3 - Optimal Fixed Location M/m/s Server Allocation Using Network Flows

Adam Quentin Colley, Southern Methodist University, 1814 Tune Ave, Florence, AL, 35630, United States, acolley@smu.edu, Eli Olinick

We consider a server allocation problem in which a fixed number of servers is to be allocated to a fixed number of locations such as distributing a given number PBX's across multiple corporate campuses. In this model, a fixed number of servers has been predetermined along with the fixed locations to which one or more servers must be allocated. Demand at each location is stochastic with a known mean and variance. Since the cost model is convex and nonlinear, we present a two-step approach to solving the problem that first determines costs based on the M/M/s model. The costs are then input to a min-cost network flow model to optimally allocate the servers across the locations.

Queueing Models

Contributed Session

Chair: Fatemeh Aarabi, University at Buffalo, Amherst, NY, 14228, United States

1 - A New Approximation for G/G/c Queues

Abhijit Gosavi, Associate Professor, Missouri University of Science & Technology, Rolla, MO, United States, gosavia@mst.edu, Carlos Chaves

Existing closed-form models in the literature for multi-server queues with generally distributed inter-arrival and service times (G/G/c) are often not accurate. Further, one does not always have extensive data for the input random variables, and only the values of means and variances are available. A new approximation, based on means and variances of the inter-arrival and service times, for the medium traffic G/G/c queue is presented. The new approximation generates encouraging numerical evidence for gamma-distributed inter-arrival times, often found in many manufacturing and service settings, and double-tapering distributions, such as normal, triangular, and gamma, for the service time.

2 - Decomposition Based Approaches for Tandem Polling Queues

Ravi Suman, University of Wisconsin-Madison, Madison, WI, United States, rsuman@wisc.edu, Ananth Krishnamurthy

We develop a decomposition-based approach to analyze tandem polling queues under different strategies, namely the independent, synchronous polling, and out-of-sync strategies. Using a decomposition approach, we estimate queue lengths and waiting times, compare the performance under different settings, and provide managerial insights for applications in manufacturing and healthcare.

3 - Conditional Waiting Time Analysis in Tandem Polling Queues

Ananth Krishnamurthy, Professor, University of Wisconsin-Madison, Madison, WI, United States, ananth.krishnamurthy@wisc.edu, Ravi Suman

We analyze a tandem network of polling queues with two product types and two stations under Markovain settings. For this system, we determine the mean conditional waiting time for a customer using sample path analysis that classifies system state upon arrival into scenarios and exploits an inherent structure in the sequence of events that occur till the customer departs.

4 - A Parametric-decomposition Methodology for Solving Queueing Networks with Capacity Restrictions and Simultaneous Resource Possession

Ronny Pacheco, PhD Student, Oklahoma State University, Stillwater, OK, United States, ronnyp@okstate.edu, Manjunath Kamath

Motivated by applications in healthcare systems, we consider queueing network models with capacity restrictions in different sections and one or more instances of simultaneous resource possession. By analyzing a diverse set of scenarios, we develop a building-block approach to solve more general situations. Our approach builds on the parametric-decomposition method and two-moment approximations for fork-join queues. Numerical examples will be presented to illustrate the application of the proposed methodology.

5 - Exact and Approximate Methods for Comparing Resource Allocation Strategies for Biomanufacturing Projects

Yasemin Limon, University of Wisconsin-Madison, Madison, WI, United States, ylimon@wisc.edu, Ananth Krishnamurthy

We analyze resource allocation challenges in protein purification operations where differences in scientist capabilities can lead to significantly different outcomes. We use queuing models to capture the underlying dynamics and quantify the performance of different strategies based on solutions obtained using the Matrix-Geometric approach. We show that a simple server utilization metric can be very effective in rank ordering strategies.

Chair: Stephen Leider, University of Michigan, Ann Arbor, MI, 48109, United States

1 - Using Wait Time Information to Nudge Patients' Waiting Experience in the Emergency Department

Danqi Luo, Stanford University, Stanford, CA, 94305, United States, dluo@stanford.edu, Mohsen Bayati, Erica Plambeck

This work looks at the effect of wait time information provision on patients' pain, waiting experience, and related behavior in the Emergency Department (ED). Three different wait time information (1.no information, 2. single wait time estimate, 3. range wai time estimation) are looked using a field experiment in an ED, where we survey patients' waiting experience while waiting under each treatment. A lab-experiment involving pain, waiting, perceived waiting, wait time information and related behavior is carried as well to study this phenomenon.

2 - On the Non-equivalence of Trade-ins and Upgrades in the Presence of Framing Effect: Experimental Evidence and Implications for Theory

Mahdi Mahmoudzadeh, Georgia Institute of Technology, Scheller College of Business, Atlanta, GA 30308, United States

Manufacturers of durable goods often buy back older versions of their products from customers to induce them to switch to improved versions. Classical model has long ignored the framing of these buyback schemes, i.e., trade-ins or upgrades, and its relevance for consumer behavior and theory. Using reference-point shift mechanism, through controlled experiments we find that the alternative frames are not isomorphic and that they shift customers' reference points. We then use the experimental findings to extend a reference-dependence version of the classical model of trade-ins and upgrades and show that the behavioral extension modifies predictions of the classical model in line with reality.

3 - Enterprise Social Media Platform Design and White Collar Productivity

Samer Charbaji, PhD Student, University of Michigan Ross School of Business, Ann Arbor, MI, United States, charbaji@umich.edu, Stephen Leider, Roman Kapuscinski

Enterprise social media platforms (ESMPs) have been widely adopted by companies to promote help between employees, with mixed success. We experimentally study the effect of different ESMP designs on employee helping behavior and performance. Participants are assigned real effort tasks and have access to a platform allowing them to request and give help. Our treatments add design features to promote help: aggregate and individual information on helping, and symbolic rewards for achieving helping goals. We show that symbolic rewards for achieving goals yields the most help and the best participant performance, whereas helping information has little effect on helping behavior or performance.

4 - On Mechanisms with a Fairness-concerned Supplier: Theory and Experiments

Wanshan Zhu, Tsinghua university, Beijing, China, zhuws@mail.tsinghua.edu.cn, Zewu Jiang, Yang Zhang, Zhao Xiaobo, Jinxing Xie

Behavioral factors such as fairness affect the decisions and performance of partners in a supply chain; they need to be accounted for in mechanism design. We study the optimal nonlinear and linear mechanisms for the retailer and find both mechanisms has its merits under different conditions due to behaviors.

1 - Identifying Subgroups with Enhanced Peer Influence: A Large-scale Randomized Controlled Trials in Social Advertising

Shan Huang, Massachusetts Institute of Technology, Cambridge, MA, 02142, United States, Tong Wang, Haojun Wu

Peer influence is of central importance in social science. The goal of this paper is to identify subgroups where peer influence exerts enhanced effect on users' responses to social advertisements. Our model characterizes such a subgroup using a set of interpretable rules, constructed from information regarding a user (susceptibility), his/her friend (influence), and their relationship. We present a Bayesian framework for learning a rule set. The Bayesian model consists of a prior to control the size and shape of a rule set and a Bayesian logistic regression to characterize interactions of features, treatment and subgroup membership. We also develop an efficient inference method for learning a MAP model. For this study, we partnered with a world leading mobile social-network platform, WeChat, and conducted a large-scale randomized con- trolled field experiment on WeChat Moments (i.e., newsfeed), on more than 28 million users across 99 ads. We compared our model with state-of-the-art baseline methods on this data set. Our model showed competitive performance and demonstrated high robust- ness for different types of product ads. This is the first paper on a machine learning model to identify subgroups with enhanced peer influence in social advertisements across different product categories. This study provides important insights for advertisers to increase the effectiveness of peer influence in propagating new products of different categories in social networks.

2 - Sooner or Later? Learning from Delivery Speed Information

Ruomeng Cui, Emory University, 1935 Ridgemont Lane, Decatur, GA, 30033, United States, Tianshu Sun

Online retailers who sell physical products need to inform customers how fast an order can be delivered. On one hand, an aggressive (faster) delivery estimate could meet more demand and thus may increase current sales. On the other hand, however, it may also raise the likelihood of customers experiencing a loss in time due to a longer than expected wait, which might hurt future sales. Collaborating with an online store selling custom products, we exploit its shipping rule changes intending to identify the effect of delivery information. We leverage the exogenous policy change and use a difference-in-difference approach to examine whether and how consumers respond to the delivery information.

3 - Effects of Online-offline Channel Integration on E-healthcare Providers: Evidence from a Natural Experiment

Haonan Yin, Beijing Institute of Technology, Beijing, China, Ni (Nina) Huang, Zhijun Yan

Leveraging a natural experiment on a prominent online health community website in China, we empirically investigate the impact of online-offline channel integration on the healthcare providers' online and offline demand, as well as their reputation. Employing multiple identification strategies, our results show several interesting findings: i) Online-offline integration, on average, leads to increases in the e-healthcare provider's online demand and decreases in the provider's offline demand; ii) Online-offline integration, on average, results in increased reputation for the e-healthcare providers; iii) The providers' medical specialty (chronical vs. non-chronical) moderates the main effects, such that the providers who specialize in treating chronical diseases experienced stronger increases in both online demand, and offline demand, and greater elevation in reputation; iv) The healthcare provider's status (professional vs. novice) moderates the main effects, such that the providers with high professional titles experienced stronger increases in online demand, weaker decreases in offline demand, and greater elevation in reputation. This work helps to answer the research questions on the online-offline channel integration as an antecedent to the healthcare providers' performance, which offers valuable design implications for the online healthcare communities.

4 - Connecting Customers and Merchants Offline: Experimental Evidence from the Commercialization of Last-mile Pickup Stations at Alibaba

Brian Rongqing Han, University of Southern California, Los Angeles, CA, 90017, United States, rongqinh@marshall.usc.edu, Tianshu Sun, Leon Zhu, Lixia Wu

Many e-commerce platforms have established extensive networks of last-mile stations as their logistics infrastructure. In this study, we investigate how this last-mile infrastructure may serve as an offline platform for commercial activities (e.g., free sample distribution) to connect customers and merchants. In collaboration with Alibaba, we design two large-scale experimental studies and provide the first evidence on how platforms can leverage the walk-in traffic (organic interaction) and prompt nearby customers through online intervention (induced interactions) to improve customers' online engagement with the merchants and offline utilization of logistics infrastructure.

Auctions and Remanufacturing

Contributed Session

Chair: Zhaohui Geng, University of Pittsburgh, Pittsburgh, PA, 15213, United States

1 - A Logistics Service Quality Based Auction Mechanism for Procuring Last Mile Delivery Capacity

Guangxin Gao, Assistant Professor, Nanjing University of Aeronautics & Astronautics, Nanjing, China, gxgao@nuaa.edu.cn, Zhiping Fan

The increasing demand for last mile delivery has created a challenge for urban consolidation centers (UCCs). Due to the UCC's limited capacity, it has to procure carriers' spare capacity to fulfill the last mile delivery needs. In the procurement, many potential risks may result in low logistics service quality (LSQ). Thus, we propose an LSQ based auction mechanism for the procurement, in which we introduce the LSQ in last mile delivery and then we construct an auction model to ensure UCC's incentive and award business to the carriers delivering high LSQ. The numerical study shows that the proposed mechanism is an efficient procurement tool for the UCC by total cost saving and effective use of resources.

2 - On Finding Stable and Efficient Solutions for Assigning Students to Project Centers with Cohort Considerations

Hoda Atef Yekta, Youngstown State University, Youngstown, OH, United States, hatefyekta@ysu.edu, Andrew C. Trapp, Pitchaya Wiratchotisatian

Global projects are a cornerstone of the project-based curriculum at Worcester Polytechnic Institute (WPI). Recent increases in applications have caused the manual process of placing students (nearly 1,000) into international project centers (nearly 50) to become increasingly complex. We propose an optimization-based mechanism that matches students to project centers by considering student preferences, center capacities and priorities over student skills. Our model finds stable and efficient solutions, and seeks to satisfy multiple cohort characteristic (like gender and major combinations) for project centers.

3 - Evaluating Profitability of Remanufacturing Operations

Akshay Mutha, University of Vermont, Burlington, VT, United States, Saurabh Bansal, V. Daniel R. Guide

We compare different methods for evaluating profitability of remanufacturing operations. We show the application of our model to current industry practices.

4 - Reverse Engineering System: Tolerance Estimation and Analysis for Remanufacturing

Zhaohui Geng, Doctoral Student, University of Pittsburgh, Pittsburgh, PA, United States, zhg17@pitt.edu, Bopaya Bidanda

Reverse engineering (RE) technique possesses dual roles in the RE system (RES): by definition, it can be used to extract the design and tolerancing information from physical parts; as a manufacturing process, it possesses variable nature. We first propose an algorithm to extract 'empirical' tolerance information by analyzing the small batch of products. Firstly, the variational behavior of the calculated mean volumetric data is analyzed from multiple scanning data cloud. Next, a GD&T standard is included in the analysis to classify data cloud into tolerancing database. By deducting the tolerance from RE, the remaining tolerance region can be used for the process design of future remanufacturing.

Flash Session VII

Flash Session

Chair: Soemon Takakuwa, Chuo University

1 - Outsource (some of) What You Do Best, To Better Outsource the Rest

Sébastien Mitraille, Toulouse Business School, Toulouse, France, s.mitraille@tbs-education.fr, Christophe Bernard

When choosing to externalize differentiated operations to a supplier whose cost is unknown and lower on a subset of the production process, an efficient (respectively inefficient) manufacturer minimizes its expected total cost by over (resp. under)-outsourcing to this supplier. When facing its preferred type is likely enough, an efficient manufacturer may choose to unbundle the most costly operations and internalize the worst; a one-size-fits-all contract can be more profitable. When under (resp. over)-outsourcing occurs, the ex-ante total expected cost is more (resp. less) sensitive to the manufacturer's internal cost than at first best.

2 - Predicting Degree Completion Using Neural Networks

Tatiana A. Cardona, PhD Candidate, Missouri University of Science and Technology, Rolla, MO, United States, tacvhd@umsystem.edu, Elizabeth A. Cudney

Increasing retention and completion rates in STEM majors for higher education in the United States, is one of the objectives of the U.S. Department of Education. In these terms, the analysis of student data is vital to determine the factors that influence degree completion rates, providing an opportunity to investigate and improve intentional student advising. To this end, this paper presents the application of neural networks (NN) using a database comprised of 283 entries with 14 variables collected from a community college in the Midwest. The model performance for prediction of completion was over 95 percent. The model also presents a rank of factors that influence the student completion rates.

3 - Intermediary Agri-service Providers with Co-production: The Impact of Farm Size on Performance

Omkar D. Palsule-Desai, Indian Institute of Management-Indore, Indore, India, omkardpd@iimidr.ac.in, Yini Gao, Teo Chung Piaw

A challenge for an intermediary agri-service provider is achieving an appropriate balance between yield improving efforts and assured prices to be offered to the farmers. We develop a noncooperative game theoretic model that captures farming yield of traditional and high-value farm-produce, the trader's commission rates in the open-market, and the supply chain players' farming and effort-cost functions. We describe the economics associated with co-production, gather farmer level data from a firm, and validate observed behavior of players in the real-world setting.

4 - Product Return Predict and Precisely Purchase Freight Insurance for Online Buyers

Bingnan Yang, Huazhong University of Science and Technology, Wuhan, China, yangbingnan@hust.edu.cn, Xianhao Xu

One of the most controversial issues in after-sales service is who should assume the return freight insurance. Now most of merchants choose to buy freight insurance for their buyers to ease dispute and improve customer satisfaction, especially in special festival promotion. Hence, in order to increase the return on investment (ROI), identifying which buyer will return the goods and only buying freight insurance for them is very significant. So, we propose an auto purchase freight insurance system (FIS) to help merchants purchase freight insurance scientifically for their buyers. Our system has been proved to reduce the total cost of merchants effectively.

5 - Production Control in Conjunction with Real-time Simulation Using IoT

Soemon Takakuwa, Chuo University, 6-22-5, Ono-cho, Tokyo, 486 0926, Japan, takakuwa@indsys.chuo-u.ac.jp, Wenhe Yang, Kohtaroh Yoshida, Yifei Tan

Real-time simulation is proposed to see the current status of a physical manufacturing system especially by applying IoT. A framework for integrating management systems such as the ERP/MES system with associated simulation models is presented to perform more effective production control in the IoT/Industry 4.0 environment.

6 - Optimization Model for Work Shifts Generation in the Operation of a Massive Transport System

David Alvarez Martinez, Universidad de Los Andes, Bogota, Colombia, d.alvarezm@uniandes.edu.co, Daniel Esteban Cortes, Luis Miguel Escobar-Falcón, Kenny Cardenas Parra, Rubén Bolaños, Cesar Marín

The formation of work shifts is a problem in a Bus Rapid Transit System, due to costs of hiring drivers to carry out the routes. The generation of shifts consists of putting together work schedules blocks, to cover the operation of the routes designated by the transport system (Megabus). To solve this problem, a two-phase solution methodology was proposed, based on a Column Generation Algorithm that combines the work blocks, minimizing the number of shifts. The proposed methodology was compared using real world instances, presented by Megabus. The proposed methodology reaches feasible solutions in reasonable computing times and outperforms all the proposed solutions of the skilled practitioners.

7 - Optimization Model for Work Shifts Generation in the Operation of a Massive Transport System

David Alvarez, Universidad de Los Andes, Bogota, Colombia, Daniel Esteban Cortes, Luis Miguel Escobar-Falcón, Kenny Cardenas Parra, Rubén Bolaños, Cesar Marín

Operations Management VI

Contributed Session

Chair: Xiaoyun Xiong, China University of Petroleum, Qingdao, 266580, China

1 - Application of AHP with Multi-item Inventory Management Using Part Period Algorithm

Hossein Jamshidi, Alabama A&M University, Normal, AL, United States, hossein.jamshidi@aamu.edu

This empirical study deals with integration of Analytical Hierarchy Process (AHP) with multi Item Inventory Management using Part-Period Algorithm. this study considers the variables of Lot-sizing rules, sequencing, demand pattern, coefficient of variations, and change over cost. AHP is used to pick a sequencing rule and performance criteria. The proposed study presents a methodology to provide tools in the form of multiple tables to assist production managers to utilize work centers in a Group Technology environment in a manner to minimize employee and machine idleness and in making decisions on order quantity size.

2 - A New Data Driven Debiasing Method for Behavioral Newsvendor Problem

Byeong-Yun Chang, Ajou University, Suwon, Korea, Republic of, bychang@ajou.ac.kr, Quan Ha

In many empirical studies on behavioral newsvendor problem, managers' decisions are found to be suboptimal due to biases in their decision-making behaviors. This study developed a data-driven method to support newsvendors to improve their decision performance. The method provides the order quantity that empirically maximized expected profit (EMEP quantity), computed from historical data as a supporting statistical reference for manager to adjust their next order decisions. The study provides a mathematical evidence of the method's efficiency in an ideal condition and statistical evidence on its potentials in improving newsvendor's order quantity over time.

3 - Research on the Behavior of Sewage Enterprises under Sudden Environmental Inspection Incidents

Dan Luo, Tongji University, Shanghai,China, China, 1550724@tongji.edu.cn

Environmental inspection is an environmental governance system with Chinese Characteristics. Central environmental protection inspectorate has formed an organic system with local governments, sewage enterprises, pollution control enterprises, third-party detection agencies, the public, the media and the ecological environment. The various stakeholders in this system usually choose their own behavior from their own interests. Based on Emergency Management and Planned Behavior Theory, the behavior of sewage enterprises under sudden environmental inspection incidents is studied according to the top-down thinking.

4 - An Exact Branch-and-Price Algorithm for Multitasking Scheduling on Unrelated Parallel Machines

Xiaoyun Xiong, China University of Petroleum, Tsingtao, China, xiongxy618@163.com, peng zhou

We consider the multitasking scheduling problem on unrelated parallel machines to minimize the total weighted completion time, the processing of a selected job on a machine may be interrupted by other jobs scheduled on the same machine that are available but unfinished. To solve this problem, we propose an exact branch-and-price algorithm, where the master problem at each search node is solved by a in-out column generation. We use a hybrid strategy combining a genetic algorithm and an exact dynamic programming algorithm to solve the pricing subproblems approximately and exactly, respectively. Using randomly generated data, we evaluate the performance of the proposed solution approach.

Innovation/Entrepreneurship

Contributed Session

Chair: Sameer Borwankar, Purdue University, West Lafayette, IN, 47906, United States

1 - Blockchain: Trust, Gender and Risk

Juan Andrei Villarroel, Professor of Innovation and Entrepreneurship, School of Management Fribourg, Fribourg, Switzerland, andrei.villarroel@hefr.ch

This research investigates how blockchain technology —or more technically, distributed-ledger technology (DLT)— enables 'trust' in the context of the news media. A body of literature posits the critical role of traditional news media organizations due to "trust" considerations. However, an emergent literature posits that DLT brings a technological alternative to "trust", which extends it beyond the realm of traditional institutions. Our survey of 2'200 respondents in Switzerland, unveils the actual "trust" that individuals put onto DLT, by contrast to traditional news media —international and local. The results should have important managerial and policy implications.

2 - Price Discrimination in Crowdfunding: An Investigation of Coupons

Xiahua Wei, Assistant Professor, University of Washington, Bothell, WA, United States, Weijia You, Yong Tan

Offering coupons is emerging as a new strategy for fundraisers to attract backers in crowdfunding. Using project-level panel data from a large crowdfunding platform, we analyze how coupons contribute to the amount of funds raised and the probability of funding success. We find that the backing options with coupons captivate more backers, without crowding out backers of other options where coupons are unavailable. This positive impact decreases with the coupon duration. Further, only regular backers, rather than wholesale or lottery backers, are drawn by coupons. These findings provide new insights into how a traditional marketing strategy of price discrimination creates value for crowdfunding.

3 - Technology Innovation under Quality Uncertainty

Yiwei Wang, University of California-Irvine, Irvine, CA, United States, willwangyiwei@gmail.com

Firms constantly invest on improving the product quality with innovative technology. However, the innovative technology's performance could be inconsistent from time to time. This paper studies how should the firm set the level of its quality improvement under deterministic technology, uncertain technology, or offer the existing product with no improvement at all. These conditions are affected by a number of driving forces, such as level of uncertainty and cost structures.

4 - A Theory of Value Appropriation of Patent Trolls

Mingtao Xu, Purdue university, West Lafayette, IN, United States, mingtaoxu@purdue.edu

We develop a model of patent monetization. We compare the practicing method, where value appropriation occurs in the product market, and the litigating method, where value appropriation occurs via the threat of legal action. We show that differences in both the technical strength and the exclusionary strength of the patent lead to differences in the value that firms can appropriate from monetization. The profit of practicing is convex in exclusionary strength, while that of litigating is convex. The model provides a theory of non-practicing entities (NPE) by explaining how firms with different monetization methods value patents differently and how valuations affect patent acquisitions.

5 - Effect of Digital Merger & Acquisition on Innovation

Sameer Borwankar, Purdue University, West Lafayette, IN, United States, sborwank@purdue.edu

In 2018, nearly one-third of companies logging M&A activity described themselves as traditional companies acquiring digital companies or assets. This type of M&A activity differs from the traditional acquisition which is focused on increasing the revenue or decreasing the costs through synergies in the short to medium duration. The literature on the traditional merger and acquisition suggests that the innovation level of the post-integration entity is lower than that of the parent firm. In this research, we empirically study the digital merger and acquisition and its effect on the innovation of the post-integration entity.

Big Data II

Contributed Session

Chair: Floris Herrema, EUROCONTROL, Prins Hendrikweg 23, Noordwijk, 2202EC, Netherlands

1 - Application of Machine Learning Algorithms for Identification of Entrepreneurial Digital Profiles Based on Information from a Big Russian Social Network

Margarita Gladkova, Graduate School of Management, St. Petersburg University, St. Petersburg, Russian Federation, gladkova@gsom.spbu.ru, Evgenii Gilenko

The goal of this unique study is to create detailed portraits of entrepreneurs operating on a digital platform. The data for analysis is provided by the biggest Russian social network - VKontakte where more than 400 000 businesses are registered. The modern methods of statistical analysis and machine learning are used to classify the businesses and build their profiles.

2 - Stroke-risk Stratification Scheme an EHR Based Predictive Analytics Study

Rupesh K. Agrawal, Research Assistant, Oklahoma State University, Tulsa, OK, United States, rupesh.agrawal@okstate.edu, Farooq Junaid, Dursun Delen, Bruce A. Benjamin, Matt Wilkett

Stroke-Risk Stratification scheme (RSS) is the gold standard for calculating the stroke risk of a patient with Atrial Fibrillation (AF). Stroke-RSS is based on prevalence numbers and does not include significant factors, e.g. Comorbidities: obstructive sleep apnea, COPD: clinical markers, e.g., cholesterol levels. The goal of this study is to scrutinize significant factors extracted from a national patient data repository, to improve Stroke-RSS using predictive analytics tools.

3 - Data Capacity and Statistical Quality Considerations in Support of Healthcare Modeling Efforts

Steven B. Cohen, Vive President, RTI International, Washington, DC, United States, scohen@rti.org

To complement current state assessments of health care, policymakers depend on model-based future state estimates under alternative assumptions subject to greater levels of uncertainty beyond sampling and nonsampling error. The integration of national survey data with content derived from big data sources and nonprobability based samples is gaining traction to inform these efforts. Comparable standards of data quality and statistical integrity for these modeling and simulation efforts are needed to convey levels of uncertainty in results. This presentation focuses on these sources of uncertainty in resultant estimates and methodologies to better quantify their error bounds.

4 - An Incremental Learning Risk Model: A Data Streaming Approach

Sandeep Goyal, Associate Professor, University of Louisville, Louisville, KY, United States, Donghui Shi, Jozef Zurada, Jeff Guan, Waldemar Karwowski

Changes in situations modifies the input data thereby inducing changes in risk model. Batch processing techniques such as regression are unable to keep up with such changes. We present a novel approach that uses data streaming to develop a risk model which accounts for data drifts. The goal of this risk model is to determine which combinations of human-social-infrastructure development projects are most effective in reducing risks. A data stream approach using three data stream algorithms is compared to batch-based algorithms—namely, the newer machine learning algorithms as well as the traditional regression approach. The results show that the data stream methods models risk better.

5 - Analyzing Large-scale Human Mobility Patterns for Disaster Management and Planning

Boyeong Hong, New York University, Brooklyn, NY, United States, Constantine E. Kontokosta, Bartosz Bonczak, Arpit Gupta

This paper presents a novel analytic approach, integrating big data, geospatial analytics, and machine learning, to understand individual- and neighborhood-level evacuation and recovery patterns in Houston, Texas before, during, and after Hurricane Harvey in August 2017. Using a detailed dataset of geolocations from more than 400,000 unique mobile devices, we develop unsupervised clustering and statistical models to identify socio-spatial disparities in evacuation behaviors. Our findings support data-driven and hyperlocal emergency management strategies, such as targeted outreach to at-risk populations and more efficient and fair resource allocation to aid vulnerable communities.

6 - APOC Big Data Study at Heathrow Airport

Floris Herrema, EUROCONTROL, Noordwijk, Netherlands, floris.herrema@eurocontrol.int

Improving airport performance is at the heart of the SESAR's Airport Operations Centre (APOC) solution. In this study, we review APOC roles and responsibilities, identify the key APOC processes that could be enhanced by data-driven predictions and machine learning techniques, and demonstrate a case study of how shared data and advanced analytics can be used to make predictions of passengers' connection times. In the case study, a regression tree model is fitted to a large training set with 3.7 million passenger records. This predictive model is applied to generate forecasts of each passenger's connection time and the passenger flows during an eight-hour live trial.

Simulation and Optimization II

Contributed Session

Chair: Lu Zheng, Southeast University, Nanjing, 210096, China

1 - Optimal Design in Industrial Seeding Operations: A Simulation-based Optimization Approach

Jingyuan Feng, Dalian University of Technology, Dalian, China, Nan Kong, Xiangpei Hu

Industrial seeding is important in the modern agriculture industry for its high production intensity and controllable production time. It is a complex decision making process, along which order acceptance, backlog production, and environment control decisions should be made intelligently for revenue maximization. In this paper, we propose a hybrid event-based and time-based simulation model to evaluate the performance of the industry seeding system, and PSO combined with OCBA optimization approach to search the promising decision-making policies under a simulation budget constraint. It provides a novel applications to the agriculture production system using simulation optimization.

2 - Reliability-based Design Optimization of Airport Concrete Pavement

Ramin Giahi, Graduate Research Assistant, Iowa State University, Ames, IA, United States, rgiahi@iastate.edu, Adel Rezaei-Tarahomi, Cameron MacKenzie, Halil Ceylan, Kim Sunghwan, Kasthurirangan Gopalakrishnan

Artificial neural network alongside a design optimization framework is proposed to find the optimal design of the airfield rigid pavement. This optimal design should consider different values of the uncertain parameters. The design optimization model is solved considering different reliability levels and design lives for the airfield rigid pavement.

3 - Data Mining and Discrete-event Simulation for Improving Flight Operations at a Focal Airport

Canser Bilir, Istanbul S. Zaim University, Istanbul, Turkey, canser.bilir@izu.edu.tr, Laurence Douglas Smith

Investments in airport infrastructure (e.g., new runways and terminal modifications) cost billions of dollars. Analytical tools are needed to assess how changes in airport infrastructure, supporting resources, and operational practice may affect scheduled airline service, air cargo operations and general aviation flights that operate at commercial airports. In this study, we describe a unique blend of statistical modeling, discrete-event simulation and analytical decision support for planning of airport infrastructure, airline flight operations and airside operating practice.

4 - Simulation Optimization Using Stochastic Kriging with Robust Statistics

Linhan Ouyang, Nanjing University of Aeronautics and Astronautics, Nanjing, China, ouyang@nuaa.edu.cn, Chanseok Park

This paper provides some theoretical results on the predictive and optimization performance of stochastic kriging and proposes a robust stochastic kriging which is less sensitive to normal departure and data contamination by using robust location and scale estimations. Statistical properties of the robust estimators are briefly analyzed and the performances of the proposed methods are compared through numerical examples of different features. The comparison results show that the proposed robust stochastic kriging with the robust estimations is quite efficient no matter whether the standard assumptions hold or not.

5 - The Algorithm Which Creates the Complete Paths of Rescue Drones

Taihei Miyama, Waseda University, Tokyo, Japan, 1003taihei@gmail.com, Takashi Hasuike

In recent years, many natural disasters have occurred in Japan. In such a situation, quick rescue activities using UAVs such as drones are drawing attention.To doing rescue activities using UAVs, we should determine the flying paths of rescue drones. These drones' paths should cover the whole target area, and these paths are called Complete Path.In this study, we assume rescue activities which using some drones after disasters. Then propose the algorithm which creates the complete paths of rescue drones and verify the efficiency of the flight paths through simulation.

6 - Evolutionary Game Analysis of Information Quality under Public Participation

Lu Zheng, Southeast University, Nanjing, China, zzlu0918@hotmail.com

Sustainability II

Contributed Session

Chair: Yanqi Zeng, Huazhong University of Science and Technology, Luoyu Road 1037, Hongshan district, Wuhan, China

1 - A Supply Chain Model for 3D Printed, Orthopedic Implants

Margaret Golz, North Carolina State University, Raleigh, NC, United States, mgolz@ncsu.edu, Richard A. Wysk, Russell Edward King, Ola L. Harrysson

Personalized orthopedic medicine has previously been reserved for specialty cases but, with the advent of additive manufacturing, volume production of personalized orthopedic implants is highly anticipated. The objective of this research is to develop the supply chain model of orthopedic implants produced with electron beam melting technology and identify the effect of uncertainty in parameter estimation. The method of this analysis is to characterize key performance indices for different control variables and experimental parameter variations in order to better understand the effect of uncertainty and relationships of the manufacturing process.

2 - Supply Chain Efficiency and Performance under Sustainability Initiatives

Yabing Zhao, Assistant Professor, San Francisco State University, San Francisco, CA, United States, ybzhao@sfsu.edu, Zhuang Qian

While sustainability has gained momentum in today's global economy, it's still in the early stage of a decades-long trend. The main objective of this research is to understand firms' reporting and implementation of sustainability initiatives and their impact on firm and supply chain's future efficiency and performance through empirical analysis.

3 - A Hybrid Framework to Identify and Prioritize the Most Important Supply Chain Enablers to Improve Sustainability

Sajad Ebrahimi, North Dakota State University, Fargo, ND, United States, Joseph Szmerekovsky

Businesses currently face pressure from both government regulations and customers' expectations in reaching sustainable supply chains, and that forces them to implement sustainable practices. To adopt sustainable supply chain management (SSCM), industries need to identify influential enablers. This study aims to identify influential enablers for SSCM by using fuzzy Delphi method and then apply interpretive structural modeling to find the relationships between the recommended enablers to find impressionability and effectiveness. Finally, considering the relations between the enablers, the authors use a fuzzy analytical network process, to find the most important SSCM enablers.

4 - Customer Concentration and Supplier's Corporate Social Performance

Jia Gao, Shanghai Jiaotong University, Shanghai, China, jia.z.gao@gmail.com, Ying Rong, Zhao xiaoping

Although there are extensive studies about Corporate Social Performance (CSP), our understanding of CSP in supply chain context is limited. In this study, we first identify the correlation between customer concentration and supplier's CSP. Then we investigate several key factors to help to explain this correlation.

5 - The Effect of Corporate Equity Structure on Innovation Investment: Evidence from China

Yanqi Zeng, Huazhong University of Science and Technology, Wuhan, China, yanqizeng66@163.com

This paper explores the impact of corporate equity structure on innovation investment and studies the moderating effect of environmental uncertainty. With the data of 1417 observations of Chinese listed companies in 2015-2017, empirical results show that the higher the concentration of equity, the less invest in innovation, and firms with high shareholding ratio of executives tend to invest more in innovation, and the moderating effect of environmental uncertainty is also different.

Joint Session ENRE/Env/Practice Curated: Methods and Results for the Costs and Environmental Impacts of Ride-Hailing

Sponsored: Energy, Natural Res & the Environment/Environment & Sustainability

Sponsored Session

Chair: Matthew Bruchon, Pittsburgh, PA, 15206, United States

Co-Chair: Jeremy J Michalek, Carnegie Mellon University, Pittsburgh, PA, 15213, United States

1 - Sustainable Urban Mobility with Transit Centric On-demand Services

Samitha Samaranayake, Cornell University, School of Civil & Environmental Engineering, 220 Hollister Hall, Ithaca, NY, 14853, United States, samitha@alum.mit.edu

The rapid expansion of on-demand ride-hailing services has changed the transportation landscape in many cities worldwide. While these services are a valuable alternative travel mode, as evident by their popularity, there are many questions regarding their scalability, efficiency, equity and negative externalities (e.g. congestion, pollution etc.). One way to mitigate some of these concerns is to consider high-capacity ride-pooling services, where many passengers share a vehicle simultaneously, and better integration with public transit. This talk will present a general framework for solving problems of this type at large-scale.

2 - Socially Adoptable Energy-efficient Mobility Systems

Andreas Malikopoulos, University of Delaware, Newark, DE, United States, andreas@udel.edu

The purpose of a transportation system is not mobility but rather accessibility to goods, services, and activities. Mobility is only an unintended outcome of our accessibility needs. A mobility system involves the interactions of three heterogeneous features that constitute a sociotechnical system: 1) transportation systems and modes, e.g., connected and automated vehicles, public transit, and shared mobility, 2) social behavior of drivers and travelers interacting with these systems, and 3) institutional behavior of organized units such as regulators. The talk will discuss how we can develop an energy-efficient mobility system from a sociotechnical systems perspective.

3 - Optimizing Ride-Hailing Fleet Electrification to Minimize Costs and Emissions

Matthew B. Bruchon, Carnegie Mellon, Pittsburgh, PA, 15206, United States, mbruchon@andrew.cmu.edu, Jeremy J. Michalek, Inês Azevedo

With higher capital costs and lower operation costs, electric vehicles may be competitive for high-use applications, including transportation network companies (TNCs) like Uber and Lyft. Electric vehicles may also help reduce air emissions. This study co-optimizes TNC vehicle purchases (battery, hybrid, or conventional powertrains), routing, and charger scheduling to minimize private costs in a mixed-integer model aided by heuristics. We then assess the impact of emissions pricing by considering how the optimal fleet changes when emissions externalities are added to the objective function.

4 - Vehicle Minimum Occupancy Standards for TNCs to Encouraging Ride Pooling

Paul Leiby, Oak Ridge National Laboratory, Oak Ridge, TN, United States, Jonathan Rubin

Ride pooling (shared rides) and increased vehicle occupancy have been identified as key requirements for achieving the full benefits of new mobility systems, including transportation network companies (TNCs), vehicle automation and connectivity. We distinguish "ride pooling" from "vehicle sharing" (or ride hailing) in which vehicles are used sequentially by different users, each charged per ride or per time period. As mobility options expand, incentives for ride pooling are necessary to limit congestion, energy use, and emissions since several studies have shown that simply sharing vehicles will not significantly reduce, and could increase, vehicle kilometers travelled (VKT). This is especially a concern with connected autonomous vehicles where the convenience and lower cost per kilometer are expected to increase vehicle travel demand. The goal is to reduce congestion and energy use while still providing for high levels of mobility. To incentivize TNC fleet operators to increase vehicle occupancy (ride pooling), we propose using flexible Minimum Occupancy STandards (MOSTs). MOSTs are performance standards that would require TNCs to collectively achieve a minimum ride-weighted occupancy level across their fleets. MOSTs would deter empty vehicle kilometers and encourage ride pooling. We specify an approach for incentivizing higher ridership in Transportation Network Company (ridehail/ridepool) vehicles through an average vehicle occupancy standard and first evaluate it analytically. We utilize available data on TNC travel, geographic analysis of ride pooling potential, and economic behavioral assumptions to benchmark an illustrative numerical model, and develop initial insights on the efficiency of pooling standards or incentives, as measured by mobility and economic impacts.

5 - Analysis of Future Mobility On-Demand Systems in Global Urban Typologies

Jimi B. Oke, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, oke@mit.edu, Arun Prakash Akkinepally, Youssef M. Aboutaleb, Siyu Chen, Yifei Xie, Carlos L. Azevedo, Pericles C. Zegras, Joseph Ferreira, Moshe E. Ben-Akiva

With global urbanization expected to reach 60% by 2050, innovative solutions must be devised to meet growing demand. We thus propose a systemic approach to analyze the impacts of mobility policies on future outcomes. Building on prior discovery of 12 global urban typologies, we generate 3 high-fidelity, typology-representative prototype cities. We then simulate these cities via SimMobility, analyzing the impacts of automated mobility on-demand (AMoD) strategies using via demand, congestion, supply and energy outcomes. Our results provide insights into how AMoD can be sustainably harnessed in transit-oriented and auto-dependent cities.

Stochastic and Robust Optimization in Energy Systems

Sponsored: Energy, Natural Res & the Environment/Electricity

Sponsored Session

Chair: Andy Sun, Georgia Institute of Technology, Atlanta, GA, 30332-0205, United States

1 - Impacts of Topology Control on Zonal Markets

Quentin Lété, CORE, UCL, Louvain la Neuve, Belgium, quentin.lete@uclouvain.be, Anthony Papavasiliou

We present a two-stage model of zonal electricity markets with day-ahead market clearing and real-time redispatch that accounts for transmission line switching at both stages and N-1 robustness. We show how the day-ahead problem with switching can be formulated as an adaptive robust optimization problem with mixed integer recourse that we solve using a nested column-and-constraint generation algorithm. We apply these models on a realistic instance of the Central Western Europe system and comment on the impacts of both proactive and reactive transmission switching on the operating costs of the system.

2 - Stochastic Dual Dynamic Programming Algorithm for Nonconvex Multistage Optimization Problems

Shixuan Zhang, Georgia Institute of Technology, Atlanta, GA, 30318, United States, szhang483@gatech.edu, Andy Sun

Nonconvex multistage optimization problems can often be decomposed into relatively tractable subproblems via dynamic programming. We use the generalized conjugacy of nonconvex functions to propose an iterative approximation scheme for the cost-to-go functions. This approximation scheme is shown to be both valid and tight for a wide range of nonconvex problems. We establish the convergence rate results for the deterministic case and show the application in the stochastic dual dynamic programming algorithms.

3 - Applying Multi-stage Stochastic Programming to Investment Planning for Energy Systems.

Anthony Downward, University of Auckland, Auckland CBD, Auckland, 1024, New Zealand, a.downward@auckland.ac.nz, Andy Philpott

Energy systems around the world are adapting to new policies around emissions, this is leading to the closure of many existing plant, and the increased utilization of renewable generation sources. In this work we present a multistage stochastic integer programming framework, developed in Julia, which determines an optimal investment policy, given a scenario tree for demand growth. The individual stage problem for this is a 5-year operational policy for an electricity sector, given the endogenous investment decisions. We apply this model using the New Zealand electricity market as a case study.

4 - Distributionally Robust Optimization with Conditional Ambiguity Sets for Power System Planning

Alexander Velloso, Pontifical Catholic University of Rio de Janeiro, Rio de Janeiro, Brazil, David Pozo, Alexander Street

We propose an extension of the traditional distributionally robust optimization (DRO) framework to consider multiple ambiguities sets simultaneously. This framework can conciliate multi-scale (long and short) uncertainties for long-term decision-making, like in power systems planning. The multi-ambiguity-set DRO problem results in an infinite-dimensional problem. A new enhanced-column-and-constraint generation decomposition approach is proposed with an additional Dantzig-Wolfe step that allows a better representation of the DRO recourse function and tight lower and upper bounds. Numerical experiments for planning power systems corroborate the effectiveness of the method.

Co-Chair: Tapas K. Das, University of South Florida, Tampa, FL, 33620-5350, United States

1 - Multi-objective Electric Vehicle Facility Management: Exact Method for Network Design and Dynamic Pricing Scheme with User Decisions

Leila Hajibabai, North Carolina State University, Department of Civil Engineering, 2433 Computer Science, Raleigh, NC, 11794, United States, lhajiba@ncsu.edu, Amir Mirheli

This study develops an exact method for electric vehicle infrastructure design and management under the impacts of user-specific decisions. The objective is to determine the optimal number, location, and capacity of charging facilities in the transportation network with optimal demand-responsive pricing scheme. The problem is formulated as a bi-level optimization program that minimizes the total facility deployment and operation costs under user-equilibrium flows. The proposed solution technique solves the bi-level problem to exact optimality by generating theoretical lower- and upper-bounds to the proposed problem.

2 - Scenarios of Transportation Electrification

Matteo Muratori, NREL, Golden, CO, 80401, United States, matteo.muratori@nrel.gov

Transportation is currently the least-diversified energy demand sector, with over 90% of global transportation energy use coming from petroleum product. After over a century of petroleum dominance, however, many leading experts anticipate major electrification trends that could disrupt the transportation energy demand landscape. This talk describes scenarios of future transportation electrification and their impact on bulk power systems.

3 - Electric Vehicles Equilibrium Model that Considers Charging Queue and Complementary Traffic

Nurit Oliker, PhD, Universite de Montreal (DIRO), Montreal, QC, Canada, nurit.oliker@umontreal.ca, Miguel F. Anjos, Margarida Carvalho, Emma Frejinger, Bernard Gendron

We present an assignment model for electric vehicle (EVs) that considers both queue delay in charging stations and flow dependent travel times in the network, given the complete traffic. EVs feasible paths are found given the limited travel range and the layout of fast charging stations infrastructure. This is a user equilibrium model that considers travel, charging and queuing times in the path choice modelling of both EVs and the complementary traffic. The charging stations capacity is represented as an M/M/k queuing system. The charging time is a function of the flow and the charging quantity, considering several vehicle and driver classes. Numerical examples present the model properties.

4 - On the Integration, Location, and Operations of Smart Hubs for Shared Autonomous Electric Vehicles

Kevin A. Melendez, University of South Florida, Tampa, FL, 33613, United States, kmelendez7@mail.usf.edu, Tapas K. Das, Changhyun Kwon

Companies providing ride sharing service in cities are expected to adopt a new business model partially switching from cars owned by individuals to SAEVs leased from companies. Switching to SAEVs for ride sharing will only be possible with the availability of smart hubs to support SAEV fleet operation for efficient charging and discharging of batteries. This work presents a comprehensive methodology to operate a large fleet of SAEVS providing ride services while supporting the power grid. Our methodology considers both transportation and power systems constraints and uncertainties, including but not limited to: dynamic prices, customers arrivals, DA commitments, and RT balancing.

1 - A Log-Barrier Newton-CG Method for Bound Constrained Optimization with Complexity Guarantees

Mark O'Malley, Senior Research Fellow, NREL, Boulder, CO, United States, Stepehn J. Wright

We describe an algorithm based on a logarithmic barrier function, Newton's method, and linear conjugate gradients, that obtains an approximate minimizer of a smooth function over the nonnegative orthant. We develop a bound on the complexity of the approach, stated in terms of the required accuracy and the cost of a single gradient evaluation of the objective function and/or a matrix-vector multiplication involving the Hessian of the objective. The approach can be implemented without explicit calculation or storage of the Hessian.

2 - Representing Short-Term Uncertainties in Capacity Expansion Planning Using a Rolling-Horizon Operation Model

Espen Flo Bødal, Department of Electric Power Engineering, Norwegian University of Science and Technology, Trondheim, Norway, espen.bodal@ntnu.no, Audun Botterud, Magnus Korpås

Flexible resources such as batteries and demand-side management technologies are needed to handle future large shares of variable renewable power. Wind and solar power introduce more short-term uncertainty that have to be considered when making investment decisions as it significantly impacts the value of flexible resources. In this work we present a method for using duals from a rolling horizon operational model, with wind power uncertainty and market representations, to represent power system operation in an investment problem. The method is based on benders decomposition and special considerations are made due to the nature of the rolling horizon operational framework.

3 - Value of Energy Storage in Low-carbon Grids with High Shares of Wind and Solar Penetration

Dharik S. Mallapragada, MIT Energy Initiative, Massachusetts Institute of Technology, Cambridge, MA, United States, dharik@mit.edu, Nestor A. Sepulveda, Jesse D. Jenkins

The rapid rise in variable renewable energy (VRE) generation in the power sector has prompted interest in studying long-term system impacts of their adoption and the role for energy storage. This study uses a high temporal resolution capacity expansion model (CEM) to assess the system value of energy storage in providing multiple grid services under different grid and technology scenarios. The analysis will discuss the sensitivity of storage value to: 1) regional differences in load and VRE resource availability (e.g. U.S. Northeast vs. Texas), 2) the penetration of storage, VRE generation and 3) provision of one or more grid services (e.g. reserves, transmission deferral).

4 - Optimal Battery Sizing and Location for Offshore Wind Energy

Mehdi Jafari, Postdoctoral Associate, Massachusetts Institute of Technology (MIT), Cambridge, MA, United States, jafari@mit.edu, Audun Botterud, Apurba Sakti

With increased variable renewables in power systems, the challenge of grid integration emerges. One promising solution is using energy storage system. The traditional approach of modeling batteries for grid applications is to include fixed efficiencies or maximum power while these parameters are dependent on power and SOC. Also, batteries degrade over time. We developed a model of offshore wind-battery system, while modeling the power limit and efficiency as a function of output power and SOC and accounting for degradation. The resulting model is in the form of mixed integer linear programming (MILP). We study different configurations of system on multiple li-ion chemistries in energy arbitrage.

1 - When Does the Platform Tell You the Truth? Optimal Design of Persuasion Policy in the Two-sided Market

Andy Tao LI, School of Economics and Management, Tsinghua University, beijing, China, lit3.14@sem.tsinghua.edu.cn, Jie Zheng

We analyze the information announcement strategy for the C2C Service platform, whereas platform provides not only a less profitable standard service with stochastic stock-out risk, but also a more profitable premier service with no stock-out risk. While the expected stock-out rate is commonly known, customers do not observe the availability of the standard service when they choose between two services. Thus, their decision can be influenced by the service availability information announced by platform. We show that designing a state-contingent probabilistic disclosure policy and hence involves lying under some conditions, will be profitable and solve the optimal disclosure strategy.

2 - Optimal Referral Reward Program in a Freemium Model

Wei Geng, Southwest Jiaotong University, Chengdu, China, wgeng@swjtu.edu.cn

Freemium is a prevalent business model for selling information goods or services. In this model, firms offer basic core functions for free and sell premium functions to high-end consumers. Referral reward programs are commonly observed when those firms are trying to harness the power of social networks. We consider a firm in a monopoly market and consumers embedded in a social network, and demonstrate the optimal referral reward program for the firm. Price of the premium version, reward mechanism and reward size are considered.

3 - Perceived Risk and Its Impact on Intention to Use Mobile Banking in a Newly Emerging Country

Long Pham, University of Louisiana at Monroe, Monroe, LA, United States, pham@ulm.edu

We present research investigating if customer perceived risk in the mobile banking setting is a second-order construct comprising of first-order constructs - component risk factors. We examine which component risk factors contribute the most to customer perceived risk and the relationship between customer perceived risk and intention to use mobile banking in a newly emerging country. We analyze survey data from 403 mobile banking customers, using the structural equation modelling technique to present new insights.

4 - An Empirical Study of Promotion Effects on Store Sales

mengmeng wang, Shanghai Jiao Tong University, Shanghai, China, wangmengmeng1@sjtu.edu.cn

Mobile payment prevails in China and various promotions launched by mobile payment platform facilitate the adoption of mobile payment. This paper investigates the impacts of mobile payment promotions on store sales in the two-sided market. Our empirical analysis is based on the sales data of 40 chain stores within 5 months. Tencent launched a payment promotion, such that users can receive a random price cut . We use the difference in differences (DID) method to analyze the effect of the promotions. The estimated results show that the mobile payment promotion has a positive impact on store sales on the day of promotion but has no impact on long-term overall sales.

5 - Research on the Algorithm of E-commerce Product Name Recognition Based on the gcForest Model

Jing Ma, Nanjing University of Aeronautics and Astronautics, Nanjing, China, majing5525@126.com, Xiaofeng Li, Chi Li, Xiaoyu Guo, Bo He

Aiming at the demand of automatic catalogue identification for E-commerce commodities, this paper puts forward the problem of product name recognition for the first time in the field of e-commerce. The supervised machine learning algorithm based on the gcForest model is used to recognize the product name from the short text of the e-commerce product descriptions. Experiments show that, for 800 different products 100,000 records of product description, the accuracy of the algorithm is 0.91 and the recall rate is 0.93. Experiments prove that the algorithm is reasonable, effective and practical.

6 - Subscribing Before or Paying After? Should the Live Platform Use Pay-what-you-want Pricing?

Ling Ding, Xi'an Jiaotong University, Xi'an, China, lingding5-c@my.cityu.edu.hk, Xiuwu Liao

Subscriptions and advertising have been the main source of profit for video sites, but for live platforms, subscriptions have dominated for a long period. In recent years, live broadcast platforms have increasingly paid attention to Pay-What-You-Want Pricing. Hence which pricing strategy should be optimal for the platform? A single or mixed pricing strategy? We develop an analytical model and collect data from a live broadcast platform to study how the platform chooses the optimal pricing strategy, consumer surplus and social welfare.

Chair: Jasmina Tacheva

1 - Engaging Team Formation Problem for Maximizing Online Forum Activity

Alexander Nikolaev, Associate Professor, University at Buffalo, Buffalo, NY, 14260-2050, United States, anikolae@buffalo.edu, Rahul Swamy, Alexander Semenov

Online Health Forums (OHFs) such as WebMD and MedHelp provide structured support to users and visitors by fostering a community of users that actively engage in the forum. In order to assess the quality of forum communication, it is important to quantify and compute how “engaging” the users are. In this research, we use a co-operative game theory-based approach to quantify engagement, by extracting the temporal and network structure of an online forum. A case study using real-world data compares the results from using this approach with traditional, network centrality-based approaches.

2 - It's All about Who You Know: Exploring Weak Ties on LinkedIn

Natalie Simpson, University at Buffalo, Buffalo, NY, 14260-4000, United States, nsimpson@buffalo.edu

Collaboration is an essential part of humanitarian operations, since the synergies it creates are associated with better humanitarian outcomes at all phases of the emergency management cycle. We aim to investigate whether the primacy of collaboration in disaster management translates into more diverse social networks maintained by emergency management professionals compared to those exhibited by experts in operations and supply chain management not involved in disaster mitigation. Our approach is based on a combination of machine learning and social network analysis of data from the social network platform LinkedIn.

3 - Identifying Opioid Dependency of Twitter Users Through Personality Traits: A Machine Learning Approach

Anton Ivanov, University at Illinois, 326 Jacobs Management Center, Urbana, IL, 14260, United States

To address challenges in opioid surveillance and advance knowledge of the role of individual differences in opioid abuse, we compare the personality profiles of Twitter users who self-disclosed the fact of being addicted to opioids to non-users using the wide spectrum five-factor model. To do so, we apply a range of machine learning techniques. Our results provide (1) conceptual clarifications on the difference in personality traits between opioid addicts and non-users, and (2) suggestive evidence that multilayer perceptron performs acceptably to identify Twitter users with opioid dependency.

4 - Human Centered NLP with User-Factor Adaptation

Youngseo Son, Stony Brook University, 100 Nicolls Road, Stony Brook, NY, 11794, United States, yson@cs.stonybrook.edu, H. Andrew Schwartz, Veronica Lynn, Vivek Kulkarni, Niranjan Balasubramanian

We pose the general task of user-factor adaptation — adapting supervised learning models to user factors inferred from a background of their language, reflecting the idea that a piece of text should be understood within the context of the user that wrote it. We introduce a continuous adaptation technique, suited for real-valued user factors that are common in social science and bringing us closer to personalized NLP, adapting to each user uniquely. We apply this technique with known user factors including age, gender, and personality traits, as well as latent factors, evaluating over five social media tasks: POS tagging, PP-attachment, sentiment analysis, sarcasm detection, and stance detection.

5 - Helping Relief Organizations Help Through ML

Jasmina Tacheva, SUN Y. at Buffalo, Buffalo, NY, 14210, United States, zhasmina@buffalo.edu, Natalie Simpson

While the analysis of user-generated data for resource allocation decision-making during a disaster has been studied across different scientific fields, there is a dearth of research on how humanitarian organizations can use such data to design and implement more effective communication campaigns in order to assemble resources rather than solely distribute them. We propose a machine learning model which can be used both in real time and retroactively to parse humanitarian aid messages in social media for the purpose of identifying digital volunteers whose efforts may directly aid relief organizations in their mission to help communities in need.

Sponsored Session

Chair: Artem Prokhorov

1 - Causal Inference with Bayesian Additive Trees and Subclassification

Marcel Scharth, The University of Sydney, University of Sydney, Australia

We develop a Bayesian semi-parametric framework for the estimation of the conditional average treatment effect (CATE) function in observational and experimental studies. We flexibly model the response surface using a Bayesian Additive Regression Tree (BART) specification that adaptively combines joint and separate estimation of conditional expectations for the treatment or control groups. Treatment effect estimators based on regression methods can be severely biased in the presence of pronounced confounding. We address this problem by integrating our regression approach into a new subclassification scheme based on the propensity score.

2 - Lasso-type Regularization with Nonparametric Bernstein Copula and its Application in Financial Markets

Aixi Zhang, University of Sydney, Sydney, Australia, aixi.zhang@sydney.edu.au, Artem Prokhorov, Peter Radchenko

Modeling the dependence structure is a key aspect of data mining and statistical learning. Constraints of shape and misspecification of parametric models for complex financial data necessitate a flexible model. We propose a penalized nonparametric Bernstein copula approach. It employs the Bernstein polynomial sieves to tackle the difficulties in optimization over infinite dimensional space and utilizes an adapted LASSO penalty to reduce the risk of overfitting and efficiency loss. The weights of the penalty are set as reciprocals of the empirical copula in order to impose sparsity. We demonstrate merits of our proposed model compared with its counterparts through Monte-Carlo simulations.

3 - Feature-based Time Series Forecast Model Combination

Pablo Montero-Manso, Monash University, Melbourne, Australia

We discuss a new methodology for forecast model combination which can be used for selecting the best single model, the best subset or an accurate averaging of a set of models. A meta-learning model uses features (e.g. autocorrelations, spectral entropy) of a series to produce the weights used in the combination. The meta-model is trained on a large collection of time series with known future values by optimizing a new objective function. Empirical results on 100000 time series show good forecasting accuracy (achieved second position in the recent M4 forecasting competition) and robustness against model miss specification. The method can easily be adapted for different forecasting error measures.

4 - Application of Machine Learning Algorithms for Identification of Entrepreneurial Digital Profiles Based on Information from a Big Russian Social Network

Margarita Gladkova, Graduate School of Management, St. Petersburg University, St. Petersburg, Russian Federation, gladkova@gsom.spbu.ru, Evgenii Gilenko

The goal of this unique study is to create detailed portraits of entrepreneurs operating on a digital platform. The data for analysis is provided by the biggest Russian social network - VKontakte where more than 400 000 businesses are registered. The modern methods of statistical analysis and machine learning are used to classify the businesses and build their profiles.

Chair: Mohammad Pirhooshyaran

1 - Reinforcement Learning for Decision-making in Multi-echelon Supply Chains

Mohammad Pirhooshyaran, Lehigh University, Bethlehem, PA, 18015, United States, Mohammadreza Nazari, Lawrence V. Snyder

We discuss reinforcement learning (RL) methods for making decisions in multi-echelon supply chains. Many production-distribution structures have no known optimal inventory policies or closed-form cost functions. The fact that the optimal policies depend on the network structure and parameter values further complicates the analysis. We consider non-serial inventory networks with stochastic demands, in which each stage must make inventory decisions based on incomplete information about the supply chain as a whole. We model this problem using a multi-agent RL framework.

2 - Digital Platforms in Service Operations

Jie Sheng, University of Bristol, Bristol, United Kingdom, jie.sheng@bristol.ac.uk

Relying on information and communication technologies, organisations are increasingly digitalizing service operations to improve customer experience and business productivity. Digital platforms such as social media and mobile apps become growingly important touchpoints for firms to manage. We discuss how businesses can effectively engage in digital platforms and harness massive data generated in the platforms to improve operational practices.

3 - Digital Twinning for Healthcare Logistic in Enhancing Efficiency and Effectiveness: Case Study in Singapore

Sunil Tiwari, Research Fellow, National University of Singapore, Singapore, Singapore, tlist@nus.edu.sg

Most of the healthcare institutions in Singapore realize the inevitability of manpower challenges especially at the bottom of the workforce pyramid and in order to come up with this; they have to adopt more process-based technologies, particularly in robotics and automation. In the hospital of tomorrow, RPA will be a part of IoT to assist the new mission. This study explores productivity improvement opportunities through RPA usage, application of Data Analytics, and implementation of optimization within the HI. The transportation system within the hospital, dispatching rule of the lifts and robots, are optimized through extensive simulation.

Uncertainty Quantification:? AI-based? Modeling and Decision-making Under? Uncertainty

Sponsored: Data Mining

Sponsored Session

Chair: Aven Samareh

1 - Dirichlet Process Mixture Model-based Quality Control with Uncertainty in Advanced Manufacturing Processes

Jia (Peter) Liu, Auburn University, Auburn, AL, United States, Zhenyu (James) Kong

Nonlinear and nonstationary process dynamics in advanced manufacturing (e.g., batch production, process state shifting) incur challenges of achieving stable process states and reliable product quality. Dirichlet process mixture model, a nonparametric Bayesian model, can adaptively model latent components and capture their changes from the generated complex non-Gaussian sensor data. Therefore, quality control algorithms based on the Dirichlet process mixture model possess flexibility in modeling and mitigate the uncertainty in decision making. They outperform traditional statistical process control methods in several case studies of advanced manufacturing processes.

2 - Deep Learning and Uncertainty Quantification for Climate Resilience

Thomas Vandal, Research Scientist, NASA Ames, Moffett Field, CA, United States, vandal@beari.org

Modeling and monitoring of earth's processes through physical models and satellite observations at high resolutions is crucial for ensuring society's ability to adapt to climate change. Deep learning (DL) has been shown to be a valuable tool for generating high resolution data, emulating physical models, and detecting weather patterns which can then be used to inform stakeholders and decision makers. However, both the data and model parameters contain substantial uncertainties that may alter users' decisions. In this work we present two DL applications on high-resolution climate and satellite datasets using Bayesian neural networks to generate well calibrated uncertainty estimates.

3 - A Deep Reinforcement Learning Approach for Real-time Sensor-driven Decision Making

Erotokritos Skordilis, University of Miami, Coral Gables, FL, United States, sge12@miami.edu, Ramin Moghaddas

Complex industrial equipment requires robust real-time control policies. Deep reinforcement learning (DRL) is capable of deriving such policies due to its capacity to address highly complex control and decision making problems. DRL describes interactions between an agent and its environment through actions that maximize a cumulative reward. The environment is described with a set of states that denote system degradation and can be inferred using particle filtering (PF). We propose a decision making method that combines DRL and PF for real-time control regarding degrading systems under partial information. Numerical results are provided for a NASA C-MAPSS turbofan engine degradation dataset.

1 - How New Technologies are Transforming Medicine

Krzysztof “Krys” Cios, Virginia Commonwealth University, Richmond, VA, United States, kcios@vcu.edu

We will focus on technologies that are transforming the practice of medicine. Majority of those technologies generate huge amounts of heterogeneous digital data that humans can neither integrate nor analyze. It is thus technology that must be used to mine in these data to find new information and present it to health care practitioners in an understandable way, best visual. Some of the disruptive technologies we will talk about include wearable devices, artificial intelligence and machine learning, image understanding, and social networks. We will end by describing some deployments of new technologies in terms of case studies.

2 - Tagging Medical IoT Devices with Token Data

Yue (Richard) Xie, VP of Data Science and Application, Cylera, New York, NY, United States, richardxy@gmail.com

We have seen exponential growth rate of medical IoT devices being utilized in nationwide healthcare institutes The network security of those IoT devices has become a great concern for all the stakeholders. One of the first challenges in providing cybersecurity to industrial IoT devices is to accurately and timely identify the devices on a network. This talk introduces the approach to applying natural language processing (NLP) methods to analyze and transform textual tokens transmitted between devices to construct a classification model for tagging the devices.

3 - Understanding the Vulnerable Community Through Social Network Analytics and Text Mining

Xin Tian, Assistant Professor, Kennesaw State University, Marietta, GA, United States, xtian2@kennesaw.edu, Wu He, QIng Wen, Weidong Zhang

This study investigates the vulnerable groups from social media using social network analysis and text mining techniques. Increasing patients and their family are publicly expressing their thoughts and feelings about health care issues and challenges facing them on the Internet. Guided by the social exchange theory, this study revealed some evidence that indicates and classifies the benefits and concerns of cancer patients and caregivers in the U.S and China. This research demonstrates how cancer patients and their families use social media to exchange social support with others who experience similar challenges.

4 - Optimal Imputation and Outlier Detection

Maxime Amram, Research Scientist, Interpretable AI, Cambridge, MA, United States, maxime@interpretable.ai, Dimitris Bertsimas, Ying Zhuo

Data quality issues such as missing values and outliers remain a key roadblock to deriving value from big data and machine learning deployments. We developed Optimal Imputation, a novel framework to impute missing data by jointly optimizing the values and the model (KNN, SVM, or decision-tree based models) on the data. In large-scale synthetic and real data experiments, we show Optimal Imputation produces the best overall imputation in the majority of all datasets benchmarked against state-of-the-art methods. We also discuss how this approach can be used to detect outliers.

5 - Training Data Selection in Plant Breeding

Reyhaneh Bijari, Graduate Research Assistant, Iowa State University, Ames, IA, United States, rbijari@iastate.edu, Sigurdur Olafsson

In plant breeding, a decision to advance an experimental plant variety to the next year of testing must be made on very limited data. However, some experimental varieties behave in a similar manner and have similar genotype-by-environment (GxE) interactions. In this paper, an efficient training data selection algorithm is performed to find the best varieties which help describe the true distribution of yield for a given target variety to inform the decision making. This methodology helps to improve the model performance and to determine training observations which result in the best model. Additionally, we obtain insights into the GxE interactions for the target and selected varieties.

Optimization in Clustering and Applications

Sponsored: Data Mining

Sponsored Session

Chair: Gokce Kahvecioglu

1 - A Graph-theoretic Dissimilarity Measure for Flow Field Classification

Eli Olinick, Southern Methodist University, Dept Eng Mgmt Info and Systems, Po Box 750123, Dallas, TX, 75275-0123, United States, olinick@lyle.smu.edu, Paul Krueger, Michael Hahsler, Sheila Williams, Mohammadreza Zharfa

We propose a generalization of the well-known Gabriel graph to represent key features in repeated patterns of vortices in fluids (flow fields) generated by various means, including swimming animals. The representation is designed for clustering and classification of flow fields; it is sensitive to the topological and geometric structure of the field, but relatively insensitive to small changes in vortex location. We present a suite of binary integer programs to measure dissimilarity between graphs constructed with our model for input as distances to a hierarchical clustering algorithm. Experiments with computer-generated flows demonstrate the high accuracy of the resulting classification.

2 - Fluxcom:A Local Strategy for Community Detection in Dynamic Networks

Rodrigo Francisquini, Universidade Federal de São Paulo, São José dos Campos, Brazil, francisquini.r@gmail.com, Mariá C. Nascimento

Several complex systems can be represented by dynamic graphs that change over time. Community detection strategies are commonly used to analyze and understand the structure of these networks. Although the literature of community detection in static networks is vast, there are a few strategies that can effectively find communities in dynamic networks. This study presents a strategy to detect communities in dynamic networks capable of locally correcting communities through modularity maximization. In computational experiments with real-world biological and social networks, the introduced strategy showed excellent results with low computational cost.

3 - Interpretable Clustering: An Optimization Approach

Agni Orfanoudaki, Massachusetts Institute of Technology, Cambridge, MA, 02142, United States, agniorf@mit.edu, Dimitris Bertsimas, Holly Mika Wiberg

We present a new unsupervised learning method that leverages optimization techniques to generate interpretable tree-based clustering models. Utilizing a flexible framework, our algorithm approximates the globally optimal solution leading to high-quality partitions of the feature space. Our method can optimize for various clustering internal validation metrics and naturally determines the optimal number of clusters. It achieves comparable or superior performance to K-means on both synthetic and real-world datasets while offering significantly higher interpretability.

4 - An Objective for Hierarchical Clustering in Euclidean Space and its Connection to Bisecting K-means

Yuyan Wang, Carnegie Mellon University, Pittsburgh, PA, United States, yuyanw@andrew.cmu.edu, Benjamin Moseley

Divisive algorithms are widely used to construct hierarchical clusterings, yet many currently used algorithms are not known to optimize a global objective function. This paper develops a new natural global objective for hierarchical clustering. The objective captures the criterion that has motivated the use of bisecting clustering algorithms: that two clusters separated at a level in the tree should contain points that are closer than points across clusters. This paper proves that iteratively adopting optimal k-means gives a constant approximation for the objective function proposed. This is the first paper to show optimal k-means optimizes a global objective over the entire tree.

5 - Parametric Bicriteria Clustering on a Graph

Gokce Kahvecioglu, PhD Student, Northwestern University, Evanston, IL, 60208, United States, gokcekahvecioglu2014@u.northwestern.edu, David Morton

Given an undirected graph with positive weights on the edges we study a parametric bicriteria graph clustering problem. We remove a subset of edges to break the graph into smaller pieces, i.e., connected components, or clusters. We seek to maximize the number of clusters while minimizing the weight of the removed edges. We identify nested solutions that lie on the concave envelopeof the efficient frontier, yielding a hierarchical family of clusters, in strongly polynomial time. We demonstrate the performance of our approach on a network dened by the schedule of football teams in the National Collegiate Athletic Association (NCAA), which has a known hierarchical structure.

1 - Optimizing Ensemble Weights and Hyperparameters for Machine Learning Models for Regression Problems

Guiping Hu, Iowa State University, Ames, IA, United States, gphu@iastate.edu, Mohsen Shah Hosseini

Ensembles are gaining more popularity among data scientists and researchers due to their superior performance. While different studies show the power of weighted ensembles, there is no systematic approach to find the best weights. A novel optimization approach for regression problems is proposed, that formulates the weights for each model. Besides, the effect of tuning hyperparameters on optimal ensembles is studied. Experiments on several data sets show the better performance of the suggested optimization model compared to both individual learners and unweighted average ensembles. Furthermore, it was shown that the best ensemble is not necessarily resulted from optimal hyperparameters.

2 - Efficient Retrieval System for Similar and Same-process Blueprint Images

Hisaya Miyao, Waseda university, Tokyo, Japan, orange.380138@toki.waseda.jp, Takashi Hasuike

When we make a product in somewhere like a factory, we often refer past blueprints which are similar to the blueprint of it. This is a CBIR(Content-Based Image Retrieval) problem but not simple one, because it is necessary that not only the blueprints are similar to original one but also they have same processes. In addition, it is desirable to retrieve blueprints efficiently, so we have to build a efficient image retrieval system that retrieve similar blueprints which have same processes as those of original one. In order to achieve this task, we build some various systems and compare them. We evaluate each systems from the points of view of similarity, accuracy and process time.

3 - Combining Artificial Intelligence and Blockchains: Identification of Use Cases and Business Value

Rajhans Mishra, Indian Institute of Management-Indore, Indore, India, rajhans111@gmail.com, Mukul Gupta

Artificial Intelligence and blockchains are two emerging technologies. Sectors as health, retail and banking are using AI. Blockchain has become popular as an enabling technology of Bitcoin. Primarily blockchain has provided a technology platform where encrypted data is stored and new blocks are added by the miners sequentially. These two technologies can be amalgamated to capture the value for various purposes including intellectual property rights for content, smart contract, etc. The paper explores the synergy between these two technologies for real use cases and business value.

4 - A Hidden Markov Models Approach to Predict Early Detection of Equipment Failure

Prince Agarwal, Indian Institute of Technology Kharagpur, IIT Kharagpur, Kharagpur, We, Kharagpur, 721302, India, princeagarwal12@gmail.com, Akhilesh Kumar, Saptarshi Das, Venkatesh Madyastha

There have been considerable advances in sensing instrumentation, hardware, signal processing algorithms, and internet technology infrastructure that have eventually paved the way for the long-envisioned concept of smart factories under the purview of Industry 4.0. To leverage the available system data, factories across the globe are embracing Predictive Maintenance in the era of Industry 4.0. In the current study, the objective is to identify the early failure of equipment and determine the remaining useful life. Towards this end, a Hidden Markov Model-based sequential clustering algorithm has been developed and tested on sensor signals of different components of an oil and gas Company.

5 - A Fuzzy Inferenced Based Approach to Feature Selection for Supervised Machine Learning Models

Wilkistar Otieno, University of Wisconsin - Milwaukee, Milwaukee, WI, United States, otieno@uwm.edu, Phillip LaCasse, Francisco Maturana

The big data environment enabled by smart manufacturing technology is such that many thousands of independent variables might be utilized as inputs for training applied machine learning models. This research provides an algorithmic approach to reducing the feature set through sequential filtration and quantifying the value associated with remaining features by means of a fuzzy inference system. The approach is validated in an applied case study in electronic assembly manufacture.

6 - Most Important Fundamental Rule of Poker Strategy

Sam Ganzfried, Ganzfried Research, 1504 Bay Road Apt 1706, Miami Beach, FL, 33139, United States, Max Chiswick

Poker is a large complex game of imperfect information, which has been singled out as a major AI challenge problem. Recently there has been a series of breakthroughs culminating in agents that have successfully defeated the strongest human players in two-player no-limit Texas hold 'em. The strongest agents are based on algorithms for approximating Nash equilibrium strategies, which are stored in massive binary files and unintelligible to humans. Using techniques from machine learning we have uncovered a new simple, fundamental rule of poker strategy that leads to a significant improvement in performance over the best prior rule and can also easily be applied by human players.

1 - Medication Recommendations Using the Unsupervised Learning Algorithm

HU Yang, Central University of Finance and Economics, Beijing, China, hu.yang@cufe.edu.cn

The use of electronic health records that can bring valuable improvements to hospital practices by integrating patient information. In fact, the understanding of these data can help us recommend medication prescriptions to doctors and also prevent mistakes that may put patients' lives at risk. These problems can be modeled as a recommendation system that recommends the treatments based on drug-disease association, patient information and laboratory test information. In this study, we propose an unsupervised method to recommend medication prescriptions to the doctors.

2 - Using Analytical Modeling to Better Manage High-Risk Patients: A Population Health Approach

Hengwei Zhang, Claremont Graduate University, Claremont, CA, United States, hengwei.zhang@cgu.edu

Patient Risk stratification models are of great interests for both providers and payers in the U.S. healthcare system. As the top 5 percent of sickest patients count towards 50% of the total healthcare cost in 2016, the ability to identify these patients and design interventions have great potentials in reducing the healthcare cost and improving population health.This presentation focuses on the process of translating specific business questions to feasible predictive modeling questions, designing data pipelines that are capable of real-time scoring of new data, modeling, and results evaluation by using a real-world case study from a health plan in Southern California.

3 - A Matrix Decomposition Approach to Predicting Brugada Syndrome Based on ECG Data

Qingpeng Zhang, City University of Hong Kong, Kowloon, 12180, Hong Kong, qingpeng.zhang@cityu.edu.hk, Jiandong Zhou, Gary Tse

In this research, we present a nonnegative matrix factorization (NMF)-based approach to predicting the Brugada syndrome using ECG data. A set of ECG data in HK is used to evaluate the performance of the proposed approach. We show that the NMF-based approach outperforms traditional regression-based methods by capturing the complex interrelations among different risk factors.

Computational and Economic Considerations in Social Media Analytics

Sponsored: Social Media Analytics

Sponsored Session

Chair: Abhinav Maurya, Pittsburgh, PA, 15206, United States

1 - Optimal Transport Embeddings for understanding Occupations and Skills in the Labor Market

Abhinav Maurya, Carnegie Mellon University, Pittsburgh, PA, United States, ahmaurya@gmail.com

We propose a simple distribution-to-distribution optimal transport approach for (i) learning occupation and skill embeddings (OccupationEmbedding and SkillEmbedding) and (ii) identifying occupation-specific skills from these embeddings using OccupationSkillRanking with the goal of career-driven skill training for unemployed and underemployed workers. Our approach beats a number of baselines on metrics evaluating the quality of occupation-personalized skill recommendations, indicating that the Wasserstein metric can effectively model the distance between entity histograms such as those associated with multidisciplinary occupation histories and skill sets.

2 - Knowledge Sharing in the Sharing Economy – Evidence from Virtual Communities on Airbnb

Srikar Velichety, University of Memphis, Memphis, TN, 38111, United States, svlchety@memphis.edu

We investigate the drivers of knowledge sharing in host communities on sharing economy platforms using the literature on social capital and peer-effects. We also explain the impact of three different aspects of knowledge sharing on the performance of services in these platforms. Using a large multiyear dataset of posts collected from a virtual knowledge sharing community of hosts on AIRBNB, we estimate the impact of quantity, quality and diversity of knowledge sharing on the occupancy rates of properties. We also quantify the impact of peer-effects on knowledge sharing in these virtual communities.

3 - Effects of Subsidy Payment in Two-sided Market – The Case with Sponsored Data Programs

Jialin Song, University of Illinois at Urbana Champaign, Urbana, IL, 61801, United States, jsong83@illinois.edu, Qiong Wang

Mobile content access is a two-sided market where the network is the platform that connects providers and consumers of information products. As the platform operator, major Mobile Service Providers (MSPs) in the US have all introduced sponsored data programs that allow a Content Provider (CP) to pay for the use of network capacity by consumers to access its contents. Based on developing and analyzing a Stackelberg Game model, we discuss how the level of the subsidy payment affects profits of the MSP and the CP, and its impact on consumers' access to these programs and the resulting consumer surplus.

Ergodicity of Stochastic Systems

Sponsored: Applied Probability

Sponsored Session

Chair: Guodong Pang, Penn State University, University Park, PA, 16802, United States

1 - Exponential Ergodicity and Convergence for Generalized Reflected Brownian Motion

Wenpin Tang, UCLA, Los Angelos, CA, United States

In this talk, we discuss convergence analysis for a class of Brownian queues in tandem by establishing an exponential drift condition. A consequence is uniform exponential ergodicity for these multidimensional diffusions, including the O'Connell-Yor process. A list of open problems is also presented.

2 - Stationary Distributions and Convergence for M/m/1 Queues in Interactive Random Environment

Andrey Sarantsev, Assistant Professor, University of Nevada, Reno, Davidson Math & Science Center 314, Reno, NV, 89557, United States, asarantsev@unr.edu

We study a Markovian single-server queue in interactive random environments. The arrival and service rates of the queue depend on the environment, while the transition dynamics of the random environment depends on the queue length. We consider two types of Markov random environments: a pure jump process and a reflected jump-diffusion. In both cases, the joint dynamics is constructed so that the stationary distribution can be explicitly found in a product form. We derive an explicit estimate for exponential rate of convergence to stationarity via coupling.

3 - Convergence Rates to Stationarity for Reflected Brownian Motions

Sayan Banerjee, University of North Carolina, Chapel Hill, Chapel Hill, NC, United States, sayan@email.unc.edu, Amarjit Budhiraja

In this talk, we will explore methods to obtain rates of convergence to stationarity in L1-Wasserstein distance for obliquely reflected d-dimensional Brownian motion (RBM) in the nonnegative orthant that are explicit in the dimension and the system parameters. These processes emerge as heavy-traffic scaling limits of Jackson networks. The results are then applied to a class of RBMs considered by Blanchet and Chen (2016) and to rank-based diffusions including the Atlas model. In the first case we improve the relaxation time estimates of O (d4(log d)2) obtained in Blanchet and Chen (2016) to O ((log d)2). In the case of the standard Atlas model, the relaxation time is O (d6(log d)2).

4 - Stability of Certain Classes of Multi-pool Networks in the Halfin-Whitt Regime

Hassan Hmedi, University of Texas at Austin, Austin, TX, United States, hmedi@utexas.edu, Ari Arapostathis, Guodong Pang

We study ergodic properties of certain classes of multi-pool queueing networks having no abandonment. The system is heavily loaded in the Halfin-Whitt regime, and the scheduling policies are work-conserving and preemptive. We provide a unified approach by establishing Foster-Lyapunov equations for the limiting diffusion showing exponential ergodicity uniformly over all stationary Markov controls. We also employ these results in the study of the pre-limit diffusion-scaled queueing processes and define the notion of wide-sense jointly work conserving policies. We show that the diffusion-scaled processes are also exponentially ergodic, uniformly over all such policies.

5 - Stability of a Class of Markov Processes under Fast Regime Switching

Yi Zheng, The Pennsylvania State University, State College, PA, 16801, United States, yxz282@psu.edu, Ari Arapostathis, Guodong Pang

We study the stability of a class of Markov-modulated general birth-death processes under fast regime switching. We assume that the “averaged” fluid limit exists when a scale parameter is taken large, and the Markov-modulated process is centered and scaled. We provide a sufficient condition for the exponential ergodicity of the Markov-modulated process. We also establish Brownian steady-state approximation for the Markov-modulated process, and provide the convergence rate for the moments of diffusion-scaled processes to the steady-state moments. Some results of p-stability and sub-exponential ergodicity for the Markov-modulated process are also considered.

Stochastic Dynamic Games in Economics

Sponsored: Applied Probability

Sponsored Session

Chair: Dharma Kwon, University of Illinois at U-C, Champaign, IL, 61820, United States

1 - Predatory Pricing under Uncertainty: Revisiting the Deep Pocket Argument

Maria Lavrutich, Tilburg University, Tilburg, Netherlands, Jacco Thijssen

We analyze a dynamic Cournot equilibrium in a continuous time stochastic game between capital constrained firms. Firms can choose both the production strategy and the dividend policy. When profits evolve stochastically, a negative demand shock can lead to bankruptcy. Firms then may have an incentive to start a price war. We focus on the link between predatory pricing and dividend policy and find that the presence of product market competition and the possibility of predation induces fewer dividend payouts. Predatory behavior only occurs when the prey is not distributing dividends. When both firms pay out dividends the equilibrium strategy is to be myopic and produce per-period Cournot quantities.

2 - Economically Valuable Exit from a Duopoly and the Feedback Effects Between First and Second Mover Advantages

Jan-Henrik Steg, Bielefeld University, Bielefeld, Germany, jsteg@uni-bielefeld.de, Jacco Thijssen

We analyse a dynamic model of a duopoly in which firms have an economically valuable option to exit by switching from one market to another. We construct a subgame-perfect equilibrium in Markovian mixed strategies and show that both preemption and attrition can occur along typical equilibrium paths. The presence of both effects implies different tradeoffs than in existing strategic real option models, and, accordingly, it changes the nature of the stopping problems to be solved. As a consequence, preemption and attrition cannot be analysed separately. In equilibrium, the threat of preemption gives firms an incentive to start a war of attrition sooner than they would without preemption.

3 - Pareto Optimality Versus Nash Equilibrium, Price of Anarchy Versus Price of Stability

Renyuan Xu, Oxford University, Oxford, United Kingdom, dorisxu1026@gmail.com, Xin Guo

Pareto optimality (PO) is an important concept in game theory to measure the global efficiency when players collaborate. In this talk, we start with the PO for a class of continuous-time stochastic games with finite number of players. To explicitly solve for a PO, we consider a central controller who coordinates the system and transform the problem into a sequence of Skorokhod problems. We then discuss the PO with infinity number of players, which leads the McKean-Vlasov dynamics. Another common criterion in game theory is the Nash equilibrium (NE) which captures the stability under competition. In the end, we compare the PO solution with the NE via price of stability and price of anarchy.

4 - Game of Variable Contributions to the Common Good under Uncertainty

Dharma Kwon, University of Illinois at U-C, Champaign, IL, 61820, United States, dhkwon@illinois.edu

We consider a stochastic game of contribution to the common good in which the players have continuous control over the degree of contribution, and we examine the gradualism arising from the free rider effect. Previously known examples of variable concession games in the literature yield equilibria characterized by singular control strategies without any delay of concession. We find that a variable contribution game with a single state variable possesses an equilibrium characterized by regular control strategies that result in a gradual concession. We also find that asymmetry between the players can mitigate the inefficiency caused by the gradualism.

Advances in Machine Learning Models and Applications

Sponsored: Applied Probability

Sponsored Session

Chair: Floske Spieksma, Leiden University, Leiden, Netherlands

Chair: Michael N Katehakis, Rutgers University, Newark, NJ, 07010, United States

1 - New Reinforcement Learning Models and Algorithms for Healthcare Treatment Choices

Debopriya Ghosh, Rutgers University, New Brunswick, NJ, United States, Daniel Pirutinsky, Michael N. Katehakis, Odysseas Kanavetas, Spiros Papadimitriou

Starting with a large dataset of cancer patients, which contains patient level historical information on patient demographics, disease markers, diagnoses, previous treatments etc, we construct and analyze reinforcement learning models for patient centered treatment recommendations. The objective is to provide near optimal dynamic policies for treatment choices so as to maximize the probability of patient survival for a fixed time horizon.

2 - Inventory Management Enabled with Blockchain System

Jasmine (Aichih) Chang, New Jersey Institute of Technology, Newark, NJ, United States, Junmin Shi, Michael N. Katehakis

Blockchain has been widely embraced as a disruptive technology for inventory management. This study examines the Newsvendor model enabled with a blockchain system. It aims to shed light on how blockchain adoption impacts the optimal inventory decisions, illustrated with some selected demand types, such as Uniform and Normal distributions.

3 - Dynamic Inventory Control with Fixed Setup Costs and Unknown Discrete Demand Distribution

Mehdi Davoodi, Rutgers University, New Brunswick, NJ, United States, Michael N. Katehakis, Jian Yang

We study a dynamic inventory control problem involving fixed setup costs and random demand distributions. We depart from the traditional literature by allowing the stationary demand distribution to be largely unknown. We propose a policy that controls the pace at which a traditional (s,S)-computing algorithm is applied to the empirical distribution of the demand learned over time. It incurs a regret that would grow at an O(T^{1/2}(ln T)^{1/2})-sized rate.

4 - A Comparison Reinforcement Learning Algorithms

Daniel Pirutinsky, Rutgers University, New Brunswick, NJ, United States, Wesley Cowan, Michael N. Katehakis

In this talk we consider the basic reinforcement learning model dealing with adaptively controlling a Markov Decision Process (MDP) with unknown rewards and transition probabilities. We provide a survey of existing algorithms and numerically compare their performance.

Operations in On-Demand Platforms

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Guangwen Kong, University of Minnesota, Minneapolis, MN, 55414, United States

1 - If You Love Your Agents, Set Them Freeish

Vasiliki Kostami, HEC Paris, Jouy-en-Josas, 78350, France, kostami@hec.fr

Flexibility is beneficial for matching supply with demand, but comes at a cost. In modern digital workplaces, users possess a spectrum of different skills associated with variable task preferences: Some are inclined to give up part of their payment to avoid unfavorable matches. The platform manager gains extra freedom in allocating tasks by possibly charging servers for a favorable assignment. We introduce an innovative mechanism for task assignment where agents are allowed some task discretion in exchange for a fee. We model different working environments and different servers' preferences and study how the preferences, the task cost, and the flexibility fee, affect the equilibrium assignment.

2 - Harnessing the Double-edged Sword via Routing: Information Provision on Ride-hailing Platforms

Dongyuan Zhan, University College London, School of Management, Gower Street, London, WC1E 6BT, United Kingdom, d.zhan@ucl.ac.uk, Leon Zhu, Zhixi Wan

We consider a ride-hailing platform that provides free information to taxi drivers. The platform broadcasts the origin and destination of the riders to idle drivers, who accept or ignore the request depending on the profitability. The first driver to accept the request serves the rider; if no driver accepts the request, the rider leaves. We show that such information provision is a double-edged sword: drivers may wait for more profitable riders via inefficient idling. When multiple drivers compete for the same request, how the platform breaks the tie affects the incentives of the drivers. We propose a routing policy that can align the incentives and achieve the first-best outcome for large systems.

3 - Two-sided Competition Between On-demand Service Platforms

Shining Wu, The Hong Kong Polytechnic University, LMS Dept., Hong Kong, 999077, Hong Kong, sn.wu@polyu.edu.hk, Shihong Xiao, Saif Benjaafar

On-demand service platforms compete for both agents and customers, and hence form a two-sided competition. In this paper, we perform a comprehensive study on the two-sided competition problem of two platforms with an in-depth analysis of its subgame. We separate our discussion into two cases where agents and customers may move sequentially or simultaneously. We find that these two settings yield different sets of subgame outcomes, and multiple subgame equilibria are possible. To obtain a unique prediction, we further examine some commonly used refinement rules and discuss their appropriateness. Lastly, we relate our findings to various possible competition outcomes that arise in practice.

4 - Surge Price or Subsidy? Information Sharing or Suggestion? A Behavioral Investigation of Workers' Relocation in On-demand Platforms.

Guangwen Kong, Temple University, Philadelphia, PA, Yinghao Zhang, Zhongzhong Jiang

We have witnessed a rapid rise of on-demand platforms, such as Uber, in the past few years. This research studies how workers respond to these policies and which policy (or policies) can effectively reduce supply-demand mismatch across regions in an on-demand platform. This research investigates workers' decisions from the behavioral perspective. We first analytically characterize the standard equilibrium predictions and then test them using a series of controlled laboratory experiments. We finally propose a behavioral model to explain the observed behavior in the lab.

Decision Analysis II

Contributed Session

Chair: Mona Khoddam, Arizona State University, School of Computing, Informatics, Tempe, AZ, 85281, United States

1 - An Optimal Policy for an Assignment of Police Patrols in the UMPD Precincts

Tongqing Chen, University of Minnesota-Twin Cities, Minneapolis, MN, United States, chen4823@umn.edu, Darin A. England

We developed a model applying the concepts of Markov Chain Process and Dynamic Programming to assign police officers to precincts of the local Police Department (UMPD). An optimal policy allocates officers for all the states to minimize the expected total number of crimes of the following shifts with considerations of both the short-term effects and the long-term effects. Our model can be applied to other police precinct areas to find optimal policies for police assignments.

2 - Realizing Context Effects by Ideal Point Estimation

Shotaro Kotani, Waseda University, Tokyo, Japan, phiokari@gmail.com, Takashi Hasuike

We suggest the model predicting human choice behavior.The characteristic of our model is to be able to represent the preference changing in some contexts.We respect the hypothesis that people generate the ideal choice when they make a decision from multiple alternatives.They then compare these alternatives with the ideal point and finally decide.We make the discrete choice model based on the hypothesis.To make a numerical experiment,we show the performance of our model.

3 - Mode of Improvement for Efficient Global Optimization of Expensive Stochastic Black Box Functions

Rajitha Meka, University of Texas-San Antonio, San Antonio, TX, United States, rajithameka14@gmail.com, Adel Alaeddini

In this study, we propose the mode of improvement (MI) algorithm for efficient optimization of stochastic black box functions. MI algorithm leverages the relationship between the expected value and standard deviation of the stochastic improvement in Bayesian optimization to dynamically balance exploration and exploitation to reduce the number of expensive evaluations. We validate the proposed algorithm using several simulated examples.

4 - Analysis of a Functional Response from a Mixture Experiment

Mona Khoddam, Arizona State University, Tempe, AZ, United States, mkhoddam@asu.edu

Mixture experiments are widely used in applications where the levels of the experimental factors are varying proportions of several chemical components that sum to a 100%.Previous and current work on the analysis of mixture data only involve single-response values.In this work,we discuss an application where the response from a mixture experiment is a series of data points collected over a continuum,known in the literature as functional data. This rheological response measure relates to a critical-to-customer attribute.Taking a single viscosity value at a fixed shear rate fails to capture the rheological differences among chemical formulations.

Capacity Management and Pricing for Services

Sponsored: Manufacturing & Service Oper. Mgmt/Service Operations

Sponsored Session

Chair: Serhan Ziya, University of North Carolina, Chapel Hill, NC, 27599, United States

Co-Chair: Eda Kemahlioglu Ziya, North Carolina State, Raleigh, NC, 27695-7229, United States

1 - Food Delivery Services for Restaurants: Friend or Foe?

Jianfu Wang, Nanyang Business School, Nanyang Technological University, Nanyang Avenue, Singapore, 639798, Singapore, Manlu Chen, Ming Hu

This paper studies the food delivery services using which customers can hire deliverymen to pick up food on behalf of them. To investigate the impact of food delivery service, we model a restaurant serving food to customers as a stylized single-server queue with two streams of customers. One stream is tech-savvy customers who can access the food delivery service. The other stream is walk-in customers who cannot access the food delivery service. We discover that when more customers have access to the food delivery service, both the society and the food delivery firm may be worse off. We propose remedies that may potentially create better coordination in a queue with food delivery service.

2 - On Designing a Socially-optimal Expedited Service when Customers Have Heterogeneous Usage Rates

Aditya Shetty, Simon Business School, University of Rochester, Rochester, NY, United States, aditya.Shetty@simon.rochester.edu, Ricky Roet-Green

We look at the problem of a congested system where a mandatory service is being provided. There are two variants of the service: a base version that customers can join at no cost and an expedited one that customers can join by paying a fixed one time fee. The service provider has a fixed total capacity and it must make a decision on how to split that capacity between the two services. Our goal is to find the socially optimal allocation while taking into account the equilibrium behavior of the customers.

3 - When Service Times Depend on Customers' Delays: A Solution to Two Empirical Challenges

Chenguang (Allen) Wu, Hong Kong University of Science and Technology, Academic Building, Clear Water Bay, 60208, Hong Kong, allenwu@ust.hk, Achal Bassamboo, Ohad Perry

Service times of customers often depend on the delays in queue, as was recently observed in restaurants, call centers and intensive care units. We propose two dependence mechanisms in service systems with customer abandonment, one exogenous and one endogenous. Identifying the source of dependence from observed data is hard because both the service times and the patience times are censored due to abandonment. Further, even if the dependence is known to be exogenous, there remains the difficult problem of fitting a joint distribution to the censored data. We address these two statistical challenges in the current paper by proving an equivalence relation between exogenous and endogenous dependencies.

4 - Pricing and Capacity Decisions for Shared Service Systems under Competition

Wei Gu, University of North Carolina-Chapel Hill, Carrboro, NC, 27510, United States, wei25@live.unc.edu, H. Sebastian Heese, Eda Kemahlioglu Ziya, Serhan Ziya

We consider service systems where customers' utility depends on price as well as their service experience, which in turn depends on how crowded the service environment is and with whom the service environment is shared. We investigate how two such systems make pricing and capacity decisions under competition.

CC- Room 305

Topics in Market Design

Sponsored: Manufacturing & Service Oper. Mgmt/Service Operations

Sponsored Session

Chair: Itai Ashlagi, Stanford University, Stanford, CA, 94305, United States

1 - Designing Informative Rating Systems: Evidence from an Online Labor Market

Nikhil Garg, Stanford University, Stanford, CA, 94025, United States, nkgarg@stanford.edu, Ramesh Johari

Platforms use rating systems to learn the quality of market participants. In practice these ratings are often highly inflated. We ask: 1), can rating systems better discriminate quality by altering answer labels and their numeric interpretations? 2), how should the platform make these choices in a principled manner? We analyze the results of a randomized controlled trial on an online labor market in which an additional question was added to the feedback form. Our test reveals that current inflationary norms can be countered. We then develop a theoretical framework to optimize the design of a rating system to maximize the rate of convergence to the true underlying quality distribution.

2 - Optimal Matching with Information Design

Faidra Monachou, Stanford University, Stanford, CA, United States, monachou@stanford.edu, Itai Ashlagi, Afshin Nikzad

We study mechanism design in dynamic markets where objects are allocated to unit-demand agents who have quasi-linear payoffs in their waiting time. We consider a general class of dynamic mechanisms which determine the joint distribution of the object assigned to each agent and the agent's waiting time. We identify the optimal mechanism, and show that when the marketmaker can deploy information design, the outcome of the optimal mechanism can be implemented by a FCFS queue (where agents are allowed to decline offers) and a simple information disclosure policy that pools adjacent object types.

3 - Pricing and Information Design for On-demand Platforms

Guido Martirena, Stanford University, Stanford, CA, United States

I consider the design of information and pricing mechanisms in unobservable queues with strategic and heterogenous customers that are privately informed and time-sensitive. First, I show that if the platform can jointly optimize over pricing and information mechanisms, the optimum can be implemented by disclosing all information and a sequence of posted prices. Second, I identify situations under which information design is profitable and provide a linear program that allows for the computation of the optimal policy. Third, I show that when consumers' private information is multidimensional, the loss from releasing the level of congestion is arbitrarily large relative to the optimal mechanism.

4 - Scrip Systems with Minimal Availability

Süleyman Kerimov, Stanford University, Stanford, CA, United States, Itai Ashlagi

We consider an infinite horizon model with finitely many agents. At each time period, one agent requests service, one agent provides service, and the requester pays one scrip to the provider. Among the agents that are available to provide service, the one with the lowest number of scrips is selected as the provider. Assuming only few agents are able to provide service, we identify conditions, under which the scrip distribution is stable in the sense that free riding is eliminated, and agents do not deviate by much from their initial endowment, with high probability. Our results suggest that scrip systems are likely to lead to efficient outcomes in kidney exchange platforms, where free riding is ubiquitous.

1 - Assortment Design under Conventional Technologies and 3D Printing

Duo Shi, The Chinese University of Hong Kong, Shenzhen, Shenzhen, 518172, China, shiduo@cuhk.edu.cn, Lingxiu Dong, Fuqiang Zhang

We investigate the impacts of three features of 3D printing, design freedom, quality differentiation, and ultimately flexibility, on a firm's decision of product assortment.

2 - Retailing with 3D Printing

Yao Cui, Cornell University, Ithaca, NY, 14853, United States, yao.cui@cornell.edu, Li Chen, Hau Leung Lee

Given the promise of 3D printing, also known as additive manufacturing, some innovative consumer goods companies have started to experiment with such a technology for on-demand production with mass customization capabilities. However, the potential impact of 3D printing on retail and supply chain operations is not well understood. In this paper, we consider two adoption cases of 3D printing in a dual-channel (i.e., online and in-store) retail setting: 1) when 3D printing is adopted online, 2) when 3D printing is further adopted in-store. Through both adoption cases, we analyze and evaluate the impact of 3D printing on a firm's channel and pricing strategies.

3 - Preventive 3D Printing Spare Parts in a World of IoT

Yue Zhang, Assistant Professor, Pennsylvania State University, 152 Towhee Dr, University Park, PA, 16827, United States, yue.zhang@psu.edu, Jing-Sheng Jeannette Song

We consider using 3D printer to offer preventive after-sales service for spare parts leveraging advanced demand information in a world of IoT.

1 - A Subsidy on Effort in Sourcing Model with Credit Guarantee Mechanism

Cheng-feng Wu, Hubei University of Economics, WUHAN, China, d99741006@ntu.edu.tw

This study examines the issue of the strait of capital shortage in SME supplier and supply risks from the buyer's perspective. The buyer builds a credit guarantee mechanism in which a SME supplier is guaranteed to finance the shortfall in capital from the financial institution. Also, the buyer make decisions including placing the order quantity and assessment rate when facing supply risks.

2 - A Behavioral Analysis on the Use of an Intermediary in Manufacturing Outsourcing

Qiong Chen, University of Science and Technology of China, Hefei, China, qcchen@ustc.edu.cn, Aleda Roth, Gulru F. Ozkan-Seely, Fred Switzer

In this paper, we examine how the level of outsourcing competence of the firm, the amount of time-to-market pressure and the buyer's perceived incentive alignment with the agent, act to systematically influence the decision to outsource the new product directly or indirectly through an intermediary.

3 - Pricing Decisions in Revenue Management: An Experimental Investigation

Ummuhan Akbay, Ozyegin University, Istanbul, Turkey, ummuhan.akbay@ozyegin.edu.tr, Nur Cavdaroglu

In this paper we consider pricing and capacity allocation decisions, and report the findings of a decision-making experiment on a two-class airline revenue management problem. We find that on average pricing decisions are not significantly different from the optimal, even when subjects make both decisions simultaneously, suggesting that increased complexity of the decision problem does not necessarily worsen the quality of the pricing decisions. On the other hand, the capacity allocation decisions deviate from the optimal significantly and systematically resulting in a "too low-too high" pattern. We also find evidence of anchoring behavior for both decisions.

4 - Aligning Organizations' Decision Strategy with Employees' Exploration-exploitation Behaviour Using Capital

Crystal Chidinma Chukwuemeka, Doctoral Researcher, University of Manchester, Manchester, United Kingdom, chidinma.chukwuemeka@manchester.ac.uk, K. Nadia Papamichail, Yu-wang Chen, Richard Allmendinger

Retaining talented and valuable employees is a major challenge for firms of all sizes. However, business environments evolve requiring continuous professional development (CPD) here-in referred to as capital. Encouraging CPD, even without talent attrition or employees outgrowing their businesses, remains a challenge. We argue for decision strategy alignment between an organization and its employees. This study investigates capital predictors that enable exploration-exploitation trade-off in CPD trajectories. Preliminary findings show that capital-forms predict 24% variability in vocational decisions. The findings are useful for alignment of talent acquisition and CPD investments.

Contributed Session

Chair: Azadeh Ahkamiraad, State University of New York (SUNY) at Binghamton, Binghamton, NY, 13905, United States

1 - The Impact of Being a Procrastinator on Academic Success: A Case Study in an Online Learning Environment

Yasemin Tarakci, Universtiy of North Texas, Denton, TX, United States, Hakan Tarakci

In this paper, we study the performance of students enrolled in a fully online class. We define procrastinators as those who submit their exam within the last 5% of the allotted time. Our findings show that there is a significant difference between the academic performance of the procrastinators and the "punctuals": procrastinators' exam scores are significantly lower than those of the punctuals. We also share these results with the entire class of almost 200 students through an online announcement on the class website. Our follow-up analysis shows that the proportion of procrastinators decreases; in addition, the performance of procrastinator-cum-punctuals improves significantly.

2 - Analyzing Different Levels of Gamification in Engineering Classrooms

Sinan Tas, University of Wisconsin-Platteville, Platteville, WI, United States, sinantas@gmail.com

In this research, using three years of classroom data, we analyze how adding different levels of game elements can affect learning, knowledge, and interest of various student groups based on their major, seniority, and gender. Using knowledge and interest metrics over four areas, including foundation, methodology, tools, and analysis, we conduct statistical analysis in order to study any significant differences among students.

3 - Designing a Sustainable Built Environment for Academic Success

Anita Lee-Post, University of Kentucky, Lexington, KY, United States, dsianita@uky.edu, Chon-huat Goh

Does a sustainable built environment affect students' academic success? We attempt to answer this question by investigating the pathway linking the sustainable design of a campus building to students' academic success. A model mapping the academic support of a campus building's sustainable design features to students' academic success is proposed and validated. The implications of findings from the study will be discussed.

4 - Enhancing Engineering undergraduates' Academic and Professional Experiences Through Social Community

Valerie Washington, University of Michigan, Ann Arbor, MI, United States, vnwashin@umich.edu, Joi-Lynn Mondisa

Research lacks an in-depth examination of the effectiveness of program elements in academic and social support programs designed to increase the retention of undergraduate underrepresented minority students in science, technology, engineering, and mathematics (STEM). In efforts to identify effective program elements, we examine social community elements of the University of Michigan's STEM Academy. We use a Social Community scale and interviews to learn more about past and present participants' experiences. With this understanding, we can better design academic and social support programs.

5 - Bachelor's Degree Programs in Community College: A Solution for Shortage of Operation Research Workforce

Azadeh Ahkamiraad, Graduate Research Assistant, State University of New York (SUNY) at Binghamton, Binghamton, NY, United States, Arefeh Mohammadi

A growing number of community colleges in USA are offering four year bachelor's degree programs to cover the shortage of workforce. Professionals with operation research and management skills are increasingly needed in various service-based companies and businesses. Among these institutions, a lot of healthcare organizations, manufacturing industries, and information technology related companies are exploring new ways to train their employers to obtain skills related to operation research sciences. This study articulates new and affordable pathways to train individuals with expertise in operation research sciences through four years or 2+2 years programs in community colleges.

1 - Economic and Environmental Implications of Biomass Commercialization in Agricultural Processing

Bin Li, Singapore Management University, 50 Stamford Road, Singapore, Singapore, bin.li.2015@pbs.smu.edu.sg, Onur Boyabatli, Buket Avci

Commercializing organic waste (biomass) in various agricultural processing industries has sparked intense debates over its economic and environmental values. Motivated by this, we investigate the economic and environmental implications of biomass commercialization by establishing a stylized model that captures the main operational characteristics in these industries. We find that biomass commercialization serves as a natural hedge against spot price variability and correlation, yet not necessarily leads to lower carbon emissions as commonly perceived.

2 - Seed Manufacturing under Climate Change: The Impact of Higher Yield Variability

Utku Serhatli, INSEAD, Constance de le Boulevard, Fontainebleau, 77590, France, utku.serhatli@insead.edu, Andre Du Pin Calmon, Enver Yucesan

Climate change is the main driver of increasing yield variability in agriculture. We analyze the optimal production decisions of a seed manufacturer facing climate change and the value of operational flexibility in the form of postponement. We use a two-stage stochastic program to derive optimal decisions and use simulations to gain insight on the implication of climate change on food safety. Our analysis shows that a minor increase in yield variability can lead to a major shift in the timing of seed production. Moreover, not only does the value of postponement decreases with increasing yield variability, but low-margin seeds also become more susceptible to yield risk due to climate change.

3 - A Better Buy-one-give-one Business Model

Pi-Ying Yen, The Hong Kong University of Science and Technology, Kowloon, Hong Kong, Ying-Ju Chen, Qiao-Chu He

Buy-one-give-one (BOGO) is a prevailing business model among social enterprises in the agricultural sector nowadays. We find that the social enterprise can create more social welfare by differentiating its products into the high-end products for the purchasers (the rich) and the low-end products for the recipients (the poor) instead of providing these two segments the products of the same quality. Also, giving more products instead of just one to the poor is an effective way to increase social welfare. We also show that BOGO makes higher social welfare than cross-subsidy either when the social enterprise is highly socially responsible or when the social gap between the rich and the poor is significant.

Behavioral Decision Analysis

Sponsored: Decision Analysis

Sponsored Session

Chair: Matthias Seifert, IE Business School, IE Business School, Madrid, 28006, Spain

1 - The Effect of Forecast Inconsistency on User Trust

Jessica N. Burgeno, Graduate Student, University of Washington, Seattle, WA, United States, jburgeno@uw.edu, Susan Joslyn

Forecasts for major weather events often begin days in advance. Forecasters believe consistency among subsequent forecasts preserves user trust and can be reluctant to make changes when potentially more accurate information becomes available. The research reported here compared the effects of forecast inconsistency and inaccuracy. Subjects made decisions based on single-value, sequential snow accumulation forecasts. Both forecast inconsistency and inaccuracy negatively impacted trust; however, the effect of inconsistency was primarily seen when forecasts were accurate. This suggests that maintaining forecast consistency is ill advised when it means a potential loss in accuracy.

2 - Risky Choice Following Near Miss Events in Sequential Tasks under Ambiguity

Florian Federspiel, INCAE Business School, Alajuela, Costa Rica, florian.federspiel@incae.edu, Matthias Seifert, Robin Dillon-Merrill

Studies have shown that near miss events can lead to dangerous inconsistencies in both risk perception and risk taking behavior. Yet near misses are often clouded in ambiguity, allowing for biases and misattribution regarding what caused success or prevented failure. We provide a model of near misses and investigate the experience of such an event on risk taking in a real options task. We show that increases in risk taking following a near miss occur primarily under ambiguity.

3 - Group Decision Making with Multiple Conflicting Performance Targets

Matthias Seifert, Associate Professor of Decision Sciences, IE Business School, CIF B82334319, Maria de Molina 13, Madrid, 28006, Spain, matthias.seifert@ie.edu, Enrico Diecidue, Prana Narayanan

In many multi-stakeholder decision contexts it is of crucial importance to aggregate preferences in a way that rewards the diversity of targets met. Extending Tsetlin & Winkler's (2007) work on multiattribute performance targets, we study the properties of a novel group-weighting rule, which draws on the dis-/similarity of preferences held by individuals and assigns higher values to those alternatives that maximize the diversity of targets achieved. Using a simulation model, we then benchmark the performance of this rule against classic approaches based on equal weighting (e.g. average winner, majority voting).

Risk and Decision Analysis for Infrastructure Resilience

Sponsored: Decision Analysis

Sponsored Session

Chair: Hiba Baroud, Vanderbilt University, Nashville, TN, 37235, United States

1 - Enabling Preemptive Planning and Increased Community Resilience Through Post-disaster Temporary Housing Decision Analysis

Daniel Perrucci, Graduate Researcher, Vanderbilt University, Nashville, TN, 37235, United States, daniel.v.perrucci@vanderbilt.edu, Mohamed Hassan, Hiba Baroud

Over the last three decades, the severity and frequency of natural disasters has experienced an increasing trend which drives the post-disaster displaced populations to unprecedented levels. A multi-objective decision analysis (MODA) will provide government entities the ability to analyze temporary housing alternatives in advance of the disaster displaced population. This prior planning reduces the supply chain uncertainty, and therefore, increases community resilience during the disaster recovery.

2 - Decentralized Decision Making for Interdependent Network and Community Resilience

Buket Cilali, University of Oklahoma, Norman, OK, United States, Kash Barker, Andres David Gonzalez, Nafiseh Ghorbani Renani

Interdependence among infrastructure and community networks is an important aspect to consider when planning for disruptive events. Further, decision makers within different infrastructures often make decentralized decisions to protect and restore their own networks after a disruption. As such, we extend a tri-level optimization model to account for decentralized decisions. Social vulnerability scores are used to show the effect of community resilience and different scenarios are analyzed to reveal the effect of decentralization.

3 - AI for Rapid Damage Assessment

andrea Garcia Tapia, Stevens Institute of Technology, Hoboken, NJ, 07030, United States, agarciat@stevens.edu, Jose E. Ramirez Marquez

Disasters are the consequences of failures in economic development. Rapid damage assessment is critical to for response & recovery. This work has two phases. The first one looks at how to automatize damage detection with drone images. The second asses economic & social impact of the disruption. As case of study we analyzed three communities in Oaxaca, Mexico after the 2017 earthquake. The rapid damage assessment framework is able to detect l&slides & collapsed buildings. If the drone images are georeferenced we could give a map of the damages detected so first aid responders could optimize the help provided. We are currently working on the socioeconomic impact evaluation of the communities.

4 - A Stochastic Approach to Characterize the Persistence of Floods and Droughts Across the Conterminous United States

Jesus D. Gomez-Velez, Vanderbilt University, Nashville, TN, United States

Understanding floods and droughts and their temporal persistence is critical for risk assessment and management under present and future socio-economic and climatic conditions. In this work, a stochastic approach was used to propose novel metrics that characterize the persistence to extreme (high and low) discharge events in watersheds across the US as well as their scaling and connection with climate and infrastructure.

Revenue Management, Pricing IV

Contributed Session

Chair: Mojtaba Salarpour, University of Massachusetts-Amherst, Amherst, MA, 01375, United States

1 - Using Markov Chains to understand Pricing Dynamics in the Consumer Electronics Market

Sarah Carron, Ghent University, Ghent, Belgium, sarah.carron@ugent.be, Bram Janssens, Dirk Van den Poel

This research investigates market pricing dynamics in the online and offline consumer electronics industry in Europe among different players. We investigate leader and follower dynamics by performing Markov-chain sequence analysis on pricing data formed through web crawling the important players on the market, covering over 60,000 products.

2 - Price Optimization in Presence of Consumer Rating, Reference Price, and Cross-price Effects

Seyed Shervin Shams-Shoaaee, PhD Student, McMaster University, Hamilton, ON, Canada, shamsshs@mcmaster.ca, Elkafi Hassini

We develop a new demand model accounting for consumer rating, reference price, and cross-price effects in a multi-product, finite horizon, online retail environment. Using this demand model, we introduce a myopic pricing heuristic as well as exact solutions to the optimal pricing problem taking into account the effects of price on future consumer ratings. Furthermore, we present several analytical, managerial, and numerical insights.

3 - A Framework for Pricing Components in a Bundle with Diminishing Reservation Prices

Ritwik Raj, University at Buffalo, Amherst, NY, United States, r28@buffalo.edu, Mark Henry Karwan, Chase Murray, Lei Sun

We study pricing bundle components for a case in which consumers decide the bundle composition; and the valuation of components diminishes with the valuation of the bundle. We calculate the optimal bundle price to maximize expected profit. We also calculate the optimal split of the bundle price into component prices to maximize customer satisfaction. A complete analysis for the two-product bundle case in which stand-alone reservation prices are independent and uniformly distributed, is provided. Numerical results show that both expected profit and customer satisfaction are high when there is heterogeneity among bundled products.

4 - On the Equilibrium of Elections Game under: Majority Rule and Electoral College

Charles Thraves, Assistant Professor, University of Chile, Santiago, Chile, cthraves@dii.uchile.cl

We model elections where candidates maximize probability of winning under a game theory model. We study the equilibrium under a deterministic and stochastic model, proving its existence and uniqueness in pure strategies in a deterministic setting in a majority rule system. We then introduce a stochastic version of the game and draw insights on the equilibrium obtained through numerical instances. In addition, we describe the corresponding algorithm in each case to find the game equilibrium.

5 - An Integrated Financial and Logistical Game Theory Model for Humanitarian Organizations

Mojtaba Salarpour, University of Massachusetts-Amherst, Amherst, MA, United States, msalarpour@umass.edu, Anna B. Nagurney, Patrizia Daniele

In this paper, a game theory model for disaster relief is constructed that incorporates both financial and logistical aspects of humanitarian organizations involved in the purchasing and delivery of relief items, post-disaster, using freight services. The governing concept is that of Generalized Nash Equilibrium, since not only does the utility function of a given humanitarian organization depend on its own strategies and the strategies of the other humanitarian organizations, but the constraints do as well. The concept of a variational equilibrium is utilized to derive the variational inequality formulation of the equilibrium conditions and a case study inspired by Hurricane Harvey presented.

Ride-sharing Service

Contributed Session

Chair: Maxime Cohen, NYU Stern, New York, NY, 10012, United States

1 - Can Car Sharing Disrupt Car Ownership? A Conjoint Study of Consumer Mobility Choice

Lixian Qian, Xi'an Jiaotong-Liverpool University, Suzhou, China, lixian.qian@xjtlu.edu.cn, Zhan Pang, Didier Soopramanien

This paper investigates the broader effect of introducing car sharing, also called on-demand car rental, on urban mobility system. By conducting a choice-based conjoint study in Beijing, we identify a nested structure where bus and underground fall in a nest of "public transit" while car sharing, private car and taxi are independent in respective degenerate branches, which implies that unexpectedly car sharing is a proportional substitute to other mobility modes. Public transit users who intend to buy their first cars are more likely to adopt car sharing than car owners, which implies that introducing car sharing may indeed retard the growth of car ownership but attract public transit users to drive.

2 - Consumer Heterogeneity in Preferences for Risk-mitigating Service Attributes in the Sharing Economy: Evidence from Ride-sharing Services

Soo Jeong (Chris) Hong, Pepperdine University, Malibu, CA, United States, soojeong.hong@pepperdine.edu, Johannes M. Bauer, Kwangjin Lee, Nelson Granados

Taking advantage of ubiquitous Internet connectivity and new information technologies, platform businesses in the "sharing economy" have been rapidly growing. However, their new forms of service provision raise several issues that may concern consumers and influence their decision to adopt such services. Empirical data suggests consumer response has been mixed, with certain groups embracing the new services but others reluctant to use them. Focusing on ride-sharing services, we examine the effect of service features that would not only mitigate perceived individual risks but also reduce broader societal concerns on consumers' willingness to pay for the service.

3 - Effects of Flexibility and Security on the Decision to Work for Ride-sharing Services

Kwangjin Lee, Pepperdine University, Malibu, CA, United States, Soo Jeong (Chris) Hong, Johannes M. Bauer, Nelson Granados

This study investigates the effects of granting service providers of ride-sharing services, a menu of contracts with varying flexibility on their willingness to offer their services through a platform. Ride-sharing is one of the largest sectors in the sharing economy and can provide insights that can apply to other services in this emerging sector. Using a choice experiment, the study examines how diversification of contractual attributes affects drivers' willingness to work for the online platform. It also investigates whether service providers' preferences for flexibility and stability in the platform business are influenced by alternative employment options.

Innovative Operations in Digital Economy

Sponsored: Service Science

Sponsored Session

Chair: Jiayi Joey Yu, University of California-Berkeley, Berkeley, CA, 94720, United States

1 - A Data Analytics Approach to Integrated Location Assortment and Inventory Planning in Omni-channel Retail

Hao Shen, Renmin University of China, Beijing, China, Jian Chen, Yong Liang, Zuo-Jun Max Shen

While the rise of e-commerce provided retailers with new avenues to reach customers, fierce competition has pushed retailers to turn to data and analytics to make better business decisions. Observing retailers aggressively expanding in both online and offline channels, we study a data analytics approach enabling omni-channel retailers to make better location, assortment, and inventory decisions to maximize profits. We develop an efficient reformulation to solve the proposed decision model, and draw interesting observations that can be valuable to practitioners.

2 - Pricing and Rationing with Inventory Build-up in New Product Di Usion

Mengying Xue, Purdue University, West Lafayette, IN, United States, mengying.xue@gmail.com, Long He, Max Shen, Max Shen

It is critical for a firm to manage the demand when launching a new product. The customers' word-of-mouth e ect plays an important role in the demand di usion of a new product in the market. In this paper, we study the dynamic pricing strategy of a firm facing strategically waiting customers under the supply constraints. The firm has to make decisions on prices and initial inventory at the same time. A stylized twostage discrete-time model where the firm has no commitment power is considered, and demand is modeled as a modified Bass di usion process by introducing information flow. We characterize the existence and optimal conditions for each pricing and rationing strategy—constant high price, constant low price, price penetration, and price skimming. When the initial inventory build-up is free, our analysis highlights the tradeo between taking advantage of the demand di usion and combating with customers' strategic waiting. For example, when customer valuations are more polarized, it is optimal for the firm to only satisfy the high-value customers but still ration them in the first stage due to customers' strategic waiting behavior, if the word-of-mouth e ect in demand di usion is weak. In contrast, with stronger word-of-mouth e ect or less polarized customer valuations, it is better for the firm to penetrate the market with a low initial price. When it is costly to acquire initial inventory, the firm also needs to factor in the inventory build-up cost in the tradeo . We provide the optimal initial inventory level in joint with the pricing and rationing strategy for ranges of inventory cost and word-of-mouth e ect.

3 - Robust Transportation Scheduling and Parcel Pricing for Same-day Delivery

Mengxin Wang, University of California-Berkeley, Berkeley, CA, 94703, United States, mengxin_wang@berkeley.edu, Junyu Cao, Zuo-Jun Max Shen

We study an efficient transshipment-based same-day delivery system which combines the RDC-based system and the point-to-point system. In the transshipment-based system, the entire service region is divided into several subregions with transfer depots. A main-line network connects all the depots. We propose a data-driven framework to jointly design a robust main-line schedule and parcel price for daily delivery operations. We demonstrate the performance of our method using real data from a same-day delivery company in Beijing, China.

Game Theory I

Contributed Session

Chair: Senthil Kumar Anantharaman, IIm Indore, Rau-Pithampur Road, In, indore, 453556, India

1 - Profit-Sharing and Efficient Time Allocation

Miguel Vargas, Research Professor, Santiago de Cali University, Cali, Colombia, miguel.vargas02@usc.edu.co

Agents are endowed with time, which in turn is invested in projects that generate profit. A mechanism divides the profit generated between these agents, depending on the allocation of time as well as the profit made by every project. We study mechanisms that incentivize agents to contribute their time to a level that results in the maximal aggregate profit at the Nash equilibrium (efficiency). Our main finding involves the characterization of all mechanisms that satisfy efficiency. We characterize the class of mechanisms that are monotone in the payoffs of the agents with respect to technological improvements, the addition of time to agents, and mechanisms that are resistant to group manipulations.

2 - Games of Agreement

Chunlin Wang, Assistant Professor, Davis College of Business and Economics, Radford University, Radford, VA, United States, cwang17@radford.edu, Joyendu Bhadury

We introduce the notion of a "game of agreement" that is an extension of the well-known "Battle of the Sexes" game with the following characteristics. The game attempts to model situations where multiple parties (buyers-sellers, labor unions-management etc.) need to come to an agreement on a common issue in order for all players to be better off. We characterize the mixed-strategy Nash Equilibrium of such games by demonstrating the existence of one and then proving that under the assumption of all players using "good-faith" mixed strategies, the Nash Equilibrium we propose is unique.

3 - Benefits of Cooperation Through Shared Demand Information and Inventory Centralization in Newsvendor Settings

Juan Carlos Gocalves Dosantos, Universidade da Coruña, La Coruña, Spain, juan.carlos.goncalves@udc.es, Fernando Bernstein, Ana Meca

We consider a set of retailers serving independent regions. Each retailer manages its own inventory based on the newsvendor model. Retailers may cooperate in the acquisition of future demand information. Our goal is to quantify the benefits that can be achieved by sharing future demand information cooperatively. We then explore a setting in which retailers can cooperate not only through the acquisition of future demand information, but also by centralizing their inventories. We study the core of these cooperative games and propose appealing allocation schemes of the benefits of cooperation.

4 - Patrolling Security Games Against Mobile Intelligent Adversaries

Zhifan Xu, Rutgers, The State University of New Jersey, New Brunswick, NJ, United States

Patrolling is an important operational decision when safeguarding a public area against adversarial attacks. In this paper, we propose a discrete time Stackelberg security game on a graph in which the defender announces her patrolling policy at first. The attacker then decides on his target and his route by solving a Markov decision process, given the defender's patrolling policy and the observation of the defender's location at every turn. We also introduced the concept of detection probability for each node on the graph. To find the Stackelberg equilibrium strategies for both players, we derived a bi-level program that can be solved via bilinear programming or global optimization techniques.

5 - Modelling Public Private Partnerships Applying Game Theory

Senthil Kumar Anantharaman, Doctoral Student, IIm Indore, indore, India, f16senthilk@iimidr.ac.in, Rohit Kapoor

Governments have been preferring public-private-partnership(PPP) over traditional methods in the past few decades to procure public services for their citizens. This study provides a base for implementing PPP contractual mechanism, when the government needs to maximize it social surplus or value for money (VFM). Further, the study attempts to model the relationships between three players in a principal agent model where government and equity/lender act as the principals and the service provider act as the agent. Finally we portray the optimal contract set at equilibrium conditions that consider moral hazard, signalling aspects, incentivization and matching across the contract cycle.

Multidimensional Mechanism Design

Sponsored: Auction and Market Design

Sponsored Session

Chair: Justin Burkett, Georgia Institute of Technology, Atlanta, GA, 30313, United States

1 - A Revealed Preference Approach to Multidimensional Screening

Maxwell Rosenthal, Georgia Institute of Technology, Atlanta, GA, United States

This paper develops a data-driven approach to screening. The principal observes a population of decision makers each choose from a finite number of exogenous sets of alternatives, and her beliefs about the agent's preferences are informed by these choices. However, there are many type distributions that are consistent with the choice data. Rather than assign privilege to any one distribution, she evaluates mechanisms according to their worst-case payoff against the set of consistent distributions. We study the relationship between optimal mechanisms and the choice environments in the data set, which do not in general coincide.

2 - Welfare Properties of Competitive Insurance Markets with Risk and Preference Heterogeneity

Vitor Farinha Luz, University of British Columbia, Vancouver, BC, Canada, Humberto Moreira, Piero Gottarde

We consider a model of insurance provision with two-dimensional private information. Consumers are privately informed about their risk level and level of risk aversion. Equilibria necessarily involve pooling, mixing agents with similar willingness to pay for coverage.To study the impact of heterogeneity in risk aversion on the benckmark one- dimensional competitive insurance model we propose a novel approach. We perform a perturbation to this benchmark model allowing for a "small" amount of heterogeneity in the risk aversion dimension. This approach allows us to obtain explicit formulas for the dependence of equilibrium outcomes on the type distribution.

3 - Dynamic Mechanisms with Private Discount Factors

Justin Burkett, Georgia Institute of Technology, Atlanta, GA, United States, justin.burkett@gatech.edu, Kyle Woodward

We consider the optimality of static mechanisms in dynamic contexts. In our model participants have private values and discount rates, and the mechanism designer can use the passage of time as a screening device for surplus extraction. When discount rates and values are positively related, it is optimal for the designer to allocate the good immediately and ignore the screening potential of time. When discount rates and values are negatively related, the seller can use time as a screening device, and extract high-value participants' rents today and low-value participants' rents tomorrow. Our results generalize to non-standard discounting and arbitrary time horizons.

4 - Large Matchings in Large Markets with Flexible Supply

Shunya Noda, University of British Columbia, Vancouver, BC, Canada, shunya.noda@gmail.com

This paper studies the matching size achieved by strategy-proof mechanisms in a general model of matching with constraints. We show that naïve extensions of classical mechanisms may generate an arbitrarily small matching. Assuming a large market, we develop a technique to reshape a given resource constraint to a more structured one with which a classical mechanism performs well. We propose a mechanism that (i) satisfies strategy-proofness, (ii) always achieves at least 1-1/e = 63.2% of the maximum size (which is the best approximation ratio a strategy-proof mechanism can achieve), (iii) respects agents' preferences, and (iv) is computationally efficient, for general instances.

Retail Management

Contributed Session

Chair: Somak Paul, The Ohio State University, Columbus, OH, 43201, United States

1 - Modeling Purchase Decision Making at a Large Electronics Retailer

Bram Janssens, Ghent University, Ghent, Belgium, bram.janssens@ugent.be, Sarah Carron, Dirk Van den Poel

This study tries to model the purchasing behavior of customers at a large European electronics retail company. Building a two-stage model with both classification and regression trees, we try to pinpoint which are the most important determinants in the purchasing decision. Initial results show that, contrary to what was initially assumed, customers simply compare the retailer's price to the lowest market price, making the purchasing decision simpler than hypothesized. This would also imply that customers do not distinguish between online players and brick-and-mortar players.

2 - Fulfillment by Amazon Versus Fulfillment by Seller: An Interpretable Risk-adjusted Fulfillment Model

Libo Sun, University of Science & Technology of China, Hefei, China, libosun@mail.ustc.edu.cn, Guodong Lyu, Yugang Yu, Chung-Piaw Teo

With dual-channel choices, E-retailers fulfill their demands by either the inventory stored in third-party distribution centers, or by in-house inventory. Using data from a wedding gown E-retailer in China, we analyze the differences between two fulfillment choices - Fulfillment by Amazon (FBA) and Fulfillment by Seller (FBS). We develop a risk-adjusted fulfillment model to address this problem, where the e-retailer's risk attitude to FBA is incorporated. We apply our model on a set of real data, and develop an explicit decision rule that can be easily implemented in practice. The numerical experiments show that our interpretable decision rule can improve the E-retailer's rewards by about 48%.

3 - Optimizing Consumer Subscriptions in Online Rentals

Emre Eryigit, PhD Student, UMASS-Amherst, Amherst, MA, United States, Ahmed Ghoniem, Bacel Maddah

We consider an online retailer renting out products (e.g., fashion goods) to heterogeneous customers subscribed at different levels. Assuming that Subscribed customers only incur a periodic subscription fee, we address the retailer's problem of maximizing the expected profit by determining the optimal product assortment, the structure of the subscription levels, and the subscription fee. Realistic demand and cost functions are adopted.

4 - Buy Online Fulfill from Store - Design and Control of Order Picking Operations

Wen Zhu, New Jersey Institute of Technology, Newark, NJ, United States, wz83@njit.edu, Sanchoy Das

Fulfilling online orders from store inventory (S-Strategy) is a growing retail strategy. The primary goal of an S-Strategy is immediate order fulfillment, allowing the retailer to provide a faster service rate than fulfillment center (F-Strategy) solution. In the nominal case, orders are picked from shelf inventory, for the advanced case, popular items are assigned to fast picking zones. This research uses a database driven simulation model to evaluate the fulfillment capabilities of the S-Strategy. Models to assign items to fast picking and schedule pickers to minimize order delays and costs are presented.

5 - Estimating Consumer Decision Trees Using Aggregate Sales Data Without Identified Customers

Olga Pak, Penn State, State College, PA, United States, Olga Perdikaki, Mark Ferguson, Su-Ming Wu

In marketing and operations management research, limited attention exists on developing algorithms that allow to generate, analyze, and test theoretically driven but data-informed decision trees. Our study utilizes demand structures extracted from retail scanner data and tests dynamic hierarchies of consideration choices as decision trees. This approach has several advantages. We use widely available scanner purchase data across multiple markets and multiple stores, which involves a larger pool of customers and products. Also, our methodology allows to break away from the current assumptions of fixed product choice and consideration sets within and between stores.

6 - To Split or Not to Split - Order Characteristics That Generate Customer Calls for Split Request in Retail

Somak Paul, The Ohio State University, Columbus, OH, United States, paul.865@osu.edu

The retail fulfillment literature has looked into the order delivery from a cost minimization perspective. However, there are cases where the customer calls up the customer service to request split delivery, while the retailer is trying to bundle up the items to provide single delivery. We investigate order characteristics for a Fortune-500 furniture retailer that faces such issue. Current policy is to deliver all items at the same time - which for orders with multiple items results in a lead-time of over 1.5 months. We develop algorithms to determine whether/how to split orders into multiple shipments to enhance customer satisfaction.

Applied Statistical Studies

Sponsored: Military and Security

Sponsored Session

Chair: Mark A Gallagher, Air Force Institute of Technology, Columbus, OH, 43229-5535, United States

1 - Bayes Networks Versus Discrete Event Simulations

Mark A. Gallagher, Air Force Institute of Technology, Columbus, OH, 43229-5535, United States, markgallagherJMJ@gmail.com, Aaron Salazar

We explore comparing the outputs from discrete-event simulation models and Bayesian Networks. We start with known models, such as a queuing modeling, as a baseline to solve and extract true values. We formulate a simulation to estimate the underlying distribution and behavior of the modeled system. We also construct a Bayesian Network for comparison. We evaluate the output distribution (based on replications with the simulation and the Bayesian Network). We also examine computational time of the two approaches.

2 - A Multivariate Statistics Perspective of Military Conflicts and War

Mark A. Gallagher, Air Force Institute of Technology, Columbus, OH, 43229-5535, United States, markgallagherJMJ@gmail.com, Brandon Hufstetler, Marc Chale

We constructed an extensive database on statistics and indices on countries from the year 2000 through 2018. We applied various multivariate statistics techniques to gain insights to what conditions exist on countries being involved in war and less armed conflicts.

3 - Artillery Firing Shift with Multiple Registration Targets

Michael Bendersky, Holon Institute of Technology, Holon, Israel, michael.bendersky@gmail.com

Firing Shift is the shifting of artillery fire from one target to another with the application of corrections determined from the adjustment on the first target to the initial firing data on the second. We investigate the shift accuracy when using a simultaneous fire adjustment for two different registration targets rather than a single one. We use the resulting data to solve explicitly for four major environmental factors which affect ballistic trajectories and update them consequently for the application mission. We determine the distribution of the remaining error at the application and compare the resultant accuracy with that of the existing method.

Chair: Xufeng Yao, Arizona State University, Tempe, AZ, 85281, United States

1 - CSR Breadth or Depth? The Effect of External NGOs and Partner NGOs Pressure on the CSR Choice of a Firm

Shaili Singh, Research Scholar, Indian Institute of Management, Rohtak, India, singhshaili631@gmail.com, Mahua Guha

This study analyzes the influence of secondary stakeholders in the form of NGOs on the CSR choice of a firm. Drawing from the stakeholder theory we model two NGO-firm interactions as: 1. External NGOs which exists in the organizational field as the pressure group 2. Partner NGOs which aid firms in implementing their CSR. We empirically investigate if differences in the firms' CSR choice in the form of CSR breadth, depth and spending are related to the varying impact of the two types of NGO-firm interactions. We use a sample of Indian firms listed on the National Stock Exchange. Indian context is unique for this study as it is the first country with mandatory CSR for all firms falling under a certain criterion.

2 - Firms' Relational Capabilities and Performance: Mediating Role of Dynamic Capability

Ritu Singh, Indian Institute of Management Raipur, Raipur, India, ritu.fpm2015@iimraipur.ac.in

Drawing on the firm's relational view and literature on dynamic capability, this study investigates the interdependencies among the firm's relational capabilities, dynamic capability, and performance using structural equation modeling technique. The findings show that dynamic capability strongly mediates the effect of relational capabilities on performance. This study contributes to the management literature by integrating outward-looking perspective (i.e. firm's relationships) and inward-looking perspective (i.e. dynamic capability) and investigating these relationships in the context of emerging economies.

3 - How Do Advisors Influence on M&A? – An Analysis of Acquisitions in Japan

JaSeung Koo, PhD, Kyoto Sangyo University, Kyoto, Japan, koo.academic@gmail.com

M&A advisor is one of the most popular topics in acquisition studies. This study focuses on the differentiated influence of sell-side advisors and buy-side advisors on the deal progress. Unlike prior studies on M&A advisors, the study addresses different roles of target and acquirer advisors and explores their influences on the cumulative abnormal returns (CAR) and acquisition premiums with an empirical analysis of longitudinal data for listed Japanese non-financial firms' M&As between 1991 and 2012. The empirical result supports hypotheses of target advisor's positive association with CAR and acquirer advisor's positive association with acquisition premiums.

4 - Strategic Supply Chain Planning under Tariff Fluctuation and Demand Uncertainty

Xufeng Yao, Arizona State University, Tempe, AZ, United States, xufeng.yao@asu.edu, Ronald Askin

Long term strategic planning for a company with global supply chain network should take uncertainties such as tariff fluctuation, demand volatility in the decision-making process since those uncertainties are major factors that directly impact the profitability/survivability of such a global company. A stochastic programming model using flexibility options as a way to neutralize the effects of the uncertainties involved is proposed to deal with long term global supply chain planning problem.

1 - Modeling the Competitive Dynamics of the Multi-sided Mobile-wallet Market Using Agent-based Modeling

Muhammad Adeel Zaffar, Lahore University of Management Sciences, Lahore, Pakistan, adeel.zaffar@lums.edu.pk, Ram Kumar, Kexin Zhao

There is a dearth of research on understanding the competitive dynamics of multi-sided platform markets. In the backdrop of the growing fintech market, we propose an agent-based model to investigate factors that affect diffusion dynamics of mobile wallets in a dynamic multi-sided environment. In particular, the model focuses on the conditions under which an incumbent player exists in the market and is competitively threatened by the arrival of a newcomer. The model and its insights can be generalized in the context of any emerging platform in which more than two sides affect the value proposition and competitive dynamics of the platform operators.

2 - Leveraging Probabilistic Features of Artificial Intelligence to Induce and Sustain Perceived Humanness and Trust

Kambiz Saffarizadeh, Georgia State University, Atlanta, GA, United States, ksaffarizadeh1@gsu.edu, Mark Keil

As AI artifacts become more complicated, users face more indeterminacies in their interactions with them. We define AI indeterminacy as the unpredictability in the AI's behavior that seems not to have a directly observable cause. We posit that AI indeterminacy has paradoxical effects on the user's trust in the AI because it simultaneously decreases the perceived reliability of the artifact and increases its perceived humanness. Drawing on the uncanny valley and anthropomorphism streams of research, we explain why such paradox exists and how it changes over time.

3 - Landmark-aided Localization and Routing of Unmanned Vehicles: An Integer Programming Model, Polyhedral Analysis and Exact Algorithm

Bingyu Wang, PhD Candidate, Texas A&M University, College Station, TX, United States, bywang_xjtu@tamu.edu, Sivakumar Rathinam, Kaarthik Sundar

Unmanned Vehicles (UVs) have widespread civil and military applications. Localization is crucial for reliable navigation of UVs. In GPS-denied environments, detection of known LandMarks (LMs) from on-board sensors is an effective way of localization. We propose a joint optimization problem to simultaneously plan good paths for a fleet of UVs and place additional LMs strategically in the environment to aid localization. This problem is a variant of the multi-depot TSP with set-covering constraints. It is formulated as an integer-linear program for which polyhedral analysis and an exact algorithm are proposed. Simulation results corroborate our proposed method.

4 - Fleet Mix Optimization under Uncertainty: Evaluating Electromobility in Urban Logistics

Allan Larsen, Technical University of Denmark, Lyngby, Denmark, alar@dtu.dk, Satya Sarvani Malladi, Jonas Christensen, David Ramirez, Dario Pacino

We study the problem of optimizing the size and mix of the commercial mixed-electric fleet owned by a firm providing urban logistics services. In this problem, we consider uncertain customer requests at the strategic planning stage that are revealed before operations commence on each day. We upgrade the energy consumption model to capture the effect on temperature through the auxiliary energy component of heating and cooling loads of climate control. To solve the problem, we propose a simulation based approach at the strategic level, employing a novel adaptive large neighborhood search method for determining the operational decisions for each day.

5 - ZEV Routing and Fleet Size Minimization for Drayage Operations

Shichun Hu, University of Southern California, Los Angeles, CA, United States, shichunh@usc.edu, Maged M. Dessouky

Zero Emission Vehicles (ZEVs) have been introduced to the freight industry as a green solution for freight operations. However, the fact that ZEVs have less mile range per fueling and much longer fueling times could offset their benefits thus making it harder to replace diesel trucks. We focus on the drayage operation and propose to solve the routing and fleet size minimization problem to maximize the advantages of ZEVs.

6 - Geo-prescriptive Inventory Routing Problem

Carlos Paternina-Arboleda, Universidad del Norte, Km 5 Via Puerto Columbia, Atlantico, Barranquilla, Colombia, Daniela Cassandro-De la Hoz

Inventory Routing problems, a sub-set of vendor managed inventory problems, have commonly been solved with on-hand information available. We propose a method to perform prescriptive analytics to geographically learned demand patterns in hardware store retail companies before they are formally released to a supplier so as to propose a-priori routes for planned inventory.

Optimization, Robust I

Contributed Session

Chair: Ning Zhu, Tianjin University, Tianjin, China, Tianjin, China

1 - Multistage Adaptive Robust Unit Commitment Model with the Ellipsoidal Uncertainty Set for Demand Uncertainty

Jaehee Jeong, KAIST, Daejeon, Korea, Republic of, jh5290@kaist.ac.kr, Sungsoo Park, Hwayong Choi

Since the current power system operation has become complicated due to the volatilities in the current supply and demand, an accurate robust unit commitment (RUC) model has become more important. The drawbacks of the previous models is that they are two-stage models which do not consider the nonanticipativity of the dispatch decisions, and they use the cardinality constrained uncertainty set. We propose the multistage RUC model with an ellipsoidal uncertainty set and reformulate it as tractable one. We develop a pseudo-exact separation procedure for the constraint generation framework for the problem. Numerical results on an IEEE 118-bus system are reported.

2 - Probabilistic Guarantees in Robust Optimization: A General Methodology

Jean Pauphilet, Massachusetts Institute of Technology, Cambridge, MA, United States, jpauph@mit.edu, Dimitris Bertsimas, Dick den Hertog

We develop a principled methodology to derive probabilistic guarantees for solutions of robust optimization problems, for general uncertainty sets and general constraints. Our analysis recovers and extends most results available in the literature. We introduce the notion of robust complexity of a set, which is a robust analog of the Rademacher complexity encountered in statistics, and which drives our a priori bounds. We also derive improved a posteriori bounds, i.e., bounds which depend on the resulting robust solution. These bounds are notably tighter and computable for any general convex uncertainty set. We illustrate our findings on numerical experiments.

3 - Production Planning under Uncertainty via Distributionally Robust Optimization

Shunichi Ohmori, Waseda University, Tokyo, Japan, ohmori0406@gmail.com, Kazuho Yoshimoto

With the changing market conditions, the impact of uncertainties in supply chains became even more vital. The traditional approach is stochastic-programming, which is powerful if the probability distribution is known. In practice, however, the distribution is never observable but must be inferred from data. In this research, we study the effectiveness of an alternative approach, distributionally robust optimization, in which the objective is to minimize the worst-case expected cost over an ambiguity set, that is, a family of unknown distributions with certain known properties. Thereby, we do not need to assume distribution, yet make a decision from data with better out-of-sample performance.

4 - Robustness Analysis of UAV Information Collection Path under Limited Bandwidth

Ningji Wei, University at Buffalo, SUNY, Buffalo, NY, United States, ningjiwe@buffalo.edu, Jose Luis Walteros

In this project, the we developed models to analyze the robustness of the information collection and distribution plans in cases where the adversarial team (the red team) actively attempts to limit the amount of information that can be collected by the blue team. The principal objective of this study is then to analyze the negative effects that a conscious adversary can inflict on the information collection and distribution plan.

5 - A Distributionally Robust Approach to Virtual Station Location Problem for Free-float Bike-sharing System

Ning Zhu, Tianjin University, Tianjin, China, zhuning@tju.edu.cn, Chenyi Fu

Bike-sharing systems have been developed around the world over the past several decades. Recently, some investors in bike-sharing industry, such mobike and ofo in China, begun to employ the free-floating mode, which allows the customers use the official Apps in phones to search, rent and return the bikes without the restriction of going to fixed stations. In this study, a strategic planning is investigated to determine the vitural station location and size of bike allocation in each zone under a given initial budget. A distributionally robust approach is employed to model this problem. The numerical results show advantages of the robust approach.

Applications in Mixed-Integer Quadratic Programming

Sponsored: Optimization/Integer and Discrete Optimization

Sponsored Session

Chair: Boshi Yang, Clemson Unviersity, Clemson, SC, United States

1 - New Relaxations for Composition of Univariate Functions

Taotao He, Purdue University, West Lafayette, IN, 47906, United States, he135@purdue.edu, Mohit Tawarmalani

Recently, a new relaxation, referred to as composite relaxation, has been introduced for composite functions. In this talk, we discuss two extensions of the composite relaxation. First, for composite functions with discrete univariate inner-functions, we obtain ideal logarithmic MIP formulations for their graphs. Second, for composite functions with continuous univariate inner-functions, we construct a sequence of polyhedral relaxations that converge, in the limit, to the concave envelope.

2 - Globally Solving ACOPF by Exploiting Semidefinite-ness and Compact Disjunction

Yunqi Luo, Washington State University, Pullman, WA, United States, Hongbo Dong

ACOPF is one of the most fundamental optimization problems in power system operation. Various approaches based on semidefinite relaxations and analysis of low-dimensional convex hulls have been proposed in the article, with different strengths and drawbacks. Our contribution is to refine some existing approaches exploiting semidefiniteness and combine with recently proposed compact disjunctive approximation schemes, yielding an approach that can exploit state-of-the-art global solvers for mixed-integer convex programs and approximate the ACOPF problem in arbitrary precision. We report numerical results on various instances used in the literature.

3 - Integer Programming for Envy-free Equilibrium Pricing

Hamid Nazari, Clemson University, Central, SC, 29630, United States, snazari@clemson.edu, Akshay Gupte

We are interested in solving a combinatorial matrix assignment problem which appears in literature as a bundle pricing problem in a multi-buyer-single-seller market. It can be formulated as a MINLP when general utility functions are used, and reduces to a MIQP when the standard assumption of linear utilities is made. This problem has been extensively studied in literature from the computational complexity perspective. We work within the framework of general utilities and derive many properties of optimal solutions. Using disjunctions we also found valid inequalities to cut the exponential feasible set. Some computational results are provided to test the effectiveness of our properties.

4 - Using Conditional Logic to Tighten Miller-tucker-zemlin Inequalities for the Target Visitation Problem

Boshi Yang, Clemson University, Clemson, SC, United States, boshiy@clemson.edu, Audrey Nicole DeVries, Warren P. Adams

This talk exploits the variable structure of the target visitation problem (TVP) to derive a tightened version of the Miller-Tucker-Zemlin (MTZ) inequalities. The TVP is a hybrid between the traveling salesman problem (TSP) and the linear ordering problem (LOP), and uses both variable sets. Our strengthened MTZ inequalities are computed via a two-step approach; the first step uses a conditional logic argument involving both variable sets to motivate valid quadratic inequalities, and the second step suitably surrogates these inequalities to eliminate the quadratic terms. This approach, while devised for the TVP, affords a general framework for cuts for the TSP, the LOP, and the quadratic TSP.

Power System Operation During Extreme Weather

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Mostafa Sahraei-Ardakani, University of Utah, Salt Lake City, UT, 84112, United States

1 - Power Outage Forecasting for Adverse Weather Events

Chengwei Zhai, University of Michigan, Ann Arbor, MI, United States, Seth Guikema, Steven Quiring, Roshanak Nateghi, Elnaz Kabir, Sara Shashaani

Hurricanes and other extreme weather events regularly cause substantial damage to power systems. Pre-event forecasts of the degree and spatial distribution of power outages can be of substantial benefit in planning recovery efforts. This talk gives an overview of developments in power outage forecasting for weather events, focusing on probabilistic forecasts.

2 - Sequentially Proactive Operation Strategies for Power Systems under Extreme Weather Events

Yunhe Hou, The University of Hong Kong, Hong Kong, Hong Kong, yhhou@eee.hku.hk

This talk will discuss a sequential operating strategy for mitigating the impacts of a large-scale power system due to extreme weather events (EWEs). The sequential characteristics of EWEs and their potential damages on power systems are modeled with a Markov process. Transition probabilities are evaluated according to failure rates caused by extreme events. For each state, a recursive value function, including a current cost and a future cost, is established with operation constraints and intertemporal constraints. An optimal strategy is established by optimizing the recursive model. The proposed method has been tested on standard and realistic systems.

3 - Scalable Stochastic Unit Commitment During Hurricanes

Farshad Mohammadi, University of Utah, Salt Lake City, UT, United States, farshad.mohammadi@utah.edu, Mostafa Sahraei-Ardakani

Stochastic unit commitment with a large uncertainty set is a computationally challenging problem. The computational burden becomes challenging when the uncertainty affects integer variables, such as line status. In this talk, a new formulation is presented, which is able to solve the preventive unit commitment problem for large-scale networks. To model the damage caused by hurricanes, the uncertainty in the formulation will be the status of transmission lines that are in the hurricane track. The results show that our method can effectively solve the problem within an acceptable time and significantly reduce the power outages, through finding a preventive commitment.

4 - Planning the Grid Against the Extremes

Rodrigo Moreno, University of Chile, Tupper 2007, Santiago, Chile, rmorenovieyra@ing.uchile.cl

Although extreme natural disasters have occurred all over the world throughout history, power systems planners do not usually recognize them within network investment methodologies. To move towards a resilience centred approach, we propose a practical framework that can be used to identify network investments that offer the highest level of hedge against risks caused by natural hazards. In a first level, our framework proposes network enhancements and, in a second level, uses a simulation to evaluate the resilience level improvements associated with the network investment propositions. We use this modeling framework to find optimal portfolio solutions for resilient network enhancements.

1 - Investment Optimization of Railway Wagon Maintenance Equipment Based on Stochastic Programming

Qi Li, Associate Professor, Beijing Jiaotong University, Beijing, China, liqi@bjtu.edu.cn, Le Liu, Zengqiang Jiang, Mingcheng E, Jing Ma

Appropriate equipment investment is vital to business management. In this research, a two-stage stochastic programming model considering uncertainties is proposed to maximize investment profile of maintenance facilities for the wagon. The uncertainties are mainly including various maintenance demand based on remaining useful life prediction of wagon components, equipment price and available investment funds in every period. A case study based on a railway wagon maintenance company in China was carried out to verify the proposed model. The preliminary results show that the stochastic programming model is a promising method for enterprise equipment planning under uncertainties.

2 - Two-stage Stochastic Assignment Problem with Applications to Postage Sorting

Natasja Sluijk, PhD Candidate, University of Technology Eindhoven (TU/e), Eindhoven, Netherlands, n.sluijk@tue.nl, Joris Kinable, Wilco Van den Heuvel

We tackle a two-stage stochastic assignment problem obtained from a practical problem faced in postage sorting. In each stage, a subset of tasks Ti from T need to be assigned to agents in A, i=1,2. The tasks in T are in a specific order and are required to remain in that order when assigning them to the agents. This also holds for the tasks in T1 and T2 . The assignment made in the first stage restricts the solution space for the second assignment. The considered exact methods require exponential computation time, whereas the constructed heuristics result in near optimal solutions with shorter computation time. It is the required order of tasks that makes it a new and challenging topic for the OR community.

3 - **Online Job Shop Scheduling/Rescheduling Problem in Industry 4.0 Based Stochastic Environment Using Exact and Heuristic Optimization Methods**

Parsa Kianpour, Wichita State University, Wichita, KS, United States, pxkianpour@shockers.wichita.edu, Deepak Gupta

Scheduling in job shop environment is affected by multiple disruptions that need immediate actions. In these cases, the initial schedule may not be validated anymore. Therefore, imposed by industry 4.0 concept, this research studies the situation in which decisions are made in real time after revealing uncertain information. The performance of the rescheduling model is validated by evaluating the total cost (tardiness and earliness costs) with the goal of minimum deviation from the initial schedule using real data from local job shop. Multiple exact and heuristic approaches are studied to draw the solution for the optimization problem.

1 - **Solving a Security Game in an Urban Road Network: An Evolutionary Approach**

Sukanya Samanta, Indian Institute of Technology Kharagpur, Kharagpur, India, ssukanya@iitkgp.ac.in, Goutam Sen, Soumya Kanti Ghosh

We consider a security game in a complex urban road network, in which the defender has multiple resources to mobilize in order to interdict an attacker who is trying to escape the city limits after committing a crime. This situation is prevalent in crimes such as kidnapping, robbery, trafficking, etc. and requires the law enforcement agency to deploy the resources optimally. We adopt a mixed-integer linear programming based double oracle approach to model the corresponding zero sum game. Since the optimal solution is not available for large instances, we develop a genetic algorithm to provide reasonably effective defender strategies and validate them on the dataset of the city of Kolkata, India.

2 - **A Three-agent Nonsequential Cybersecurity Game of Timing with Learning**

Arnab Bhattacharya, Staff Research Scientist, Pacific Northwest National Laboratory, Richland, WA, United States, Samrat Chatterjee, Shaunak Bopardikar

Strategic cyber-physical security interactions involve ideal timing of agent decisions to optimize offensive, defensive and operational objectives. We propose a stochastic optimization framework to analyze resilient defensive strategies that minimize the expected wait time of a legitimate user while maximizing expected time for a successful attack. We extend the state-of-the-art in security games of timing by considering 1) non-homogeneous arrival rate of adversarial threat vectors; 2) a legitimate system user with operational objectives; and 3) online learning of successful attacks. A notional case study with single and multiple assets is presented, and future research are identified.

3 - **A Scalable Routing Solution for Dynamic Border Apprehension Analysis**

Brandon P. Behlendorf, Assistant Professor, University at Albany, Albany, NY, United States, bbehlendorf@albany.edu

Irregular migration between ports of entry along the U.S.-Mexico border represents a critical challenge for border management. We present a novel simulation platform of generalized migration routes, using a scalable multimodal network coupled with static and user-generated weighting functions, to dynamically model cross-border flow across multiple resolutions. Results are weighed against historical apprehension data, and limitations of functional simulation modeling for front-line personnel are discussed.

4 - **Worst-case Analysis for a Leader-follower Partially Observable Stochastic Game and its Security Applications**

Yanling Chang, Texas A&M University, College Station, TX, United States, yanling.chang@tamu.edu

This research examines a leader-follower partially observable stochastic game where (i) the two agents are non-cooperative, (ii) the follower's objective is unknown to the leader, and (iii) the follower is possibly irrational. We determine the leader's optimal value function assuming a worst-case scenario on the basis of the knowledge of the leader. We analyze the structural properties of this value function and its computational complexity, and then design a viable and computationally efficient solution procedure . We illustrate the potential application of the proposed approach in a homeland security context.

5 - **Atari-ing the Vehicle Routing Problem with Stochastic Requests**

1 - **A Mixed Integer Programming Approach for Job Shop Scheduling with Sequence-dependent Setup Time and Tool Overheating Constraints to Minimize Makespan**

Juxihong Julaiti, Student, Penn State, State college, PA, United States, jpj5196@psu.edu

In a high-mixed and low-volume manufacturing facility, similar jobs are often scheduled together to decrease additional setup times. However, in dry machining processes, utilizing a tool for a prolonged period of time overheats the tool and increases chances of tool damage and scrapped parts. Therefore, the optimal schedule should avoid overheating while optimizing the objective function. To solve this issue, we propose a mixed integer programming model to minimize the makespan in a job-shop scheduling environment with sequence-dependent setup times and overheating constraints. Numerical studies are conducted to validate the model.

2 - **Penalty Variables and Multiobjective Optimization**

Ryan P. Kersh, IBM, Eugene, OR, United States, rkersh@us.ibm.com

With the CPLEX 12.9 release it is possible to define multiple objectives for a single problem. In this talk we will introduce a simplified definition of a penalty variable, and present a method for taking advantage of penalty variables with a multiobjective formulation. Finally, we will compare the performance of this method against default CPLEX.

3 - **Intermodal Freight Transportation Network Design for Super Loads**

Nasibeh Zanjirani Farahani, University of Missouri, E3437 Thomas and Nell Lafferre Hall, Columbia, MO, 65211, United States, Moein Enayati, James Noble

Commercial transportation will increase by 40% in the next 25 years, and the size of loads is supposed to be doubled in a decade. Planning of oversized cargo transportation can take a few months to over a year. For regular freights, the problem can be just finding the optimal route, but if the freight itself is oversize, overweight or non-regular, then feasibility and safety of shipment itself gets crucial. This research focuses on the routing of such loads by synchronizing the use of all modes of transportation as an option to reduce service time and cost.

4 - **SMD Optimization Problem Using MIP in Odd-type Component Environment**

Jae Wook Jeong, Korea Institute of Industrial Technology, Cheonan, Korea, Republic of, sage@kitech.re.kr, Hyunchul Tae, Young Hoon Lee, Jeongin Koo

In this paper, we try to reach the optimization by using mixed integer program (MIP) for SMD optimization problem in odd-type component environment. This MIP model has different results depending on each component, head and nozzle type. We aim to minimize the cycle time for nozzle change and head dropping components.

5 - **Probabilistic Minimum-cost Hamiltonian Cycle Problem Considering Vertex and Arc Failures**

Saeid Rasti, North Dakota State University, West Fargo, ND, United States, saeid.rasti@ndsu.edu

In this work we consider single tour and multiple tour probabilistic minimum-cost Hamiltonian cycle problem where there are success probability corresponding to vertices and arcs. The objective of this problem is finding the shortest tour in a way that the probability of reaching each nodes starting from origin be equal or greater than a specific threshold. for real life instances the solver is quiet slow, therefore we propose a branch-and-cut approach to tackle the complexity of the problem.

Joint Session OPT/Network/Practice Curated: Transportation Network Analysis

Sponsored: Optimization/Network Optimization

Sponsored Session

Chair: Bahar Cavdar, Middle East Technical University, Ankara, 06800, Turkey

1 - The Pickup and Delivery Problem with Online Transfers, for the Next Generation of Public Transport

Gizem Ozbaygin, Sabanci University, Faculty of Engineering and Natural Sciences, Istanbul, 34956, Turkey, Paul Bouman, Lucas Petrus Veelenturf

We introduce and study the pickup and delivery problem with online transfers, motivated by a passenger transportation concept involving self-driving vehicles, which can couple/decouple while en-route and transfer passengers seamlessly towards more efficient capacity utilization and traffic management. Among the major contributions of our study are: (1) development of an optimization based approach to solve a complex vehicle routing problem arising in an on-demand transportation system, (2) investigating the benefits of door-to-door shared mobility service with online transfers compared to private door-to-door rides, and shared mobility services with outside transfer possibilities.

2 - Dynamic Discretization Discovery for Service Network Design with Mixed Autonomous Fleets

Yannick Scherr, TU Braunschweig, University of Braunschweig, Braunschweig, Germany, y.scherr@tu-bs.de, Bruno Albert Neumann-Saavedra, Mike Hewitt, Dirk C. Mattfeld

In this service network design problem, a city logistics service provider seeks a repeatable plan to transport commodities from distribution centers to inner-city satellites. In a heterogeneous infrastructure, autonomous vehicles in SAE level 4 may drive in feasible streets but need to be guided elsewhere by manually operated vehicles in platoons. With our model, we determine a fleet mix, schedule transportation services, and decide on routing the commodities. We apply a dynamic discretization discovery algorithm that iteratively refines partially time-expanded networks, and we analyze its efficacy.

3 - A New Algorithm for School Bus Routing, Implementation in Boston

Sebastien Martin, Lyft, Cambridge, MA, 02139, United States, 92sebastien@gmail.com

We proposes an algorithm for school bus routing based on a novel decomposition approach. We also discuss the challenges of implementation. Our application in Boston led to $5 million in yearly savings (maintaining service quality despite a 50-bus fleet reduction).

4 - Traveling Repairman Problem on a Power Network

Bahar Cavdar, Middle East Technical University, Universiteler Mah, Dumlupinar Bulv, Ankara, 06800, Turkey, bcavdar@metu.edu.tr, Qie He, Feng Qiu

Power networks are often disrupted by various events interrupting electricity service. Many of these disruptions can only be recovered by physical attendance of the repair crew. In this study, we consider a power distribution network restoration problem with repair crew routing. We provide a formulation in a general form, and develop a problem-specific bi-directional Dynamic Programming solution approach.

Sponsored Session

Chair: Chao Wang, Arizona State University, Tempe, AZ

1 - Water Routing in River Networks

Berkin Arici, Jorge Seafair

River networks are large-scale complex systems characterized by nonlinear flow dynamics. Accurate representation of flows along a river—or routing—is crucial for flood control, reservoir management, and hydropower operations, among others. Muskingum models and their variants are vastly used in hydrology for water routing as they can incorporate physical parameters of the river basin. In this work, we introduce an MIP formulation to approximate the nonlinear Muskingum-Cunge equations. Our approach captures the nonlinear dynamics while providing a tractable description of water routing.

2 - Fireline Construction Optimization in a Heterogeneous Forest Landscape

Xu Yang, Northeastern University, Boston, MA, United States, yang.xu1@husky.neu.edu, Emanuel Melachrioudis

Firefighters attack a wildfire by constructing a fireline some distance from the fire perimeter. The decision of fireline path takes into account the fire's capacity to spread. We aim to find the shortest-in-time path for firefighting crews to build this fireline around the growing fire perimeter. The forest landscape is partitioned into homogeneous polygons. Nodes are selected on the polygon boundaries. These nodes are then connected in Delaunay triangulations to form a network of the forest landscape. A methodology is developed that uses a modified Dijkstra's algorithm to find the fastest, yet safest paths, for firefighting crews to finish the containment.

3 - Analysis of Algorithmic Alternatives for Optimizing and Planning Vaccine Distribution

Larissa P.G. Petroianu, PhD Candidate, University of Washington, Seattle, WA, United States, lpetroia@uw.edu, Zelda B. Zabinsky, Mauricio G. C. Resende, Mariam Zameer, Mamiza M. Muteia, Aida L. Coelho

Planning vaccine distribution is challenging in Mozambique rural and impoverished urban communities, due to inadequate vehicles, limited cold storage, road availability and weather conditions. Such constraints on vehicle routing for last mile delivery result in a mixed-integer optimization model that is computationally difficult to solve. We present a numerical study for a vehicle routing model for vaccine distribution to health facilities, where we compare standard optimization methods with an indexing algorithm on test problems, as well as three realistic data sets.

4 - Wildlife Corridor Design under Probabilistic Species Movement and Geometry Constraints

Chao Wang, Arizona State University, Tempe, AZ, United States, cwang198@asu.edu, Jorge Sefair

Habitat fragmentation jeopardizes species survival and reproduction. Current models for wildlife corridor design focus on the efficient allocation of resources under landscape constraints (e.g., land cost) but ignore animal movement. We present an alternative approach that accommodates landscape resistance features as well as other factors influencing movement (e.g., mortality). We introduce a discrete absorbing Markov chain approach to describe species movement in space and time. We embed this model into a mixed-integer programming formulation that decides the optimal set of patches to purchase to produce a corridor with the largest usage probability and a given width.

Joint Session ICS/Practice Curated: Political Redistricting

Sponsored: Computing

Sponsored Session

Chair: Hamidreza Validi, Oklahoma State University, Stillwater, OK, 74075, United States

1 - A Bisection Protocol for Political Redistricting

Ian G. Ludden, University of Illinois at Urbana-Champaign, Urbana, IL, United States, iludden2@illinois.edu, Rahul Swamy, Douglas M. King, Sheldon H. Jacobson

We introduce the bisection protocol, a fair division approach to political redistricting in which two players alternately divide pieces of the state in half (up to rounding) to obtain a district plan. The bisection protocol is compared to the I-cut-you-freeze protocol (Pegden et al. 2017) across standard fairness metrics. Computational experiments applying (mixed) integer programming formulations of the two protocols to several states provide further evidence of each protocol's merits and limitations. Our theoretical analyses and computational results can help each state make an informed decision of whether to adopt either protocol for congressional or state redistricting.

2 - Defining and Finding Impartial Districtings

Gerdus Benade, Carnegie Mellon University, Pittsburgh, PA, United States, Ariel Procaccia, John Hooker

We propose a notion of fairness that impartial districtings should satisfy and show that it is always possible to find a fair districting. This allows us to add fairness constraints to a novel recursive model for redistricting. Preliminary computational results show the promise of this approach.

3 - Imposing Contiguity Constraints in Political Districting Models

Hamidreza Validi, Oklahoma State University, Stillwater, OK, 74075, United States, Austin Buchanan, Eugene Lykhovyd

Beginning in the 1960s, techniques from operations research began to be used for political districting. A classical example is the integer programming model of Hess et al. (Operations Research 13(6):998-1006, 1965). The model of Hess et al. does not guarantee contiguity, requiring them to manually adjust their solutions to make them contiguous. In this work, we review some existing approaches for imposing contiguity in the Hess model, propose a new one, and analytically compare them in terms of strength and size. Finally, we conduct an extensive set of numerical experiments at the county and census tract levels to evaluate the different models' strengths and weaknesses.

4 - Extended Formulations for Simple Graph Partitioning on Sparse Graphs

Demetrios V. Papazaharias, University at Buffalo, Buffalo, NY, 14214, United States, dvpapaza@buffalo.edu, Jose Luis Walteros

The problem of simple graph partitioning is to partition the vertices of an edge weighted graph into mutually node-disjoint subgraphs, such that each subgraph contains no more than r nodes and the total weight of the edges connecting these subgraphs is minimized. Where most formulations define the variables over node-pairs in the graph, we seek to take advantage of the structure of sparse graphs by defining our variables over the edges. We will discuss several extended formulations, a dynamic program for this problem which we will use as a separation algorithm on general graphs, and provide some insight on the valid inequalities of our formulations.

Recent Advances in Learning and Distributionally Robust Optimization II

Sponsored: Computing

Sponsored Session

Chair: Hamed Rahimian, Northwestern University, Evanston, IL, 60208, United States

1 - Minimax Statistical Learning with Wasserstein distances

Jaeho Lee, KAIST, Daejeon, Korea, Republic of, jaeho-lee@kaist.ac.kr

Jaeho Lee, UIUC, Urbana, IL, United States, jaeho-lee@kaist.ac.kr

We describe a minimax framework for statistical learning with ambiguity sets given by balls in Wasserstein space, and prove generalization bounds for the distributionally robust optimization counterpart of the standard empirical risk minimization procedure. As an illustrative example, we provide generalization guarantees for transport-based domain adaptation problems where the Wasserstein distance between the source and target domain distributions can be estimated from unlabeled samples. This is a joint work with Maxim Raginsky.

2 - Designing Performance-aligned Learning Algorithms Using Distributionally Robust Principle

Rizal Fathony, Carnegie Mellon University, Pittsburgh, PA, United States, rfathony@cs.cmu.edu

The goal of many prediction tasks in machine learning is to learn a prediction function that minimizes certain loss metrics (e.g., zero-one, ordinal, and cost-sensitive loss) or maximizes certain performance metrics (e.g., accuracy, precision, and F1-score) on the testing dataset. We present a new technique for designing learning algorithms for these tasks using distributionally robust principle where the uncertainty sets are defined over the predictive distributions. We demonstrate the theoretical and practical benefits of our approach in a range of prediction tasks including multiclass classification, ordinal regression, structured prediction, and graphical models.

3 - Accelerating Convergence in Wasserstein Distance in High Dimensions

Shashank Singh, Carnegie Mellon University, Pittsburgh, PA, United States, sss1@andrew.cmu.edu

Many methods for distributionally robust optimization and learning rely on convergence of the empirical distribution of n IID samples to their population distribution P in mean Wasserstein distance, as n increases. For d-dimensional data, this convergence can be as slow as O(n-1/d), prohibitively slow for even moderate d. Several recent papers have shown convergence much faster than O(n-1/d) under mild additional assumptions on P. We discuss faster rates when the data have low intrinsic dimension, the data distribution is smooth, or Wasserstein distance is replaced by one of many distances that are weaker but retain distributional robustness properties motivating Wasserstein distance.

1 - Solving Large Scale SDPs via Block-Coordinate Maximization Burer-Monteiro Approach

Nuri Denizcan Vanli, Massachusetts Institute of Tehnology, Cambridge, MA, 02141, United States, denizcan@mit.edu

We prove that the block-coordinate maximization algorithm applied to the non-convex Burer-Monteiro approach globally converges to a first-order stationary point with a sublinear rate. We also show that the block-coordinate maximization algorithm is locally linearly convergent to a local maximum under local weak strong concavity assumption. We establish that this assumption generically holds when the rank of the factorization is sufficiently large. Furthermore, we propose an algorithm based on the block-coordinate maximization and Lanczos methods that is guaranteed to return a solution that provide $1-\O{1/r}$ approximation to the original SDP, where r is the rank of the factorization.

2 - Analysis of a Two-layer Neural Network via Displacement Convexity

Adel Javanmard, University of Southern California, Los Angeles, CA, 90089, United States, Marco Mondelli, Andrea Montanari

We consider the problem of learning a function defined on a compact domain, using linear combinations of a large number of "bump-like" components (neurons). This idea lies at the core of a variety of methods from two-layer neural networks to kernel regression, to boosting. The parameters to be fitted are the centers of the bumps, and the resulting risk minimization problem is highly non-convex. We prove that in the limit in which the number of neurons diverges and the bump width tends to zero, the gradient flow has a limit which is a viscous porous medium equation. By virtue of a property named "displacement convexity", we show exponential dimension-free convergence rate for the gradient descent.

3 - Distributionally Robust Optimization and Generalization in Kernel Methods

Matthew Staib, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, Stefanie Jegelka

Distributionally robust optimization (DRO) enjoys connections to regularization, generalization, and robustness in machine learning. Work so far considered uncertainty sets based on f-divergences and Wasserstein distances, which have drawbacks. We study DRO with maximum mean discrepancy (MMD) uncertainty sets. We show that MMD DRO is roughly equivalent to regularization by the Hilbert norm. As a byproduct, we obtain an alternative generalization proof for Gaussian kernel ridge regression via a new DRO lense. Beyond kernel methods, we derive a generically applicable approximation of MMD DRO, and show that it generalizes recent work on (non-convex) variance-based regularization.

4 - Unique Sink Orientations for Homogeneous Linear Inequalities and Their Alternative Systems

Jourdain Lamperski, MIT, Cambridge, MA, United States, jourdain@mit.edu

We reduce the problem of computing a solution to a homogeneous system of linear inequalities to the problem of computing the unique sink of a certain unique sink orientation (USO). We address a question of Morris (2002) and Jaggi (2006) by showing that the USO satisfies a local property that is not satisfied by all USOs that satisfy the Holt-Klee property, raising the question of whether the local property can be leveraged algorithmically to develop faster algorithms or a strongly polynomial algorithm.

Advances in Estimation and Control for Intersections

Sponsored: Transportation Science & Logistics/Intelligent Transportation Systems (ITS)

Sponsored Session

Chair: Saif Eddin G Jabari, New York University, Abu Dhabi, United Arab Emirates

1 - A Data Fusion Approach to Traffic State Estimation

Yan Zhao, University of Michigan, Ann Arbor, MI, 48104, United States, zhaoyann@umich.edu, Xintao Yan, Henry Liu

The emergence of connected vehicle technology and ride-hailing services has enabled the collection of probe vehicle trajectory data in large scale. The newly available trajectory data and the existing fixed-location sensor data could be combined for better traffic condition monitoring and transportation network evaluation. This study proposes a data fusion approach to traffic state estimation based on matrix factorization. Validation results have shown that the proposed method could significantly improve the estimation accuracy compared to traditional methods.

2 - A Decentralized Control Approach Using Kinematic Traffic Theory

Li Li, New York University, New York, NY, United States, ll3252@nyu.edu, Saif Eddin G. Jabari

This paper derives a position weighted backpressure (PWBP) control policy for network traffic applying continuum modeling principles of traffic dynamics and thus capture the spatial distribution of vehicles along network roads and spill-back dynamics. We conduct comparisons against a real-world adaptive control implementation for an isolated intersection. Comparisons are also performed against other BP approaches in addition to optimized fixed timing control at the network level. These experiments demonstrate the superiority of PWBP over the other control policies in terms of capacity region, network-wide delay, congestion propagation speed, and response to incidents.

3 - Reinforcement Learning Based Traffic Signal Control

Xuegang Ban, University of Washington, Seattle, WA, United States, banx@uw.edu, Qiangqiang Guo

As the rise of Connected and Automated Vehicles (CAV), it becomes practical to train learning-based methods to better control traffic signals by utilizing CAVs' data. Reinforcement learning (RL) has shown great promise in agent-based interactive optimal control. Current RL based signal control methods usually assume full CAV penetration and simplify the intersection scenario to reduce the action space, which make these methods not practical. This paper proposes a new RL based signal control algorithm based on a real-world eight-phase intersection and study the control performance under limited CAV penetrations. The control performance is analyzed through numerical experiments.

4 - Virtual Platooning Control for Cooperative Intersection Crossing of Connected Autonomous Vehicles

Xiaozheng He, Rensselaer Polytechnic Institute, Troy, NY, 12180, United States, hex6@rpi.edu, Yu Wei

This study proposes a virtual platooning control mechanism to facilitate the cooperative intersection crossing of connected and autonomous vehicles (CAVs), where the approaching CAVs on different links are mapped into one platoon to support cooperated behavior. To ensure the safety of cooperative crossing, we analyze the virtual platooning stability by factoring information spread into the modeling and considering the influences of communication delay on virtual platooning. Simulation experiment results demonstrate the efficiency of the proposed control mechanism.

1 - Electric Charging Infrastructure Deployment the Past the Present and the Future

Tara Radvand, Research Assistant, Purdue University, West Lafayette, IN, United States, tradvand@purdue.edu, Mohammad Miralinaghi, Samuel Labi, Majed Alinizzi

There is a growing body of literature on optimal strategies for electric vehicle (EV) infrastructure deployment. As such, a comprehensive review of the literature is helpful to understand the current research trajectory. This talk focuses on two aspects related to charging infrastructure deployment. The first aspect is related to recent technological progress of EVs and the wireless and battery charging mechanisms. The second aspect is related to human factors such as range anxiety. The talk classifies the various solution methodologies that have been used to obtain the optimal strategies. Finally, the talk discusses the necessary future research directions to enhance the deployment process.

2 - Evaluation of Railway Hub Logistics System Scheme by Taking a Hub in China as an Example

Tao Chen, National and Local Joint Engineering Laboratory of Comprehensive Intelligent Transportation, Southwest JiaoTong University, Chengdu, China, swjtuchentao@qq.com, Boer Deng, Shaoquan Ni, Ran Li

The construction of China's railway hub logistics system has many influence factors and high costs, so it has social and economic significance to evaluate its planning scheme. This study has obtained experience from a large number of hub planning schemes, and sets up an total of 29 indicators in the macro, meso and micro levels, using the method of AHP, and proposed two index combinations for different objects: system planning and station planning evaluation. By using the improved fuzzy-grey comprehensive evaluation method to construct a model, the evaluation software was designed. Then, taking the Hefei hub in China as an example to evaluate, the final results were in line with reality.

3 - A Link Criticality Index Embedded in Iterative Solutions of User Equilibrium Traffic Assignment

Amirmasoud Almotahari, Stony Brook University, Stony Brook, NY, United States, am.almotahari@stonybrook.edu, Anil Yazici

Due to non-linearity of link performance functions in road networks, researchers select a network performance measure, remove links one-by-one, and reassigned traffic demand to calculate the impacts of each link failure. In this study, the user equilibrium formulation is utilized, and two iterative solutions (Frank-Wolfe and Gradient Projection) are exploited to identify link criticality ranking within a single traffic assignment. The developed criticality measure is compared with selected measures through numerical examples. The results indicate the proposed measure better deliberate criticality in terms of connectivity/redundancy as well as the traffic conditions in the network.

4 - Large-scale, Unconstrained Multiple Vehicle Routing Problem Using Two-Phase Assignment Approach

Joon-yeoul Oh, Associate Professor, Texas A&M University-Kingsville, Kingsville, TX, United States, kfjo000@tamuk.edu, Shivani Nilkanth Patil, Amir Hessami, David Hicks

A well planned routing can reduce transportation costs but planning an efficient routing can be complex and time consuming for a larger number of nodes to visit. This research presents an efficient yet effective algorithm for a large scale, unconstrained multiple vehicle routing problem, using a two phase grouping assignment technique. To test the practicability of the proposed algorithm, various cases are created and compared with the outputs of K means clustering algorithm. The results of the cases show that the two phase assignment technique has performed very well with average 10% better route distance and average 55% faster elapsed time than the K means clustering algorithm.

5 - understanding the Impacts of Wireless Charging and Dedicated Autonomous Vehicle Lanes on Autonomous Vehicle Adoption and Vehicle Fuel Type Choice

Yuntao Guo, Purdue University, West Lafayette, IN, United States, gyt861211@gmail.com, Dustin Souders, Irina Benedyk, Srinivas Peeta, Samuel Labi

This study investigates the potential impacts of wireless charging and dedicated autonomous vehicle (AV) lanes on travelers' willingness to use, buy, and pay for Level 4 AVs and on their choice of vehicle fuel type (gasoline-powered and all-electric). The study uses stated preference survey data. The results can potentially facilitate the development of road network design guidelines and policies, and can aid roadway agencies in planning the built environment to facilitate AV adoption.

6 - Path-Constrained Flow-Dependent Reliability-Based Traffic Assignment of Battery Electric Vehicles Considering Stochastic Rance Anxiety

Hossein Nasr Esfahani, Utah State University, Logan, UT, United States, hosseinnasr1368@yahoo.com, Ziqi Song

This study addresses the reliability-based equilibrium traffic assignment problem of battery electric vehicles (EVs) with flow-dependent stochastic energy consumption. To capture the impact of travel time uncertainty on EVs energy consumption, a model is presented with flow-dependent reliability-based path-constraints, which minimizes drivers' travel cost by reducing the weighted summation of total travel time and energy consumption plus their uncertainties. The result demonstrates a better explanation of EV drivers' different route choice decisions, such as willingness to remain in urban areas.

Signal-free Traffic Control in Connected and Automated Vehicle Environment

Sponsored: Transportation Science & Logistics/Intelligent Transportation Systems (ITS)

Sponsored Session

Chair: Leila Hajibabai, North Carolina State University, Raleigh, NC, United States

1 - Trajectory Optimization of Connected Self-Driving Vehicles at Roundabouts

Rasool Mohebifard, Washington State University, WA, 99163, United States, Ali Hajbabaie

This study formulates trajectory control of connected self-driving vehicles (CSVs) in roundabouts as a non-linear and non-convex optimization program. The program minimizes the total travel time of CAVs and includes vehicle dynamics and collision-avoidance constraints with explicit representation of vehicles paths. We introduce a customized solution technique that convexifies the collision-avoidance constraint and employs the Alternating Direction Method of Multipliers to decompose the convexified problem into two sub-problems.

2 - Max-pressure Based Autonomous Intersection Management with Pedestrians

Rongsheng Chen, University of Minnesota, Minneapolis, MN, United States, mlevin@umn.edu, Jeffrey Hu, Michael Levin

Autonomous intersection management (AIM) can drastically reduce delays for automated vehicles, but pedestrian access to AIM has yet to be addressed. This study proposes an AIM algorithm that integrates the existing trajectory planning algorithm with max-pressure control, which aims to maximize the combined vehicle and pedestrian throughput of the network. A linear program is formulated to calculate the optimal intersection control strategy based on vehicle and pedestrian queues lengths (pedestrian queues are estimated). To evaluate the impacts of pedestrians on vehicle queue lengths and delays, this study runs simulations under different combinations of pedestrian and vehicle demands.

3 - Scheduling of Heterogeneous Connected Automated Vehicles at a General Conflict Area

Xiaopeng Li, University of South Florida, Tampa, FL, 33620, United States, xpli02@gmail.com, Saeid Soleimaniamiri

Allocating time for vehicles arriving at a general conflict area to pass without collision is a common problem in traffic operations at various facilities, such as intersections, work-zones, and merging ramps. With the advent of connected automated vehicle (CAV) technologies, vehicle scheduling at a conflict area can be precise to each individual vehicle, which enables studies on a number of individual-vehicle based control strategies at various conflict areas. This research aims to address the research gaps in both fundamental methodologies and engineering applications on this general topic.

4 - Cooperative Roundabout Throughput Strategies for Connected Autonomous Vehicles

Chaojie Wang, Gatech, Atlanta, GA, United States

We propose cooperative roundabout passing throughput strategies for connected autonomous vehicles (CAVs) to enhance roundabout traffic flow performance in roundaboutse by coordinate coordinating the incoming flows into a virtual platoon. An optimization model is established to determine the optimal virtual platoon that can maximize roundabout performance based on one or more objectives (roundabout throughput, smoothness and robustness of the virtual platoon). The effectiveness and efficiency of the proposed strategies for CAV platoons will be illustrated using numerical simulation and compared with those of signalized intersections.

Bayesian Approach

Contributed Session

Chair: Babak Zafari, Babson College, MA, 02457, United States

1 - Spatio-temporal Analysis of Water Pipe Failures Using a Bayesian Network

Jared Beekman, Analyst, Innovative Decisions, Inc., Vienna, VA, United States, jbeekman@innovativedecisions.com, Craig Daly, Kate Zhao, Sepideh Yazdekhasti, Thomas Chen, Dennis Buede

We investigate the applicability of Bayesian Networks for classifying water pipe failures using spatio-temporal variables across several US utilities. Bayesian Networks illustrate probabilistic relationships that are mathematically rigorous and intuitively understandable, providing sound statistical principles for evaluating primary causal factors driving water pipe failures. This research addresses utilities' decision-making needs in prioritizing repair and replacement of deteriorating water pipe infrastructure.

2 - Bayesian Estimation of Inventory Counts

Thomas Gartner, Starbucks, Seattle, WA, United States, Renaud Lecoeuche

How can Bayesian estimation techniques be applied to more accurately process real life inventory counts? In order to automatically send a retail store the appropriate quantity of any good, knowing what they have today is essential. We present a Bayesian particle filtering approach to process thousands of hand-counted inventory estimations that are highly prone to human error, for use in an automated ordering system at Starbucks.

3 - Forecasting the Real Gas Price with BVARS: The Role of Temperature

Arthur Thomas, IFP Energies nouvelles / University of Nantes, Rueil-Malmaison, France, arthur.thomas@ifpen.fr, Benoît Sévi, Zakaria Moussa

Using some hand-collected data from the monthly energy review dating back to 1997, a monthly real-time dataset is constructed to generate forecasts of natural gas prices as established at the Henry Hub. We compare the performance of a variety of models including state-of-the-art Bayesian and time-varying-parameters (TVP) models. Considering extensions to possible structural breaks, non-Gaussian distributions and variable selection along with volatility models, we provide evidence that Bayesian and TVP models help in forecasting the real price of natural gas for horizons up to one year.

4 - Predicting Daily Power Outages Using a Fair Bayesian Model Averaging Approach

Elnaz Kabir, University of Michigan, Ann Arbor, MI, United States, ekabir@umich.edu, Seth Guikema

A wide variety of weather conditions, from wind storms to prolonged heat events, can have substantial impacts on power systems, posing many risks and inconveniences due to power outages. Being able to estimate the number of customers without power based on a weather forecast has the potential to help utilities restore power more quickly and efficiently. In this study, we apply Bayesian Model Averaging (BMA) to form an ensemble model estimating the probability distribution of daily customer outages. The model is trained using historic outage and weather data and based on an iterative statistical process.

5 - Using Natural Language Processing Models for Anomaly Detection: A Case of Medical Data

Babak Zafari, Babson College, Babson Park, MA, United States, bzafari@babson.edu

In this work, we present novel solutions on using natural language processing models for anomaly detection. We demonstrate the process by applying it to healthcare data; more specifically medical prescription data. The size and complexity of the healthcare systems as well as the cost of medical audits make use of statistical methods necessary to generate investigative leads in prescription audits. Our proposed methods offer probabilistic information of prescription patterns of providers and can reveal hidden patterns which can lead to discovery of potential cases of drug diversion.

Joint Session AAS/TSL Air: Evidence Based Empirical Studies of Airline Operations

Sponsored: Aviation Applications

Sponsored Session

Chair: Farbod Farhadi, Roger Williams University, Bristol, RI, 02809, United States

Co-Chair: David F Pyke, University of San Diego, San Diego, CA, 92110-2492, United States

1 - The Impact of Fight Outsourcing Policies in the U.S. Air Transport Industry

David F. Pyke, University of San Diego, Coronado 108, 5998 Alcala Park, San Diego, CA, 92110-2492, United States, davidpyke@sandiego.edu, Farbod Farhadi, Soheil Sibdari, Matthew Gregg

We study the impact of regional airline market share on average airfares and flight frequencies, by constructing a 20-year panel of U.S. airport-level data. Our results suggest that increases in regional airline market shares increase both average fares and flight frequencies at the airport level. Less connected airports and shorter distance flights seem to be the drivers of the flight outsourcing decisions. We further investigate these effects before and after the 2007 U.S. economic recession and show how the impact on airfares and flight frequencies vary across years.

2 - Market Selection Strategies of Regional Carriers in the U.S.

Farbod Farhadi, Roger Williams University, Bristol, RI, 02809, United States, ffarhadi@rwu.edu, Soheil Sibdari, David F. Pyke

Regional carriers play a major role in the U.S. domestic air transport industry. They operate flights from low demand destinations to larger airports creating a complementary network of routs that feeds the hub and spoke operations of the major carriers. In this study we analyze the market selection strategies of regional airlines within the U.S. domestic air transportation network.

3 - Do Employee Labor Constraints Raise Product Quality? Empirical Evidence from U.S. Airlines

Kerry Tan, Loyola University Maryland, Baltimore, MD, United States, kmtan@loyola.edu, Nicholas Rupp

Legislation H.R. 5900, approved in August 2010 and effective in August 2013, implemented more restrictive pilot rest requirements and increased the number of pilot training hours required (now 1,500 hours) to obtain a pilot license. This paper examines the effect of raising the safety standards on airline service quality. A priori, the effect is ambiguous since putting in place more restrictive requirements on labor gives a company less flexibility in managing its resources which suggests a detriment to on-time performance. On the other hand, well-rested pilots with greater experience may provide enhanced productivity for their employer which may lead to improved on-time performance.

4 - Airline Delays and Market Power

Paulos Lakew, Unison Consulting, Inc., Mission Viejo, CA, United States, Volodymyr Bilotkach

This study uses aggregated data on concentration, delays, and airfares from US airports to shed light on two issues. First, we examine the concentration-delays relationship to contribute to the airport-congestion self-internalization debate. Our study is the first investigation of this issue that uses data on sources of delays. Second, we evaluate whether increases in flight delays result in lower airfares. Our empirical results are mixed: while total delays are positively correlated with airport-level concentration (contradicting the self-internalization hypothesis), the variance of delays at larger airports falls as concentration increases.

Forecasting III

Contributed Session

Chair: Renzo Benavente, Pontificia Universidad Catolica del Peru, Velez Robles, 180, Lima, LIMA 09, Peru

1 - Statistical Analysis of Functional Data and its Application in the Study of PM10 in Bogotá, Colombia

Sebastián F. Calcetero, Lecturer, Universidad de los Andes, Bogotá, Colombia, sf.calcetero674@uniandes.edu.co, Maria Elsa Correal

The objective of this project is, on one hand, to describe some relevant concepts of functional data analysis, including some quantitative strategies developed to analyze statistically; and on another hand, to illustrate its application in the understanding of PM10 in Bogotá, and discuss its usefulness in the development of air pollution policies. Specifically, we use the approach of functional principal components to estimate multiple functional regression models, functional autoregressive moving average models, and introduce the innovate idea of functional dynamic regression models.

2 - How to Set Up a Race Between 16 Predictive Algorithms and Still Win

Kellington Neves, FICO, San Diego, CA, United States, kellingtonneves@fico.com

Come to learn how FICO analytics professionals worked with Grupo Fleury, one of the largest diagnostic medicine companies in Brazil, to develop a complete demand planning management platform. FICO® Forecaster now allows them to accurately predict their sales forecast using 16 different complex forecasting methods complemented by business knowledge, to perform management analyzes of past forecasts to help improve future forecasts, to estimate their unrestricted demand and know the potential sales that they could realize, and reduce their costs through more efficient resource allocation.

3 - One Step-ahead Predictive Ability in Nested Regression Models

Silu Lyu, Washington State University, Pullman, WA, United States, silu.lyu@wsu.edu, Stergios Fotopoulos

Our paper researches on how to make model selection considering the predictive ability in the case of overfitting. This can be an analytical tool for econometric models for a large quantity and high-dimensional data. We start with measuring the one-step-ahead predictive accuracy. Next, we develop a test hypothesis analysis to determine which model is better in terms of predictive accuracy. Simulations results confirm that the empirical approximated statistics is a function of the in-sample ratios, and the terms omitted are shown to be negligible. Also, power tests and goodness-of-fit tests are developed. Finally, three stocks from high-tech are considered to illustrate the proposed methodology.

4 - Demand Forecasting Using Subjective Rankings

Marat Salikhov, INSEAD, Singapore, Singapore, marat.salikhov@insead.edu

Please check the mobile app for this abstract.

5 - Predictive Model for a Contact Center in a Latin American Bank

Renzo A. Benavente, Pontificia Universidad Catolica del Peru, Lima, Peru, renzo.benavente@pucp.pe, Jonatan Rojas, Miguel Rodriguez

This research aims to predict incoming reclaims calls at the contact center of a Latin American bank. Significant variables that influence the number of calls entered in the period 2015 to 2018 were identified. Then the data was trained in this period with models Random Forest, Time Series, Neural Network and then the one with the best fit was chosen. With the chosen model, the months January and February of 2019 were projected, which then, when compared with the real data, had a MAPE of 4%. Comparing with the previous method of prediction that the bank had, it saved 8% in personnel costs in these 2 months of validation.

1 - Can Delivery Platforms Benefit Restaurants?

Andrew E. Frazelle, The University of Texas at Dallas, 4719 COLE AVE APT 324, Richardson, TX, 75205, United States, andrew.frazelle@utdallas.edu

In the restaurant industry, delivery platforms collect customer orders via web-based systems, transmit them to restaurants, and deliver the orders to customers. We investigate this business model, and answer the following question: can delivery platforms benefit restaurants? We conclude that the most common contract, one-way revenue sharing, has inherent drawbacks, but these can be partially mitigated by an even simpler relationship with no formal contractual agreement between the delivery platform and the restaurant.

2 - Strategic Data Sharing in Networks

Ilan Morgenstern, Stanford University, Stanford, CA, United States, ilanmor@stanford.edu, Kostas Bimpikis, Daniela Saban

We consider a setting in which competing firms may use information they derive from past transactions to price discriminate their customers. Anticipating this, customers may have the incentive to delay or altogether forgo transacting with a firm. We establish that customers' "privacy concerns" may lead to price dispersion, even in a perfectly competitive market. We also discuss the welfare implications and explore potential interventions aimed at increasing overall surplus.

3 - Labor Welfare in On-demand Service Platforms

Saif Benjaafar, University of Minnesota, Department of Industrial and Systems Engr, Minneapolis, MN, 55419, United States, saif@umn.edu, Jian-Ya Ding, Guangwen Kong, Terry Taylor

The lack of regulatory protections granted to "gig-economy" workers, coupled with the growing number of these workers, has prompted labor advocates and regulators to consider measures aimed at improving the welfare of these workers: measures that limit the labor pool size or impose a floor on the nominal wage or effective wage. This paper characterizes the effect of such measures on average labor welfare. We characterize when efforts to limit the labor pool size are counterproductive, and we provide a sharp prescription for the type of wage floor to impose.

4 - Pricing Models for Online Food Delivery

Jaelynn Oh, University of Utah, Salt Lake City, UT, 84112, United States, jaelynn.oh@business.utah.edu, Xuanming Su, Chloe Kim Glaeser

Online food delivery platforms connect restaurants with customers and deliver food to their door. In return, the platform charges restaurants a commission rate and charges customers a delivery fee. We study best pricing practices for the platform, partnering restaurants, and customers using game-theoretic models.

Joint Session RMP/Practice Curated: Practical Approaches in Solving Large-scale Revenue and Pricing Optimization Problems

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Ang Li, PROS, Inc., PROS, Inc., Houston, TX, 77002, çUnited States

1 - Sales Promotion Strategies for Substitutable and Seasonal Products with an Application to a Leading Chain Supermarket in China

Su Zhao, Ainnovation, Beijing, China, zhaosu@ainnovation.com, Xuanqi Zhang, Xiang Liu

In this presentation, firstly, a machine learning engine including top performing algorithms is designed to predict sales of product categories for a flexible time period, with top sales and high price elasticity categories generated. Then sales promotion strategies for substitutable products within categories targeting at an overall profit maximization are provided using dedicated cross product elasticity analysis. Furthermore, promotion strategies for perishable or seasonal products applying with dynamic programming over finite selling periods are suggested and have been compared with the current supermarket operational results.

2 - Optimizing Customer Stimuli in a Casual Dining Context

Jose Luis Preciado Arreola, Assistant Professor, Tecnologico de Monterrey, Monterrey, Mexico, jlpreciadoarreola@tec.mx

We explore customer susceptibility to consume augmented bundles of products as linked to their satisfaction with their experience in a casual dining setup. Specifically, we link customer satisfaction survey results to transaction KPIs at a gourmet burger chain. We then conduct controlled offering/service experiments to assess the customers' marginal propensity to modify their buying patterns in the same direction as the offering. We then use these results to perform offer optimization on a revenue basis, accounting for cannibalization across offerings. Statistical techniques involved include ensembled nonparametric regression, text mining, A/B testing and Mixed-Integer Programming.

3 - Revenue Management for Vacation Homes

Anurag Verma, PriceLabs, Chicago, IL, United States, anurag@pricelabs.co, Pedro Borges

Revenue management for vacation homes is complicated due to a few reasons: 1) Each vacation home is a unique product, and can't be compared to other homes directly; 2) Unlike hotels (multiple rooms) or airlines (multiple seats), there is only one home to be sold on any given night, which makes booking pace impossible to gauge (for any future date, you're either completely booked or not booked at all); 3) Given the small inventory, historic data can be noisy, 4) Supply and demand fluctuates a lot from one year to the next. We discuss what these challenges mean and how revenue management frameworks from hotels and airlines have been adapted to work well in this new(ish) travel segment.

4 - Competitive Rm Models with Loyal and Fully Flexible Customers

Wei Wang, PROS Inc, 3100 Main St, Suite #900, Houston, TX, 77002, United States, weiwang@pros.com, Ravi Kumar, Darius Walczak, Ahmed Simrin, Sivarama Arunachalam

Competition in the Airline RM is a topic that has been long talked about and various ways of accounting for competition have been invented. The microeconomics models of competition have been of lesser value since many of their assumptions were deemed unrealistic. One of those assumptions is to treat all customers as seeking the lowest price in the market. On the other hand almost all early RM models assumed that demand is dedicated to an airline. We show realistic competitive RM models including both those types of customers. Furthermore, we show the same idea apply not only in the existing fare class-based world but also within the classless dynamic pricing context and present numerical examples for both.

5 - A Few Practical Treatments on Optimizing Pricing on a Large Bus Network

Ang Li, PROS, Inc., Houston, TX, 77002, United States, ali@pros.com, Manu Chaudhary

We present an LP formulation that determines pricing and capacity allocation for all passenger demands over a large bus network. Due to the sheer size of our problem, several treatments were made to meet practical run-time requirements. Among these, we will discuss a theme to solve the model in chunks, and utilization of dual values and certain unconstrained-revenue-optimal prices for itineraries that do not receive demand allocation.

Seeding and Value of Network Information in Social Network Applications

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Amin Rahimian, MIT Institute for Data, Systems and Society, Cambridge, MA, 02142, United States

Co-Chair: Ankur Mani, University of Minnesota, Saint Louis, MO, 63108-2432, United States

1 - Seeding with Costly Network Information

Amin Rahimian, MIT Institute for Data, Systems and Society, Cambridge, MA, 02142, United States, rahimian@mit.edu, Dean Eckles, Hossein Esfandiari, Elchanan Mossel

Seeding the most influential individuals based on the contact structure can substantially enhance the extent of a spread over the social network. Most of the influence maximization literature assumes the knowledge of the entire network graph. However, in practice, obtaining full knowledge of the network structure is very costly. We propose polynomial-time algorithms that provide almost tight approximation guarantees using a bounded number of queries to the graph structure. We also provide hardness results to bound the query complexity and show tightness of our guarantees.

2 - Evaluating Stochastic Seeding Strategies in Networks

Dean Eckles, MIT, Cambridge, MA, 02142, United States, Alex Chin, Johan Ugander

It is common to strategize about where in a network to seed a behavior, often with an element of randomness. One stochastic strategy, one-hop targeting, is to select random network neighbors of random individuals; this exploits a version of the friendship paradox. Here we show how stochastic seeding strategies can be evaluated more efficiently, how they can be evaluated "off-policy" using existing data arising from experiments designed for other purposes, and how to design more efficient experiments. The proposed estimators and designs can dramatically increase precision. We then apply our proposed estimators to two field experiments.

3 - Think Globally, Act Locally: on the Optimal Seeding for Nonsubmodular Influence Maximization

Fang-Yi Yu, University of Michigan, Ann Arbor, MI, United States, fayu@umich.edu, Grant Schoenebeck, Biaoshuai Tao

We study the r-complex contagion influence maximization problem. In the r-complex contagion model, each vertex becomes infected if it has at least r infected neighbors. We focus on the stochastic hierarchical blockmodel, a special case of stochastic blockmodel. We prove that, under certain mild assumptions, putting all the seeds in a single community is the optimal seeding strategy. This matches the intuition that it is beneficial to put seeds near each other to maximize their synergy in a non-submodular cascade model, which is in sharp contrast to the seeding strategy in submodular cascade models. Finally, we show that this observation yields a polynomial time dynamic programming algorithm.

4 - The Impact of Network Structure on Price Discrimination

Jiali Huang, University of Minnesota, Minneapolis, MN, 55414, United States, Ankur Mani, Zizhuo Wang

We study the problem of a single seller that can potentially use social network information to provide personalized prices to customers based on their network positions. We show that in large random networks with general degree distributions, the gain in profit under such discriminative pricing (as compared to uniform pricing) depends greatly upon the network structures, and the gain in profit might not be significant. For types of networks with significant gain in profit from discriminative pricing, we propose simple implementable pricing policies that are robust against noisy observations in the networks.

5 - Efficient Polling and Estimation Methods that Exploit Friendship Paradox

Buddhika Nettasinghe, Cornell University, Ithaca, NY, 10044, United States, Vikram Krishnamurthy

We consider the problem of forecasting the outcome of an election between two candidates A and B. We propose a novel neighborhood expectation polling (NEP) strategy that asks randomly sampled individuals: "what is your estimate of the fraction of votes for candidate A?". Hence, in NEP, sampled individuals will naturally look at their neighbors (defined by the underlying network) when answering this question. Hence, the mean squared error (MSE) of NEP methods rely on selecting the optimal set of samples from the network. To this end, we propose algorithms that exploit friendship paradox for selecting samples. Results on the dependence of the MSE of the algorithms on the network properties are presented.

Operations Management/Marketing Interface III

Contributed Session

Chair: Justus Arne Schwarz, University of Mannheim, Schloss Schneckenhof Ost, Mannheim, 68131, Germany

1 - Online Order Fulfillment with Strategic Customers

Chao Liang, Cheung Kong Graduate School of Business, Beijing, China, cliang@ckgsb.edu.cn, Yuxin Chen

We study where an e-tailer should store inventory to fulfill online order: store inventory in local warehouse so the shipping cost (to customer place) is low while the holding cost is high, store inventory in central warehouse so the shipping cost is high but the holding cost is low, or store the inventory in both warehouses. We find that the firm should keep at least some (if not all) of the inventory in local warehouse when customers are myopic. However, when customers are strategic, the option of carrying all the inventory in central warehouse can be optimal. When customers are strategic, interestingly, the firm can suffer as the local holding cost decreases or a product becomes less perishable.

2 - Lot-sizing with Variable Pricing and Strategic Customers

Philippe Chevalier, UCLouvain, Louvain La Neuve, Belgium, philippe.chevalier@uclouvain.be, Alejandro Lamas

We develop a model and algorithm to jointly optimize supply in a lot-sizing environment and demand management through variable pricing with strategic customers. In particular, we study the optimal scheduling of promotions to maximize profits taking into account revenues but also operations costs.

3 - Breaking Bad: An Analysis of Customer Responses to Failures in Online Grocery Retail

Catarina Pinto, INESC TEC / FEUP, Porto, Portugal, cppinto@fe.up.pt, Pedro Amorim

Despite relying on operational excellence to survive, online grocers often fail by delivering orders that mismatch the ones requested. Few studies have evaluated how customers respond to such events in short-term. By analyzing the changes between subsequent orders, we quantify how customers defect. Our results show a reduction in spending immediately after a failure that increases with the number of failed items. We show the impact of failures depends on the type of failure, customer, and product category. Understanding the magnitude and timing of this reaction leads to personalized inventory management and compensation strategies with important consequences for customer satisfaction.

4 - Pricing and Prioritization in a Duopoly with Self Selecting Customers under Low Utilization

Arvind Sainathan, Nanyang Business School, Singapore, Singapore, asainathan@ntu.edu.sg

We use a three-stage game to investigate the competition between two service providers (SPs) offering service with relatively low utilization to impatient and patient customers. In the first stage, the SPs decide whether to offer single service in which customers are seen on a first-come-first-serve basis, or differentiated service with prioritization. In the second stage, they set their prices. In the third stage, customers self-select and make their purchase decisions. We characterize different equilibria, and show how equilibrium service delivery by the two SPs depends on customer heterogeneity and mix of impatient/patient customers.

5 - Managing Sales of a Complex New Product with Competing Salespeople: Free-riding & Synergy Between Brokers

Vahideh Abedi, California State University Fullerton, Fullerton, CA, United States, vabedi@fullerton.edu, Rahul Bhaskar

Purchase of complex new products (e.g. insurance plans) typically depends on customer word-of-mouth both about the new characteristics of the product and about the quality of service of one or more brokers. We show that this leads to synergy and free-riding effects between brokers that has not been explored in the literature. We model this sales process, and validate it from membership data for an insurance product. We measure the synergy and free-riding effects, and show how the resulting model can facilitate decision making in managing the sales force.

6 - Optimal Rollover Strategies for Stochastic Demand and Production

Justus Arne Schwarz, University of Mannheim, Mannheim, Germany, Oktay Karabag, Baris Tan

A firm that regularly introduces new product generations to the market has to manage the transition phase between generations, i.e., the product rollover. The firm has to decide about the offered quantities, the price of the old generation, and the price of the new product generation. We propose a two-stage optimization problem that explicitly considers stochasticity in demand and production. Optimal decisions are obtained analytically. Managerial insights into the optimal selection of rollover strategies and the sensitivity with respect to demand and production variability are discussed. Moreover, we highlight the differences between the results of a deterministic planning approach.

Human Trafficking

Sponsored: Public Sector OR

Sponsored Session

Chair: Kezban Yagci Sokat, Northwestern University, Evanston, IL, 60208, United States

1 - Understanding the Impact of Labor Trafficking

Kezban Yagci Sokat, Northwestern University, IEMS, Evanston, IL, 60208, United States, kezban.yagcisokat@u.northwestern.edu, Nezih Altay

Modern day slavery has become an alarming issue in supply chains. We investigate the company policies on labor trafficking and their impact on company performance.

2 - How Supply Chains Break

Shawn Bhimani, Northeastern University, Boston, MA, 37922, United States

We present an econometric analysis of the types and causes of supply chain failure, including a framework to better predict, prevent and understand catastrophic supply chain disruptions. This is critical for continuity of operations in corporate, military, and humanitarian supply chains, as well as for breaking illegal supply chains.

3 - Modeling Operations of Human Trafficking Networks for Effective Interdiction

Kayse Lee Maass, Assistant Professor, Northeastern University, Boston, MA, 02115, United States, k.maass@northeastern.edu, Thomas Sharkey, Lauren Martin, Christina Melander, Kelle Barrick, Tariq Samad

Network interdiction models are a promising method to disrupt human trafficking networks, yet no high-fidelity node-arc network data currently exists. We discuss our ongoing transdisciplinary quantitative analysis of law enforcement case files and stakeholder interviews to identify unique features of human trafficking networks, including their composition, how they adapt to interdictions, and the dependencies between their physical and cyber networks. We highlight our methods for constructing node-arc network representations from qualitative data sources and future research directions for network interdiction models to adapt for applicability to the human trafficking context.

4 - Drivers' Strategic Refusing Behavior in Competition

Xiaojing Feng, Shanghai Jiao Tong University, Shanghai, China, fengxj89@sjtu.edu.cn

Evidence shows drivers' refusing behavior contributes to high incomes, while it harms refused passengers. We propose an analytical model to capture the refusing behavior of different types of drivers, depict the game dynamics between drivers, and explore the effect of the refusing behavior on social welfare under different regulations.

Big Data V

Contributed Session

Chair: Sareh Nabi, University of Washington, Seattle, WA, 98109, United States

1 - Selecting Interactions in Multiple Regression Models Using Non-Additivity

Sumanta Singha, Indian School of Business, Hyderabad, India, sumanta_singha@isb.edu, Prakash P. Shenoy

In a multiple regression setting, which interaction effects should be included in a model? This is a key research question in statistics. Detecting interaction effects is a challenging due to spurious correlation, multicollinearity, and different meanings of interaction in different fields. The traditional p-value based sequential screening and elimination is computationally intensive and intractable for large number of predictors, besides being less reliable and sometimes misleading. Moreover, this approach often leads to models that are less interpretable. Given these challenges, we propose a novel method of detecting interaction effects using correlation-induced non-additivity.

2 - A Matheuristic to Build Linear Regression Models for Binary Classification

Oliver Strub, University of Bern, Bern, Switzerland, oliver.strub@pqm.unibe.ch

We consider the problem of building linear regression models for the binary classification problem that exhibit various desirable properties such as predictive power, sparsity, limited multicollinearity, robustness, and interpretability. For this problem, we present a matheuristic that employs mixed-integer quadratic programming, lazy constraints, and local search. In a computational experiment, the matheuristic devised, within short computational times, linear regression models exhibiting all desirable properties.

3 - Consumer Loans' First Payment Default Detection: A Predictive Model

Utku Koc, MEF University, Istanbul, Turkey, Turkan Sevgili

A Default Loan (non-performing loan) occurs when there is a failure to meet bank conditions and cannot be repaid in accordance with the terms of the loan which has reached its maturity. In this study, we provide predictive analysis of the consumer behavior concerning a loan's first payment default (FPD) using a real dataset of consumer loans with approximately 600K records from a bank. We use Logistic Regression, Naive Bayes, Support Vector Machine and Random Forest on over-sampled and under-sampled data to build eight different models to predict FPD loans. A two-class Random Forest using oversampling resulted in more than 94% on all performance measures: accuracy, precision, recall, and F1 score.

4 - Distributed Solution of Large-scale Systems of Equations via Accelerated Projection-based Consensus

Navid Azizan, California Institute of Technology, Pasadena, CA, United States, Farshad Lahouti, Salman Avestimehr, Babak Hassibi

Solving a large system of linear equations is a key step at the heart of many algorithms in scientific computing, machine learning, and operations research. When the problem dimension is large, it is necessary to perform the task in a distributed fashion. We consider a setting in which a taskmaster intends to solve a large system of equations with the aide of a number of computing machines. We propose a new algorithm called Accelerated Projection-based Consensus (APC). The convergence rate of the proposed algorithm is shown (both analytically and empirically) to compare favorably with that of alternative distributed methods, such as distributed gradient descent, block Cimmino method, ADMM, etc.

Reliability and Maintenance for Complex Engineering Systems

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Wusun Si

Co-Chair: Wujun Si, Wichita State University, Wichita, KS, 67206, United States

1 - Power System Reliability Enhancement with Corrective Topology Control

Xingpeng Li, University of Houston, 4726 Calhoun Road Room N308, Houston, TX, 77204, United States, xli83@central.uh.edu

The electric power system is the world largest human-made "machine" and it is very important to maintain system reliability for supplying continuous quality electricity to consumers. This work investigates (i) the reliability benefits provided by utilizing the flexibility in transmission networks as a corrective control approach; (ii) how those additional reliability benefits can be transferred into economic benefits in the energy management system (EMS). Numerical Simulations demonstrate corrective topology control of the transmission network can achieve substantial reliability benefits, as well as significant cost savings.

2 - Analytics Approach to Support Health-monitoring and Management of Transportation Infrastructure

Pablo L. Durango-Cohen, Associate Professor, Northwestern University, IL, United States, pdc@northwestern.edu

Motivated by recent technological advances, we describe the development and validation of a statistical framework to support health-monitoring and management of transportation infrastructure. The framework consists of formulation of structural time-series models to explain, predict, and control for common-cause variation, and use of multivariate control charts to detect special-cause variation. We present several examples from an in-service bridge to validate the framework.

3 - Forecasting Infrastructure Impacts for Socially-aware Community Resilience with Heterogeneous Data

Bayan Hamdan, University of Illinois at Urbana Champaign, Urbana, IL, United States, bhamdan2@illinois.edu, Pingfeng Wang

The occurrence of disasters remains a highly unpredictable factor in system performance, especially when predicting the resilience of an overall system. The damage of critical infrastructure (CI) needs to be forecasted in order to allocate resources for refurbishment and to increase the resilience by accelerating the recovery process. The use of social media data in conjunction with operational data of the CI will allow for real-time knowledge of damage states and optimized disaster management. Dynamic Bayesian Networks can be utilized to predict the probability of damage in certain areas by taking in sparse time series data and using historic data to predict damage to CI.

4 - Adaptive Preventive Maintenance Integrated with Job Sequence for Smart Manufacturing

Honghan Ye, University of Wisconsin-Madison, Madison, WI, United States

We focus on a joint scheduling problem that considers corrective maintenance and scheduled preventive maintenance (PM) in a generic flow shop. The objective is to find the optimal job sequence and PM schedule such that the total cost is minimized. Most existing studies on PM schedules are based on a fixed PM interval, which is rigid and may lead to poor performances. To address this issue, our novel idea is to dynamically update the PM interval based on real-time machine ages, such that the maintenance activity coordinates with the job scheduling to the maximum extent. To demonstrate the effectiveness of the adaptive strategy, simulations are conducted and a case study on mining operations is carried out.

5 - Bivariate Degradation Modeling with Long Term Memory Effects

Wujun Si, Wichita State University, 11316 E. Pine Meadow Ct, Wichita, KS, 67206, United States, wujun.si@wichita.edu

With advances in sensor technology, oftentimes more than one performance characteristics can be monitored. Conventional degradation modeling with multiple performance characteristics often ignores long term degradation dependencies. In this work, we present a bivariate degradation modeling method with the consideration of long term degradation dependency, based on which reliability analysis is developed. Simulation and case studies are conducted to validate and demonstrate the proposed model.

Engineering-driven Data Analytics for Complex Systems

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Xiaowei Yue, Virginia Tech, Blacksburg, VA, 24061, United States

1 - Gaussian Process with Input Location Error and Applications to the Composite Parts Assembly Process

Wenjia Wang, SAMSI, Durham, NC, 27713, United States, wenjia.wang234@duke.edu, Xiaowei Yue, Benjamin Haaland, C. F. Jeff Wu

We investigate Gaussian process regression with input location error, where the inputs are corrupted by noise. Here, we consider the best linear unbiased predictor for two cases, according to whether there is noise at the target untried location or not. We show that the mean squared prediction error does not converge to zero in either case. We investigate the use of stochastic Kriging in the prediction of Gaussian processes with input location error. We show that stochastic Kriging is a good approximation when the sample size is large. Several numerical examples are given to illustrate the results, and a case study on the assembly of composite parts is presented.

2 - Active Learning for Gaussian Process Considering Uncertainties with Application to Shape Control of Composite Fuselage

Xiaowei Yue, Virginia Tech, Blacksburg, VA, 24061, United States, xwy@vt.edu, Yuchen Wen, Jeffrey Hunt, Jianjun Shi

In the machine learning domain, active learning is an iterative data selection algorithm for maximizing information acquisition and improving model performance with limited training samples. The existing active learning methods do not incorporate engineering uncertainties (e.g., measurement errors and intrinsic input noise) for Gaussian process. In this paper, we propose two new active learning algorithms for the Gaussian process with uncertainties, which are variance-based weighted active learning algorithm and D-optimal weighted active learning algorithm. Through numerical study, we show that the proposed approach can realize better prediction performance.

3 - Discovering Structure in Longitudinal Data via Coefficient Tree Regression

Ozge Surer, Northwestern University, Evanston, IL, 60201, United States, ozgesurer2019@u.northwestern.edu, Daniel Apley, Edward C. Malthouse

When the data have a spatial and/or temporal component, we often expect that predictor variables that are closer in space and/or time are more likely to be associated with the response in the same way. In such situations, we can exploit those aspects and discover groups of predictors that share the same coefficient according to their spatial and/or temporal proximity. In this study, we propose a new algorithm called coefficient tree regression for longitudinal data to understand the underlying spatial and/or temporal characteristics of the data.

4 - Design and Analysis of Experiments of Tissue-mimicking Meta-structure with Application to Personalized Heart Surgery Planning

Jialei Chen, Georgia Institute of Technology, Atlanta, GA, United States, jialei.chen@gatech.edu, Simon Mak, Roshan J. Vengazhiyil, Chuck Zhang

3D-printed medical phantoms, which use synthetic metamaterials to mimic biological tissue, are becoming increasingly important in urgent surgical applications. However, the mimicking of tissue mechanical properties via 3D-printed metamaterial can be quite difficult and time-consuming. We propose a novel functional-input, functional-output, SpeD emulation model for efficient tissue-mimicking. The proposed emulator model can provide much quicker and more accurate tissue-mimicking performance, compared to existing methods in the medical literature. We then demonstrate the effectiveness of our SpeD emulator in a real-world study on mimicking human aortic tissue.

Data Fusion for Improved Decision Making

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Mahboubeh Madadi, San Jose State University, Louisiana Tech University, Ruston, LA, 71272, United States

Co-Chair: Anahita Khojandi, University of Tennessee, Knoxville, TN, 37996, United States

1 - A Combined Approach of Change Point Detection and Remaining Useful Life Prediction Based on Double Long Short-term Memory Networks

Zunya Shi, University of Michigan-Dearborn, Dearborn, MI, United States, zunyas@umich.edu, Abdallah A. Chehade

Remaining useful life (RUL) refers to the time left that a system will no longer perform functions. RUL prediction is essential to maintenance scheduling. Due to advanced sensing technologies, large-scale sensor signals can be collected. Among these signals, change points usually exist, indicating the increase of the failure probability. Such information should be considered when predicting the RUL. Therefore, a combined approach of change point detection and RUL prediction using the double long short-term memory (LSTM) networks is proposed in this paper. This new approach is proved to be effective on the turbofan engine degradation simulation dataset carried out by C-MAPSS in the case study.

2 - A Dynamic “Predict and Store” Approach for Renewable Energy

Romesh Saigal, University of Michigan, Ann Arbor, MI, 48103, United States, J. Wang, A. AlSelahi, S. Chung, R. Al Kontar, Eunshin Byon

We explore the use of battery sets to solve the uncertainty from the renewable energy production and the customers’ demand. We propose a stochastic convex program to determine the amount of energy charged into or withdrawn from the battery. The objective is to minimize the expected cost from excess production and shortfall. An iterative approximation algorithm is developed to solve the stochastic convex program. A case study using California Independent System Operator confirms that the resulting battery charge/discharge decision can stabilize the integrated output, neutralizing the volatility of both the renewable energy generation and the demand.

3 - Optimizing Condition-Based Maintenance for Systems with Degrading Sensors

Mahboubeh Madadi, San Jose State University, College of Engineering and Science, PO Box 10348, San Jose, CA, 71272, United States, Anahita Khojandi

We consider a degrading system with silent failures. System failure is costly and it requires an immediate system replacement. The system status can be partially observed using a series of heterogeneous sensors at a given cost. The sensors are not only noisy, but also are prone to degradation themselves, and hence, the sensor noise level is a function of the sensor status. We develop a POMDP model to determine the optimal condition-based maintenance scheme to minimize the total expected discounted cost over an infinite horizon.

4 - Real-Time Sensor Anomaly Detection and Recovery in Connected Automated Vehicle Sensors

Yiyang Wang, University of Michigan, Ann Arbor, MI, United States, Neda Masoud, Anahita Khojandi

In this talk we propose a novel observer-based method that combines signal filtering and anomaly detection together to improve the safety of connected and automated vehicles (CAVs). Specifically, we use extended Kalman filter (EKF) to smooth sensor readings, in which we utilize the leading vehicle’s information to detect sensor anomalies by using trained One Class Support Vector Machine, and a communication time delay factor is considered. Experiments show that compared with the EKF with a traditional fault detector, our method achieves a better anomaly detection performance. They also demonstrate that a larger time delay factor has a negative impact on the overall detection performance.

Vaccine Supply Chains

Sponsored: Health Applications

Sponsored Session

Chair: Zahra Azadi, University of Miami Business School, Coral Gables, FL, 33146, United States

1 - Optimization of Pediatric Vaccine Distribution Network Using Chance Constraint Programming

Zahra Azadi, University of Miami Business School, Coral Gables, FL, 33146, United States, zazadi@bus.miami.edu, Sandra D. Eksioglu

We propose a stochastic optimization model that identifies distribution strategies for vaccine vials in developing countries. This is a data driven model which is developed using real life data from Niger. The model captures uncertainties of demand for vaccination via chance constraints. A sample average approximation (SAA) method is used to solve the problem. A comprehensive sensitivity analysis is conducted to evaluate the impact of (i) changing the hierarchy of vaccine distribution network, (ii) changing vaccine vial size from multi-dose to single-dose, and (iii) replacing regular vaccines with dual chamber and thermostable on immunization coverage.

2 - Pricing Strategies in the United States Pediatric Vaccine Market

Banafsheh Behzad, Assistant Professor, California State University, Long Beach, 1250 Bellflower Blvd, MS 8506, Long Beach, CA, 91101, United States, banafsheh.behzad@csulb.edu, Kayla Cummings, Susan E. Martonosi

Pricing strategies in the United States pediatric vaccines market are studied using a game theoretic approach along with an optimization model. The game analyzes the competition between asymmetric, capacity-constrained manufacturers (i.e., manufacturers with unequal and limited production capacities) producing differentiated products in a market with linear demand. The optimization model from the CDC’s perspective minimizes negotiated government costs while ensuring adequate national vaccination levels, linking dynamics in public and private sectors, and incorporating competitive manufacturer behavior.

3 - Modeling Outreach for Who-EPI Vaccine Distribution

Yuwen Yang, University of Pittsburgh, Pittsburgh, PA, 15213, United States, Jayant Rajgopal

In many low and middle-income countries with geographically dispersed or nomadic populations, last-mile vaccine delivery can be extremely complex. Without convenient access to clinics and hospitals, an approach known as outreach is typically utilized. A set of remote population centers is chosen, and over an appropriate time horizon, clinical teams are sent from a depot to set up mobile clinics at these locations to vaccinate people in the immediate surrounding area. We present and discuss a model that is a combination of a set covering problem to choose mobile clinic locations and assigning population centers to them, and a vehicle routing problem to select routes to visit these mobile clinics.

4 - An Or-based Hypothetically Coordinated Vaccine Market

Ruben Proano, Rochester Institute of Technology, Gleason College of Engineering, 81 Lomb Memorial Drive, Rochester, NY, 14623, United States, rpmeie@rit.edu

This study presents a hypothetically coordinated vaccine market where coordinating entities rely on an optimization-based process to make procurement decisions on behalf of buyers grouped in market segments to ensure affordability and profitability. We illustrate the effect of several experimental factors on affordability. Results show that increasing the number of market segments per coordinating entity increases welfare and that having entities with few markets to support favors low-income affordability. This study shows the implications of this study on optimal market segmentations for low-income and middle-income countries.

Cancer Treatment Plan Optimization

Sponsored: Health Applications

Sponsored Session

Chair: Ehsan Salari, Wichita State University, Wichita State University, Wichita, KS, 67260, United States

1 - Integrating DVH Constraints and Beam Angle Optimization into Automated Radiotherapy Treatment Planning

Masoud Zarepisheh, Memorial Sloan Kettering, New York, NY, 10017, United States, Linda Hong, Sovanlal Mukherjee, Vicki Taasti, Joseph Deasy

This study automates IMRT treatment planning by formulating that as a hierarchical constrained optimization problem (also known as prioritized optimization). We introduce a 2-phase technique to handle the DVH constraints efficiently, where the first phase solves an optimization problem with a convex relaxation version of the DVH constraints. The second phase then imposes maximum dose constraints on the low dose voxels identified in the first phase which guarantees the DVH constraints satisfaction. We also show how the Bayesian Optimization technique can be used to optimize the beam angles.

2 - Towards Optimal Stopping of Radiation Therapy Through Dynamic Information Flow

Ali Ajdari, Research fellow, Harvard Medical School & Massachusetts General Hospital, Boston, MA, 02115, United States, aajdari@mgh.harvard.edu, Thomas Bortfeld

In the era of precision medicine and personalized radiation therapy, there is an ever-growing need to tailor the treatment plans to individual patient's radiosensitivities. Optimal Stopping in Radiotherapy (OSRT) is a novel approach in which treatment plans for each individual patient get adapted midway through the treatment course, using information provided by predictive biomarkers. Using dynamic programming and predictive modeling, we investigate the effect of dynamic information flow on the performance of OSRT, and show how the frequency, quality, and the timing of information acquisition can affect the therapeutic window, and the subsequent adapted plans.

3 - A Control-theoretic Framework for Real-time Organ Motion Management in Radiation Therapy

Seyed Ali Mirzapour, Wichita State University, Wichita, KS, 67220, United States, mirzapour.ie@gmail.com, Thomas Mazur, Gregory Sharp, Ehsan Salari

Internal organ motion during irradiation is a major concern in the treatment of thorax and abdominal cancers. A recent development is the advent of radiotherapy devices with an on-board MRI scanner, capable of providing a real-time view of the patient anatomy with a high temporal resolution during radiation delivery. This research aims at developing a control-theoretic framework that uses real-time MRI information to monitor and correct the radiation delivery progress in real time. This is achieved by continuously estimating the cumulative deposited dose during irradiation, which serves as a feedback signal for a stochastic control problem to dynamically adjust the treatment plan if warranted.

4 - A Risk-based Modeling Approach for Radiation Therapy Treatment Planning under Tumor Shrinkage Uncertainty

Saba Ebrahimi, University of Houston, Houston, TX, 77054, United States, sebrahimi@uh.edu, Gino J. Lim, Wenhua Cao, Laleh Kardar

We proposed a risk-based robust approach using CVaR representation of dose-volume constraints to mitigate the risk and achieve risk-averse. Our results showed that the proposed approach outperformed conventional robust optimization in terms of dose variability and control on the worst-case scenarios while delivering the prescribed dose to the tumor target and sparing organs at risk.

5 - Multi-modality Radiotherapy Optimization

Roman Levin, University of Washington, Seattle, WA, United States, rilevin@uw.edu, Aleksandr Y. Aravkin, Minsun Kim

Radiotherapy is used to treat cancer patients using ionizing radiation to damage the tumor. X-rays are the most widely used radiation modality, however, there is a growing interest in using other radiation types, e.g.protons, due to their unique dosimetric and biological properties. Current attempts to determine an optimal radiation modality or a combination of modalities are mostly empirical. We propose a novel mathematical framework to maximize the damage to the tumor while sparing normal tissue in the multi-modality setup. We develop algorithms to efficiently solve the underlying non-convex optimization problem and find the optimal radiation dose distributions with the number of fractions.

Illicit Supply Chain in Healthcare

Sponsored: Health Applications

Sponsored Session

Chair: Naoru Koizumi, George Mason University, Arlington, VA, 22201, United States

Co-Chair: Monica Gentili, University of Louisville, Louisville, KY, 40292, United States

1 - Identification of Functional Entities Engaged in Sale and Distribution of Illicit Commodities

Saurav Kumar Dubey, PhD, South Dakota School of Mines and Technology, Rapid City, SD, United States

A functional entity is defined as an organization or a group of people performing a critical task that serve as a vital link in the sustainment and resiliency of an illicit supply chain (ISC). The focus of this study will be to identify such entities and propose an allocation model that would assist law enforcement agencies with deployment of constrained fiscal resources to maximize impact of interdiction efforts. The proposed model will assign relative numerical importance or weights to ISC members comprising of Manufacturer, Wholesaler, Distributor and Retailer. To validate the proposed model, flow of illicit commodities in the healthcare industry will be the subject of investigation.

2 - A Preliminary Analysis of Illicit Kidney Sales in Developing Countries

Monica Gentili, PhD, University of Louisville, Louisville, KY, United States, monica.gentili@louisville.edu

The illicit organ sales network system often consists of multiple players, typically involving organ (mostly kidney) sellers, buyers, transplant service providers, brokers and financial institutions that pass money from organ buyers to other actors. Inter-actor social networks are inherent in organ trafficking. However, no rigorous analysis has been applied thus far to investigate the system. We present some preliminary results in this context related to the analysis of illicit organ sales in Bangladesh.

3 - A General and Adaptive Approach to Studying Falsified Pharmaceutical Supply Chains

Eugene Wickett, Northwestern University, Evanston, IL, United States, eugenewickett2022@u.northwestern.edu, Reut Noham, Karen Smilowitz

Falsified and substandard drugs constitute at least 10% of supplies in low- and middle-income countries, driving high levels of mortality and morbidity from otherwise preventable causes. We develop a general and adaptive approach to understand the conditions under which low-cost detection devices can be used to detect falsified and substandard pharmaceuticals. The flexible structure described allows stakeholders to ascertain the limitations and feasibility of sample testing policy for a particular drug before committing valuable resources.

4 - Analysis of Illicit Kidney Trade Networks

Naoru Koizumi, George Mason University, School of Public Policy, 3351 North Fairfax Drive, Arlington, VA, 22201, United States, nkoizumi@gmu.edu, Abu Bakar Siddique, Amit Patel, Brian Wilson

The transnational transplant tourism has been on the rise. Several regional hubs are emerging in recent years. The kidney trade networks tend to be complex involving transnational actors of buyers, sellers, brokers and surgeons. However, this field lacks scientific tools and empirical data that can help understand the extent of the problem. We developed an algorithm to gather data from newspaper articles about the regional hubs of kidney trade and then identified the factors determining the country networks.

Reliability II

Contributed Session

Chair: Carlos Solorio, IENAC/CETYS, Calexico, CA, 92232-4184, United States

1 - Reliability Analysis and Modeling of Concrete Bridge Decks

David W. Coit, Rutgers University, Piscataway, NJ, United States, coit@soe.rutgers.edu, Nooshin Yousefi, Hani Nassif, Jian Zhou

Degradation modeling is an important issues for reliability analysis and failure prediction. We develop a stochastic degradation model for corrosion deterioration of a concrete bridge deck with different types of steel reinforcement. Various parameters such as crack width, crack depth and Sodim chloride concentrations as the environment stress are the most important factors to be considered for the stochastic degradation modeling. For different types of steel reinforcement and Sodium chloride concentrations, the time for corrosion initiation and propagation is different. The proposed degradation model is used to analyze the reliability and predict the failure time of concrete bridge deck.

2 - Covariate Selection Considering Measurement Error with Application in Accelerated Life

Samira Karimi, University of Arkansas, Fayetteville, AR, United States, sakarimi@uark.edu, Haitao Liao

Unimportant covariates and measurement error in important covariates are common issues faced by practitioners. The errors and irrelevant information may decrease the precision and accuracy of the estimates of interest while significantly wasting computational efforts. Despite the extensive studies on Accelerated Life Testing (ALT), the presence of measurement errors in covariates of ALT data has not received much attention. Using Measurement Error Boosting algorithm, in this work, a number of widely used distributions in reliability, including Weibull and Lognormal, are studied for covariate selection and measurement error elimination.

3 - Statistical Modeling of Multivariate Destructive Degradation Tests with Blocking

Qiuzhuang Sun, National University of Singapore, Singapore, Singapore, qiuzhuang.sun@u.nus.edu, Zhi-Sheng Ye, Yili Hong

In degradation tests, test units are usually divided into groups. Due to block effects, degradation differs among blocks but is more homogeneous within a block. Motivated by an application of emerging contaminants, this study proposes a multivariate statistical model to account for the two-layer block effects in destructive degradation tests. Through a case study, we show the existence of the block effects from a proposed test. Decision-makers can then readily make risk assessment of each contaminant and determine the minimal water treatment time for their removal by using the proposed model.

4 - Planning Accelerated Degradation Tests with Two Stress Variables

Guanqi Fang, Arizona State University, Tempe, AZ, United States, gfang5@asu.edu, Rong Pan, John Stufken

In this talk, a methodology to provide optimal design for accelerated degradation tests with two stress variables will be given. Decisions including selecting the stress levels with the corresponding test unit allocation are to be made. It will be demonstrated using a real optical media industrial dataset.

5 - Data Intensive Industrial Asset Management for Distributed Energy Resources

Hamid Seifoddini, University of Wisconsin-Milwaukee, Milwaukee, WI, United States, Farhad Balali, Adel Nasiri

The reliability of the electrical networks significantly impacts customer as well as energy providers' bottom line. Prognostics and Health Management (PHM) becoming a critical factor in the efficiency of the energy sector. Degradation based analysis is one of the valuable approaches to condition-based algorithms in order to obtain reliability information. The main purpose of the degradation-based models is to predict the future condition of the asset and perform the maintenance in an optimized time window. The methodologies of the General Path (GP) and Autoregressive(AR) models as robust degradation models would be discussed in detail.

6 - Multi-state System Reliability Subject to Multiple Failure Modes.

Carlos Solorio, CETYS University, Mexicali, Mexico, carlos.solorio@cetys.mx

This research studies the reliability of complex multi-state engineering systems that suffer multiple failures caused by common degradation of physical systems and catastrophic failures caused by sudden shocks. A reliability model is presented based on multi-state systems with multi-state components, the reliability of the system is computed based on the state of the components. New performance measures for the system are presented considering component degradation at any level and the disutility function is incorporated. The proposed reliability model can be used directly or customized to many complex systems that experience degradation due to wearing and sudden shocks.

Health Care, Processes

Contributed Session

Chair: Kleber Esposto, Universidade de Sao Paulo, R Douvidor Cunha 116, Sao Carlos, 13569580, Brazil

1 - Patient Flow Improvement at the Emergency Department of a Local Hospital through Simulation Modeling

Hongyi Chen, University of Minnesota Duluth, Duluth, MN, United States, honchen@d.umn.edu

A two-stage simulation model was developed to help improve the patient flow in the ED of a local hospital in Duluth, Minnesota. In the first stage, a general model was built focusing on verifying bottlenecks perceived by the ED physicians and staffs. In the second stage, a detailed model was built to further identify bottlenecks and test impacts of process changes proposed by the vertical triage team at the hospital. Seeing great improvement to the patients' door-to-bed time as forecasted by the simulation model, a new process called JET was implemented in the ED. Performance metrics acquired after the implementation of JET validated the forecasts from the simulation model.

2 - Impact of Patient Complexity on Patient Flow in EDs

Seung Yup Lee, University of Calgary, Calgary, AB, Canada, seungyup.lee@haskayne.ucalgary.edu, Marco Bijvank

ED patient condition entails two notions, urgency and complexity. While the notion of urgency is well established, referring to the clinical priority of a patient, complexity is an immature concept that could bring significant operational implications on ED care delivery. We characterize patient complexity levels by proposing a measurement method designed by a system-wide study on operational/clinical data from four different EDs and report operational insights. The results provide a novel view point on decision makings (e.g., patient selection) in managing clinical needs of ED patients.

3 - The Role of Team Familiarity to Improve Surgical Team Performance in Operating Room

Jaeyoung Kim, Clemson University, Clemson, SC, United States, jaeyouk@clemson.edu, Lawrence Fredendall, Robert Allen, Marissa L. Shuffler, Dana Verhoeven

This study examines the impact of team familiarity (team experience working together in the past) on surgical team performance using a perioperative dataset from a major local hospital system. First, the existing team familiarity measurements are reviewed, and appropriate measures of team familiarity of surgical teams in operating room are selected. Next, the case-level perioperative data such as scheduled procedure durations and actual procedure durations are analyzed to identify how team familiarity affects surgical team performance.

4 - Blockchain in Healthcare: How Smart Contracts Can Change Prescriptions

Leston Alvarez, Researcher, University of Lethbrisge, AB, Canada, Lethbridge, AB, Canada, Afrooz Moatari-Kazerouni

Healthcare sector is lagging behind when it comes to adopting with technology advancements. Blockchain being one of the current leading technologies, within this research, the blockchain technology is examined in the context of smart contracts for replacing paper prescriptions. The idea of utilizing blockchain for allowing doctors, clinics and patients to create smart contracts for simpler transactions is explored. The current method of organizing data is inefficient to what could be potentially resolved by implementation of blockchain technology. The solution of blockchain could prevent medical mistakes and misplacements of healthcare data within the current system.

5 - Utilization of System Modelling Techniques in Lean Healthcare Applications

Raja Jayaraman, Khalifa University of Science & Technology, Abu Dhabi, United Arab Emirates, raja.jayaraman@ku.ac.ae, Mecit Can Emre Simsekler, Maitha AlKaabi, Kudret Demirli, Emin Murat Tuzcu

There is an increasing awareness on the utilization of lean in healthcare to implement waste-free operational processes. Another potential approach that can be merged with lean is systems approaches, such as System Modelling Techniques (SMTs), to help identify comprehensive list of wastes in a systematic way. To investigate the potential linkage between lean and SMTs, this paper reviews the literature in the field and provides a conceptual framework between these two complementary approaches.

6 - Literature Review of Critical Success Factors for Lean Healthcare Sustainability

Kleber F. Esposto, USP - Universidade de São Paulo, Sao Carlos, Brazil, kleberesposto@usp.br, Debora Helal, Rapinder Sawhney

According to literature review conducted for this study, little has been addressed about sustainability of lean healthcare improvements. In this way, this paper aims to review the critical success factors for lean sustainability in healthcare settings reported in literature. To accomplish that, a compilation of critical success factors of lean and lean healthcare was carried out, where 47 articles with 231 critical success factors were analyzed and grouped into 17.

Green Manufacturing and Operations/ Finance Interface

Contributed Session

Chair: Tiffany Zhu, University of Pittsburgh, Pittsburgh, PA, 15232, United States

1 - Quality and Productivity Trade-off in Powder-bed Additive Manufacturing

Huseyin Kose, University of Tennessee, Knoxville, TN, United States, Mingzhou Jin

Quality and productivity are the two key concerns in Powder-bed AM processes. Because of keyhole and porosity formation occurring in the object's structure, quality is considered a difficult factor to manage. Focusing only improving quality could result in high building cost. In this study, outcomes obtained from previous studies were combined in a systematic way to create an empirical model to optimize major process parameters to make a trade-off between quality and productivity. The lowest building cost obtained in case study among other studies selected from literature. Results showed how empirical model is effective on minimizing building cost by maximizing productivity at any quality level.

2 - Improving Product Service Systems through Modular Architecture

Johnson Adebayo Fadeyi, University at Buffalo, Buffalo, NY, United States, jfadeyi@buffalo.edu, Leslie Monplaisir

Manufacturers are moving from product selling towards product service system (PSS). It is argued that PSS enhances environmental sustainability because fewer products are required for extensive usage, thereby reducing resources consumption. However, products with high environmental impact at the "use phase" will not realize this objective. Therefore, it is essential to consider the eco-indices of the products' parts during product development. This study determines the eco indicators of module variants and identifies the product architecture that enhances environmental sustainability. The study provides product configuration decision guide to the original equipment manufacturer.

3 - Market Reactions to Changing Fuel Efficiency Standards

Caroline Swift, PhD Student, The Pennsylvania State University, University Park, PA, United States, cas669@psu.edu, V. Daniel R. Guide, Suresh Muthulingam

We use publicly available financial information to understand stock market reactions to changes in automobile fuel efficiency standards. We analyze how market valuations differ across affected industries and manufacturers' product line composition.

4 - Milestone-Based Supply Chain Finance

Yuxuan Zhang, PhD, Tsinghua University, Beijing, China, Hau L. Lee, Christopher S. Tang, S. Alex Yang

This study examines the value of information updating in a milestone-based supply chain finance scheme. We find that the value of information increases as the trade process becomes more reliable, and as the value of the traded goods increases significantly as the order successfully passes the milestone. The value of information becomes also higher as the bank's cost of equity increases.

5 - A Real Option Theory of Financial Hedging and Operational Flexibility

Chenchen Di, UIUC, Champaign, IL, United States, cdi2@illinois.edu, Arkadiy Sakhartov

This paper investigates the relationship between financial hedging and operational flexibility. Using a formal model, we show that whether financial hedging and operational flexibility are substitutes or complements depends on the inducements including return volatility, redeployment cost and risk aversion. The model provides an integrated framework and rationale to reconcile the tension about the relationship between financial hedging and operational flexibility.

6 - The Impact of Board Diversity on Corporate Social Responsibility and Operating Efficiency

Tiffany Zhu, University of Pittsburgh, Pittsburgh, PA, United States, zhz90@pitt.edu

More and more studies have shown that board diversity affects the firm's performance. Nowadays, shareholders pay more attention to board diversity. This study empirically examines how the diversity of a firm's board members affect its Corporate Social Responsibility performance and operating efficiency. We use cross-country firm-level data and explore board diversity on the dimensions of gender, race, age, tenure, power, expertise, insider-outsider ratio, education, experience, network connections among board members, and nationality.

Supply Chain Management and Remanufacturing

Contributed Session

Chair: Morteza Alizadeh, Mississippi State University, Starkville, MS, 39759, United States

1 - Product Recovery Decision-making in the Context of Internet of Things: A Review and Generic Roadmap

Xianghui (Richard) Peng, Assistant Professor, Penn State Erie The Behrend College, Erie, PA, United States, xzp17@psu.edu, Kai Meng, Ying Cao, Victor R. Prybutok

We provide a state of the art review on End-of-Life (EOL) product recovery decision-making in the context of Internet of Things. We contextualize an implementation framework to enable sustainable EOL product management based on enriched information. We propose a generic roadmap for model and methodology selection to assist practitioners.

2 - Research on Recovery Model of Closed Loop Supply Chain for Electronic Products in Online to Offline Model

Dong Yang, Xidian University, Xi'an, Shaanxi, China, xjtuyd@163.com

Compared with the traditional closed loop supply chain recycling model, the selection strategy of the manufacturing enterprises and consumers has changed in the O2O model. The steady state equilibrium values of two models are given by constructing the closed loop supply chain recovery model of consumer electronics products under the dominant model of manufacturing enterprises or O2O platform. The results show that the government subsidies, the recycling price, quantity and instantaneous profits gradually increased over time. Recovery costs, except the recovery prices, will affect the recycling model choice of manufacturing enterprises.

3 - Robust Design of Bioenergy Supply Chain Network under Multidimensional Uncertain Environment

Qiaofeng Li, Tsinghua University, Beijing, China, lqf16@mails.tsinghua.edu.cn, Jingran Liang, Zhihai Zhang

Bioenergy is one of the rapidly growing renewable energy worldwide. The investment in bioenergy is expected to increase in the future. This article investigates strategic recycling network planning for bioenergy supply chain under multiple uncertainties to minimize the total cost. Extensive numerical experiments are conducted. And, an industrial case study is considered to illustrate that the proposed approach is efficient.

4 - Sustainable Supply Chain Performance: A Relational View

Gopal Kumar, Assistant Professor, IIM Raipur, Raipur, India, gopalkumar@iimraipur.ac.in, Purushotam L. Meena, Rita Maria Di Francesco

By focusing on partnering capabilities, this study explores the need to build capabilities to cope with the fast-changing business environment to achieve supply chain sustainability. This study underlines collaboration, capabilities, and commitment in developing triple-bottom line (TBL) performance. Empirical analysis shows that collaboration, culture, and commitment play a crucial role in building capabilities, which in turn achieve TBL performance. Culture- and commitment-related traits are strong for downstream collaborating firms.

5 - Marine Debris Collection Ship Routing Problem

Morteza Alizadeh, Graduate Research Assistant, Mississippi State University, Starkville, MS, United States, ma1845@msstate.edu, Gang Duan, Farjana Nur, Mohammad Marufuzzaman, Junfeng Ma

We propose an overall framework to collect debris throughout ocean in three phases. First phase determines initial locations of debris using satellite imagery with remote sensing. Wind and ocean currents drift debris to other locations. Second phase uses GNOME to predict momentary trajectory of debris. Third phase develops a ship routing optimization model to collect and remove debris from ocean. Due to provisional debris locations, hard time window is set debris locations that restricts ships to reach debris locations within a certain time range. Carbon cap policy is applied to minimize carbon emissions of ships. Results reveal capability of proposed framework in handling marine debris problem.

Cost Analysis and Inventory Management

Contributed Session

Chair: Xiaotong Liu, Tsinghua University, Nanshan Distrct, Shenzhen, 518055, China

1 - Selecting Between Batch and Batch Synchronized Zone Picking Considering Learning Effects

Jun Zhang, Central China Normal University, Wuhan, China, zhangj@mail.ccnu.edu.cn

We compare batch picking and batch-synchronized zone picking strategies. To better predict picking performance and more accurately evaluate the picking efficiency of the two strategies, pickers' learning effects are considered. We formulate the batch generation and batch assignment models with learning effects to minimize the total service time. The improved batching methods are proposed to solve the batch models, and a series of experiments are addressed to compare the picking efficiency. The results show that when pickers have good learning abilities, although batch picking performs better at beginning, batch-synchronized zone picking can surpass it after several days' learning.

2 - A Cost and Performance Optimisation Model Proposal for Integrating Predictive and Scheduled Maintenance in Aviation

Danilo G. Pinto, Maj Engr. MSc, ITA (Technological Institute of Aeronautics), Sao Jose dos Campos, Brazil, danilodf@ita.br, Fernando T. Abrahão

The full realisation of the potential benefits offered by IVHM (Integrated Vehicle Health Management) technologies requires yet the harmonisation of predictive and preventive maintenance tasks in a single plan. In this sense, an unprecedented optimisation model is proposed for minimising cost and downtime while also taking into consideration the uncertainties involved in Remaining Useful Life (RUL) forecasts. The method encompasses all relevant parameters in order to combine the two types of maintenance in a unified framework that is intended to support decision over which activities should be performed according to prognostics and which should be left in preventive maintenance packages.

3 - Total Cost of Ownership Analysis for Power Battery Consumer under Charging Modes

Chunyan Duan, Tongji University, Shanghai, China, duanchunyan77@163.com, Xiaoyue You, Qiang Chen, Mengmeng Shan

To analyze the total cost of ownership for power battery consumer, charging modes must be considered. We conducted a sensitivity analysis of total cost of ownership for power battery consumer under the fast charging and slow charging modes by taking the power battery of a private consumer's electric vehicle as an example. These results provide positive supports consumers' decisions, manufacturers' decisions and so on.

4 - Cycle Costs in Continuous Review Inventory Control

Dincer Konur, Texas State University, San Marcos, TX, United States, d_k141@txstate.edu, Gonca Yildirim

In this study, we consider cycle costs in the analysis of continuous review inventory control models. In particular, we first investigate a (Q,R) model with the objective of minimizing the maximum cycle cost possible. Then, a bi-objective model is presented to minimize both the expected cost per unit time and the maximum cycle cost possible. An extensive set of numerical analyses demonstrate the benefits of the proposed methods.

5 - Deployment Model with Network Inventory

Nayeon Kim, PhD Candidate, Georgia Institute of Technology, Atlanta, GA, United States, nkim97@gatech.edu, Benoit Montreuil, Walid Klibi

We model dynamic inventory deployment over an open distribution network in North America under service level requirements with network inventory. The model allows multi sourcing, flexible order allocation and lateral transshipment. The proposed model is evaluated by being compared to alternative deployment and inventory control models and distribution networks.

6 - Analysis of Logistics Service Supply Chain for the One Belt and One Road Initiative of China

Xiaotong LIU, Tsinghua University, Shenzhen, China, tju_lxt@163.com

This paper explored the supply chain coordination issues arising from the One Belt and One Road initiative (OBOR), and investigated the impacts of the cost sharing contract on the key decisions for logistics service supply chain with mass customization. As a result, several key managerial insights were discovered in our modeling study. More importantly, the impacts of cost-sharing on the key decisions of each player was analyzed in details, and the interaction mechanism of mass customization was also estimated. From our perspective, it will be indeed beneficial to improving logistics service in the OBOR region.

1 - An Analysis of Consumers' Attitudes Toward Smart Home Internet of Things Privacy Risks

Daeeun Choi, Virginia Tech., Blacksburg, VA, United States, dechoi@vt.edu, Paul Benjamin Lowry

This study analyzes consumers' attitudes toward privacy, of those who might potentially purchase smart home Internet-of-things (IoT) products. We conducted random scraping and cleaning of IoT privacy-related data via Google search, and analyze them with sentiment analysis and machine learning methods. To automatically collect and analyze the data, we used Python with textblob and the natural language processing toolkit. The results suggest that consumers tend to ignore privacy risks toward IoT technology. This outcome will be tested via a survey research to measure the consumers' attitude toward privacy of IoT.

2 - Wearables and Health Behavior Change: A Qualitative Investigation of Barriers

Madhav Sharma, Spears School of Business, Stillwater, OK, United States, madhav.sharma@okstate.edu

Wearable technologies are becoming increasingly pervasive and advanced. With sustained market share and rapid advancements in design, wearables have the potential to be the information system that can bring about a significant change in user's lifestyle and healthcare behaviors. The goal of this research is to create a deeper understanding of the factors inhibiting the relationship between use of wearables and health behavior change using an interpretivist approach. In this paper, we qualitatively identify barriers and attempts to overcome the said barriers via interviewing participants with varying degree of context knowledge.

3 - The Role of Media Richness, Victim-offender Relationship, and Demographic Characteristics in Cyberbullying: A Country Wide Investigation

Zhuojian Jia, Nanyang Technological University, Singapore, Singapore, Mariana G. Andrade-Rojas, Lai Lai Tung

We examine the relationship of media richness and victim-offender relationship with intensity of victim's responses in cyberbullying. We analyze a country-wide survey of more than 13,000 responses. Using multinomial logistic models, we find that victim responses become more active with greater media richness or offender intimacy. Factors including gender, age, and cyberbullying frequency show significant moderating effects. This project is funded and supported by Nanyang Technological University under the Undergraduate Research Experience on CAmpus (URECA) programme.

4 - Interpersonal Social Media Uses: Within-person and Between-person Relationships with Citizenship Behavior and Job and Life Satisfaction

Kriti Chauhan, University of Louisiana - Monroe, Monroe, LA, United States, chauhan@ulm.edu, Sridhar P. Nerur, Marcus Butts

Social media use during work has become commonplace. This study explores within-person and between-person relationships among different types of social media uses with employee citizenship behavior and job and life satisfaction. The three types of interpersonal social media use examined in this study are private - interacting with friends and family, professional - interacting with work colleagues, and public - interacting with others online. Nature and strength of relationships differs by type of social media use and the level of analysis. Multilevel modeling is carried out on experience sampling data from 91 people over three weeks.

5 - An Examination of the Impact of Health Information Technology on Knowledge Transfer Across Hospitals

Onyi Nwafor, University of North Carolina at Greensboro, Greensboro, NC, United States, Xiao Ma, Norman Johnson

A widely-accepted tenet of the organizational learning literature is that the technological ties between organizations can facilitate knowledge transfer between them. However, there is little empirical evidence to support this notion. Moreover the literature provides little insight on the mechanisms by which technological ties between organizations can facilitate knowledge transfer. Using a sample of hospitals organized in healthcare systems as a point of reference, we examine the impact of health information technology (HIT) ties on knowledge transfer and consider the relative impact of various attributes of the HIT ties between the hospitals that may explain measured knowledge transfer.

6 - Requirement Engineering: Elicitation and Validation for Small and Medium-sized Enterprises

Mahdi Boucetta, Mississippi State University, Starkville, MS, United States, mb3736@msstate.edu, Raed Jaradat

The uncertainty of customers' demands require small and medium-sized enterprises (SMEs) to be more responsive and resilient and also achieve better prosperity and recognition. This research addresses the problem of introducing systems with integrated management applications of SME-type enterprises. In particular, we consider the main phase of this project as the Requirements Engineering phase.

Sponsored: Information Systems

Sponsored Session

Chair: Antino Kim, Indiana University, Bloomington, IN, 47405, United States

1 - Blockchain Platform Network Externalities

Hemang Subramanian, Asst. Professor, Florida International University, Miami, FL, 33193, United States, hsubrama@fiu.edu

Blockchain technologies allow the sharing of revenues from traditional exchange-based markets to network participants. In this paper, I model externality effects among different sides of a blockchain platform extending Parker and Van Alstyne(2006). Next, I empirically analyze the causal direction of flow of value from exchange markets to participants on a blockchain based content platform using time series regressions and Granger Causality analysis. Then, I analyze, the effects of user heterogeneity and content heterogeneity on the externality effects and value flows in this market. Results indicate a value transfer between token markets and content creators based on the type of content.

2 - Economics of Ransomware Attacks

Duy Duc Dao, University of Calgary, Calgary, AB, 95111, Canada, Terrence August, Marius Florin Niculescu

In this paper, we examine how ransomware impacts software vendors and consumer behavior. When victims face an option to mitigate losses via a ransom payment, both the equilibrium market size and the vendor's profit under optimal pricing can actually increase in the ransom demand as well as the risk of residual losses following a ransom payment (which reflect the trustworthiness of the ransomware operator). We also show that the expected total ransom paid is non-monotone in the risk of success of the attack, increasing when the risk is moderate in spite of a decreasing ransom-paying population.

3 - Optimal Policies for Information Sharing in Information System Security

Yueran Zhuo, Harvard Medical School, Boston, MA, United States, Yzhuo1@mgh.harvard.edu and University of Massachusetts-Amherst, Amherst, MA, United States, yzhuo1@mgh.harvard.edu, Senay Solak

Information sharing has become a significant part of information security, as many firms have come to realize that it is difficult to defend against the sophisticated information security attacks with the limited resources of one single firm. The sharing of information security related knowledge and experience helps firms better prepare for upcoming information security challenges. We show our analysis under symmetric and asymmetric information sharing environment respectively. The results provide insights on optimal information sharing level decisions for different sized firms over different operational environments. The value of information sharing is also examined.

4 - Data Breaches and Firm IT Investment

Kathy Cao, Iowa State University, Ames, IA, United States

This paper explores how a firm responses to a security breach happened regarding its information technology (IT) investment. We explore two aspects of information technology, total IT budget, and number of IT employees. We analyze the IT investment change at both the firm- and establishment-level with a panel data of over 3,000 firms and 350,000+ sites from year 2010 to 2016. The analysis shows overall a breached firm invests more in IT after the breach took place. However, the firm does not necessarily invest more in the establishment where the breach happened, unless the establishment is a regional headquarter, close to the headquarter, or in the primary industry of the firm.

5 - Source Ratings in the Fight against Disinformation on Social Media

Patricia Moravec, University of Texas at Austin, Kelly School of Business, Austin, TX, United States, Antino Kim, Alan R. Dennis

The rise of fake news has become a major concern for social media platforms and their users. One possible solution is to attach a rating of the source that produced the article to every article when it is first published. We conducted online experiments to investigate the effects of source ratings on user's belief in news articles on social media.

Student Successes - Practical Magic from our EMBA/MBA/DMBA/MSDA Programs

Emerging Topic: INFORMS Section on Practice

Emerging Topic Session

Chair: Peter C Bell, Ivey Business School at Western University, Canada, London, ON, N6G 0N1, Canada

1 - EMBA Student Projects as Examples of Applied Analytics

Peter C. Bell, Ivey Business School at Western University, Canada, Ivey School of Business at Western Universty, 1255 Western Road, London, ON, N6G 0N1, Canada, pbell@ivey.ca

Join us as our panelists present practical magic: successful student presentations, learning outcomes, projects, and more from Executive MBA, MBA, and Data Analytics programs. Many of these programs are geared to teach direct job skills in a very short period of time. Panelists include the university perspective with contributions from Western University in Canada and UC Irvine, and the industry perspective from Analytics2Go. Do you want to know what's brewing in terms of skill set development? Come see this panel and find out.

Panelists

- Peter C. Bell, Ivey Business School at Western University, Canada, Ivey School of Business at Western Universty, London, ON, N6G 0N1, Canada
- Kenneth E. Murphy, University of California Irvine, Irvine, CA, 92866-1005, United States, murphyke@uci.edu
- Aaron Burciaga, Analytics2Go, Tysons, VA, 22102, United States

Flash Session VIII

Flash Session

Chair: Jyotishka Ray, Assistant Professor, California State University, East Bay

1 - Recommendation in a High Online Traffic under Constrained Inventory

Jyotishka Ray, Assistant Professor, California State University - East Bay, Hayward, CA, United States, jyotishka.ray@csueastbay.edu

Holiday buying seasons like Cyber Monday, Black Friday and others are characterized by high online demand with a high stockout risk. To mitigate the adverse effect of stockout the e-retailers, in general, had to forego some of the profit margin to provide stockout compensation in terms of price discount, free shipping and gift cards for the backordered item. This study designs a RS from the retailer's perspective who maximizes her expected profit by recommending protable yet popular items while incurring stockout compensation cost in case of backorder.

2 - Rolling Tree as a Source of Flexibility: Its Added Value in an Agriculture Case

Elbio Avanzini, Pontificia Universidad Catolica de Chile, Santiago, Chile, elavanzini@uc.cl, Alejandro Francisco Mac Cawley, Jorge R. Vera, Lluis Pla, Sergio Maturana

Both the decision support model (DSM) and resources provide flexibility and offer different alternatives to deal with uncertainty. DSM could be different in terms of stages and information requirements. In previous works, we explored the contribution of multistage stochastic programming (MSSP) and the expected value problem (EVP) in a case of fruit harvest under uncertainty, with different flexible resources. In this document, we expanded that work by applying a rolling tree that combines MSSP and EVP. We hope to understand the effects of the structure on the value of the system under uncertainty with known flexible resources, to obtain managerial insights that facilitate the selection of the DSM.

3 - Studying Milkrun Logistics Using Multiple Objective Evolutionary Algorithms

Eduardo Castillo Fatule, The University of Texas at El Paso, El Paso, TX, United States, jecastillofatule@miners.utep.edu, Jose F. Espiritu

Transportation logistics have struggled to adapt to new business models due to a wild increase in demand variability, which can cause problems which traditional approaches can not always address. A deterministic problem is formulated by which multiple objectives can be considered for the formulation of a solution to a milkrun logistics problem. A Multi Objective Genetic Algorithm is created which will try to minimize both total delivery time as well as costs for a small delivery business.

4 - Security Breach and Information Technology Investment

Chengxin Cao, Iowa State University, Ames, IA, United States, ccao@iastate.edu

This paper explores how a firm responses to a security breach happened regarding its information technology (IT) investment. We explore two aspects of information technology, total IT budget, and number of IT employees. We analyze the IT investment change at both the firm- and establishment-level with a panel data of over 3,000 firms and 350,000+ sites from year 2010 to 2016. The analysis shows overall a breached firm invests more in IT after the breach took place. However, the firm does not necessarily invest more in the establishments, unless the establishment is a regional headquarter, close to the headquarter, or in the primary industry of the firm.

5 - Machine Learning Applied to Spectroscopy

Driss Lahlou Kitane, Massachusetts Institute of Technology, Cambridge, MA, United States, driss@mit.edu, Dimitris Bertsimas

Laser Induced Breakdown Spectroscopy plays an increasingly role in in-situ and real time chemical analysis. After irradiating the surface of a material to be analyzed, spectra are collected and use to determine the chemical composition of the material with high precision. We present a novel method using sparse regression to interpret and estimate chemical composition using collected spectra. Presented method significantly improve accuracy and interpretability.

6 - Spatio-temporal Characteristics of Shared Bicycle Riding Based on Data Analysis

Qi Liu, SouthWest JiaoTong University, Chengdu, China, luci20599@163.com, Yong Yin

In order to solve the increasingly serious environmental pressures and energy pressures and reduce pollution and carbon emissions, major cities have actively introduced shared bicycles to alleviate the short-distance travel and “last mile” of residents. This paper selects the data of Mobike cycling in Shanghai in August 2017, and uses Python software and Arc GIS spatial analysis tools to analyze the temporal and spatial distribution patterns and differences of shared bicycle riding in the city, and identify the traffic hotspots and traffic corridors. What’s more, it is connected to the passenger flow of the track line site.

Decision Support Systems II

Contributed Session

Chair: Suman Das, Indian Institute of Technology Kharagpur

1 - Designing a Deceptive Comment Detection Platform with a Rule Based Artificial Intelligent Algorithm

Hongrui Liu, San Jose State University, California, San Jose, CA, 95008, United States, hongrui.liu@sjsu.edu, Arman Toplu

One of the most important factors in a purchasing decision nowadays is the evaluation of comments online. Businesses or individuals use deceptive comments to mislead people for the sake of economic gain and thus hurt the benefit of the customers and the welfare of society. In this research, we propose a rule-based artificial intelligent (AI) machine learning (ML) model for online review fraud detection. The proposed methodology features an AI and ML hybrid architecture, where the AI part prioritizes and customizes the fraud detection rules based on human intelligence to improve the accuracy of the result and increase computational efficiency.

2 - An Early Warning Method Based on the Focus Theory of Choice

Xiuyan Ma, Dalian University of Technology, Dalian, China, max@dlut.edu.cn, Xiangpei Hu

The early warning provides the decision makers with the decision support for the future failures under the uncertainty environment. The warning decision is based on the prior probabilities of possible scenarios and their outcomes, and on the decision maker’s preferences and knowledge. This research proposed a non-expected utility, the focus theory of choice based early warning method. The decision-making process of this method is as follows: anomaly detection, trend analysis of the typical scenario, focus point selection and early warning decision making. The proposed method provides possible solutions of early warning problems in the internet of things environment.

- Mathematical Optimization for Habitable Layout Design Driven by Psychophysical Criteria

Claudia Ramirez-Wade, University of North Carolina-Charlotte, Charlotte, NC, United States, cramir16@uncc.edu, Simon Hsiang, Churlzu Lim

We evaluated different spacecraft layout designs based on psychophysical attributes correlated to proximity and functionality of identified task volumes to minimize volume while maximizing the crewmembers’ health, performance, and safety for the duration of a mission to Mars. The objective of the evaluation model is to help decision makers reach a decision by looking at every need and design strengths of the layout by comparing layouts on its overall effectiveness in relation to all of its needs. The proposed model is a mapping reference between physical arrangements and the psychophysical satisfaction of needs that provides greater insight in the design of the layout based on mission parameters.

4 - Predicting Dairy Cow Milk Yield in Early Lactation by Applying Convolutional Neural Networks on Sequential Information

Arno Liseune, Ghent University, Ghent, Belgium

In this research, we present a framework that predicts a cow’s milk yield in early lactation. In particular, we show how convolutional neural networks are able to uncover a relationship between a cow’s milk yield in the first days after calving and preceding sequential information such as milk yields and health events. In addition, we investigate if the inclusion of herd information enhances the predictive performance. The results presented in this research can be used to detect anomalies between a cow’s expected and true milk yields, hence enhancing current animal monitoring systems.

5 - Necessity of Fuzzy Geometry in Fuzzy Interpolation

Suman Das, Research Scholar, Indian Institute of Technology Kharagpur, Kharagpur, India, pnksmdas@gmail.com, Debjani Chakraborty

A series of works on fuzzy geometry has gained its existence on establishing the fact that a hazy object in the space can be visualized as fuzzy point. The locus of fuzzy point is captured efficiently with fuzzy geometry. In order to explore its applicability, fuzzy interpolation has been chosen a field of study. A rule base can be visualized as combination of fuzzy points. The dimension is dependent on the total number of antecedents and consequents in a rule. Thus fuzzy geometry provides a tool to accommodate an unknown antecedent or consequent in the rule base. A methodology has been developed to capture the behaviour of fuzzy rule base and a discussion has been initiated to facilitate fuzzy interpolation.

1 - Network Structures and Sustainability of Joint Liability: Authoritarian vs Egalitarian Networks

Bahar Rezaei, UCLA Anderson School of Management, Los Angeles, CA, United States, rezaei@ucla.edu

Lack of well functioning formal institutions leads to reliance on borrowers’ social networks to enforce group lending contracts with joint liability. We develop a model in which connections between borrowers serve as monitoring tools and examine the effect of various borrower network structures, especially decentralized and centralized networks, on the performance of a joint liability group. Our results show that while for smaller groups, the highly decentralized ring networks (egalitarian) may have a higher performance than the highly centralized star networks (authoritarian), for larger groups, star networks outperform the rings.

2 - The Impacts of Mergers, Capacity Expansion and Adoptions on Animal Shelter Performance: a Queuing Analysis

Janice Carrillo, University of Florida, Gainesville, FL, United States, Nazli Turken, Anand Paul

In this paper, we define, compare and perform a sensitivity analysis of performance metrics involving Erlang loss queues. We capture a unique reneging and retainment process germane to the euthanization practices typically utilized by traditional animal shelters. We ultimately provide recommendations for animal shelters on the most efficient investments and analyze the effects of mergers and capacity expansion on various performance metrics. Furthermore, we expand our model to incorporate state dependent euthanization processes.

3 - Social Enterprise Welfare and New Product Diffusion: Model and Empirical Validation at World Bicycle Relief

Vadim Glinskiy, PhD Student, Kellogg School of Management, Evanston, IN, United States, vadim.glinskiy@kellogg.northwestern.edu, Jan A. Van Mieghem

We present a dynamic model of a social enterprise (SE) that offers a product through its not-for-profit and for-profit channels. Product offered in either channel stimulates future market (for-profit) demand. We present a continuous-time, 2 channel product diffusion model and a closed-form expression for the optimal production policy. We perform sensitivity analysis on two conflicting objectives: maximize social welfare or profitability. Our theoretical results are validated with a rigorous empirical study of World Bicycle Relief. We find conditions for which the for-profit channel can increase social welfare and the not-for-profit channel can increase profitability.

4 - Product Innovation in the Presence of Strategic Consumers with Uncertainty About New Product

Jihyun Hong, PhD Candidate, Korea University Business School, Seoul, Korea, Republic of, hjhheehee@korea.ac.kr, Kyungsam Park

In a situation where a firm releases a new product with new attributes and a previous model of the same product coexists, we study the effect of strategic purchase decisions of consumers who are uncertain about their future needs of new attributes on the firm's strategy for product innovation.

5 - Crowdfunding for New Product Development: The Role of Information Disclosure

Jue Liu, Nanjing University, Nanjing, China, hiliujue@hotmail.com, Houcai Shen

This study examines the strategic role and value of information disclosure in crowdfunding for new product development with quality uncertainty. In such a crowdfunding campaign, disclosing information about early investors' decisions allows late investors to update their beliefs based on the observations of the early investors' behavior. We show that if the target is sufficiently high or sufficiently low, information disclosure increases the expected total investment. Otherwise, information disclosure decreases the expected total investment.

Big Data III

Contributed Session

Chair: Hyunsang Son, The University of Texas at Austin, Fort Collins, CO, 80525, United States

1 - Using Customer Behavior Big Data to Optimize Collection and Delivery Points for Online Retailers

Yeming Gong, Professor, Em Lyon Business School, Ecully, France, gong@em-lyon.com, Yaohan Shen, Xianhao Xu, Wanying Chen

While previous delivery points optimization researches do not use customer behavior data, we propose a new procedure, integrating with customer behavior data analysis, to optimize collection and delivery points for online retailers. Our research shows an optimal approach to locate attended and unattended collection and delivery points such that online retailers can trade off consumer service level and the total logistics cost. We extract feature set from raw customer behavior data which decides the upper bound of a prediction algorithm's performance, and regard outputs of state-of-art purchase prediction algorithm as the demand level of customers in each period.

2 - Data-driven Platform-based Supply Chain Management: Eco-label Standard Design and Competition Strategy

Sijie Zhou, University of Science and Technology of China, Hefei, China, zhsijie@mail.ustc.edu.cn, Yugang Yu

This paper is motivated by practical example of a furniture trade platform, to certify the most environmental furniture brands. We explore the operational data and analyze the causal effect of eco-label through DID approach with machine learning. Our analytical model shows that. If there are 2 quality-heterogeneous firms, the optimal standard is equivalent to high quality and the labeled brand won't rise price. Our results demonstrate platform must set the standard near the expectation of the total firms' quality with a continuous quality distribution for many firms. This paper is the first that regards platform as certifier and considers the dependence between quality and eco-label stringency.

3 - The Number of Tourists Prediction Between Cities

Yuquan Xu, XI'an Jiaotong University, Xi'an, Shaanxi, China

Travel prediction between cities is a widely application among many tourism research topics, such as travel package design. This paper propose a method to predict trourists' flow between cities. It can bring benefit to tourism research and promote tourism development.

4 - Predicting Genotype-by-environment (GxE) Interaction Effect Using Genetic Marker Predictors

Samira Karimzadeh, Graduate Research Assistant, Iowa State University, Ames, IA, United States, samirak@iastate.edu, Sigurdur Olafsson

In application of machine learning in plant breeding, predicting yield of a seed variety based on past observations is a big challenge. Since the yield is a function of genotype-by-environment called GxE effect, sufficiency of the past observations in target environments is crucial in building the prediction model. When observations of the target variety is not enough to train a model, using observation of related varieties those have same GxE behavior could be a possible solution. In this study, we have developed a supervised prediction model to identify related varieties using genetic marker predictors when there is no yield observation available to identify related varieties based on GxE effect.

5 - What Did People Seek and Share in Natural Disasters

Hyunsang Son, The University of Texas at Austin, Austin, TX, 78701, United States, hyunsangson@utexas.edu, Jisoo Ahn, Arnold Dongwoo Chung

This study applies a community detection method utilizing infinite edge partition models to observe the information-spreading patterns during an earthquake in Japan. The findings of communication hubs in the social networks can help practitioners understand the flow of information and prepare more effective message strategies during natural disasters.

6 - Change Point Detection in Partial Correlation Networks

Jessica Wai Yin Leung, University of Sydney, Sydney, Australia, jessica.leung@sydney.edu.au, Dmytro Matsypura

We study the change point detection problem in similarity network over time. Correlation matrix is commonly used in constructing similarity networks. Yet, it is well-known that it suffers from the illusion of spurious relationships within the system. Therefore, we adopt partial correlation as an alternative measure and developed a statistical testing procedure with minimal distributional assumption. Preliminary simulation results shows high statistical power across different sample sizes and dimensions.

1 - A Data Mining Topology Control Heuristic for Post-Contingency ACPF Violation Reduction in Real World, Large Scale Systems

William Eric Brown, Texas A&M University, College Station, TX, United States, webrown@tamu.edu, Erick Moreno-Centeno

Topology control (TC) has proven a useful recovery technique for post-contingency power grid operations. However, because of concerns over computational complexity, uncertain AC performance, and real world scalability, TC remains implemented only in limited capacity. This work proposes a data mining heuristic to identify TC actions which reduce post-contingency AC power flow violations. Tested on real world power system data, the proposed method significantly outperforms current distance-based heuristics. For voltage magnitude violations, we identify optimal actions in over 97% of studied instances and attain an average search depth roughly one tenth that of distance-based heuristics.

2 - Distribution Electricity Pricing under Uncertainty

Robert Mieth, New York University, Brooklyn, NY, United States, robert.mieth@nyu.edu, Yury Dvorkin

Distribution locational marginal prices (DLMPs) facilitate the efficient operation of low-voltage distribution systems. We propose an approach to internalize the stochasticity of renewable resources and risk tolerance of the distribution system operator in DLMP computations. This is achieved by means of applying conic duality to a chance-constrained AC optimal power flow. We show that the resulting DLMPs consist of the terms that allow to itemize the prices for the power production, balancing regulation, and voltage support provided. Finally, we prove the proposed DLMP constitute a competitive equilibrium, which can be leveraged for designing a distribution electricity market.

3 - Networked Synthetic Dynamic PMU Data Generation: A Generative Adversarial Network Approach

Dileep Kalathil, Assistant Professor, TAMU, College Station, TX, United States, Xiangtian Zheng, Dongqi Wu, Le Xie

Due to the confidentiality of real PMU data and no public access to detailed real power systems model, the lack of credible PMU data becomes a growing concern for research and education purposes. In this paper, using partial power systems infrastructure information, we develop a GAN-based method to synthesize realistic networked PMU data, which satisfy basic physics laws and mimic dynamic behavior of simulated power system. We validate the realistic dynamic characteristics of networked synthetic PMU data via a modal analysis method.

4 - Effect of UHV Grid on the China Power Market: A Parameterized Supply Funciton Equilibrium Analysis

Kaiying Lin, Johns Hopkins University, Baltimore, MD, United States, Southeast University, Nanjing, China, Beibei Wang, Chang Xie, Benjamin Field Hobbs

We consider a supply function equilibrium for the power market under the proposed UHV (Ultra High Voltage) grid in China. Parameterized supply functions for energy and spinning reserves are considered. Diagonalization is used to obtain equilibria among generators' unit commitment problems. We simulate the effect of assumptions concerning network congestion, load growth, import power characteristics, reserve activation payments, reserve cost allocation, market power mitigation, and alternative network configurations. Results of Q-learning algorithms for obtaining equilibria are also compared.

5 - Market Value of HVDC Corrective Control Capabilities

Andrea Tosatto, Technical University of Denmark, Kgs. Lyngby, Denmark, antosat@elektro.dtu.dk, Stefanos Delikaraoglou, Jalal Kazempour, Spyros Chatzivasileiadis

To guarantee a safe operation of power systems, TSOs enforce the N-1 security criterion. If no recourse actions are considered, the resulting dispatch is extremely expensive. By controlling power flows, HVDC lines can help accommodate the new situation, avoiding costly generation redispatching. This service can be offered if part of HVDC capacity is reserved, and not used for energy trading. Thus, it should be provided at a cost, especially in the case of merchant lines. The scope of this work is to determine the value of HVDC corrective control and how HVDC line owners can benefit from it.

6 - A Hierarchical Decomposition Approach for Optimal Grid – Distributed Energy Resource Coordination

Panagiotis Andrianesis, Boston University, Brookline, MA, United States, panosa@bu.edu, Michael C. Caramanis

In this work, we present a hierarchical decomposition approach that is based on centralized AC Optimal Power Flow capability interacting with Distributed Energy Resource (DER) self-dispatch that adapts to real and reactive power distribution locational marginal costs. We illustrate that the discovery of spatiotemporally varying marginal costs in distribution networks, which apart from network congestion also reflect asset degradation, is key to optimal DER scheduling. We discuss the applicability and tractability of the proposed approach on actual distribution feeders, while modeling the full complexity of spatiotemporal DER capabilities and preferences.

1 - Nonparametric Tests for Convexity, Monotonicity, or Positivity of Multivariate Functions with Noisy Observations

Eunji Lim, Assistant Professor, Adelphi University, Garden City, NY, United States, elim@adelphi.edu

We propose a new method of testing for a function’s convexity, monotonicity, or positivity, based on noisy observations of the function over a finite set T of points in the domain, where the observations can be made multiple times at each point in T. The proposed method fits a convex, monotone, or positive function to the data set and examines the sum of squared differences between the fit and the data set as the number of observations taken at each point in T increases to infinity. This leads to a test procedure that does not require the estimation of any additional parameters, and hence, does not need any artificially plugged-in parameters. Theoretical properties and numerical results will be presented.

2 - Drivers’ Perception of Headways in the Operations of Connected and Autonomous Vehicles

Yujie Li, Purdue University, West Lafayette, IN, United States, li2804@purdue.edu

This study proposes an innovative psychological method to investigate drivers’ perception of headways at Level 3 automation, which is important to achieve a good balance between mobility and user experience. The experiments are carried out using a driving simulator that can transition between AV mode and manual mode. In addition, participants’ physiological data were collected to reinforce their subjective response data. Pilot test data were also collected. The results indicate that multiple headway thresholds can be estimated and that, drivers’ attitudes towards the AV operations can be inferred.

3 - A Simulation Model of Staffing Decisions for Wafer Ingot Manufacturing

Yu-Han Ke, National Chiao Tung University, Hsinchu, Taiwan, yhke.iem07g@nctu.edu.tw, Sheng-I Chen

We consider the staffing decision in an ingot manufacturing plant, where there are types of machine to produce products in different diameters and dopant chemicals. A crystal growing process involves a serial of activities, and each of them requires a different number of operators. The overall duration of the process and runs in each batch are uncertain. Operators are required to set up the equipment and refill raw materials whenever starting a new batch. Also, activities of moving and equipment maintenance are performed by labors periodically. We develop a simulation model to capture the above considerations. The model is applied for assessing personnel allocation under various facility layouts.

4 - Impact Analysis of Over Tourism by Multi-agent Simulation

Ichirota Nakada, Waseda University, Tokyo, Japan, Takashi Hasuike

Japanese government has been focusing on the tourism industry since about fifteen years ago, and the increase in the number of foreign tourists in recent years is striking. Over-tourism however has become a trend word in various parts of the world in recent years, and even in Japan, the adverse effects on residents of tourist spots are being scattered. So, in this research, in order to analyze the various influences on the tourist destination by over tourism, we build a dynamic model by agent simulation. And the purpose is to get more realistic hints of strategies for solving problems.

5 - Teaching Monte Carlo Simulation for Retirement Planning

Chester G. Chambers, Associate Professor, Johns Hopkins University, Baltimore, MD, United States, cchamber@jhu.edu

The distribution phase of retirement planning is a very hard problem that has received great interest from anyone planning to retire in the coming years. Students are overwhelmed with biased information regarding spending rules and failure rates. We address student needs with a case designed to evaluate common withdrawal rules, asset allocation, utility maximization, and the role of leverage in the allocation process. This case is intended for MS and MBA audiences and is delivered using either Excel as a simulation platform or R as a coding language.

6 - Analytics Framework to Improve People Flow on Large Buildings

Valeria Puyo, Universidad de los Andes, Bogotá, Colombia, v.puyo@uniandes.edu.co, Liseth Daniela Grosso, Jorge Huertas, Diego Monroy, Maurix Suárez, Andres L. Medaglia

Improving the people flow in congested buildings is relevant when planning disaster mitigation strategies that might ultimately save lives. To improve people flow in large buildings we propose an analytics framework comprised of three layers. In the descriptive layer, we collect data and estimate the building’s origin-destination matrix, which is the input of a discrete-event simulation model that recreates the flow dynamics. In the predictive layer, we simulate scenarios varying the traffic and load of the building to measure the impact on congestion. Finally, in the prescriptive layer, we simulate several infrastructure interventions and recommend actions that relieve congestion.

Resource Allocation & Climate Change

Contributed Session

Chair: Tetsuya Tamaki, Kagawa University, Fukuoka City, 8190395, Japan

1 - Two-sided Assortment Optimization

Asrar Ahmed Mohammed, Indian School of Business, Hyderabad, India, asrar_ahmed@isb.edu, Milind Sohoni, Chaithanya Bandi

We consider the problem of online service platforms which match job applicants with potential employers. Unlike traditional formulations which treat the participants as passive, we allow both employers and job applicants to exercise their choice. We introduce a two sided assortment optimization model which captures the platforms constraint that it can only provide recommendations to each participant. We present a mixed integer linear programming formulation of the model and provide performance bounds for a greedy online algorithm that can be solved efficiently. The algorithms are evaluated on real-world dataset from a leading freelancing platform

2 - Re-planning Airport Infrastructure and Operating Practices with Information from Simulation Modeling

Anthony Gerard Vatterott, University of Missouri-Saint Louis, Saint Louis, MO, United States, anthonygvatterott@gmail.com, Liang Xu, Canser Bilir, Laurence Douglas Smith

De-hubbing by major airlines has left many U.S. airports operating with traffic volumes that differ dramatically from projections used when developing their infrastructure. We describe the application of a discrete-event simulation model to assess the impact on individual carriers if airport resources were re-purposed and operating practices were changed in an effort to contain costs at an airport with excess capacity.

3 - Optimizing Dynamic Green Infrastructure Placement in an Urban Watershed: A Distributionally Robust Approach

Masoud Barah, Northwestern University, Evanston, IL, United States, mbarah@northwestern.edu, Anahita Khojandi, Xueping Li, Jon Hathaway

Green infrastructure are mostly implemented in a reactive manner instead of being incorporated as a coherent part of urban spatial planning. Here we develop a mathematical model to optimally place GI practices when (re-)designing an urban area, subject to uncertainties in population growth and future precipitation. Specifically, we develop a distributionally robust finite-horizon Markov decision process model to determine the extent to which GI practices need to be incorporated in different parts of a given urban area to maximize their benefits, considering the dynamic changes in population density and precipitation. We conduct a case study, perform sensitivity analyses and provide insights.

4 - Regulation of CO2 Emissions for Each Area in a Region

Tetsuya Tamaki, Dr., Kagawa University, Kagawa, Japan, tamaki@eng.kagawa-u.ac.jp

This study proposes a model analyzing the economic impacts of global warming in a region to maintain the consistency of the global model. This model estimates best regulations for each area in a region under the condition that the upper limit of emission is given by a global model. We analyze the case of Japan and find that more developed areas should implement stricter regulations in all scenarios. However, the policy by area scenario is not always preferable than that of policy by region (comprising multiple areas). The policy by area scenario results in disparities in the region and may decrease the total output even if the total utilities increase.

1 - Electricity Markets in Presence of Strategic Prosumers

Sepehr Ramyar, University of California Santa Cruz, Santa Cruz, CA, United States

We investigate the formation of wholesale power prices in presence of strategic prosumers and analyze how the unconventional behavior of agents capable of consumption and generation at the same time can impact wholesale power markets. In this study, the price is determined endogenously by strategic prosumers along with other market participants. We study the behavior of prosumers in Stackelberg formulation of the induced game in the power market with the prosumer as the leader and other agents as followers. We discuss and report the ensuing market outcomes and contrast it with other strategies by the prosumer.

2 - An Integer Programming Approach to Optimal Load Shedding

Yu Zhang, Assistant Professor, UC Santa Cruz, Santa Cruz, CA, 4592921, United States, zhangy@ucsc.edu, Masoumeh Ghanbarpour, Scott Moura

In this talk, we provide an optimization framework for stochastic optimal load shedding in networked microgrids that include heterogeneous load zones. Considering uncertain estimates of power consumption and energy shortfall, we formulate the system planning task as a chance-constrained integer quadratic program. By leveraging binary decomposition and McCormick relaxations, we develop two efficient algorithms yielding minimum total load shedding cost while respecting fairness among end users. Simulation results corroborate the merits of our proposed framework and algorithms, which outperform the off-the-shelf solver BARON.

3 - Environmental Policy in Maritime Transport Sector: Vertical Integration and Competition

Mari Ito, Tokyo University of Science, Chiba, Japan, Ryuta Takashima

In this work, we propose a model of economic evaluations for the vertical integration of shipping and port firms. In a social welfare analysis, maritime emission regulations are comprehensively examined. We also analyze the effect of emission control at partial region on total emissions and surplus of shipping and port firms. We have found that it is preferable to regulate the integrated route from the viewpoint of social welfare.

4 - Optimal Configuration of Air Conditioning System by Using Statistical Method and Machine Learning

Haruki Inoue, Osaka University, Suita, Osaka, Japan, Yuta Izumi, Hiroshi Morita

We consider the equipment configuration to minimize energy consumption. Energy consumption is calculated by computer simulation and hard to handle. We propose an efficient iterated local search algorithm for the black box optimization problem. We reduce the calculation time of the black box function by using extreme statistics and lasso regression. Training data are given from the results of simulation obtained in iterated local search. The proposed method is applied to the optimization of the air conditioning system configuration.

Recent Developments on Optimization of Grid Integrated Energy Storage

Sponsored: Energy, Natural Res & the Environment/Electricity

Sponsored Session

Chair: Qifeng Li

1 - Market Evaluation of Energy Storage Systems Incorporating Technology-specific Nonlinear Models

Tu Nguyen, Senior Member of Technical Staffs, Sandia National Laboratories, Albuquerque, NM, 87185, United States, tunguy@sandia.gov

This presentation provides an overview of technology-specific nonlinear energy flow models based on nonlinear operating characteristics of the storage devices. These models are incorporated into an optimization problem to find the optimal market participation of energy storage systems. A dynamic programming approach is used to solve the optimization problem. Two case studies are conducted for maximizing the revenue of a Vanadium Redox Flow Battery (VRFB) and a Li-ion battery system in PJM’s energy and frequency regulation markets.

2 - Energy Storage Management via Deep Q-Networks

Ahmed Zamzam, National Renewable Energy Laboratory, Golden, CO, 55455, United States, ahmed.zamzam@nrel.gov

We study the problem of real-time control of storage units installed in distribution grids with integrated renewable energy generation. Unlike many previous approaches, no distributional assumptions are being made on the renewable energy generation or the real-time prices. Building on the deep Q-networks algorithm, a reinforcement learning approach utilizing a neural network is devised where the storage unit operational constraints are respected. The neural network approximates the action-value function which dictates what action to take. Simulations indicate that near-optimal performance can be attained with the proposed learning-based control policy for the storage units.

3 - Stochastic, Robust and Distributionally Robust Dispatch of Smart Buildings Loads

Yury Dvorkin, New York University, Metrotech Center, NY, 11201, United States, dvorkin@nyu.edu

Controllable electrical appliances in smart buildings can adjust their consumption to help meeting operational power grid limits. However, the dispatchable flexibility of these appliances depends on the ability to accurately model their behavior. This presentation describes an approach to dispatch an ensemble of smart buildings using the Markov Decision Process framework immunized against uncertain buildings and appliances parameters. This robustification is considered under different statistical assumptions using methods from stochastic programming, robust and disitrbutionally robust optimization, which leads to different analytical and/or numerical dispatch policies.

4 - A Convex Nonlinear Model for Grid-integrated Battery Energy Storage

Qifeng Li, University of Central Florida, Orlando, FL, 32816, United States, qifengli@mit.edu

Battery energy storage (BES) is considered an essential component of future power systems. The convexification of mathematical models of another essential power system component, i.e. the power networks, has been widely studied in the past decade. In this talk, we will talk about the convexification of BES models: first, a nonlinear model of BES units is developed based on an equivalent BES circuit; then, a tight convex relaxation for this nonlinear model is introduced; finally, with the developed convex BES model, we build a convex model for grid optimization considering BES units.

1 - Flow Solvers for Natural Gas and Water Distribution Networks

Manish Singh, Virginia Tech, Blacksburg, VA, United States, Vassilis Kekatos

Natural gas and water distribution networks are interconnected with electric power systems since gas compressors and water pumps needed to regulate pressure run on electricity. At the heart of operating these networks, lies a set of nonlinear flow equations. These equations are shown to enjoy a unique solution. Moreover, if compressors and pumps do not occur in loops, this solution can be found via convex minimization. For more general setups, solving the flow equations is posed as a mixed-integer non-convex minimization, which is relaxed to an MIQP. The relaxation is shown to be exact in networks with non-overlapping loops or if overlapping loops do not involve compressors and pumps.

2 - Pipeline Transient Optimization for A Gas-electric Coordination Decision Support System

Anatoly Zlotnik, Los Alamos National Laboratory, Los Alamos, NM, United States, azlotnik@lanl.gov, Alexandr M. Rudkevich, Pablo A. Ruiz, Richard D. Tabors, Xindi Li, Charles Russell Philbrick, Alexandr Beylin, Kaarthik Sundar

Transient optimization of gas pipelines has experienced a resurgence of interest inspired by the need to coordinate intraday operations of wholesale electricity and natural gas transmission networks. An organized exchange of information between optimization-based auction markets for scheduling energy production and delivery over these systems is increasingly critical. Economically and operationally efficient intraday coordination will require assimilation of real-time data to produce real-time optimization-based solutions. This talk will describe such mechanisms, recent validation studies, and research needs for a future decision support system for gas transportation.

3 - Chance-constrained Coordination of Power and Natural Gas Systems: A Conic Relaxation Approach

Anubhav Ratha, PhD Student, Technical University of Denmark, Kgs Lyngby, 2800, Denmark, arath@dtu.dk, Jalal Kazempour, Pierre Pinson, Ana Virag, Ana Virag

Accessing flexibility from coordinated dispatch of power and natural gas is a promising solution to increase renewable energy share in power systems. We implement a chance-constrained co-optimization of power and natural gas operation wherein flexibility from short-term gas storage in pipelines ('linepack') is made accessible to power systems. The non-linear and non-convex equations governing flows in power and gas networks are convexified using DC power flow approximation and second-order cone relaxation, respectively. Recourse actions, based on linear decision rules, allow adjustments to dispatch during real-time operation when uncertainty in demands and productions is revealed.

4 - A Heat Unit Commitment Model with Power Systems Awareness

Lesia Mitridati, PhD, Georgia Institute of Technology, Atlanta, GA, United States, lmitridati3@gatech.edu

The penetration of stochastic renewable energy production in power systems can be facilitated by exploiting the sources of flexibility at the interface with other energy systems, such as heat. Therefore, we introduce an electricity-aware heat unit commitment model for the coordination of heat and electricity systems. The sequential heat and electricity markets are modeled as lower-level problems. In the upper-level problem, the heat unit commitment relies on bid validity constraints to endogenously model the interactions between heat and electricity markets. The resulting trilevel optimization problem is recast as a single-level problem using a lexicographic order and strong duality.

Electrified Transportation: A Rising Nexus

Sponsored: Energy, Natural Res & the Environment/Energy Sponsored Session

Chair: Matteo Muratori, NREL, Golden, CO, 80401, United States

1 - Electrified Transportation: A Rising Nexus

Matteo Muratori, NREL, Golden, CO, 80401, United States, matteo.muratori@nrel.gov

After over a century of petroleum dominance, many anticipate major electrification trends that could disrupt the transportation landscape. These changes complement profound changes happening within electric systems: the traditional system based on the premise that generation is dispatched to match demand is evolving to create a system with greater participation in power system planning and operations from traditionally passive consumers. This broader context underscores the importance of understanding how transportation electrification will impact electricity demand, including changes in the load shapes and the opportunity to leverage flexible EV charging to balance demand and supply.

2 - Power Sector Capacity Expansion Modeling of an Electrified Energy System

Trieu Mai, National Renewable Energy Laboratory, Golden, CO, United States, trieu.mai@nrel.gov

Electrification can alter both the shape and the amount of electricity consumption. Adoption of heat pumps could introduce new winter peaks while transportation electrification introduces a new source of demand altogether. Moreover, electrification could shift natural gas consumption between sectors, thereby affecting the economics for natural gas-fired generation. Electrification could also amplify opportunities for demand-side flexibility. Here, we present our representation of these effects in the Regional Energy Deployment System (ReEDS) model, an optimization-based power sector capacity expansion model used in the Electrification Future Study.

3 - Distribution System Constrained Vehicle-to-Grid Services

Sunil Chhaya

Please check the mobile app for this abstract.

4 - Optimized Charging of Electric Vehicles in on Demand Mobility Services

Jonathan Donadee, Research Engineer, Lawrence Livermore National Laboratory, Livermore, CA, United States, donadee1@llnl.gov, Brenden Petersen

In this work, we apply deep reinforcement learning to optimize the driving and charging strategy of an electric vehicle that operates in an on-demand mobility service, such as ride-hailing. The optimal strategy seeks to minimize electric energy costs and emissions while maximizing mobility service provided and resilience to charging station congestion and outages. Results are presented for a test case with mobility demand modeled on New York City taxi and with a solar power generation dominated electric grid.

5 - Advances in Integrating Hydro-climate Research in Regional Power System Analytics

Nathalie Voisin, Pacific Northwest National Laboratory, Seattle, WA, United States, Nathalie.Voisin@pnnl.gov

As the grid is changing with increasing integration of renewables, evolving markets and technology innovation, the conceptual and highly parameterized representations of hydropower and thermo-electric plants are challenged. Advances in integrating hydro-climate research through enhanced parameterization and physics based processes in regional power system analytics are presented through a series of numerical experiments. The Western U.S. water-energy dynamics are simulated using combinations of scale-appropriate hydrological-water management-production cost models to evaluate opportunities in short to long term energy planning and water-energy trade offs.

1 - The Effects of SNS Advertisement Attributes on Product Image and Purchase Intention According to Consumption Propensity

Eunju Ahn, Kyungpook National University-Korea, Daegu, Korea, Korea, Republic of, dmswn8808@naver.com, SungSu Kim

This research's purpose is to investigate the effects of product advertisement on product image and purchase intention through SNS. In particular, the emphasis is on moderating effects of consumption propensity. SNS advertising has the characteristic of inducing consumers' interest rather than searching for the product to buy by themselves. Therefore, it is necessary to study what kind of strategies should be established according to consumers' propensity to consume. We present the SNS advertising strategies by consumption propensity through the analysis of the structural equation model.

2 - How Do Country Characteristics Affect Cross-border E-commerce Sales in Europe? An Empirical Study

Nevin Mutlu, Eindhoven University of Technology, Eindhoven, Netherlands, n.r.mutlu@tue.nl, Zohreh Khooban, Sarah Gelper, Ton de Kok

One of the priorities of the European Commission is to establish a Single Digital Market in Europe, where customers can seamlessly make online purchases from other countries. The objective of this study is to develop insights that aid retailers and policy-makers in decision-making towards establishing a Single Digital Market in Europe. Towards that end, we conduct an empirical analysis using a unique dataset on the European consumers' cross-border shopping behavior. Specifically, we examine how country characteristics at the economic, regulatory, and cultural levels moderate the effects of individual-level drivers of cross-border sales.

3 - The Effects of Guanxi Circles for Customer Entrepreneurs on Social E-commerce Platforms

Yumeng Miao, Xidian University, Xi'an, China, ymmiao@stu.xidian.edu.cn

Recent practice shows that companies can diffuse new products faster by encouraging customers to share products knowledge in social media and transforming them into salesforce. We conducted a case study in an electronic commerce company to explore how different guanxi circles embedded in social media work for customer entrepreneurs' knowledge sharing and the role of cloud business platform in helping them get benefits. We found that guanxi-based knowledge sharing via WeChat consists of familial, familiar, and acquaintance ties, which subsequently helps realize physical, psychological, economic, and social benefits, but with the exception of familial ties' modest role along with the process.

4 - Three-stage Dynamic Game for Logistics Decision with Self-run Logistics and Unmanned Aerial Vehicle

Sun Qi, Shanghai Jiao Tong University, Shanghai, China, sun_qi@sjtu.edu.cn

In this paper, the e-commerce logistics capability decision system is divided into self-run logistics and unmanned aerial vehicle (UAV). The uncertainties of e-commerce orders are described as the main source of systematic noise, and then three kinds of flexible intensity supplement of UAV distribution capability are designed to deal with different situations for capability decision system. The three-stage dynamic game model is proposed in three cases, so that the decision maker can choose the best operation scheme on the basis of the change of unit cost of UAV distribution.

Machine Learning: Theory and Applications

Sponsored: Data Mining

Sponsored Session

Chair: Theja Tulabandhula

Co-Chair: Danial Mohseni-Taheri, University of Illinois at Chicago, Chicago, IL, 60610, United States

1 - Overbooking in Network of Energy Storage

Danial Mohseni-Taheri, College of Business, University of Illinois at Chicago, Chicago, IL, 60610, United States, Selvaprabu Nadarajah, Theja Tulabandhula

Ethanol production has increased in the past few years and can also be sourced globally (e.g., Brazil), which results in regular supply and demand imbalances that are handled by storage assets. Storage service providers sell capacity to users via long-term contracts and need to deal with the under-utilization of their assets during supply droughts and high usage during supply gluts. Motivated by a large US ethanol storage provider, we study the overbooking of capacity in a network of storage assets by considering the parameters of the users.

2 - Confounding-Robust Policy Improvement

Angela Zhou, Cornell University ORIE, 206 Rhodes Hall, Ithaca, NY, 14853, United States, az434@cornell.edu, Nathan Kallus

We study the problem of learning personalized decision policies or estimating heterogeneous treatment effects from observational data while accounting for possible unobserved confounding in the data-generating process. We calibrate policy learning for realistic violations of this unverifiable assumption with uncertainty sets motivated by sensitivity analysis in causal inference. For estimation of individual causal effects, we develop a functional interval estimator. We prove that if the uncertainty set is well-specified, our policy is asymptotically minimax-optimal, and demonstrate improvement and robustness on case studies from clinical trials.

3 - A Single Time-scale Stochastic Approximation Method for Nested Stochastic Optimization

Saeed Ghadimi, Princeton University, Princeton, NJ, United States, sghadimi@princeton.edu, Andrzej Ruszczynski, Mengdi Wang

We propose a single time-scale stochastic approximation algorithm, which we call the Nested Averaged Stochastic Approximation (NASA), for solving nested stochastic optimization (NSO) problems in which the objective function is a composition of two functions whose exact information are not available. We show that NASA achieves the sample complexity of $O(1/\epsilon^2)$ for finding an ϵ-approximate stationary point, thus outperforming all extant methods for NSO. Our method and its analysis are the same for both unconstrained and constrained problems, without any need of batch samples. This property makes NASA attractive for online learning where samples are received one by one.

4 - Prior-aware Spectral Inference for Co-occurrence Modeling

Moontae Lee, Assistant Professor, Universitty of Illinois at Chicago, Chicago, IL, United States, moontae@uic.edu

Spectral inference operate on matrices/tensors of co-occurrence statistics to learn low-dimensional geometries such as topics of documents or communities of networks. These algorithms are efficient and provable, but can no longer learn low-dimensional compositions of individual examples. Thresholder Linear Inverse is developed to map observations back to their latent compositions. But its linear characteristics limit inference quality without considering latent correlations. This talk proposes Prior-Aware Dual Decomposition/Manifold Iteration that leverage the latent correlations as a generic prior successfully on various data, completing the missing half of spectral inference.

5 - Learning to Partition Using Score Based Compatibilities

Theja Tulabandhula, UIC, FF07 Ajanta Vihar, Yelahanka, Chicago, IL, United States, Arun Rajkumar, Koyel Mukherjee

We study the problem of learning to partition users into groups, where one must learn the compatibilities between the users to achieve optimal groupings. We define objectives that optimize for compatibilities and propose algorithms for adaptively learning optimal partitions. We show that in general, the group formation objectives considered are NP hard to solve, and we either give approximation guarantees or prove inapproximability results. We then introduce an elegant structure, namely that of intrinsic scores, that makes many of these problems polynomial time solvable. We also propose an online low sample complexity PAC algorithm for learning the optimal partitions.

Data Analytics for Supply Chain Optimization

Sponsored: Data Mining

Sponsored Session

Chair: Ashton Kappelman

1 - Optimal Control in Food Supply Chain Using Big Data

Ashton C. Kappelman, Kansas State University, Manhattan, KS, 66506, United States, kappelmana@ksu.edu, Ashesh Sinha

We consider a dynamic food supply chain with multiple process steps and model it as a Markov Decision Process. The decisions at each step include supplier selection and settings for their process parameters. We propose an integrated approach that uses Big Data mining techniques to study the interaction of these decisions on the process's performance and the quality of the end product. This method uses stochastic optimization models to provide policies for the preferred suppliers and the settings for their process parameters.

2 - Machine Learning Methods for Revenue Prediction in Google Merchandise Store

Vahid Azizi, Graduate Research Assistant, Iowa State University, Ames, IA, 50010, United States, vazizi@iastate.edu, Guiping Hu

Machine learning has gained increasing interests from various application domains for its ability to understand data and make predictions. In this study, we apply machine learning techniques to predict revenue per customer for Google Merchandise Store. Exploratory data analysis (EDA) was conducted for the customer dataset and feature engineering was applied to find the best subset of features. Four machine learning methods including Gradient Boosting Machine (GBM), Extreme Gradient Boosting (XGBoost), Categorical Boosting (CatBoost), and Light Gradient Boosting Machine (LightGBM) and one ensembling method have been applied to predict revenue per customer.

3 - A Process Monitoring Framework for Supply Chain Management using MLCPM2

Mohammad Najjartabar Bisheh, Kansas State University, Manhattan, KS, United States, mnajjartabar@ksu.edu, Shing Chang

This research presents a process monitoring framework named MLCPM (Multi Layer Classifier Process Monitoring) to predict the likelihood of having safety problem comes from any raw material batch in a batch dispersion problem. This approach will help company to trace and call all finished or in process product which has problem before delivering to customers. Obviously recalling problematic material before delivering to customer will save a significant amount of budget and minimize amount of finished defect product while it tracks and find the reason fast because the more raw mixed materials in batches means the bigger recall, and higher cost.

4 - Optimization of Farm Management Strategies using Crop Models

Javad Ansarifar, Iowa State University, Ames, IA, 50010, United States, Faezeh Akhavizadegan, Lizhi Wang, Guiping Hu

Farm management strategies have both short-term and long-term consequences, economically, environmentally, and socially because of interactions of human, natural and material resources. Using crop models as promising tools for evaluating these strategies has two major challenges: 1. Parameters of models need manual calibration for every new dataset, 2. Because of complex structures, most crops models have been mainly used for prediction purposes and not for optimization. We address these challenges by training an explainable model to approximate the relationship between the performance of crop models and the parameters and optimize this model to identify optimal farm management strategies

1 - Spatiotemporal Missing Data Imputation for Photovoltaic Power Generation

Burak Tabak, Bogazici University, Istanbul, Turkey, burak.tabak@boun.edu.tr, Ismail Toyhan Yumru, Dilara Aykanat

Utility companies make use of automatic meter reading data to obtain production series of PV stations in their region. In order to be able to make reliable forecasts for their market operations, the continuity of the metering data should be flawless. Nevertheless, data transmission is frequently interrupted since the PV stations are generally located in rural areas. In this study, a tree-based method is proposed for the imputation of spatially distributed production time series of over a thousand stations with a total capacity of over 1 GWe, located in Turkey. The uncertainty introduced by the weather conditions are covered using the 0.25° Global Forecast System numerical weather predictions.

2 - Similarity-based Time Series Classification using Randomized Tree-based Transformation

Berk Gorgulu, University of Toronto, Toronto, ON, Canada, bgorgulu@mie.utoronto.ca, Mustafa Gokce Baydogan

Distance calculation between time series is a challenging task due to potential translation and dilations of patterns. Therefore, standard measures (L1, L2, etc.) fail to calculate distance properly. In this work, we utilize series of random trees to represent time series in terms of terminal node information. This new representation handles these potential problems successfully, allows using standard distance measures and provides competitive performance for 128 time series classification datasets from UCR Archive. Moreover, to deal with the sparsity of proposed representation, alternative feature selection approaches are evaluated without distracting the classification performance.

3 - Ntreeclus: A Model-based Partitioning Clustering of Sequential Data

Mustafa Gokce Baydogan, Bogazici University, Bogazici University, Department of Industrial Engineering, Istanbul, 34342, Turkey, Hadi Jahanshahi

Our study proposes a new Model-based approach for clustering sequence data, namely nTreeClus. The proposed approach is at the intersection of the conceptions behind existing approaches, including Decision Tree Learning, k-mers, and autoregressive models for categorical time series, culminating with a novel numerical representation of the categorical sequences. This new representation is used to perform clustering considering the inherent patterns in categorical time series. Furthermore, the only parameter of the method, the window size (n), is examined and the robustness of the method to its parameter has been shown.

Key Drivers of Hospital Performance in a Value-Based World

Sponsored: Data Mining

Sponsored Session

Chair: Kate Li

1 - Neighborhood Racial Segregation, Hospital Cancer Technology, and Racial Disparities in Cancer Outcomes: An Exploration

Nirup M. Menon, Professor, George Mason University, Fairfax, VA, 22030, United States, nmenon@gmu.edu, Cara Frankenfeld, Timothy Leslie

Black patients appear to suffer worse cancer outcomes than white patients. The role of the hospital and that of the cancer diagnosing and treating capabilities of the hospital in racial disparities has not been well-studied. This research explores the relationship between racial residential segregation and the availability of cancer technologies in hospitals. It explores the relationship between cancer technologies in a hospital, the race of the patient, and cancer outcomes (time to chemo, time to surgery, time to death) of the patient. The data consists of detailed patient-level data from the Georgia registry and the hospital-level data from AHA.

2 - The Impact of Health Information Technology on Hospital Staffing Decisions

Kate Li, Suffolk University, Boston, MA, 02108, United States, kjli@suffolk.edu, Mona Al-Amin

Healthcare Information technology (HIT) influences the clinical, operational and financial domains of performance in healthcare organizations. Previous research has focused mainly on the association between HIT and clinical outcomes, with limited research on the association between HIT and operational performance. In particular, literature on the impact of HIT on staffing decisions is scant and hospital managers lack evidence and guidance on staffing decisions with the implementation of HIT. In this study, we examine the impact of HIT on hospital staffing levels and mix of key medical staff, including different types of physicians and nurses.

3 - Continuity of Care and Risk of Readmission

Claire Senot, Tulane University, New Orleans, LA, 70118, United States

This study investigates the association between continuity of care mechanisms and a patient's risk of readmission in the context of one chronic condition, heart failure. Continuity of individual referring provider, continuity of physical location, and continuity of Accountable Care Organization are measured dynamically using patient-level claims. Results from a competitive-risks survival model reveals that all three continuity mechanisms are associated with a patient's lower risk of readmission.

4 - Predictive Analytics for Inpatient Readmissions

Hui Jia, University of Tennessee, Knoxville, UTK, Knoxville, TN, United States, Bogdan C. Bichescu, Haileab Hilafu

Recent Medicare initiatives linking reimbursements to readmission rates have placed renewed pressure on hospitals to reduce patient readmissions. We provide predictive analytics technique to predict inpatient readmissions with features related to physician, hospital and patient. Preliminary results indicate that our approach yields competitive performances compared to existing methods.

Sponsored Session

Chair: Amy Pan

1 - Optimal Display and Replenishment for Perishable Products Using Neural Reinforcement Learning

Xiajun Amy Pan, University of Florida, Gainesville, FL, 32611-7169, United States, amy.pan@warrington.ufl.edu, Fan Lu, Xiyao Ma, Xiaolin Li

We consider the problem of a retailer managing the inventory and display of perishable products in an infinite time horizon. We develop a neural reinforcement learning approach to effectively characterize the best ordering and display policies and discounting schemes for old products. We provide valuable guidance for practitioners.

2 - Dynamic Assortment Optimization in the Presence of Outlier Customers

Yining Wang, University of Florida, Gainesville, FL, 15213, United States, ynwang.yining@gmail.com

In this paper, we study the problem of dynamic assortment planning in the presence of outlier customers. In our setting, while most customers follow multinomial logit choice models, a fraction of the arriving customers will be “outliers” and might have arbitrary preferences of the items. We show how to handle such outlier customers by developing an “active elimination” type algorithm that sequentially remove items not preferred by non-outlier customers. Rigorous theoretical results are established to show the near-optimality of our proposed algorithm. An adaptive algorithm which does not require prior knowledge of outlier portions is also given.

3 - News Event-driven Predictive Models for Forecasting Socio-economic Indicators

Sunandan Chakraborty, Indiana University IUPUI, Indianapolis, IN, United States, sunandanchakraborty@gmail.com, Ashwin Venkataraman, Srikanth Jagabathula, Lakshminarayanan Subramanian

We present Event Class Model, a novel generative model of real-world events and employ it to extract events from a large corpus of news articles. We use the extracted events to generate time-stamped event embeddings and use them for predicting the fluctuations of socio-economic indicators. Then, we introduce the concept of Recurrent Event Networks (RENs), which makes use of a recurrent neural network (RNN) for predicting fluctuations in the socio-economic indicator of interest. We have trained RENs food prices and disease outbreaks and show that they can perform significantly better (up to 33%) than linear predictive models employing the same time-stamped event embeddings.

4 - A Deep MNI-bandit Approach for Personalized Food Recommendation with Social Networks

Na Zhang, University of Florida, Gainesville, FL, United States, Fan Lu, Xiajun Amy Pan

We develop a personalized food recommendation system for an on-demand service platform taking into account consumers’ locations, historical purchasing, and peer reviews of social networks. We formulate this problem as a Multinational Logit-Bandit model and propose an efficient deep bandit learning solution approach.

Sponsored Session

Chair: Shahin Shahrampour

1 - New Sample Complexities for Inference from underdetermined Models with Statistical Priors

Piya Pal, University of California, San Diego, La Jolla, CA, United States, pipal@eng.ucsd.edu, Ali Koochakzadeh

In recent years, the application of higher order statistics in identifying latent variable models has gained a great attention due to the powerful inherent expressivity of multilinear models. In this paper, we consider linear underdetermined models characterized by sparse parameters and show that in presence of certain priors on d-th order statistics, it is possible to reliably recover sparse supports of size O(M^d), where M denotes dimension of measurement vectors, with a probability of error approaching zero, exponentially fast as the number of independent measurement vectors increases.

2 - When Does Non-Orthogonal Tensor Decomposition Have No Spurious Local Minima?

Sina Baharlouei, University of Southern California, Los Angeles, CA

Tensor Decomposition approaches are demonstrated to be effective tools for modeling and solving a wide range of problems in the context of signal processing, statistical inference, and machine learning. In this talk, we analyze the optimization landscape of the d dimensional fourth-order Tensor decomposition problem with k non-orthogonal components. We show that under mild statistical assumptions, all local minima of this problem are global. To recover the decomposition components, we introduce the tensor power method (TPM) augmented by deflation and restarting.

3 - Parameter Tuning in High-Dimensional Problems

Arian Maleki, Columbia University

Please check the mobile app for this abstract.

4 - On the Dynamics of Gradient Descent for Autoencoders

Thanh Nguyen, Iowa State University, Ames, IA, United States

Why is gradient descent effective in machine learning? We ask this question in the context of unsupervised learning - specifically, learning weight-tied autoencoders - and provide two partial answers from the statistical learning standpoint: (1) a local result establishing the efficacy of gradient descent for reliable parameter estimation in the underparameterized setting, and (2) a global result which establishes conditions for gradient descent to converge optimally in the overparameterized setting.

1 - Novelty in Online Reviews and Review Helpfulness

Dicle Yagmur Ozdemir, University of Texas-Dallas, Richardson, TX, United States, yagmur@utdallas.edu, Sumit Sarkar

User generated contents such as reviews and ratings are valuable for platforms. To better leverage such reviews, platforms enable users to vote on reviews such as their helpfulness. We are investigating the relationship between review novelty and helpfulness. We characterize novelty as information not mentioned in other reviews, and identify a suitable measure for our task. We evaluate reviews by the new information they provide and examine the impact on helpful votes received. A related question is whether the repetition of information helps or hurts the helpfulness of a review. Therefore, we also examine the effect of such reinforcement on the helpfulness of a review.

2 - Understanding Longitudinal Impact of Preference Biases on Recommender Systems' Performance

Meizi Zhou, University of Minnesota, Minneapolis, MN, United States, zhou0793@umn.edu, Gediminas Adomavicius, Jingjing Zhang

Prior research shows that online recommendations have significant influence on consumers' preference ratings and economic behavior. Biases induced by recommender systems' predictions can lead to distortions in users' self-reported preference ratings after consumption, which, in turn, contaminate the subsequent inputs to the system with inaccurate user preferences. In this work, we use an agent-based simulation approach to examine the longitudinal impact of users' preference biases on recommender system's performance under a variety of conditions. We also investigate multiple factors that influence recommender system's capability of correcting the system's performance over time.

3 - Predicting Alliances Using Prior Firm Relationships Using Machine Learning

Ramanath Subramanyam, University of Illinois, Champaign, IL, United States, rsubrama@illinois.edu, Carla Fernandez-Corrales

Predicting the potential alliance partner of a firm is a rigorous exercise with seemingly innumerable possibilities; yet, this is an activity strongly associated with outcomes such as firm performance and product innovation. In this paper, we present a heterogeneous network model that employs firm alliance data to predict a firm's alliance partner in the near horizon.

1 - Black-box Data-driven Optimal Decisions via the Machine Transform

Evan Barlow, Weber State University, Ogden, UT, United States

Machine learning methods represent a significant advance in predictive analytics. Prediction is most fitting, however, when inputs and outputs are out of decision makers' control. Optimizing predicted objective functions over decision variable inputs is very difficult (if possible at all) for current machine learning tasks. The novel machine learning task presented here, called the Machine Transform, promises a scalable approach to black-box optimal decision making. The approach has successfully been applied to prescribe optimal decisions using several large-scale sandbox datasets.

2 - The Influence of Feature Scaling on the Stock Prediction

WenYi Lee, Shih Hsin University, Taipei, Taiwan, wylee@mail.shu.edu.tw

This study analyzes the forecasting performance of stock prices by applying two feature scaling methods, normalization and standardization, with comparing to non-scaling method, in machine learning. After transforming the feature boundaries into scales, the features reduce gradients to achieve an optimal solution more efficiently. The models applied include logistic regression, decision trees, and support vector machine. The results using the S&P 500 composite stock returns show the prediction performance and the timing to apply of various scaling methods.

3 - Optimal Predictive Clustering

Matthew Sobiesk, Massachusetts Institute of Technology, Cambridge, MA, United States, Dimitris Bertsimas, Yuchen Wang

The ability to make high quality predictions in an interpretable and scalable manner is a key problem in machine learning. In this work, we present a novel interpretable machine learning methodology called Optimal Predictive Clustering that uses integer optimization to cluster data followed by the training of cluster-specific regression models in order to make predictions. We report a comparison of our method with other interpretable machine learning models, such as optimal regression trees with hyperplanes, and show that our method exhibits comparable accuracy and significantly faster training times on large scale data without sacrificing interpretability.

4 - Comparison of Interpretability Between Optimal Trees and Popular Explainability Tools

Jeremy J. Toledano, Research Scientist, Interpretable AI, Cambridge, MA, United States, jeremy@interpretable.ai, Dimitris Bertsimas, Jack W. Dunn

Explainability tools like LIME and SHAP are often used to justify the choice of black-box machine learning models in fields where understanding how a model impacts decision-making is critical, e.g. finance. Let us explore how such tools compare to inherently interpretable machine learning algorithms like Optimal Trees.

5 - Machine Learning-based Pricing in Online Marketplaces

Xuying Zhao, University of Notre Dame, Notre Dame, IN, United States, xzhao1@nd.edu, Mike Chapple, Robert F. Easley, Hong Guo, Sriram somanchi

Merchants compete intensely for potential customers in online marketplaces such as Amazon. Setting the prices in such a highly dynamic, competitive environment is a challenging problem. In this paper, we build a machine learning-based demand prediction model and then derive the corresponding pricing strategy to improve sales.

1 - Risk Disclosures and ST Prediction: A Machine Learning Approach

Hongwei Wang, Tongji University, Shanghai, China, Yuan Song

Publicly traded firms with abnormal financial status will be marked as "ST" (Special Treatment) by China Stock Exchanges since 1998. This study applies Latent Dirichlet Allocation model to analyze textual risk disclosures in annual reports, and examines their associations with firms' ST.

2 - A Study on the Effect of Financial Structure on Technological Innovation Performance – the Mediating Effect of Innovation Input

Siwei Huang, Huazhong University of Science and Technology, Wuhan, China, 1045568892@qq.com

By structural equation model, we find that: the innovation investment of the GEM (growth enterprise market) enterprises of China has been formed diversification of financing system, including endogenous (corporate cash flow, retained earnings) and external financing (equity financing, debt financing, government subsidy). Cash holdings have a smooth effect on innovation investment; Retained earnings, equity financing and debt financing improve innovation investment and performance of technological innovation;Government subsidies promote innovation investment, but corporate innovation performance was negative correlation with it. Innovation investment plays a mediating role.

3 - An Analysis of the Correlations Between Stock Prices of Chinese Listed Firms and Their Financial Information: An Empirical Study Based on the Information Industry

Danxia Guo, Associated Professor, Xiamen University, Xiamen, China, Sijia Cao

The associations between stock prices and financial information can be used to assess the development of the stock market in China and levels of rationality of its investors. Considering stock prices and relevant financial information as endogenous factors, this paper analyzes the extents of short-term dynamics and long-term equilibria of the interrelations between stock prices and financial information of firms in the information industry. Our study suggests that the information industry on the stock market in China is semi-strong efficient. Stock prices are partly capable of reflecting the state of operation in the past of the firms but limited in predicting the state in the future.

4 - The Influence of Managerial Ability on Corporate Innovation

Shaoqin Ye, Xiamen University, Xiamen, China, ysq@xmu.edu.cn

Based on the data of Chinese listed firms from 2007 to 2015, this paper investigates the impact of the heterogeneity of managerial ability on corporate innovation. We find that there is a significant negative correlation between managerial ability and corporate innovation. We further find that the nature of property right has a certain moderating effect on the relationship between managerial ability and corporate innovation.

5 - Can Information from Twitter Predict Economic Statistics?

Bing Anderson, Cal Poly State University, San Luis Obispo, CA, United States, bianders@calpoly.edu, Karen Freberg, Shuyun Li, Laura Freberg

If someone loses his job, he could easily be on Twitter talking about it that very same day. For that person to file an initial unemployment insurance claim, and for the initial claims statistics to be compiled and released, that process could easily take a lot more time. Hence, studying tweets on job losses could help one gain information about the upcoming initial jobless claims statistics release by the US Government. Studying the correlation between "lost"+"job" tweet counts and the non-seasonally-adjusted initial jobless claims, we found a statistically significant positive relationship between the two time series.

Chair: Yuan Zhong, University of Chicago / Booth School of Business, Chicago, IL, 60637, United States

1 - Reinforcement Learning for Network Control

Qiaomin Xie, Cornell University, Ithaca, NY, 02139, United States, Bai Liu, Eytan Modiano

With the rapid growth of information technology, network systems have become increasingly complex. In particular, designing network control policies requires knowledge of underlying network dynamics, which are often unknown, and need to be learned. We propose to use model-based reinforcement learning. By applying Lyapunov analysis, our algorithm can be applied to queueing networks with unbounded state spaces. We prove that under our algorithm, the average queue backlog can get arbitrarily close to the optimal result. We also implement simulations to illustrate the effectiveness of our algorithm.

2 - Dynamically Protecting Privacy, under Uncertainty

Mine Su Erturk, Stanford Graduate School of Business, Stanford, CA, 94305, United States, Kuang Xu

We propose and analyze the -Noisy Goal Prediction Game, to study the fundamental privacy vs. efficiency tradeoff in dynamic decision-making problems with non-trivial uncertainty. An agent is trying to quickly reach a final goal in a network, through a sequence of intermediate actions, while the effects of her actions are subject to random noise and perturbation. Meanwhile, an overseeing adversary, who observes the effects of the agent's past actions, is trying to predict the goal before the agent reaches it. We are interested in understanding the probability that the adversary predicts the goal correctly (prediction risk) as a function of the time it takes the agent to reach her goal (delay).

3 - Collaboratively Learning the Best Option on Graphs, Using Bounded Local Memory

Lili Su, Massachusetts Institute of Technology, 459 Coordinated Science Lab MC 228, 1308 W. Main St., Cambridge, MA, 61801, United States, lilisu@mit.edu, Martin Zubeldia, Nancy Lynch

We consider multi-armed bandit problems in social groups wherein each individual has bounded memory. We say an individual learns the best option if eventually it pulls only the arm with the highest expected reward. While provably impossible for an isolated individual, we show that, in social groups, this goal can be achieved easily with the aid of social persuasion under mild network conditions. To deal with the interplay between the randomness in the rewards and in the social interaction, we employ the mean-field approximation method. Since the individuals in the networks may not be exchangeable, we go beyond the classic mean-field techniques and apply a refined version of mean-field approximation.

4 - Beating the Curse of Dimensionality in Optimal Stopping

Yilun Chen, Cornell ORIE, 292 Rhodes Hall, Ithaca, NY, 14853, United States, yc2436@cornell.edu, David Goldberg

High-dimensional optimal stopping arises in various practical settings and is notoriously challenging due to the curse of dimensionality. Typical modern approaches (ADP, simulation, duality) either scale poorly, or have limited performance guarantees. We overcome this computational obstacle by proposing the first algorithm that can trade-off between accuracy and runtime(analogous to a PTAS). Our algorithm outputs an epsilon-approximation with runtime and sample complexity both polynomial in time horizon T (effectively independent of the dimension) for any fixed epsilon. Time permitting, we also discuss several faster/more practical algorithms built on the same framework.

Optimization and Approximations for Queues

Sponsored: Applied Probability

Sponsored Session

Chair: Mariana Olvera-Cravioto, University of North Carolina-Chapel Hill, Chapel Hill, NC, 27599, United States

1 - High-order Lindley Equations in Write-only Systems

Mariana Olvera-Cravioto, University of North Carolina-Chapel Hill, Chapel Hill, NC, 27599, United States, molvera@email.unc.edu

We study a model for read-only database systems where users request simultaneous writing access to a random number of files. While files are being used, no other users can access them, creating blocking and idleness. We focus on the stationary waiting time of customers prior to receiving access to their requested files, and characterize its tail distribution. Moreover, when the access-time is allowed to depend on the number of files being requested, the waiting time is seen to satisfy a new type of high-order Lindley equation.

2 - Online Optimal Pricing and Capacity Sizing for G/ G/ 1 Queue with Demand Learning

Yunan Liu, North Carolina State University, Raleigh, NC, 27695-7906, United States, yliu48@ncsu.edu, Xinyun Chen

We consider a pricing and capacity sizing problem in a G/G/1 queue with an unknown demand curve. The service provider's objective is to adaptively adjust the service price p and service rate μ so as to maximize cumulative expected revenues (the service revenue minus the delay penalty) over a given finite time horizon; in doing so, the service provider needs to resolve the tension between learning the unknown demand curve (p) and maximizing earned revenues. We develop an adaptive algorithm based on stochastic gradient descent and provide asymptotic bounds for the regret. We also discuss possible accelerating methods for the algorithm.

3 - When Does Collaboration Help?

Rhonda Righter, UC Berkeley, Berkeley, CA, United States, rrighter@berkeley.edu, Kristen Gardner

We consider a Markov skill-based queueing system with heterogeneous jobs and servers, where the job class determines the subset of servers that can serve that job. In the collaborative model, the same job can be served by multiple compatible servers, with service rate that is the sum of the individual servers' service rates. In the more standard, noncollaborative, queueing model, at most one server can work on each job. In general, collaboration helps in symmetric systems, but may not in asymmetric systems.

4 - Resource Sharing Networks and Brownian Control: A Lower Bound on Asymptotic Cost

Michael Conroy, University of North Carolina-Chapel Hill, Chapel Hill, NC, United States, mconroy@live.unc.edu

A family of resource sharing networks proposed as models for internet flows is considered. Under heavy traffic, the asymptotic cost of this system can be approximated by a Brownian control problem (BCP), which is an optimization problem in terms of a Brownian motion on some space. For both a discounted cost and ergodic cost criterion, an appropriate BCP gives a lower bound on the best achievable asymptotic cost under any sequence of admissible policies. These lower bounds show that certain control policies constructed in previous work are, in fact, optimal. This talk is based on joint work with Amarjit Budhiraja.

5 - Ergodic Control of Diffusions with Compound Poisson Jumps under a General Structural Condition

Guodong Pang, Penn State University, Industrial and Manufacturing Engineering, University Park, PA, 16802, United States, Yi Zheng, Ari Arapostathis

We study the ergodic control problem for a class of controlled jump diffusions driven by a compound Poisson process. The formulation of the problem arises from queueing networks in the Halfin-Whitt regime, which motivates the new methodology framework with a general structural assumption. We derive the HJB equations and provide the characterization of optimality and the regularity properties of the optimal solutions. We establish the epsilon-optimality for the controlled jump diffusions by using the spatial truncation method. The results with the pathwise optimality is also discussed.

Decision Analysis III

Contributed Session

Chair: Suhao Chen, Oklahoma State University

1 - Ordinal One Switch Independence in Multi Attribute Utility

Shuoli Liu, Harvard University, Cambridge, MA, United States

We introduce a Rn generalization of ordinal one-switch independence (Abbas&Bell, 2015). Both necessary and sufficient conditions are presented for this ordinal property. We further characterize Homothetic Utility and partially separable utility with these new conditions.

2 - Calibrating a Group Utility Function That Minimizes Interview-data Requirements

Yupo Chan, University of Arkansas, Little Rock, AR, United States, ychan@alum.mit.edu, Raymond Staats, Oluwamuyiwa Adeegbe

We use multi-attribute utility-theory to define a mathematical representation of a decision-maker's utility. By eliminating the use of lottery questions, the survey is simpler to administer. The calibrated utility-function is then used in a multicriteria-optimization model for scheduling purposes. A case study is conducted in which two different decision-makers' preferences are combined to characterize a group utility-function. Again, a simple procedure is proposed to arrive at a group utility-function.

3 - Uncertainty Characterization Using Quantile-parameterized Distributions and Belief Functions: A Practitioner'S Perspective

Neil Hamlett, Education Data Scientist, IBM, Vienna, VA, United States, neil.hamlett@uncertainty-research.science, Patrick Leach

We explore the practical application of Theory of Evidence (ToE) to framed decision analysis. The dominant paradigm for decision framing follows a methodology first described separately by Howard [Howard2016] and Raiffa [Raiffa1970]. A decision tree represents decisions, framed as alternative scenarios. Scenario-outcome probabilities from the decision tree are represented using "metalog" distributions [Keelin2016], which are mixtures of distinct event distributions. We employ Keelin's framework to unwind the mixtures. We employ statistical characterizations to compare ToE-based and "traditional" uncertainties.

4 - Power Index of Nodes in Interdependent Networks: Coalitional Game Theory Approach

Katherine E. Barnett, University of Oklahoma, Norman, OK, United States, kathebarnett@ou.edu, Shima Mohebbi

During and after a disruptive event, interdependent infrastructure sectors complete or partially cooperate to allocate limited resources such as time, repair crews, and money to restore the networks. We will formulate a cooperative game model to measure the power and contribution of nodes in interdependent networks. We will propose a utility function that considers node precedence and infrastructure interdependencies. The results will assist utilities in allocating limited resources in a shared interdependent network.

5 - A Design Loop for Managing Many-goal Problems

Suhao Chen, Oklahoma State University, Stillwater, OK, United States, suhao.chen@okstate.edu, Lin Guo, Jelena Milisavljevic-Syed, Janet Katherine Allen, Farrokh Mistree

Multi-goal problems have been well studied. There are decision-support methods working effectively for two-goal and three-goal problems, however, as the number of goals increases, the accuracy and computational efficiency of those methods diminish. A method that particularly works for many-goal problems is required. We propose the Formulation-Approximation-Exploration method, to deal with the many-goal problems in five modules - model formulation, generation, clustering, converting, and exploration. A test problem in multi-criteria engineering design is used to verify the utility of the method.

CC- Room 302

Joint Session MSOM/Practice Curated: Operations of Innovative Retail Models

Sponsored: Manufacturing & Service Oper. Mgmt

Sponsored Session

Chair: Robert Swinney, Duke University, Durham, NC, 27708, United States

1 - What is in the Subscription Box: Managing Content to Acquire and Retain Subscribers

Soudipta Chakraborty, Duke University, NC, 27708, United States, sc390@duke.edu, Fernando Bernstein, Robert Swinney

We consider a model of a subscription service like Blue Apron or Birchbox that ships boxes of physical products to subscribers at regular intervals for a fixed, pre-determined, per-box price. While subscribers know their preference for a product, they learn their utility from using the service only after subscribing. We study how the service provider should allocate her total budget for content to boxes over a planning horizon to maximize total demand from new and existing subscribers.

2 - Pick-up, Delivery, or Both? An Online Grocer's Optimal Fulfillment Model

Chloe Kim Glaeser, University of North Carolina, Kenan-Flagler Business School, Chapel Hill, NC, 27514, United States, chloe_glaeser@kenan-flagler.unc.edu, Kenneth Moon, Xuanming Su

We partner with an online grocery retailer to answer the practice-based question of the optimal mix of delivery zones and fulfillment options using data-driven analytics. Based on this empirical evidence, we build and estimate a structural model and perform a counter-factual analysis to estimate the revenue increase from additionally offering delivery. We examine how the retailer can leverage data to customize locally available fulfillment options while scaling operations.

3 - Inventory Management for Exclusive Products

Ruslan Momot, HEC Paris, 1 Rue de la Liberation, Jouy-en-Josas, 78350, France, Elena Belavina

Firms selling conspicuous goods face a trade-off: producing more today allows for extracting more revenues but compromises the product's future reputation for exclusivity. We capture this trade-off in a dynamic model of strategic customer and firm behavior. We find that firms should optimally follow stationary cyclic strategies alternating scarcity and overproduction stages. The former builds reputation for exclusivity whereas the latter exploits it.

4 - Revenue Sharing and Subscription Platforms for Digital Content Distribution

Robert Swinney, Duke University, 100 Fuqua Drive, Box 90120, Durham, NC, 27708, United States, robert.swinney@duke.edu, Zhenhuan Lei

We analyze subscription services for digital information goods like books and music. Two content creators (low and high quality) choose whether to sell through the same subscription platform and are paid proportional to the percentage of total "use" that they generate on the subscription service. We show that with such a linear revenue splitting rule (commonly seen in practice), inducing the high quality creator to list on the subscription service is excessively costly, and typically not viable for the platform, which leads to low quality content on the service. We discuss remedies to this problem in the form of non-linear allocation rules to split revenue between content creators.

CC- Room 303

Research & Decision Support Systems

Contributed Session

Chair: Yasser Davizon, University of Texas-El Paso, El Paso, TX, 79968, United States

1 - Managerial Incentives and Research and Development Investment: The Moderating Role of Institutional Ownership and Product Market Competition

Furong Qian, University of Science and Technology of China, Hefei, China, Jin Hong

Studies have rarely discussed that the effect of managerial incentive on corporate R&D investment through external governance. This study examines the effect of managerial incentives on corporate R&D investment and how external factors affect this relationship. Based on panel data of 881 Chinese listed firms, our results reveal several interesting findings. Top managers' compensation with a degree of convexity promote corporate R&D investment. Further, institutional ownership and product market competition have significant moderating roles on this relationship. Additionally, when institutional ownership is higher, we indirectly verify agency problem with limited competence.

2 - Using Network Science Approach to Investigate Additive Manufacturing Readiness and Adoptiveness

Junfeng Ma, Assistant Professor, Mississippi State University, Mississippi State, MS, United States, ma@ise.msstate.edu

Additive Manufacturing is a fast growing manufacturing technology, however, the readiness and adoptiveness of this technology is still open question. This research utilizes a network science-based approach to investigate when and how additive manufacturing should be adopted, aiming to provide adequate recommendations to the potential clients of additive manufacturing and support their adoption decision making.

3 - Removing Barriers to Deploying Models to Business Users for Faster ROI

Libin Koshy Varghese, Principal Consultant, FICO, Secaucus, NJ, United States

Companies that have invested in predictive and prescriptive analytics are still experiencing high failure rates in deploying analytics that generate a positive ROI. Why build models if they never reach their intended users or aren't the right fit? In this talk, we will discuss some of the barriers data science and OR teams face when trying to put their analytics into action. We will also cover how a collaborative approach with the right tools can help teams avoid wasted effort, while delivering advanced analytics applications to end-users at higher quality than traditional methods.

4 - A Graphical Approach to Topic Modelling and Text Summarization

Neeraj Gadkari, Columbia University, New York, NY, United States, neeraj.gadkari@columbia.edu, Hardeep Johar, Aries Li

Topic based approaches to document summarization use word frequencies, LSA, etc., to identify topics and keywords in a document as a precursor to generating a summary. In this paper we present a methodology that uses knowledge graphs and graph properties to identify topics and generate document summaries. We use POS tagging and named entity analysis to construct a knowledge graph for a document, apply measures of centrality to identify topics represented by entities and their relationships, and use these centrality based topics to generate document summaries clustered around topic headings.

5 - Evaluation of the Efficacy of National Quality Infrastructure in China

Shiying Ni, Tsinghua University, Beijing, China, nisy13@163.com

National Quality infrastructure (NQI) is the ecosystem of institutions and regulations which establish and implement standardization, accreditation, metrology and conformity assessment. China has been developing NQI for decades to promote commodity quality. However, there is a lack of literature studying the efficacy of NQI. This paper will compensate this blank to provide evaluation of NQI efficacy and thus to give suggestions to NQI developing.

6 - Modeling, Analysis and Optimal Control for a Class of Production-decoupling Inventory System

Yasser Davizon, University of Texas at El Paso, El Paso, TX, United States, yadavizonca@miners.utep.edu, Heidi Taboada, Jose F. Espiritu

This research work presents a mathematical modeling and optimal control for a production-decoupling inventory system (PDI). A set of coupled ordinary differential equations represents the proposed PDI, which approximates the dynamic behavior of a factory. An optimal control analysis considers the minimum energy and time optimal control problems. Lyapunov stability and sensitivity analysis are present in PDI.

Empirical Research on Workforce Management

Sponsored: Manufacturing & Service Oper. Mgmt/Service Operations

Sponsored Session

Chair: Yong-Pin Zhou, University of Washington-Seattle, Seattle, WA, 98195-3226, United States

Chair: Qiuping Yu, Kelley School of Business, Indiana University, Kelley School of Business, Indiana University, Bloomington, IN, 47405-1701, United States

1 - Impact of Task-level Worker Specialization, Workload, and Product Personalization on Consumer Returns

Hailong Cui, University of Southern California, Marshall School of Business, Data Sciences and Operations, Los Angeles, CA, 90089-0809, United States, HailongC@marshall.usc.edu, Sampath Rajagopalan, Amy R. Ward

We study the impact of key operational levers on return rates, while controlling for numerous factors. We find that increased task specialization helps reduce return rates, but the impact is U-shaped. Increased workload levels in production result in higher return rates, whereas product personalization leads to lower return rates.

2 - Help or Hindrance? The Role of Familiarity in Collaborative Product Development

Necati Tereyagoglu, University of South Carolina, Scheller College of Business, 800 West Peachtree Street NW, Columbia, SC, 30308, United States, necati.tereyagoglu@moore.sc.edu, Karthik Ramachandran, Murat Unal

We empirically study product development in the video game industry by coupling a granular database of development credits with sales data. We find that familiarity in the team is associated with a decrease in sales. Separating this effect into different roles shows that familiarity between designers has a negative influence, while familiarity between producers has a positive influence on sales. We find that the positive influence by familiarity across producers is dominated due to an additional negative influence by the hierarchical familiarity between producers and designers. We further study how the effects can vary based on the nature of the experiences and the current role of the team members.

3 - Labor Planning in Retail Stores Using Customer Traffic Data

Marcelo Olivares, Associate Professor, Universidad de Chile, Santiago, Chile, molivares@uchile.cl

This work combines empirical analysis of point-of-sales data, customer traffic and employee staffing, with optimization methods to build a decision support tool that can be used by managers to plan labor allocation and working schedules, balancing gross margins, labor costs and employee satisfaction. An econometric model is developed to estimate the effect of labor on sales in an hourly basis, decomposing the effect of labor into conversion and ticket value. The empirical results are used in mathematical program that seeks to find the best feasible schedule to maximize store profitability, accounting for labor regulation restrictions and practical constraints.

CC- Room 306

Supply Chain Platforms

Sponsored: Manufacturing & Service Oper. Mgmt/Supply Chain

Sponsored Session

Chair: Milind Sohoni, Indian School of Business, Indian School of Business, Hyderabad, 500032, India

1 - Robust Optimal Recommendations for Risk-aware Customers

Yam Huo Ow, Northwestern University, Evanston, IL, United States, yamhuo.ow@kellogg.northwestern.edu, Chaithanya Bandi

We consider optimal recommendations problem for risk-aware customers with possibly uncertain risk preferences, where an online insurance platform has to offer the best insurance plan that matches the customers' risk preferences. We present a novel approach to model the uncertainty in risk preferences using robust optimization; and discuss tractable approaches for passive estimation and active learning to construct the uncertainty set of risk preferences from historical and interaction data, respectively. Lastly, we examine Linear Programming formulations which allow for tractable optimization with insightful solutions.

2 - Two-sided Assortment Optimization

Asrar Ahmed, Indian School of Business, Hyderabad, India, asrar_ahmed@isb.edu, Milind Sohoni, Chaithanya Bandi

We consider the problem of online service platforms which match job applicants with potential employers. Unlike traditional formulations which treat the participants as passive, we allow both employers and job applicants to exercise their choice. We introduce a two -sided assortment optimization model that captures the platforms constraint that it can only provide recommendations to each participant. We present a mixed-integer linear programming formulation of the model and provide performance bounds for a greedy online algorithm that can be solved efficiently. The algorithms are evaluated on real-world data set from a leading freelancing platform.

3 - Supplier Encroachment in a Non-Exclusive Reselling Environment

Parshuram Hotkar, University of Texas-Austin, McCombs School of Business, Austin, TX, 78712-1277, United States, Stephen Gilbert

We consider a setting in which a non-exclusive reseller procures partially substitutable products from two suppliers, one of whom introduces a direct-channel. We find that the presence of the second supplier alters many of the existing results about the interactions between a reseller and an encroaching supplier. For instance, the encroaching supplier may either sell exclusively through its direct-channel even when that channel is less efficient than the reselling-channel or sell through both channels even when its direct channel is more efficient than the reselling channel when the reseller is non-exclusive.

CC- Room 307

Procurement and Purchasing Management

Contributed Session

Chair: Hua Jin, University of Southampton, Southampton, SO17 1BJ, United Kingdom

1 - How the Risk Averse Buyers Choose the Marketing Strategy for New to Be Released Products

Xinran Shen, College of Management and Economics, Tianjin, China, xrshen@tju.edu.cn

The upgrading speed of products increasingly fast in the fierce competing niche market, many risk-averse companies adopt the advance selling strategy to deal with uncertain market when releasing the new product. We consider the risk averse behavior and experienced customer, aiming to explore the impact of the above two factors on how to develop the strategy (AS) and the decisions of company. We find that company's risk aversion leads to the decrease of the sales volume, but the increase of the company's utility. AS strategy is beneficial to the company, AS strategy with high discount is better than the low discount, it can also eliminate the demand uncertainty, thus offsetting the impact of risk aversion.

2 - The Effect of Information Policies in Procurement Negotiation: An Experimental Study

Junlin Chen, Central University of Finance and Economics, Beijing, China, chenjunlin@cufe.edu.cn, Cheng Qian

We consider a procurement negotiation between a buyer and a supplier, in which the buyer has private information about how to evaluate the suppliers' endogenous and exogenous qualities. Two types of information policies are examined. We establish two behavioral models characterizing the supplier's risk preference and judgment bias, respectively, and test the models using an experiment. We show that under EN policy, the suppliers are risk-loving and over-estimating; in contrast, under EX policy, the suppliers are risk-averse and under-estimating. The implications of our results for procurement negotiations are discussed.

3 - Developing Ensemble Predictive Models for Smart Procurement

Ramkumar Harikrishnakumar, Supply chain research analyst, Wichita state university, Wichita, KS, United States, rxharikrishnakumar@shockers.wichita.edu, Krishna Krishnan, Saideep Nannapaneni

In the era of industrial internet of things (IIOT, Industry 4.0), integration of information technology and acceleration of competitiveness are necessary for an effective supply chain management (SCM). Due to uncertain customer preferences, and fluctuating market demands, procurement plays a significant role in accomplishing the strategic goals of an organization. We develop a two-stage supplier selection framework by combining ensemble data-driven learning and probabilistic risk assessment.

4 - Information Seeking Biases in Supplier Selection

Somaye Ramezanpour Nargesi, University of Texas at Arlington, Arlington, TX, United States, somaye.ramezanpournargesi@mavs.uta.edu, Kay-Yut Chen

In this project we used a discrete choice setting to study information seeking behavior of procurement managers. Supplier selection has been studied from different aspects, most of which are prescriptive studies. We took a behavioral perspective to conduct a descriptive study of information seeking biases such as willingness to overpay for information, misjudgment of value of information,and pursuing irrelevant information in supplier selection context.

5 - Dynamic Procurement Strategy with Correlated Yields

Yi Li, Xi'an Jiaotong University, Xi'an, China, yili92-c@my.cityu.edu.hk, Lina Bao, Yimin Yu, Wei Zhang

We study a dynamic sourcing problem for a firm that faces unreliable suppliers, whose yields are correlated. The yield is specified by a supply function. Unsatisfied demand is fully backlogged. Our objective is to minimize the expected cost over a finite horizon. We introduce the notion of multi-dimensional upper-set monotonicity and establish a new preservation property of the monotonicity. Then we provide sufficient conditions to ensure the optimality of a threshold policy for the firm's order decision, which are applicable to a class of supply functions. Finally, we find that the optimal set of suppliers with positive orders is weakly consecutive in the minimum effective cost rates.

6 - A Methodology for Constructing Inventory Management Models Accounting for Taxation Schemes: the Case of the Dynamic Lot Sizing Problem

Hua Jin, University of Southampton, Southampton, United Kingdom, hj1g08@soton.ac.uk, Patrick Beullens

The OR literature in the area of logistics pays scant attention to cash flows that arise in order for the firm to fulfil its legal obligations. This research develops a methodology for constructing models for inventory management that explicitly account for UK taxation schemes. In this paper we focus on the case of the dynamic lot sizing problem. A fairly robust insight is that optimal ordering decisions often become synchronised with the value added tax/corporation tax return points within a standard tax scheme, while the benefit of considering taxes explicitly into the decision models increases the higher the product value and/or the lower the marginal profit on a product.

CC- Room 308

Service Science and Decision Analysis

Contributed Session

Chair: Takashi Irohara, Sophia University, 7-1 Kioi-cho, Chiyoda-ku, Tokyo, 102-8554, Japan

1 - Service Science

Diwas S. KC, Emory University, Atlanta, GA, United States

Please check the mobile app for this abstract.

2 - Service Order Allocation under Uncertain Demand: Risk Aversion, Peer Competition and Relationship Strength

Di Wang, Tianjin University, Tianjin, China, wd0410tju@126.com, Weihua Liu

This paper discusses the order allocation in service supply chains under uncertain demand, and builds a Stakelberg game model composed of a service integrator (SI), a key service supplier (SP), and an ordinary SP. There are three influencing factors: risk aversion, peer competition, and relationship strength. It was found that there is an offset effect between risk aversion and relationship strength and an amplification effect between peer competition and relationship strength. Only if three factors meet the equilibrium effect, can SI achieve higher expected utility. The "incentive upgrade and cost sharing" contract is proposed to improve SI's optimal expected utility.

3 - Green Product Design with Competition and Fairness Concerns

Tianqin Shi, San Jose State University, San Jose, CA, United States, Qingying Li, Xiaotong Guan

We consider a supply chain consisting of one manufacturer and two retailers, with one retailer having a distributional fairness concern. By investigating the impact of the retailer's distributional fairness concern on supply chain performance, we find that, for marginal-intensive green products, the manufacturer will lower the wholesale price but retain the green level; but for development-intensive green products, the manufacturer will lower both the wholesale price and the green level. For both types of products, the retailer with fairness concern will earn a smaller market share than its opponent. If an inequity outcome is unattained, the supply chain always performs worse.

4 - Optimal Container Selection in a Conflicting Objective Environment

Avnish Kishor Malde, Graduate Research Assistant, Clemson University, Clemson, SC, United States, Tugce Isik, Carrie Cline

We consider a warehouse with multi-product inventory, where the parts are continuously consumed based on the line-side demand. The inventory level is replenished using the available trailers and sea-containers. The sea-containers and trailers arrive overtime and we incur penalty on daily basis for holding them. We study the problem of optimally selecting the sea-container and trailers so as to reduce the number of remnant parts in the warehouse along with minimizing the detention penalties of the sea-containers and trailers. We model this problem using the Multi-Objective Mixed Integer Programming and solve it by using Goal Programming and -constraint method and present the numerical results.

5 - Optimal Storage Assignment for Order Picking in the Automotive Parts Warehouse with Multi-level Racks

Takashi Irohara, Professor, Sophia University, Tokyo, Japan, irohara@sophia.ac.jp

In this research, storage assignment for order picking are considered. Multi-level racks are used in the target warehouse holding automotive parts which are relatively large and heavy. In this reason, picking time at each level of rack is different and higher position needs longer time for picking. But no usage of higher level of rack takes wider space for storage assignment and incurs longer walking time for the order picking. Then we propose a three-dimensional storage assignment model to optimize the order picking and formulate it as a mixed integer programming problem. In order to demonstrate the effectiveness of the proposed model, numerical experiments using actual data are conducted.

2 - Incorporating Climate Modeling into Dengue Outbreak Predictions

Ying Zhang, Johns Hopkins University, Baltimore, MD, United States, ying.zhang@jhu.edu, Ensheng Dong, Sauleh Ahmad Siddiqui, Lauren Gardner

Dengue, a mosquito-borne viral disease, poses a serious global burden. Accurate prediction of dengue outbreaks can help effectively conduct disease surveillance and vector control. We proposed a model that incorporates the state-of-the-art real-time climate seasonal forecast from the North American Multi Model Ensemble (NMME) along with other known dengue risk factors into an outbreak prediction framework, and apply it to the dengue-prone region of Negombo, Sri Lanka. A sensitivity analysis is performed to evaluate how reliability of NMME climate predictions affects dengue predictions.

3 - Network Effects in Influenza Spread: The Impact of Mobility and Socio-economic Factors

Courtney Burris, University at Buffalo, Buffalo, NY, United States, cburris2@buffalo.edu, Alexander Nikolaev, Ling Bian, Shiran Zhong

This project reveals and quantifies the patterns in the spread of influenza over a region within a big city, as a function of population mobility. With census block groups taken as units of study and travel frequency as weighted connections between the units, a weighted attributed network is constructed and analyzed using social network analysis techniques. A new approach is presented to conduct hypothesis testing, regression, and surprise-based analyses on such networks.

CC- Room 310

Supply Chain, Managing Disruptions

Contributed Session

Chair: Hasmukh Gajjar, Associate Professor, Indian Institute of Management Indore, Rau-Pithampur Road, C#208, Prabandh Shikhar, Indore - Madhya Pradesh, 453331, India

1 - Effect of Salience of Available and Relevant Information About a Supply Disruption Trigger and Occurrence on Severity of Impending Supply Disruption

Rahul Pandey, The Ohio State University, Columbus, OH, United States, pandey.79@osu.edu, Hyunwoo Park, Manus Rungtusanatham

We examine how early supply disruption warning information availability (signal earliness) and warning information fluctuation (signal oscillation) about a supply disruption trigger (hurricanes) and supply disruption occurrence influence severity of impending supply disruption (flight delays and cancellations). We also explore the moderation effect of variability in the source of warning signal (signal source variability).

2 - Competitive Contract Design for a Backup Supplier under Demand Uncertainty and Supply Disruption Risk

Ashutosh Sarkar, Associate Professor, Indian Institute of Management-Kozhikode, Kozhikode, India, asarkar@iimk.ac.in, Stefan Minner

We analyse the use of an options contract for the backup supply for a manufacturer who faces disruption risk for its supply from the main supplier. The relationship is modeled as a Stackelberg game and the analysis focuses on the manufacturer's trade-off between 'responsiveness and costs', and 'supplier opportunism and incentives.' The analysis reveals that demand and supply uncertainty prompt the manufacturer to utilize more of its backup options while the backup supplier exploits it with a price increase. Further, we also observed that the backup supplier incentivises the manufacturer with a lower options buy price when the lost sales penalty is lower.

3 - Inland Waterway Disruption Response under Uncertain Conditions

Jingjing Tong, Southeast Missouri State University, Cape Girardeau, MO, United States, jtong@semo.edu, Heather Nachtmann

The U.S. inland maritime system is a commercially and strategically important transportation mode. Unexpected disruptions can cause non-navigable water levels or destroy major navigation infrastructures, resulting in inland waterway closures and consequent economic and societal impacts. We developed an optimization approach to the cargo prioritization and terminal allocation problem (CPTAP) to minimize the total value loss of cargo disruptions. We are currently developing an enhanced CPTAP model to improve pre-event disruption response by assessing the resiliency of the inland waterway transportation system to handle disrupted cargo under uncertain conditions.

4 - Intermediation in the Supply of Agricultural Products in Developing Economies

Ehsan Valavi, Harvard Business School, Boston, MA, United States, evalavi@hbs.edu, Kris Johnson Ferreira, Joel Goh

The agricultural industry has been growing in developing economies, yet farmers continue to struggle. Recently, e-intermediaries (fixed-price channels who use technology) have emerged as an alternative channel to the traditional local auctions for which farmers can sell their crop. We study the impact that e-intermediaries have on the supply chain.

5 - Assortment Optimization for Retailers with Two Sales Channel Considering Customer Behavior

Cheng Zhenxia, Shanghai Jiao Tong University, Shanghai, China

Recently, retailers are able to sell products through two channels, say online and offline (physical store). In this case, there are three types of customers who prefer to shop online, to shop offline and to experience offline but buy online respectively. So it is critical for retailers to decide how to assort the products through the two channels. We aim to maximize the total profit of retailers.

6 - Inventory Planning for Retailers Using Realtime Consumption Data

Hasmukh Gajjar, Associate Professor, Indian Institute of Management Indore, Indore, India, hasmukh@iimidr.ac.in, Bhavin J. Shah

IoT devices have made possible for retailers to track the real-time consumption of items done by their consumers. It provides early signal to retailers to make their inventory planning better. Using simulation approach, this paper attempts to showcase the usefulness of real-time tracking of consumption data in inventory planning.

Joint Session DAS/HAS: Decision Analytics and Economics of Information in Healthcare

Sponsored: Decision Analysis

Sponsored Session

Chair: Yeongin Kim, Virginia Commonwealth University, Glen Allen, VA, 23059, United States

Co-Chair: Mehmet U.S. Ayvaci, University of Texas at Dallas, Richardson, TX, United States

1 - Augmenting Radiologists' Decision Making Based on Mammography Using Deep Learning

Mehmet Eren Ahsen, University of Illinois, Champaign, IL, United States, Mehmet Ayvaci

Despite their increasing ubiquity, we are yet to understand when and how machine learning algorithms best augment human intelligence. Motivated by the complementarities between machine learning methods and human intelligence in solving prediction problems of heterogeneous difficulty, we propose an algorithm that optimally combines algorithmic predictions with expert judgments. We apply our algorithm on an imaging and radiologist assessments database that was used in a crowdsourced deep learning challenge for risk stratification of screening mammograms. We structurally and empirically characterize when and how radiologists' diagnostic decision making is enhanced.

2 - Drivers of Referral Networks: How Does Health Information Exchanges Impact Physicians' Decisions?

Saeede Eftekhari, State University of New York-Buffalo, Buffalo, NY, 14228, United States, Niam Yaraghi, Ram Gopal, Ram Ramesh

This study focuses on identifying the factors impacting the primary care physicians' referral decision making processes. After the clinical need for a referral has been recognized by a primary care physician, the referral could be modeled as the outcome of a two-stage decision process: During the first stage, the physician considers a set of potential specialists for the referral. During the second stage, the physician determines the volume of the patients to be referred to each specialist in the identified set. Our findings show that similarity with regards to participation in HIE has an impact on the primary care physicians' decisions during the first stage, and thus their consideration set.

3 - Health Information Exchanges' Pricing Strategies in a Competitive Environment

Yonghua Ji, University of Alberta, Business School, University of Alberta, Edmonton, AB, T6G 2R6, Canada, yji@ualberta.ca, Can Sun, Subodha Kumar

We study a setting two health information exchanges (HIEs) compete for healthcare provides (HP) to join its platform. The utility for an HP is determined by the intrinsic value offered by an HIE and the network effect. We use a game theoretical model to investigate how HIEs should price the basic and value-added services to maximize their profits. We also study how parameters affect the basic service price and value-added service price.

4 - Physician Decision-making Process in Admitting or Discharging Observation Patients

Paulo J. Gomes, Florida International University, Miami, FL, 33199, United States, pgomes@fiu.edu, Tala Mirzaei

This work examines the physician decision-making process in admitting or discharging patients from the observation unit of a hospital. Using patient-level data set covering one year of operations, we examine the drivers for length-of-stay, admission rate, readmissions and total cost per visit. The results explain the significant variability among physicians as observed in practice.

5 - A Data Analytics Framework for Smart Asthma Management Based on Remote Health Information System with Bluetooth-Enabled Personal Inhalers

Junbo Son, Assistant Professor, University of Delaware, Newark, DE, 19716, United States, junboson@udel.edu, Patricia Brennan, Shiyu Zhou

Patients diagnosed with asthma may experience significantly reduced quality of life if their asthma is not properly controlled. To facilitate better asthma self-management, a new health IS (smart asthma management system) is developed. Taking advantages of the monitoring capability of the system, we proposed a data analytics framework for detecting abnormal inhaler use that is out of the patient's normal usage pattern. We showed the satisfactory performance of our method through rigorous comparison with various benchmark methods. Also, practical implications of our analytics framework to data-driven asthma management practice is discussed.

Operations and Revenue Management

Contributed Session

Chair: Gaurav Pal, Fishbowl

1 - Measuring Hospital Performance under Comorbidities

Stefan Feuerriegel, ETH Zurich, Zurich, Switzerland, Patrick Zöchbauer

Health care reimbursements in the US exceeded USD 3.7 trillion in 2018. However, these reimbursements to providers are variable if healthcare providers fail to achieve a pre-defined quality of care. Key to performance-based reimbursements is a quality measure of hospital performance that caters for the fact of providers serving different patient cohorts. Despite extensive research on performance measures, prior attempts neglects comorbidities, i.e., co-occurring patterns of secondary diseases. We introduce a novel statistical model to learn the effect of comorbidities. In fact, we find that this results in extensive annual misallocations of reimbursements in the order of USD X bn

2 - An Empirical Exploration of Quality Management Practices and Firm Performance from Chinese Manufacturing Industry

Huiming Liu, Tsinghua University, Beijing, China, Su Wu, Chongwen Zhong, Ying Liu

This paper employs the event study methodology to determine whether companies can enhance operational and financial performance by implementing quality management frameworks. The results show that while quality awards winners have advantages in terms of their profitability indicators, their market performance and operating efficiency are not improved as expected. Specifically, the innovation capability of award winners strongly underperforms compared to that of their counterparts. This study also highlights that the positive impact on profitability may disappear after the certification and that the most significantly positive stimulus occurs in the certification year.

3 - Click-through and Purchasing Rates Optimization for E-tailer Plate-form: Leaning, Optimal Control and Long-run Average Objectives

Yina Ning, City University of Hongkong, Hongkong, China, yinaning2@gmail.com, Houmin Yan

We propose an online click-through and purchasing rate optimization framework that learns customer click-through and purchasing behavior. In this model, the selection of product advertising is modeled as a multi-armed bandit problem and the click-through rate can be adjusted by the product advertisement; and the purchasing behavior is modeled as a Markov chain and it can be enhanced by a dynamic pricing strategy. We demonstrate the proposed learning and optimal control framework optimizes a long-run average-cost. An initial study is carried out with data obtained from Tmall. <!—EndFragment—>

4 - Optimal Multi-Product Pricing and Generalizations

Seetharama Chandrasekhar Manchiraju, The University of Texas at Dallas, Richardson, TX, United States, chandumanchi@gmail.com, Milind Dawande, Ganesh Janakiraman

Our work is motivated by a multi-product price-optimization problem studied in Gallego and van Ryzin (1997). In this problem, there are supply constraints on the resources that are required to produce these products; these constraints form a system of linear inequalities. An interesting variant of this problem, also mentioned in Gallego and van Ryzin (1997), is when (a) the prices of the products are restricted to discrete sets and (b) we are allowed to change prices through time subject to the aggregate consumption of resources. This problem is an exponential size linear program. We present methods for solving this problem which are provably optimal in some special cases and near-optimal in others.

Queueing and Scheduling

Contributed Session

Chair: Yan Chen, Columbia University, New York, NY, 10027, United States

1 - The Airport Shuttle Service Scheduling Problem

Ça rı Koç, Social Sciences University of Ankara, Ankara, Turkey, cagri.koc@asbu.edu.tr, Nihat Öner, Hakan Gultekin

Airport shuttle services transfer passengers from or to the airport and city center. The main objective is to maximize the profit while satisfying the limited seat capacity, the predefined flight times, and the number of passenger constraints. Such considerations give rise to an integrated variant of a vehicle routing problem and machine scheduling. This paper introduces the airport shuttle problem, presents a mathematical formulation, and develops a hybrid metaheuristic based on simulated annealing. Extensive computational experiments have shown that the metaheuristic is highly effective. Several managerial analyses have been conducted to investigate the impact of some parameters.

2 - Appointment Scheduling in Dialysis Clinics

Farbod Farhadi, Roger Williams University, Bristol, RI, United States, ffarhadi@rwu.edu, Sina Ansari

Unpunctuality of patients in arriving to homo-dialysis clinics has direct impact on system operational performance and quality of care patients receive. In this paper, we propose an appointment scheduling framework to minimize patient waiting time and maximizing resource utilization, accounting for patient unpunctuality.

3 - Queue Joining Decisions When There is a Prerequisite Condition for Receiving Service

Mona Imanpoor Yourdshahy, University of British Columbia, Sauder School of Business, Vancouver, BC, Canada, mona.imanpoor@sauder.ubc.ca, Woonghee Tim Huh, Steven Shechter

We consider an M/M/1 queueing system in which customers require some conditions to be met prior to receiving service. We investigate whether an individual arriving to this system should join the queue at that time, or wait to join at some future time. We formulate the problem as a Markov decision process and show how the structure of the optimal policy depends on various model parameters. Furthermore, we use a level-k framework to characterize the equilibrium strategy and to model the bounded rationality of customers. We also present the socially optimal solution and compare it to the equilibrium policy.

4 - Designing Service Systems in the Age of Yelp: Incorporating Reviews in Queueing Decisions

Abhishek Roy, Temple University, Fox School of Business, Philadelphia, PA, United States, abhishek.roy@temple.edu, Debjit Roy

Online reviews have become an increasingly ubiquitous source of information about the quality of products and services. We propose a model where customers decide to join a queue based on the information obtained from online reviews. In doing so, we consider two cases - (a) customers infer quality solely from reviews, and (b) customers infer quality both from the length of the queue and from the reviews. We provide insights on optimizing the service system design, the product quality decision, and implementation of any incentive scheme for reviews.

5 - Simple Views of Queues: Set-valued Performance

Yan Chen, Columbia University, New York, NY, United States, yc3107@columbia.edu, Ward Whitt

We propose a new approach to performance analysis of queueing models. In particular, we propose developing set-valued performance descriptions given limited partial information. We illustrate this approach for the steady-state waiting time distribution in the GI/GI/K queue given the first two moments plus additional information about these underlying distributions, including support bounds, higher moments and Laplace transform values. In each case, the extremal models maximize or minimize the waiting-time tail probability in the exponential form associated with large deviations asymptotics. These extremal models are then applied to compute a range of possible mean.

CC- Room 4C-2

Large Scale Electric Vehicle Fleet Management in Transportation and Power Systems

Sponsored: Service Science

Sponsored Session

Chair: Dongfang Zhao, Year, Tampa, FL, 33617, United States

1 - Large Electric Vehicle Sharing Fleet Management System Interfacing Transportation and Power Systems

Dongfang Zhao, University of South Florida, Tampa, FL, 33617, United States, dongfangzhao@mail.usf.edu, Xiaopeng Li

In this study, we propose a linear optimization model to optimize the operations of a large fleet of shared EV fleet interfacing both transportation systems and power systems. The model investigates operations of a large shared EV fleet that may opt to serve travel demands in transportation systems or charge or discharge to the power grid in power systems. The sum of rebalancing cost, charging cost and distribution network line cost are minimized through the operation process. Real-world data on the configurations of these two systems are used to build numerical examples. Sensitivity analysis are constructed to draw insights into the influence of large EV fleet to power systems.

2 - Incentive Design for Decentralized Autonomous Electric Vehicle in Power Distribution Network

Zhaomiao Guo, University of Central Florida, Orlando, FL, 32816, United States, guo@ucf.edu

Autonomous electric vehicles (AEVs) provide unique opportunities to cope with the uncertainties of distributed energy generation in distribution networks. However, the effects are limited by both inherent radial topology and the behaviors of decentralized AEVs. In this paper, we investigate the potential benefits of dynamic distribution network reconfiguration (DDNR), taking into account AEVs' spatial-temporal availability and their charging demand. We propose a mixed integer programming model to optimally coordinate the charging/discharging of AEVs with DDNR, while satisfying AEVs' original travel plan.

3 - Transportation Network Infrastructure Design under Continuous Traffic Equilibrium

Xin Wang, University of Wisconsin-Madison, Madison, WI, 53562-4278, United States, Yikang Hua

Transportation network infrastructure design used to be a long-term decision, and relies on rough estimation of travel distribution. However, the recent development of smart transportation system requires the infrastructure to be adaptive to various uncertainties, which leads to the short-term infrastructure planning challenge, such as the number of dedicated automated vehicle lanes, reversible lanes, etc. For the first time, we develop an integrated infrastructure capacity planning framework under the concept of continuous modeling of traffic equilibrium. This continuous bi-level optimization model can provide fast traffic control instrument to various traffic conditions.

4 - Integrated Design of Dynamic Wireless Charging Location and On-board Battery Size for Electric Bus Systems Considering Battery Lifetime

Tingting Zhao, University of South Florida, Tampa, FL, 33612, United States, tingtingzhao@mail.usf.edu

This work focused on the integrated dynamic wireless charging facility (DWCF) location and battery size design of electric bus (E-bus) systems that is formulated as a nonlinear integer programing problem. The objective is to minimize system lifecycle cost. The componential facility cost, battery cost, and energy consumption cost, intertwine with each other through the design of DWCF location and battery size. The battery lifetime estimation introduces complicated non-linear feature to this problem that is tackled by transferring to optimization over the frontier of a bi-objective problem. The capability of the developed solution algorithm is illustrated on a case E-bus system design problem.

Disclosure in Mechanisms

Sponsored: Auction and Market Design

Sponsored Session

Chair: Kyle Woodward, University of North Carolina at Chapel Hill, Chapel Hill, NC, 27599-3305, United States

1 - Self-Auditable Auctions

Kyle Woodward, University of North Carolina at Chapel Hill, Department of Economics, Chapel Hill, NC, 27599-3305, United States, kyle.woodward@unc.edu

We consider the information necessary to verify that an auction has been run honestly. A mechanism is audited by information release if each outcome maximizes the seller's utility, conditional on consistency with information release. One mechanism is more auditable than another if any information that audits the latter also audits the former. Without supply commitment, only menus are auditable without information release. Discriminatory auctions are no more auditable than uniform price auctions. Audit-incomparability is relaxed under constraints on the form of information or nonnegligible marginal costs, and strengthened when the disclosure policy must be incentive compatible.

2 - Credible Mechanisms

Shengwu Li, Harvard University, Cambridge, MA, United States, Mohammad Akbarpour

Consider an extensive-form mechanism, run by an auctioneer who communicates sequentially and privately with agents. Suppose the auctioneer can deviate from the rules provided that no single agent detects the deviation. A mechanism is credible if it is incentive-compatible for the auctioneer to follow the rules. We study the optimal auctions in which only winners pay, under symmetric independent private values. The first-price auction is the unique credible static mechanism. The ascending auction is the unique credible strategy-proof mechanism. These results extend naturally when we permit asymmetry and payments from losing bidders.

3 - Learning Before Trading: on the Inefficiency of Ignoring Free Information

Anne-Katrin Roesler, University of Toronto, Toronto, ON, Canada

We analyze a bilateral trade model in which the buyer's valuation for the object is uncertain and she can privately purchase any signal about her valuation. The seller makes a take-it-or-leave-it offer to the buyer. The cost of a signal is smooth and increasing in informativeness. We characterize the set of equilibria when learning is free, and show they are strongly Pareto ranked. Our main result is that when learning is costly but the cost of information goes to zero, equilibria converge to the worst free-learning equilibrium.

Reliability & Retail Management

Contributed Session

Chair: Sushil Punia, Indian Institute of Technology Delhi, Vishwakarma Bhawan, IIT Delhi, Hauz Khas, New Delhi, 110016, India

1 - Life Cycle Cost Model for Tunnel Ventilation Systems Considering Vehicle Fleet Mix Forecast

Weihong Guo, Rutgers, The State University of New Jersey, Piscataway, NJ, United States, wg152@rutgers.edu, Qi Tian, Shenghan Guo

Tunnel ventilation systems must be able to provide adequate air quality during normal operations and emergency incidents. As the vehicle emission technology advances rapidly, the vehicle fleet is constantly being renewed. Thus, realistic forecasting of life cycle cost of tunnel ventilation systems must include models that incorporate the ever-changing fleet mix of zero emission, hybrid and combustion vehicles. In this study, both short-term and long-term forecasts of vehicle fleet mix are developed, considering conservative, moderate, or aggressive EV adoption. These forecasts are used to estimate CO emission, which will guide the optimal operations to minimize the systems' life cycle cost.

2 - Reliability Computation of a Repairable System Using Increasing Failure Rate

Berna Dengiz, Professor, Baskent University, Ankara, Turkey, bdengiz@baskent.edu.tr, Merve Uzuner Sahin, Orhan Dengiz

In today's highly competitive industry, companies try to find cost-effective solutions to improve system productivity. Several measures such as reliability, availability, maintainability are used to evaluate the performance of such complex manufacturing systems. Generally it is assumed that components are maintained with a constant failure rate for the system reliability.. However in many real world systems, the failure rate of each component increases depending on its lifetime. In this study, unlike studies in the literatüre component repair is considered to maintain a system. ncreasing failure rate is used to compute system reliability due to obtain more realistic system performance

3 - Reliability Optimization for Balanced System with Spherically Distributed Units

Jingbo Guo, Rutgers University, Piscataway, NJ, United States, Elsayed A. Elsayed

Balanced systems with spherically distributed units are emerging in a diverse range of applications such as Spherical Unmanned Aerial Vehicles used for underwater exploration. A limited number of units (usually motors and rotors) is mounted on the spherical surface and are required to operate in a balanced arrangement for the system to operate properly. The units' placement is key in reliability estimation for such balanced systems and thus is of interest for both designers and engineers. In this presentation, the optimal allocation of the units on the spherical surface while maintaining balance and maximizing the system reliability is studied. Numerical examples are provided for validation.

4 - Temporal Hierarchies for Demand Forecasting in Multi-channel Retailing

Sushil Punia, IIT Delhi, SA02 Vindhyachal Hostel, IIT Delhi, Huaz Khas, New Delhi, 110016, India, s.punia.official@gmail.com, Surya P. Singh, Jitendra Madaan

This paper proposes the use of temporal hierarchical framework as a strategy for forecasting in retail. The proposed framework uses the temporal hierarchies to generate short-term up to long-term coherent forecasts for a multi-channel retailer. For base forecasts for hierarchical framework, we used deep learning with long-short-term-memory networks for time-series forecasting. We evaluated the performance of proposed forecasting approach on point-of-sales data from a large multi-channel retailer. Several performance metrics and statistical test were employed to test the accuracy of forecasts from proposed framework and evidence suggests significant improvements across all metrics.

5 - Impact of Supplier's Capacity Constraint on the Platform's Business Model Choice

Bin Dai, Wuhan University, Wuhan, China, dbbudstar@gmail.com, Jing YU

We consider a supply chain consists of a supplier and a retailing platform, and the platform could choose the business model of reselling, agency or even hybrid. We investigate the impact of supplier's capacity constraint on the platform's business model design.

1 - Promotion of Women vs Men in the Canadian Armed Forces

Peter G. Boyd, Department of National Defense, Ottawa, ON, Canada

In order to ensure employment equity in the Canadian Armed Forces (CAF), it is important to understand if women benefit from the same promotion opportunities experienced by men. We examine historical CAF member service data broken down by sex and military occupation to see if women have an equal consideration for promotion to a higher rank. Equality is assessed based on metrics such as time in rank before promotion, and promotion rates.

2 - Infantry Career Lifecycle and Resource Planning Simulation Model

John Rumbavage, Deloitte Consulting, Arlington, VA, United States, jrumbavage@deloitte.com

A large-scale discrete event simulation model for manpower management in a major branch of the U.S. Armed Forces is considered. The military suffers from a shortage of qualified rifle squad leaders and has searched for a solution set that will reduce the severity of their problem under given constraints. Our simulation-based model accounts for complex career life cycles and unit deployment schedules that translate to 172 input parameters and constraints that are temporal, fixed point, or randomly distributed. The final product enables users to see how policy-driven parameter changes will affect operational force readiness as well as individual personnel assignment to alternate duty occupations.

3 - Optimal Scheduling of Flight Training for a United States Navy Strike Fighter Squadron Detachment

Joseph Carl Foraker, Assistant Professor, United States Naval Academy, Annapolis, MD, United States, foraker@usna.edu, Gary Lazzaro

We discuss the problem of creating daily flight schedules for 2- week training detachments of VFA-106 in Key West, FL called Fighter Det. The daily flight schedule requires pairings of students, instructors, 3 variants of F/A-18 aircraft, limited adversary aircraft, airspace deconfliction, sequential syllabus events, discrete flight time windows, and crew rest requirements. We formulate a binary integer program to automate the scheduling of flight events with the goal of maximizing daily events scheduled. The output of the model is a printable flight schedule in MS Excel format. Implementation of our model results in an average increase of 1.16 more events per day than a hand-written schedule.

4 - Simulating and Optimizing Shrapnel Spray from a Warhead

Erkam Guresen, Lethal Ballistics LLC., Ankara, Turkey, erkamguresen@gmail.com

Detonation of warheads is a critical issue in two ways; it should detonate when needed and it should detonate effectively. Failure to denote is considered by defense companies but generally effectiveness of the detonation is not considered. In this paper we present the state of the art warhead design procedure with detonation simulation that gives control capability of shrapnel spray after the detonation. This simulation capabilities enables specific warheads for specific target types.

1 - The Effect of the China Feed-in Tariff Scheme on Renewable Energy Technical Innovation: An Empirical Analysis for Electric Power Sector

Ge Zhao, Nanjing University of Aeronautics and Astronautics, Nanjing, China, zhaogezzu@qq.com, Peng Zhou, Peng Zhou

Feed-in tariffs have pushed mass of innovation of electricity on renewable energy in China. The subsides of renewable power generation have experiencing slope down provoking an public debate on whether promote renewable energy innovation. Focusing specifically on electric power sector, feed-in tariffs how influence the development of heterogeneous technologies were explored. We build a unique sample of China's provinces from 2008 to 2017 to identify the determinants of renewable energy technology innovation. We give a comprehensive interpret of technology innovation and present the managerial implication at the provincial level.

2 - Decision Right Allocation and Platform Market Effectiveness: Evidence from Online P2P Lending

Anparasan Mahalingam, Purdue University, West Lafayette, IN, United States, anparasan@purdue.edu, Tony Tong

This study proposes that platform owners can mitigate problems of information asymmetry in platform markets and enhance market effectiveness through appropriate allocation of decision rights among participants. By exploiting a quasi-experimental design in the online peer-to-peer (P2P) lending industry, we show causal evidence that retaining pricing rights with the platform increases platform market effectiveness, measured by loan sanction rates. This effect is strengthened by the hard information and mitigated by the soft information available in the local financial market, highlighting a strong connection between online platforms and offline information environments.

3 - Global Value Chain, Industrial Agglomeration and Industrial Innovation Performance: Insights from China's Manufacturing Industries

Nana Yang, University of Science and Technology of China, Hefei, China, ynn916@mail.ustc.edu.cn, Qiming Liu

This study explores GVC involvement along two dimensions-participation and position-and examines its effects on innovation performance in China's manufacturing industries, including its direct effects on innovation performance and moderating effects on the relationship between industrial agglomeration and innovation performance. The results show that GVC participation has an inverted U-shaped effect on innovation performance, whereas the effect of GVC position follows a U-shape. Finally, industrial agglomeration is found to positively affect innovation performance and the relationship is differently moderated by GVC participation and GVC position.

4 - Modern Predictors to Support the Human Development Index

Zachary James Steever, University at Buffalo, Gowanda, NY, 14070, United States, Hailie Suk, Ritwik Raj, Sayanti Mukherjee

The Human Development Index (HDI) is a metric used by the United Nations (UN) to assess the development of the world's nations. The standard HDI metric takes a linear combination of three features - years of schooling, life expectancy at birth, and per capita income. We propose that there exist modern indicators of human development, and that these predictors may not interact linearly with the development index. Using a suite of predictive models, this work explores a set of such factors which were gathered from the UN data explorer. We find that internet access, cell phone use, gender equality in the labor force, homicide rates, and secondary education enrollment are strong indicators of development.

5 - An Integrated Energy System Model to Evaluate Climate Policy on Industrial Sectors

Yoonmo Koo, Seoul National University, Seoul, Korea, Republic of, yyounmo@snu.ac.kr, Hwarang Lee

We integrate the top-down and bottom-up models to evaluate climate policy on 10 energy-intensive industries in South Korea. A dynamic recursive computable general equilibrium model accounting for interactions between economic agencies is used as the top-down model, while positive mathematical programming predicting technology substitution is used as the bottom-up model. The hybrid model can evaluate impact of carbon tax and give reasonable explanation for the unexpected rebound effect when energy efficiency of technology is improved.

1 - Insights from Causal Relations Extracted from Text Documents

Lipika Dey, Tata Consultancy Services, Delhi, India, lipika.dey@tcs.com, Tirthankar Dasgupta

Detecting causal relations from texts is challenging due to ambiguity, uncertainty and subjectivity. We propose linguistically informed deep transfer learning models to extract causal relations from text. Drug manufacturers mine scientific literature reporting causal relations between genetic conditions and diseases or effects of drugs on specific conditions. Similarly mechanic's notes having expert knowledge on causal relationships between various components are used to boost machine learning based health monitoring systems for smart machines. Causal relationship detection from safety incident reports provide actionable insights to enterprises. More industrial use cases exist.

2 - Utilizing Deep Learning and Machine Learning Algorithms in Disease Prediction

Buket Aydas, Albion College, Albion, MI, United States, baydas@albion.edu

Metabolomics, proteomics, and genomics (in general omics) hold the promise as a new technology to diagnose highly heterogeneous diseases. Here we use omics data to test the accuracies of feedforward networks, a deep learning (DL) framework, as well as five widely used machine learning models, namely random forest (RF), support vector machines (SVM), linear discriminant analysis (LDA), prediction analysis for microarrays (PAM), and generalized linear models (GLM) to predict some very important diseases.Some of the diseases that we work to predict are pancreatic cancer, cervical cancer, autism, down syndrome, cerebral palsy, pediatric concussion, miscarriage and Alzheimer disease.

3 - Simulation and Control Framework of Infectious Diseases Using Deep Reinforcement Learning

Hyunsoo Lee, Kumoh National Institute of Technology, Gumi, Korea, Republic of, hsl@kumoh.ac.kr

While most of the research studies handling infectious diseases have formulated Ordinary / Partition Differential Equations (ODE/PDE) based diffusion models, the effective control frameworks are provided comparatively less due to its dynamics. This research proposes a deep reinforcement learning based framework for controlling effectively several infectious diseases. The provided framework changes the locations of a disease control center considering multiple occurrences of infectious diseases and dynamics of diseases' status. Then, the framework is compared with other existing methods.

4 - A Load-Balancing Formulation for Disaster Response

Timothy Murray, University of Illinois, Champaign, IL, United States

Most models for disaster response and preparedness are based, implicitely or explictely, on the Network Flow Problem. This paper proposes an alternate formulation based on the Load Balancing Problem. The proposed model more easily incorporates concepts that are cumbersome in a network flow formulation, and is more adaptable to uncertainty in job duration for future work. An Integer Programming formulation is provided for exact solutions, then used to benchmark state of the art Load-Balancing algorithms.

5 - Discrete Network Location and Assignment Model under Cooperative Coverage in Fire Service

Han Liu, Tsinghua University, Beijing, China, hanliu@tsinghua.edu.cn, Xiaopeng Li, Saeed Amiri, Siyang Xie

Fire service quality relies on fast response and cooperation of various fire vehicles to maintain efficient operations and reliable rescue service. This paper investigates a cooperative station location and vehicle assignment problem where fire vehicles can be dispatched jointly for cooperation. A mixed-integer non-linear program is proposed to minimize facility construction/operation costs and fire damage losses. The results show vehicle locations become more decentralized and the average response times increase at slower rates of fire damage. An empirical case study with real-world data is also conducted to reveal managerial insight under a range of implementation scenarios.

Optimization, Robust II

Contributed Session

Chair: Mona Issabakhsh, University of Miami, South Miami, FL, 33143, United States

1 - Analyzing Reviewers' Influence on Amazon.com

Ji Hae Choi, Yonsei University, Seoul, Korea, Republic of, jiha9139@yonsei.ac.kr

This study analyzes periodic bipartite graph networks between reviewers and products. For every pre-defined time period, we create a bipartite graph consists of two sets of nodes (product nodes and reviewer nodes) and a set of edges representing the user's review on the product. As new edges are created, the graph network evolves. The analysis of network evolution reveals a tendency that if two users are coupled, i.e., they have reviewed the same product, one user is more likely to write a review on the product previously reviewed by the other user. This tendency becomes more significant when a user with few reviews is coupled with a heavy reviewer, which confirms the influence of heavy reviewers.

2 - A Data-driven Approach to Modeling Multiple Customer Satisfactions for New Product Development Using Canonical Correlation Analysis

Jaeho Lee, Sungkyunkwan University, Suwon, Korea, Republic of, jongseok@skku.edu, Jong-Seok Lee

Understanding the relationship between design attributes and customer satisfaction has received a great attention in new product development. While many research works have been done to model a single customer satisfaction on design attributes, the fact is that there are several types of satisfaction. Therefore, we propose a new data-driven approach consisting of three main components: canonical correlation analysis to find the relationship between product and customer, regression to establish the models, and solving a linear inverse problem to predict customer satisfaction scores. This method can help product engineers to consider customer satisfactions in new product development.

3 - Applying the WOWA Criterion to Two-stage Problems

Jaeyoong Lim, Korea Advanced Institute of Science & Technology, Daejeon, Korea, Republic of, jae0908@kaist.ac.kr, Sungsoo Park

Weighted OWA (WOWA), a criterion which generalizes many of the traditional criteria used in decision making under uncertainty, has been widely used in multi-objective problems. In this research, we apply the WOWA criterion to two-stage problems with discrete uncertainty. Use of the criterion generalizes both the stochastic and the robust version of the problem, and risk preference of the decision maker can be taken into account. We compare different algorithms to solve the problem, including an algorithm based on Benders dual decomposition method, and report their performance.

4 - Multi Appointment Infusion Therapy Scheduling Problem with Uncertainty

Mona Issabakhsh, University of Miami, South Miami, FL, United States, mona.issabakhsh@gmail.com, Seokgi Lee, Hyojung Kang

In this paper, a mixed-integer programming doctor-infusion appointment scheduling mathematical model is developed based on patient appointment data obtained from a cancer center of an academic hospital. The objective of the model is to simultaneously find the doctor-infusion appointment sets of patients who need to visit a doctor before infusion while minimizing patient wait times, infusion completion times, and the number of infusion beds used. A mixed-integer programming robust mathematical model is designed to find the optimal patient appointment set when doctor's appointment time and/or infusion time of patients take longer than expected.

1 - A Two-Step Approach to Optimal Selection of Alerts for Investigation in a Cyber Security Operations Center (CSOC)

Rajesh Ganesan, George Mason University, Fairfax, VA, 22030, United States, rganesan@gmu.edu, Ankit Shah

There exists a critical gap between the time needed (demand) and the time available (limited analyst resource) for alert investigation at a Cyber Security Operations Center (CSOC). Current ad-hoc triaging (or prioritization) method is insufficient, and an intelligent method for optimal selection of alerts that considers organization-specific factors must be developed, which is described as a two-step process in this research.

2 - Interactive Simulations in Support of Cybersecurity Risk Analysis

Shaun Doheney, ProbabilityManagement.org, Stafford, VA, United States, shaun@probabilitymanagement.org, Sam Savage

The Open SIPmath™ Standard from 501(c)(3) ProbabilityManagement.org allows simulations in any environment to be networked by communicating uncertainties as arrays of Monte Carlo realizations called Stochastic Information Packets (SIPs). This sort of modeling is particularly applicable to assessing risk associated with difficult-to-measure cybersecurity risks. Examples will include communications network modeling and analysis, and vulnerability analysis associated with layered network security. We encourage all participants to download some of the companion models to our presentation in advance available here: https://www.probabilitymanagement.org/models.

3 - On Combining Mission Mapping and Robust Network Analysis Methods to an Air Force System

Les Servi, The MITRE Corporation, M/S M230, Bedford, MA, 01730-1420, United States, lservi@mitre.org

We infer the topology mapping of a mission's components and the dependencies between the components from the enterprise network traffic it generates. Using robust optimization methods and MILP we identify critical nodes while hedging against imperfect dependency estimates. The results and approach are illustrated with a numerical example.

4 - Strategy-to-task Assessments

Mark A. Gallagher, Air Force Institute of Technology, Columbus, OH, United States, markgallagherJMJ@gmail.com, Leah Nestico, John Pav, Adam Campbell, Joseph M. Tama

We present a quantitative method to assess how well a budgetary plan complies with strategic guidance and aligns to enterprise priorities. We construct a hierarchy that links program elements to enterprise goals. We utilize the dot product of the priority weights and individual budgetary expenditures as a quantitative measure of overall budget alignment for each goal. Further, we compare a proposed budget to a prior year budget to develop relative assessments of budgetary alignment. We propose a greedy algorithm for a single goal, and preemptive goal programming for multiple goals. Analysts may use our approach to inform decision makers of possible tradeoffs between various enterprise goals.

Aspects of Unit Commitment

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Bismark Singh, Sandia National Laboratories, Sandia National Laboratories, Albuquerque, NM, 87185, United States

1 - Learning to Solve Stochastic Unit Commitment

Feng Qiu, Argonne National Laboratory, Lemont, IL, 60439, United States, fqiu@anl.gov, Alinson Xavier, Shabbir Ahmed

Stochastic UC remains a computationally challenging problem, especially for large-scale systems. State-of-the art methods, based on scenario decomposition and Progressive Hedging, are currently able to solve instances of small to moderate size, with a modest number of scenarios. We investigate how can ML extract information from a small number of scenarios that have already been solved to speed up the solution of the remaining ones, improving the performance of the entire procedure. Learned information includes redundantconstraints, warm starts and binary variable decisions. We present computational results on a variety of realistic and large-scale instances.

2 - Modeling Flexible Generator Operating Regions via Chance-constrained Stochastic Unit Commitment

Bernard Knueven, Sandia National Laboratories, Albuquerque, NM, 87185-1326, United States, bknueve@sandia.gov, Bismark Singh, Jean-Paul Watson

We introduce a chance-constrained stochastic unit commitment model to address renewables production uncertainty in power systems operation. For most thermal generators, underlying technical constraints that are universally treated as "hard" by deterministic unit commitment models are based on engineering judgments, such that system operators can periodically request operation outside these limits in non-nominal situations, e.g., to ensure reliability. We incorporate this practical consideration into a chance-constrained stochastic unit commitment model, specically by at most occasionally allowing minor deviations from minimum and maximum thermal generator power output levels.

3 - Synchronous and Asynchronous Parallel Algorithms for SDDP

Daniel Felipe Ávila Girardot, Université Catholique de Louvain, Louvain La Neuve, Belgium, daniel.avila@uclouvain.be, Anthony Papavasiliou, Nils Löhndorf

In our work we consider the Stochastic Dual Dynamic Programming algorithm (SDDP). In particular, we develop a terminology to establish what synchronous and asynchronous would mean for this algorithm, and study different approximations to achieve parallelism. The aim of the present work is to get an insight of different approaches to achieve parallelism, determine which parallel setting would imply a better time performance of the algorithm. Eventually we aim to show that SDDP performs well for handling battery storage decisions in distribution systems.

1 - Structured Actor-Critic for Managing and Dispensing Public Health Inventory

Yijia Wang, University of Pittsburgh, Pittsburgh, PA, 15213, United States, yiw94@pitt.edu, Daniel Jiang

Public health organizations face the problem of dispensing medications to groups of affected populations during emergency situations, typically in the presence of complexities like demand stochasticity and limited storage. We formulate a Markov decision process (MDP) model with two levels of decisions: the upper-level decisions come from an inventory model that "controls" a lower-level problem that optimizes dispensing decisions that considers the heterogeneous utility functions of the random set of arriving patients. We derive structural properties of the model and propose an approximate dynamic programming (ADP) algorithm that leverages structure in both the policy and the value space.

2 - Robust Location Problems under Spatial Uncertainty

Khaja Irfan Babu Soudagar Abdul, National University of Singapore, Singapore, e0046957@u.nus.edu

We propose a data-driven framework to solve location problems with continuously distributed demand. Leveraging the historical data to obtain the spatial information of demand distribution, we present a distributionally robust optimization approach to solve location problems under demand location (spatial) uncertainty. Employing clustering approach, we partition the study region into clusters, and estimate the probability of demand occurrence and mean demand location in each cluster from the historical data. Modelling this spatial distributional information into an ambiguity set, we provide tractable formulations for the robust median and gradual coverage problems.

3 - The Roaming Delivery Problem with Stochastic Travel Times

Joris Kinable, Eindhoven University of Technology, De Lismortel 62, Eindhoven, 5612 AR, Netherlands, j.kinable@tue.nl, Afonso Henrique Sampaio Oliveira, Lucas Petrus Veelenturf, Tom Van Woensel

We address a stochastic variant of the Vehicle Routing Problem with Roaming Delivery Locations (VRP-RDL), a last-mile delivery problem in which packages are delivered directly to the customer's car. Unique to this problem is that we can recover from missed deliveries by meeting up with the customer's next vehicle location. To accommodate for uncertainty in travel times, we solve the problem via a two-stage stochastic model. Our solution approach is based on an efficient heuristic for VRP-RDL, embedded in a customized SAA framework. Evaluation of this model shows that cost savings of over 30% can be realized when explicitly taking uncertainty as well as varying delivery locations into account.

4 - Robust Aircraft Routing

Chiwei Yan, Uber Technologies, San Francisco, CA, United States
Chiwei Yan, University of Washington, Seattle, WA, United States, Jerry L. Kung

We propose a robust optimization approach to minimize total propagated delay in the aircraft routing problem. We develop exact and tractable solution approaches for our robust model. The major contribution of our model is that it allows us to explicitly model and handle correlation in flight leg delays that existing approaches cannot efficiently incorporate. Computational experiments show superior performance over existing stochastic approaches.

5 - On the Values of Vehicle-to-grid Electricity Selling in Electric Vehicle Sharing

Yiling Zhang, University of Michigan, Ann Arbor, MI, 48105, United States, zyiling@umich.edu, Mengshi Lu, Siqian Shen

We study electric vehicle (EV) sharing systems with vehicle-to-grid (V2G) integration under uncertain electricity selling prices and trip requests. We formulate the problem as a two-stage stochastic linear program. In the first stage, we optimize service planning decisions. In the second stage, we optimize EV operational decisions using a time-and-charging-status-expanded transportation network. Via testing on real-world data, we demonstrate that the benefit of V2G can prevail with battery degradation and can be significant when combined with fast charging, stringent service level requirement, traffic congestion, or when the urban spatial structure has concentrated residentialareas.

2 - A Novel Methodology for Scheduling the Steelmaking - Continuous Casting Process

Kwansoo Lee, POSTECH, Pohang, Korea, Republic of, michelan73@postech.ac.kr, Kangbok Lee

This paper proposes a novel solution methodology for scheduling the steelmaking - continuous casting (SCC) process. The SCC process is a bottleneck in the steel production, so an efficient schedule for the SCC process will reduce costs and allow the just-in-time delivery. An MILP model was established first, but since the complexity of the problem makes the problem hard to solve optimally, a constructive heuristic algorithm based on matheuristic was developed. The numerical results show the efficiency of the proposed algorithm.

3 - Targeted Jump Gradient Descent Algorithm for Global Optimal Control in Non-Convex Problem

Yuyang Chen, Kansas State University, Manhattan, KS, United States, cyy@ksu.edu

With increasing pressure of healthcare issue for infectious diseases, policymakers are busy to search the optimal control that can efficiently prevent the spreading of epidemic under the limited budget. In this case, the global optimal strategy plays a crucial role for balancing the healthcare and economic pressure. Therefore, we propose a new Targeted-jump gradient descent (TJGD) algorithm to explore the global optimal control. We provide two simulations to demonstrate the effectiveness of the proposed algorithm for both convex and non-convex optimization problems. The simulation results show that our algorithm can converge to the global optimal control strategy of the control systems.

4 - Improving Restart Strategies for Radial Basis Function Surrogate Global Optimization

Nanxi Liu, National University of Singapore, Singapore, Singapore, e0225114@u.nus.edu

We introduce two restart strategies for radial basis function surrogate algorithm that use some subsets of the previously evaluated points. One alternative is to keep a certain percentage of the worst evaluated points in previous search steps, which helps the algorithm spend less time in the vicinities of bad function values. Another approach is to remove the points around the best point. This is designed to encourage search in promising areas without immediately moving to the best decision vector previously found. Experimental results indicate that the new restart strategies obtain better objective function values using fewer evaluations, compared with the global optimization algorithm DYCORS.

5 - Gaussian Dispersal Model for Controlling a Biological Invader

Sevilay Onal, NJIT, Newark, NJ, United States, Esra Toy, Sabah Bushaj

Sericea Lespedeza has been acknowledged as a very aggressive perennial legume and was included in the Federal Noxious Weed Act in 2000 to reduce the harmful impacts on biodiversity and bioeconomy in the Great Plains of the U.S. An integrated simulation-optimization model is developed where the seed dispersal is estimated using Gaussian cell-to-cell transition probabilities, and the treatment locations are prescribed over a predetermined time period.

1 - Competition in Tiered Spectrum Measurement Market with Licensed and Unlicensed Access

Arnob Ghosh, Indian Institute of Technology-Delhi, Delhi, India, ghosh39@purdue.edu

A three-tier spectrum sharing framework for the Citizens Broadband Radio Service (CBRS) enables commercial users to share spectrum with the incumbent users is proposed. Sharing is assisted by Environmental Sensing Capability operators (ESCs) which determine when the incumbents are absent. Two key aspects of this framework that impact how spectrum access firms (SAs) using this spectrum may compete are the different ESCs' information and how different SAs use the licensed and unlicensed band. We show that if the SAs use the unlicensed band more, they will obtain information from different ESCs. If one of the SAs uses the licensed band more, both the SAs obtain information from the same ESC.

2 - Performance Optimization with Load Coupling in Mobile Networks

DI YUAN, Professor, Uppsala University, Uppsala, Sweden, di.yuan@it.uu.se, Lei You

In this presentation, we review the load coupling model for performance evaluation and optimization of mobile communication networks. Here, the load refers to the amount of resource usage of each base station. The load values are coupled due to interference. Using the model, network performance can be assessed via solving a nonlinear equation system. A number of use cases of the model are highlighted. Next, we outline the challenges and research opportunities of extending the model to 5G networks, and present recent developments of the modeling approach for resource optimization for 5G systems with non-orthogonal multiple access (NOMA) and spectrum sharing between cellular and WiFi networks.

3 - Mobile Device Team Interconnection Game in the Internet of Things

Rupei Xu, The University of Texas at Dallas, Richardson, TX, United States, rupei.xu@utdallas.edu, Andras Farago

The emerging IoT technologies, such as edge and fog cloud, provide more powerful services for high demanding customers. The mobile device team(delivery drone system, self-driving car team, service robot team etc.) needs to maintain connectivity and connected to IoT to be assisted and controlled. However, in the existing literature, this problem is a dynamic quadratic assignment problem, which is very difficult to approximate and runs extremely slow with existing solvers. This paper innovatively created a two-level network creation game, which can avoid quadratic assignment problem and it can control the system performance by simple parameters, independently and in a distributed way.

1 - An Augmented Self-adaptive Parameter Control in Evolutionary Computation: A Case Study for the Berth Scheduling Problem

Maxim A. Dulebenets, Florida A&M University-Florida State University, Tallahassee, FL, 32311, United States, mdlbnets@gmail.com, Masoud Kavoosi, Olumide Abioye, Junayed Pasha, Hui Wang, Hongmei Chi

This study aims to enhance the marine container terminal seaside operations and addresses the berth scheduling problem. An innovative augmented self-adaptive Evolutionary Algorithm (ASAEA) is designed to solve a linear mixed integer mathematical model, formulated for the problem. In ASAEA, the crossover and mutation probabilities are encoded in the solutions and evolve throughout the search process. The numerical experiments show that the ASAEA outperforms the alternative metaheuristic algorithms, which have been widely used in the literature, in terms of the solution quality.

2 - Accelerated Tabu Search with GPU for Solving Vehicle Routing Problem with Time Windows

Deyi Zhang, Walmartlabs, Sunnyvale, CA, United States, Mingang Fu, Madhavan Vasantham

Large-scale Vehicle Routing Problem with Time Windows (VRPTW) appears often in last-mile delivery routing for modern E-commerce fulfillment. To solve large-scale VRPTW efficiently, we propose a parallel tabu search algorithm that conducts local search and tabu list comparison on graphical processing unit (GPU). The algorithm is implemented with OpenACC and is tested on all 300 Gehring and Homberger instances. This algorithm allows speed-up in the order of magnitude and significant reduction in total distances within very short time of computation in solving all the benchmark instances.

3 - An Exact Algorithm for a Rich Vehicle Routing Problem with Private Fleet and Common Carrier

Said Dabia, Vrije Universiteit Amsterdam, Amsterdam, Netherlands, said.dabia@gmail.com, David S.W. Lai

The Vehicle Routing Problem with Private Fleet and Common Carrier (VRPPC) is a generalization of the classical Vehicle Routing Problem in which the owner of a private fleet can either visit a customer with one of his vehicles or assign the customer to a common carrier. The owner's objective is to minimize the variable and fixed costs for operating his fleet plus the total cost charged by the common carrier. We consider cost structures that account for quantity discounts on outsourcing costs. We present an exact approach based on a branch-and-cut-and-price algorithm and test the algorithm on instances from the literature.

4 - The Vehicle Routing Problem with Private Fleet, Common Carrier and Stochastic Demand

David Lai, Vrije Universiteit Amsterdam, Amsterdam, Netherlands, david.lai@vu.nl, Said Dabia, Yossiri Adulyasak, Guy Desaulniers

The Vehicle Routing Problem with Private Fleet & Common Carrier (VRPPC) is a generalization of the Vehicle Routing Problem in which the owner of a private fleet can either visit a customer with one of his vehicles or outsource the customer to a common carrier. This family of problems has many practical applications in the design of last mile distribution services, and has received some attention in the literature. We extend the VRPPC by considering stochastic demand and a realistic cost structure that accounts for quantity discounts on outsourcing costs. We model the problem as a two-stage stochastic program, and present an exact approach based on Benders' decomposition and branch-and-cut-and-price.

5 - Inventory Rebalancing in Bike Sharing Systems Using a Combined Clustering and Vehicle Routing Approach

Mohammad Dehghanimohammadabadi, Northeastern University, Boston, MA, United States, mdehghani@northeastern.edu, Mohit Bansal, Tong Zhang

Bike sharing systems have grown vastly over the past few years as a sustainable means of transportation. A key element for such systems is rebalancing the number of bikes using multiple vehicles with fixed capacity across the network. We present a hybrid metaheuristic algorithm that combines genetic algorithm to find the optimal number of station clusters and the number of vehicles required along with simulated annealing to minimize the distance within a cluster for each vehicle. The method was evaluated for real-world data and results are provided which illustrate the effectiveness of the hybrid algorithm in determining the most optimal route while satisfying rebalancing requirements.

Sponsored Session

Chair: Qie He, University of Minnesota, Minneapolis, MN, 55455, United States

1 - A Fast Exact Algorithm for Minimum Convex-costFlow on the Dynamic Lot Size Network

Qie He, University of Minnesota, Minneapolis, MN, 55455, United States, qhe@umn.edu, Zeyang Wu

We study a minimum convex-cost flow problem on the dynamic lot size network, which finds many applications in production planning, transportation, and resource allocation. The current best algorithm for the integer version of the problem has a time complexity of $O(n^2 \log n \log(B/n))$, where n is the total number of sink nodes in the network and B is the total demand. We develop an $O(n^2 \log(B/n))$-time algorithm for the integer version of the problem and an $O(n^2\log(B/n/\epsilon))$-time algorithm for the continuous version.

2 - A Cost Scaling Algorithm for the Minimum Average Cost Flow Problem

Dorit Simona Hochbaum, University of California-Berkeley, Berkeley, CA, United States, dhochbaum@berkeley.edu, Xu Rao

The minimum average cost flow problem (MACFP) is a network flow problem with a fixed cost for using the network as well as variable flow costs depending on the amount of flow on each arc. The objective is to minimize the total fixed and variable cost per unit of flow going from any supply node to any demand node. Previous algorithms for MACFP apply binary search on the total amount of flow, where in each iteration solving the minimum cost network flow associated with the guessed amount. . We introduce here an algorithm that solves MACFP directly utilizing cost scaling technique.

3 - Cutting Planes for Global Optimization of Water Distribution Network Design

Byron Tasseff, Scientist, Los Alamos National Laboratory, Los Alamos, NM, United States, btasseff@lanl.gov, Russell Bent, Pascal Van Hentenryck

Physical systems governed by nonlinear resistances and potential-driven flows exist in a variety of important applications, including the optimization of potable water distribution networks. This work considers water network design problems with monotonically increasing potential loss functions and discrete resistance choices. A relaxation of the potential loss constraint is first used to reformulate the design problem as a mixed-integer convex program. Cuts based on a separate novel convex system are then derived and compared with conventional no-good cuts to remove infeasible designs.

4 - Branch-and-Cut Algorithms for Steiner Tree Problems with Privacy Conflicts

Alessandro Hill, California Polytechnic State University, San Luis Obispo, CA, 93407, United States, ahill29@calpoly.edu, Stefan Voss, Roberto Baldacci

We propose two novel variants of the Steiner tree problem in graphs, motivated by applications in secure strategic telecommunication network design. The optimization models incorporate two types of privacy conflicts between pairs of conflicting terminals that affect the tree structure. We develop non-compact integer programming formulations and elaborate branch-and-cut methods. Valid inequalities are suggested that are crucial when solving these problems, and dominance relationships between the induced polyhedra are established. The cutting plane effectiveness with respect to the dual bound and the performance of the exact algorithm are assessed on SteinLib-based test instances.

1 - Approximate Equitible Partitions and Synchronized Networks

David Phillips, PhD, US Naval Academy, Annapolis, MD, 21402, United States, dphillip@usna.edu

We present a model for network synchronization model well known in the dynamical systems literature. In this model, the usual graph model is complemented by a state vector at each node which updates at each time point according to a given vector field as well as interactions with adjacent nodes' state vectors. Of interest are nodes that synchronize, which means their state vectors converge under the given transition functions. For unweighted edges, the graph topology completely determines which nodes synchronize but this does not hold with respect to random perturbations. We describe a model that accounts for random perturbations and discuss limitations, implications, and associated computations.

2 - Optimal Heterogeneous Asset Location Modeling for Expected Spatiotemporal Search and Rescue Demands Using Historic Event Data

Bruce A. Cox, Assistant Professor of Operations Research, Air Force Insititute of Technology, Dayton, OH, United States, bruce.cox@afit.edu, Zachary Hornberger, Brian J. Lunday

The USCG is charged w/search & rescue in maritime regions. Given the size of the Pacific & limited resources, the service seeks to posture itself to reduce expected response time. Leveraging historic records, we propose & demonstrate a two-stage approach. 1st stage: We develop & apply a stochastic zonal distribution model to evaluate spatiotemporal trends for emergency events & associated responses. 2nd stage: These results enable parameterization & solution of a MIP to ID the best locations to station limited assets. Our models ID basing strategies that yield a 9-18% increase in coverage over current basing using existing locations & 57-67% increase when considering a larger set of basing locations.

3 - Coverage-based Destruction Algorithms for Reliability Evaluation of a Wireless Sensor Network

Nicholas Boardman, University of Arkansas, Fayetteville, AR, United States, Kelly Sullivan

Wireless sensor networks (WSNs) consist of a set of sensors, distributed over a region, that monitor and report conditions out of the network. One important design consideration is the WSN's reliability of region coverage as sensors fail over time. Monte Carlo methods for WSN reliability evaluation give rise to a "network destruction" (ND) optimization problem that determines the instant of network failure given fixed sensor failure times. We propose an algorithm to solve the ND problem for coverage reliability, analyze the algorithm's complexity, and compare its theoretical and empirical performance to logical alternative algorithms.

4 - The Shortest Path Interdiction Problem with Randomized Interdiction Strategies

Timothy Holzmann, Clemson University, Engineering, Computing and Applied Sciences, Riggs Hall, Clemson, SC, 29634, United States, Cole Smith

In this Shortest Path Interdiction Problem variant, the leader's selects a probability distribution for randomized interdiction actions. The follower knows this distribution (but not the realization) and seeks to minimize the shortest expected-cost path. The leader seeks to maximize the follower's objective. Our problem is relevant to problems such as border control, where the leader's may reasonably randomize the interdiction resource. We present the complexity of this problem, and several algorithms for various assumptions on the cost functions. We examine the efficacy of our algorithms on a test bed of randomly generated instances.

1 - The Social Robot Routing Problem

Kyle Booth, University of Toronto, Toronto, ON, M8W 2N6, Canada, kyle.booth@mail.utoronto.ca

The variety of tasks that social robots are being designed to complete is rapidly expanding and the constraints on their coordination becoming increasingly complex. We introduce the social robot routing problem (SRRP), an extension of vehicle routing that focuses on the constraints associated with routing teams of heterogeneous social robots in human-populated environments. We present mixed-integer linear programming (MILP) and constraint programming (CP) approaches for the SRRP, designed to optimize routes for teams of social robots. The proposed models synthesize ideas from electric vehicle routing with time windows and vehicle routing with multiple synchronization constraints.

2 - Optimizing Surveillance Routes for a Team of Robots: Solving the Graph-clear Problem

Michael Morin, Université Laval, 201-1381 rue de Jupiter, Québec, QC, G6W 8H9, Canada, Kyle Booth, Margarita Paz Castro, Tony T. Tran, Chang Liu, Chris Beck

We develop optimization approaches to the graph-clear problem, a pursuit-evasion problem where mobile robots must clear a facility of intruders. The objective is to minimize the number of robots required to execute a surveillance operation ensuring no intruder can escape the facility without being noticed. In this talk, we discuss the formal problem, its applications as well as state-of-the-art solving techniques based on the model-and-solve framework. Finally, we give insights on recent formal and empirical results on that problem.

3 - Real-time Ride Sharing Systems

Pascal Van Hentenryck, Georgia Institute of Technology, Atlanta, GA, 30332, United States, Connor Riley, Antoine Legrain

This presentation considers real-time dispatching for large-scale ride-sharing services over a rolling horizon. It presents RTDARS which relies on a column-generation algorithm to minimize wait times while guaranteeing short travel times and service for each customer. Experiments using historic taxi trips in New York City for instances with up to 30,000 requests per hour indicate that the algorithm scales well and provides a principled and effective way to support large-scale ride-sharing services in dense cities.

4 - Solving the Minimum Travel Time Problem Using Dynamic Discretization Discovery

Edward Yuhang He, PhD, Georgia Institute of Technology, Atlanta, GA, United States, edwardhe@gatech.edu, Natashia Boland, Martin Savelsbergh, George L. Nemhauser

Finding a shortest path in a network is a fundamental optimization problem. We focus on the settings in which the travel time on arcs depends on the starting time of traversal. In such settings, reaching the sink as early as possible is not the only objective of interest. If waiting is allowed, minimizing the travel time along a path can be important. We start with a constructive proof that the ``Minimum Travel Time Problem" can be solved in polynomial time. The approach is then refined using the ideas of Dynamic Discretization Discovery, which we show to be effective using our computational results. Finally, we conclude with new complexity results for a large class of time-dependent shortest path problems.

5 - A Study on the Traveling Salesman Problem with a Drone

Ziye Tang, Carnegie Mellon University, Pittsburgh, PA, United States, Willem-Jan Van Hoeve, Paul Shaw

A promising new model for future logistics networks integrates trucks with drones. The drone can pick up packages from the truck and deliver them by air while the truck is serving other customers. In this work, we consider the scenario of a single truck and one drone, with the objective to minimize the makespan. Strong NP-hardness is shown even when the truck route is given. We then present a compact constraint programming formulation. Experiments show solving CP to optimality is significantly faster than the state-of-the-art exact algorithm. For larger instances, our CP-based heuristic algorithm is competitive with a state-of-the-art heuristic method.

1 - Applying a Classifier to Solve Mixed Integer Quadratic Problems in CPLEX

Pierre Bonami, IBM, Calle del Plomo 18, Esc 2, Piso 3, Puerta C, Madrid, 28045, Spain, pierre.bonami@es.ibm.com, Giulia Zarpellon, Andrea Lodi

Within state-of-the-art optimization solvers such as IBM-CPLEX the ability to solve both convex and nonconvex Mixed-Integer Quadratic Programming (MIQP) problems to proven optimality goes back few years, but still presents unclear aspects. We are interested in understanding whether for solving an MIQP problem it is favorable to linearize its quadratic part or not. Our approach employs Machine Learning techniques to learn a classifier that predicts, for a given MIQP instance, the most suitable resolution method within IBM-CPLEX's algorithmic framework.

2 - On Using the P-median Problem for Clustering with Feature Selection

Juan Antonio Orozco Guzman, Sr. Data Scientist, Gurobi, Guadalajara, Mexico

Recently, a mixed-integer linear program was introduced to perform clustering and feature selection simultaneously. This model is in fact an extension of the radius formulation for the p-median problem, where the distance between objects is calculated by only considering the q most important features. We present an alternative model that uses patterns rather than the usual cumulative decision variables, allowing for a much sparser structure, which can also be applied to the classic p-median problem.

Keywords: Unsupervised learning, clustering, feature selection, mixed-integer linear programming, p-median problem, radius formulation.

3 - Sparse Robust Regression with Continuous Exact K-sparse Penalties

Jun-ya Gotoh, Chuo University, 1-13-27 Kasuga, Bunkyo-ku, Tokyo, 112-8551, Japan, jgoto@indsys.chuo-u.ac.jp, Shummin Nakayama

In this talk we study applications and efficient algorithms for k-sparse recovery problem on the basis of the Continuous Exact k-Sparse Penalties (CXPs) or which is also known as partial regularizers. Each CXP is defined by a non-convex but continuous function and the equality forcing the function value to be zero is known to be equivalent to the k-sparse constraint defined with the so-called l0-norm. Algorithms based on the proximal mapping of the lp-norm based CXPs will be examined for sparsity-seeking estimation problems such as a sparse robust.regression problem.

4 - Inferring Optima from Random Forests: An Empirical Approach

Haris Krijestorac, University of Texas-Austin, Austin, TX, 78705, United States, haris.krijestorac@utexas.edu

Although non-linear models may facilitate feature selection and improve predictive accuracy, a drawback of such models is their lack of interpretability. To address this limitation, we propose a data mining approach to strategically unpack the "black box" of random forest classification by inferring optimal values associated with model features. Our approach is based on gradient search within strategic neighborhoods, coupled with k-nearest-neighbors. We demonstrate the accuracy of our method across feature spaces of varying dimensionality, as well as varying data size and sparsity. Our approach can be especially useful in identifying feature spaces that are beneficial, yet under-explored.

1 - An Accelerated Proximal Point Method for Solving Nonconvex-Concave Min-max Problems

Weiwei Kong, Georgia Institute of Technology, Atlanta, GA, 30318, United States, wwkong92@gmail.com, Renato D.C. Monteiro

An emerging problem of interest within the area of nonconvex optimization is the (possibly nonconvex-nonconcave) nonlinear min-max problem. In this talk, we present an efficient inexact proximal-point algorithm for solving a class of nonconvex-concave min-max problems under various termination conditions. An extension to a linearly-constrained variant of these problems is also discussed.

2 - Distributed Optimization under Communication Constraints

Thinh Doan, Georgia Institute of Technology, Atlanta, GA, 30332, United States, thinhdoan@gatech.edu

We study distributed optimization problems over a network when the communication between the nodes is constrained, and so information exchanged over the network must be quantized. Our main contribution is to propose a novel adaptive quantization method, where the main idea is to quantize the nodes' estimates based on the progress of the algorithm. We then derive the bounds on the rates of the proposed method as a function of the bandwidths. Our results show that using the adaptive quantization, the rates of distributed gradient methods are unaffected by finite bandwidths. Our results achieve the optimal rates of distributed gradient methods under finite bandwidths.

3 - Proximal Point Method for Optimization with Nonconvex Functional Constraints

Digvijay Boob, Georgia Institute of Technology, NW, Atlanta, GA, 30332, United States, digvijaybb40@gatech.edu, Guanghui Lan, Qi Deng

In this work, we pose a new proximal point method for nonconvex (possibly nonsmooth) program with nonconvex constraints which has applications in risk averse ML and robust optimization. We show our algorithm converges to a t-KKT point in O(1/t) iterations under a famous constraint qualification. We show same convergence rates when the subproblem in each iteration is solved approximately. We propose an accelerated (stochastic) dual method converging to a t-approx solution of the subproblem in O(1/t^(0.5)) or O(1/t) iterations for strongly convex deterministic or stochastic problem, respectively. This seems to be the first work applying proximal point method for this class of nonconvex problem.

4 - A Doubly Accelerated Inexact Proximal Point Method for Nonconvex Composite Optimization Problems

Jiaming Liang, Georgia Institute of Technology, Atlanta, GA, United States, Renato D. C. Monteiro

We describe and establish the iteration-complexity of a doubly accelerated inexact proximal point (DAIPP) method for solving the nonconvex composite minimization problem whose objective function is f + h where f is a (possibly nonconvex) differentiable function whose gradient is Lipschitz continuous and h is a closed convex function with bounded domain. DAIPP performs both outer and inner iterations. Its outer iterations correspond to the ones of the accelerated inexact proximal point scheme. Its inner iterations are the ones performed by an accelerated composite gradient method for inexactly solving the convex proximal subproblems generated during the outer iterations.

1 - Safe Stopping Distance for Autonomous Intersection Management

Di Kang, University of Minnesota, Minneapolis, MN, 55455, United States, kang0275@umn.edu, Michael Levin

Previous studies have proposed signal-free autonomous intersection management (AIM) which uses connected vehicle communications and precision of automated systems to plan and follow collision-free trajectories. However, safety during abnormal conditions (such as a vehicle malfunction) within AIM has received little attention. Building on a conflict-point optimization model of AIM, we add buffers and develop a response protocol to avoid collision when a vehicle malfunctions. We present a mixed integer linear program and investigate the effects of these safety buffers on efficiency.

2 - Simlite: An Open Modeling Framework for Integrated Traffic Flow Simulation and Optimization

Jiawei Lu, Arizona State University, Tempe, AZ, 85281, United States, jiaweil9@asu.edu, Xuesong Zhou

The emergence of connected and autonomous vehicle (CAV) makes it possible to coordinate the motion of vehicles in a cooperative way. We introduce SIMLite here to provide an open modeling framework for integrated traffic simulation and optimization, especially in a CAV environment. We will discuss a CA(M)-based traffic flow model for vehicle motion simulation and a mixed integer linear programming (MILP)-based vehicle trajectory optimization model.

3 - Integrated Control of Traffic Signals and Vehicle Trajectories

Jiaqi Ma, University of Cincinnati, Cincinnati, OH, United States, jiaqi.ma@uc.edu

Connected and automated vehicle (CAV) technologies offer promising solutions for challenges facing our transportation systems. Vehicle trajectory control and traffic signal control based on CAV technologies are two approaches that have great potential and should be integrated into a single process such that both aspects can be optimized to achieve maximum benefits. This paper proposes an efficient algorithm, based on dynamic programming and an acelerated trajectory construction and evaluation method, for the integrated optimization problem that can simultaneously optimize the trajectories of CAVs and signal timing and phasing of traffic signal controllers.

4 - A Data-driven Optimization Based Cooperative Connected and Automated Driving Model

Kuilin Zhang, Michigan Technological University, Civil and Environmental Engineering, 870 Dow Environmental Sciences, Houghton, MI, 49931, United States, klzhang@mtu.edu

We propose a data-driven optimization based online predictive cooperative connected and automated driving control model using real-time high-frequency connected vehicle data via vehicle-to-vehicle communication technologies. An online real-time learning algorithm is used to predict the immediate preceding vehicle driving dynamics using streaming sensing data based on the concept of forecasting the forecasts of others. The predicted driving dynamics will be integrated into a data-driven optimization based model predictive control model for a robust cooperative adaptive cruise control model of a fleet of connected and automated vehicles.

5 - A Game-theoretic Framework for Autonomous Vehicle Velocity Control

Zhaobin Mo, Columbia University, New York, NY, United States, Sharon Di, Kuang Huang, Qiang Du

A transportation system with fully autonomous vehicles can be modeled as a multi-agent system, where autonomous vehicles interact with one another through coupled optimal driving strategies. However, the existing literature on autonomous vehicle longitudinal control suffers from scalability issues. This study tackles such a challenge by employing mean field approximation and deriving a macroscopic game-theoretic framework for autonomous vehicles traffic flow from microscopic velocity control. The developed game is mean field game (MFG), which is essentially the limiting differential game with an infinite number of agents.

1 - A New Look at the Hyperpath-based Algorithms for Transit Assignment Problems

Zhandong Xu, Southwest Jiaotong University, Chengdu, China, Jun Xie, Xiaobo Liu

Compared to the traffic assignment problem (TAP) in a highway network, the transit equilibrium assignment problem (TEAP) is much less studied, especially in terms of solution algorithms. This paper proposes two Newton-type hyperpath-based algorithms for a frequency-based TEAP. These newly developed algorithms, as well as two benchmark algorithms from the literature, are tested and compared on two real-world transit networks, in addition to a number of randomly generated grid networks. The results show the proposed hyperpath-based algorithms significantly outperform the benchmark algorithms in large networks.

2 - Fast-charging Station Deployment for Battery Electric Bus Systems Considering Electricity Demand Charges

Ziqi Song, Assistant Professor, Utah State University, Logan, UT, United States, ziqi.song@usu.edu, Yi He, Zhaocai Liu

Fast charging battery electric bus system is getting popular in recent years. However, fast charging may result in high electricity demand charges. In this study, a mixed integer linear program that minimizes the total costs of a battery electric bus system, including battery costs, fast charging station costs, demand charges, and ESS costs, is proposed to locate the fast charging stations and determine whether to install ESS as well as design the battery size for the electric buses simultaneously. Numerical studies are provided to demonstrate the effectiveness of the proposed model.

3 - Reexaming Rail Transit's Comparative Advantages in Travel Time and Cost Over Taxis: An Empirical Analysis of Washington, D.C. and Chicago

Sajeeb Kumar Kirtonia, Research Assistant, Florida State University, Talahassee, FL, United States, sajeeb.kumar.kirtonia@gmail.com, Yanshuo Sun

Due to its flexibility, taxi is a desirable transportation means for urban travelers, while rail transit characterized by its dedicated right-of-way could be more reliable, or even faster. The taxi trip data in the public domain provide an unprecedented opportunity to investigate the taxi performance in the urban environment. Most rail transit schedules and fares are also publicly available. Thus, this study compares rail transit and taxi in terms of travel time and cost, based on the real-world taxi trip data in Washington, D.C., and Chicago.

4 - Economic Analysis of On-route Fast Charging for Battery Electric Buses: Case Study in Utah

Zhaocai Liu, Utah State University, Logan, UT, United States, zhaocai.liu@aggiemail.usu.edu, Ziqi Song, Yi He

This study conducts a quantitative economic analysis of on-route fast charging for battery electric buses, thereby providing some guidelines for transit agencies. An integrated optimization model is first proposed to determine battery size, charger type, and recharging schedule for a general battery electric bus route. Based on the model, an economic analysis of on-route fast charging is then performed on ten real-world bus routes and a simplified general bus route with different parameters. A sensitivity analysis is also conducted to show the impact of potential price reductions of batteries.

5 - Data-driven Origin-destination Matrix Estimation in Large-scale Integrated Transport Systems

Jorge Huertas, Universidad de los Andes, Bogotá, Colombia, huertas.ja@uniandes.edu.co, Sergio Cabrales, Carolina Osorio, Andres L. Medaglia, Marcelo Botero, Alejandro Palacio

The OD matrix estimation problem is at the core of decision making for transport operators all around the world. Integrated transport systems that interoperate various services are common in big cities in Latin America. Bogotá's integrated transport system consists of two articulated components; a BRT system and a bus system that supply approximately 60% and 40% of public transport demand respectively. We propose a methodology for calculating an OD matrix for the bus service incorporating information from diverse sources. This information is collected from smart-cards transactions, bus geolocalization, mobility surveys and OD matrix estimations for other means of transport.

6 - Optimization of Paratransit Service with TNCs

Charalampos Sipetas, PhD Student, University of Massachusetts Amherst, Amherst, MA, United States, Eric J. Gonzales

A methodology is proposed to optimize Boston's paratransit system in coordination with a Transportation Network Company (TNC). Daily routes are constructed with a greedy algorithm. The position of each trip in the route determines the marginal cost by contributing to required fleet, vehicle hours, and vehicle miles of operation. These costs are compared with TNC fares for the same trips. The main output is a set of trips that, if assigned to a TNCs, leads to minimum combined costs for paratransit and TNCs. The algorithm accounts for the set of trips that cannot be assigned to TNCs for various reasons.

Advances in Traffic Information and Vehicle Platooning

Sponsored: Transportation Science & Logistics/Intelligent Transportation Systems (ITS)

Sponsored Session

Chair: Neda Masoud, University of Michigan, Ann, MI, 48109, United States

1 - Two-stream Multi-channel Convolutional Neural Network for Multi-lane Traffic Speed Prediction Considering Volume Impact

Ruimin Ke, University of Washington, Seattle, WA, United States, ker27@uw.edu, Wan Li, Zhiyong Cui, Yinhai Wang

Existing traffic speed prediction studies have two major limitations. First, they predict aggregated traffic speed rather than lane-level speed; second, most studies ignore the impact of other traffic flow parameters in speed prediction. To address the issues, we propose a novel model for multi-lane traffic speed prediction considering volume impact. In this model, we first introduce a new data conversion method that converts raw traffic data into spatial-temporal multi-channel matrices. Then we carefully design a two-stream convolutional neural network to effectively learn the features in multiple dimensions. Accordingly, a new loss function is developed.

2 - Itinerary Planning for Cooperative Truck Platooning: Exact Methods and Approximation Algorithms:

Mojtaba Abdolmaleki, University of Michigan, Ann Arbor, MI, United States, mojtabaa@umich.edu, Mehrdad Shahabi, Yafeng Yin, Neda Masoud

A cooperative truck platoon is a set of virtually linked trucks driving with a small intra-vehicle gap. Truck platooning yields several benefits but this talk focuses on scheduling travel itineraries of a given set of trucks to maximize platooning opportunities to save energy. We formulate the problem as a concave minimum cost flow problem and devise solution algorithms to find the optimal formation for medium to large size fleet. Finally, a fast approximation algorithm with guaranteed performance is proposed and tested.

3 - Optimization of Coordinated Platooning for Heavy-duty Vehicles

Xi Xiong, New York University, New York, NY, United States, xi.xiong@nyu.edu, Li Jin

Platooning of heavy-duty vehicles (HDVs) has the potential for remarkable efficiency and environmental benefits. In this paper, we study the coordination of HDV platooning on a highway section. Multiple HDVs are merged into one platoon based on between-HDV headways. The merging is done by accelerating the following vehicles to catch up with the leading ones. We study the optimal set of headways to determine the platooning coordination that leads to minimal fuel consumption in deterministic and stochastic scenarios. We also compare our results with that from Simulation of Urban MObility (SUMO).

4 - Adaptive Information Dissemination Strategy in a Vehicle-to-Vehicle Communication System by Considering Service Differentiation

Yangjiao Chen, Georgia Institute of Technology, Atlanta, GA, United States, Srinivas Peeta

This study develops a dynamic adaptive scheme to ensure the optimal utilization of available communication resources to maximize spatiotemporal coverage of information based on different service requirements and communication reliability. Transmission power and the number of multicast receivers are adapted by factoring frequently changing network topology and traffic characteristics. Numerical experiments demonstrate the effectiveness of the proposed model under different traffic conditions.

1 - Rack Design for 3D AS/RS Considering the Equipment's Speed Profile

Wenquan Dong, University of Tennessee, Knoxville, TN, United States, dwenquan@vols.utk.edu, Mingzhou Jin

In this study, we consider the optimal rack dimension problem for crane-based 3D automated storage and retrieval systems (AS/RS) with shuttle-based depth movement systems (DMMs) under random storage policy. The system consists of shuttles taking care of depth movement of SKUs in the rack and an automated crane moving SKUs along the horizontal and vertical direction. If the number of shuttles is less than lanes, the crane is also responsible for moving shuttles across lanes. The objective of this study is to analyze the impact of rack dimensions and equipment's speed on system performance and find the optimal dimension of the system under a given speed profile.

2 - See the Light: Optimization of Put-to-light Order Picking Systems

Konrad Stephan, Friedrich Schiller University-Jena, Jena, Germany, Nils Boysen, David Füßler

Put-to-light (P2L) order picking inverts the basic logic of conventional picker-to-parts systems. Instead of successively visiting the storage positions of stock keeping units (SKUs) when picking an order, an order picker accompanies successive bins each containing multiple items of a SKU. When the picker passes an order requiring the current SKU he puts the requested items into the associated order bin. This talk evaluates 4 different setups of P2L systems, which require the solution of different storage assignment and SKU sequencing problems during operations. We state the problems, prove computational complexity, provide solution algorithms and benchmark the impact on picking performance.

3 - Cloud-enabled Platform for Service Assignment and Control in Equipment Maintenance

yu chen, The University of Hong Kong, hong kong, Hong Kong

This research is one of the earliest studies to systematically propose the concept of real-time cloud equipment maintenance service (CEMS). CEMS is an important part of equipment maintenance services. It implements and controls real-time information and maintenance task allocation control of equipment to meet the requirements of maintenance service operators and equipment users. The aim of the research is to promote the characteristics of CEMS through real-life industrial cases and develop practical methods to improve CEMS efficiency in the daily equipment operations.

4 - Profit Allocation and Subsidy Mechanism for Public-Private Partnership Toll Road Projects

Lulu Jin, Dalian University of Technology, Dalian, China, jinlulu1226@126.COM

Public-Private Partnership (PPP) toll road projects are widespread around the world. However, it is difficult to predict traffic demand and cost accurately, which may lead to high profit risks for the private sector or bump up the fiscal burden for the government. This paper proposes an effective framework for the probabilistic evaluation of the excess profit allocation between the government and the private sector, as well as the subsidy mechanism. It aims to provide a knowledge base so that the decision makers can recognize the importance of accurately forecasting profit risks to provide a reasonable and fair profit redistribution mechanism to facilitate PPP contract design.

5 - Confidence Regions in Wasserstein Distributionally Robust Estimators

Jose Blanchet, Stanford University, Stanford, CA, United States, Nian Si, Karthyek Murthy

Wasserstein distributionally robust optimization (DRO) estimators are obtained as the solution of a min-max problem in which the statistician selects a parameter minimizing the worst-case loss among all probability models within a certain distance from the underlying empirical measure. In addition to producing estimators endowed with enhanced robustness properties, Wasserstein DRO estimators recover as a particular case a wide range of regularized estimators, including LASSO and support vector machines. This paper studies the asymptotic normality of underlying DRO estimators as well as the properties of an optimal confidence region induced by the Wasserstein DRO formulation.

6 - A Physical Ergonomic Compatibility Analysis of the Classroom Furniture

Benhur Satir, Cankaya University, Ankara, Turkey, benhur@cankaya.edu.tr, Filiz Erdo an Çelikçi

In this study, the classroom furniture that the Turkish students within10-14 years-old range use is assessed. It is aimed to understand whether using the same furniture over 4 year education period causes ergonomic discomfort and take necessary precautions if it exists. For this purpose, Maltepe Primary School is selected to conduct the study, which is one of the largest schools in Ankara, under the control of Ministry of Education. 119 students are selected as the sample and six anthropometric measures are taken on each student. Fitness tests are performed between classroom furniture dimensions and anthropometric measures using SPSS software. In the analyses, high level of mismatch is observed.

Network Optimization and Freight Transportation

Contributed Session

Chair: Masoud Barah, University of Tennessee, Knoxville, TN, 37996-2315, United States

1 - Inventory Repositioning via Price Optimization

Hoda Sabeti, Hertz, Naples, FL, 34119, United States, Montgomery Blair, Anirudha Kulkarni, Kevin Yeh

Rental car industry offers a range of products. Of all the products offered, intercity product is particularly important as it not only generates revenue but also moves cars without the use of shuttles. As part of intercity initiatives, we present different approaches to use intercity products for inventory repositioning based on value of a car in different cities. Results show reduction of shortage of inventory and improvement in overall revenue.

2 - A Time-expanded Formulation for the Locomotive Routing Problem with Maintenance Considerations

Pedro Miranda, HEC Montreal, Montreal, QC, Canada, pedro.miranda@hec.ca, Jean-François Cordeau, Emma Frejinger

In this talk we address the Locomotive Routing Problem (LRP), a large-scale optimization problem faced by railroad companies that aims to determine the optimal sequence of trains each locomotive is assigned to, while considering locomotives maintenance requirements over the planning horizon. A mixed integer formulation, based on a time-expanded network, and computational results are presented.

3 - Hub Location with Heterogeneous Economies of Scale

Masoud Chitsaz, Element AI, Montreal, QC, Canada, masoud.chitsaz@elementai.com, Borzou Rostami, Okan Arslan, Gilbert Laporte, Andrea Lodi

We study the single allocation hub location problem with heterogeneous economies of scale in which the hub-hub connection costs are piecewise linear functions of flow volume. We model the problem as a mixed integer linear program (MILP) and also a quadratically constrained linear program (QCLP). We use an integer L-shaped decomposition to solve the MILP formulation. We dualize a set of complicating constraints to generate a Lagrangian function to solve QCLP. We perform extensive computational experiments on both uncapacitated and capacitated large-scale problem instances. The results indicate the efficacy of our solution methods.

4 - An Optimization Tool for Rail Road Intermodal Transportation Network System

Fereydoun Adbesh, J.B. Hunt Transport Inc, Lowell, AR, United States, fereydoun.adbesh@jbhunt.com, Douglas Mettenburg

This research propose an optimization tool to analyze the rail road intermodal network for decision makers. The tool has two main purposes: i) identify the most beneficial shipments in the network and ii) analyze the network under different scenarios. A new periodic intermodal freight selection model during specified time periods is developed and formulated as a mixed integer program. The model selects the shipments that maximize the total profit while minimizing the total cost of empty movements in the network in each period. Empty movements on either road or rail is mostly because of imbalances between the number of pickups and deliveries in the ramp areas. Optimal solutions are found using CPLEX 12.8

5 - Designing an Efficient Exact Solution Approach to the Time-discretized Job Shop Scheduling Problem

Masoud Barah, Post-doctoral Research Fellow, Northwestern University, Evanston, IL, United States, mbarah@northwestern.edu, Jim Ostrowski

This research investigates a condition for which the polyhedron of the job shop scheduling problem is Integral. This condition is then used to construct an efficient solution approach. Specifically, by exploiting the problem integrality condition, we present a novel branching and pruning strategy in the branch and bound tree. The solution approach is boosted with a heuristic that sequentially solves a series of linear programming models to enhance the incumbent solutions. Computational experiments show that the developed solution approach can efficiently solve benchmark job shop and flow shop problems to optimality.

Joint Session AAS/TSL Air: Data Science for Air Transport Optimization

Sponsored: Aviation Applications

Sponsored Session

Chair: Xiaoqian Sun

1 - Estimating Airport Ground Transport Mode Choice Using Market Aggregate Data

Wenyi Xia, University of British Columbia, Vancouver, BC, Canada

We propose an empirical approach to estimate air travelers' airport ground transport mode choice using aggregate data. We match the flow of airport passengers with the ridership of airport ground transport modes. This approach is applied to Incheon International Airport (ICN). We show that passengers incur higher disutility from schedule delay than travel time. We also find that passengers flying low-cost airlines are more likely to take public transportation. We estimate how ridership of airport ground transport would be if the schedules were adjusted. We find that the existing schedules at ICN are suboptimal and could be substantially improved to achieve higher ridership.

2 - Characterizing Economic Outcomes Using Satellite Data for Transport Development

Weizun Zhao, City University of Hong Kong, Hong Kong, wzzhao6-c@my.cityu.edu.hk, Lishuai Li

Nighttime lighting satellite data are proven to be a good proxy for economic well-being, i.e. Gross Domestic Product (GDP). However, most methods are based on traditional regression analysis and the prediction accuracy is limited. We aim to develop a new method based on deep learning to predict GDP using nighttime light data and daytime image date from satellite. Since the data are publicly available, we can measure growth of sub regions instead of using countries as the unit of analysis and obtain a more detailed distribution of GDP in a region. We may further combine the satellite data with GIS data to analyze the impact of transport development in a region.

3 - Airline Network Design Problem with the Consideration of Demand Price Relationship

Liang Zhe, Tongji University, Shanghai, China

In the traditional airline network design, airlines first estimate the demand and price of each flight based on the market share and the historical data. This demand and price information is used by the fleet assignment problem as the input constant. In our research, instead of consider the demand and price as the constants, we use a piece-wise linear function to describe the demand and price relationship. We formulate the fleet assignment problem as a quadratic problem and propose an efficient heuristic to solve it.

4 - Data Mining over ADS-B Trajectories

Sebastian Wandelt, Beihang University, Beijing, China

With ADS-B, Automatic Dependent Surveillance-Broadcast, aircraft determine their positions based on satellite technology; their broadcasted signals are being received, decoded and merged by receiver networks around the globe. This presentation gives an overview on the data management challenges coming with data science analysis of trajectories and provides prototypical solutions which scale up to planet scale data. Previously-unseen in-depth analysis of global flight patterns leads to the derivation of novel prediction models and, in turn, to safer and more efficient aviation.

5 - Impact of HSR on Aviation in Europe and China

Pengfei Yi, Beihang University, Beijing, China

Research on competition and cooperation between high-speed rail (HSR) and air transportation is usually limited to single city pairs or inside smaller regions, induced by either lack of data or lack of computational resources. We aim to build a generic model for traffic connectivity at continental scale. Multiple globally available datasets, including OpenStreetMap, GPWv4, and other socioeconomic data, are joined, cleansed, and fitted. Actual railway and airline schedule data is used to verify the effectiveness of the model. An emphasis is put on the impact of HSR on aviation.

Joint Session RMP/Practice Curated: Forecasting Methods and Analysis in Practice

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Manu Chaudhary, PROS, Houston, TX, 77054, United States

1 - Forecasting Hotel Reservations Using Deep Learning

Jian Wang, RealPage, Alpharetta, GA, 30022, United States, Jian.Wang@RealPage.com

In this talk, we review three methods commonly used to forecast hotel reservations, and then propose two long short-term memory (LSTM) models based on recurrent neural networks. To measure the relative performance, we estimate the two LSTM models as well as six machine learning (ML) models against actual reservations of four hotels. The empirical results show that, on average, the forecasting accuracy of using LSTM models has been improved about 3.0% over that of using the best of the six ML models.

2 - Forecasting Improvement with Short-term Adjustment and Long-term Stability

Chih-Hsien Wu, PROS, Houston, TX, United States, Ross Winegar

A common practice to forecast booking behavior is to use time-series with a time-weighting parameter to control how forecasts adjust over time as new data is observed. This can produce the unintended consequence of data having outsized impacts between seasons - e.g. a drop in bookings in February affects summer peak forecasts in July. A proposed solution is to ensemble together forecasts using different drift learning rates, so that changes in bookings are reflected in near-term departures while maintaining stability for longer-term departures.

3 - Analyzing Hierarchical Forecasts

Manu Chaudhary, PROS, Sugar Land, TX, United States, Jiabing Li

Forecasts for a typical Revenue Management system are generated for a combination of multiple dimensions, which could lead to millions of forecast entities because of which users typically analyze the forecast results at a higher level of dimensionality. However, in doing so they lose resolution of the lowest level forecast and it can difficult to understand the reasons behind the different forecast patterns. We propose metrics and workflow to analyze the low level forecasts to guide the user to the reasons which lead to the forecast numbers different than their expectation.

4 - Unconstrained Demand Forecasting and Accuracy Assessment for Car Rental

Jordan Cuevas, Sr Data Scientist, Hertz, Estero, FL, United States

Forecasting future demand when historic observations are censored due to supply limits is an important problem in the hospitality industry, particularly in the car rental space where the fleet size can be increased relatively quickly. Here we present two approaches to forecast unconstrained demand, along with some results showing their robustness and accuracy.

Joint Session RMP/Practice Curated: Matching Platforms for Services

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Peng Shi, University of Southern California, Los Angeles, CA, 90064, United States

1 - Dog Eat Dog: Measuring Returns to Scale Using a Digital Platform Merger

Chiara Farronato, Harvard Business School, Boston, MA, United States, Andrey Fradkin

In this project, we use transaction-level data to study a merger between the two largest US-based digital platforms for overnight dog-sitting. This merger provides an opportunity to study the returns to consolidation in digital marketplaces and to measure the mechanisms underlying these returns. An advantage of our setting is that the market for dog-sitting is highly local and that the diffusion of the two platforms varied across geographies. Consequently, the merger affected different locations to a varying extent. We use an event study approach to show how the merger affected the volume of transactions as well as their quality.

2 - Random versus Directed Search for Scarce Resources

Teddy Mekonnen, PhD, Brown University, Providence, RI, United States, mekonnen@brown.edu

This paper studies how different search protocols affect social welfare in a search market with scarcity. Agents search for objects that differ in quality either through a random or a directed search protocol. Random search protocol, in which agents are randomly paired to an object of any quality, gives rise to adversely selected markets. Directed search protocol, in which agents choose with which quality types to pair, gives rise to congestion. When utility is either non-transferable or transferable through Nash bargaining, I show that random search dominates directed search in terms of welfare, even though each agent would prefer to be able to direct her search.

3 - Cream Skimming and Information Design in Matching Markets

Alex Smolin, Toulouse School of Economics, 104 Nicoll Street, Toulouse, 06511, France, alexey.v.smolin@gmail.com, Gleb Romanyuk

Short-lived buyers arrive to a platform over time and randomly match with sellers. The sellers stay at the platform and decide whether to accept incoming requests. The platform designs what buyer information the sellers observe before deciding to form a match. We show full information disclosure leads to a market failure because of excessive rejections by the sellers. If sellers are homogeneous, then coarse information policies are able to restore efficiency. If sellers are heterogeneous, then simple censorship policies are often constrained efficient as shown by a method of calculus of variations.

4 - Consumer Protection in an Online World: An Analysis of Occupational Licensing

Chiara Farronato, Harvard Business School, Soldiers Field Road, Boston, MA, 02163, United States, Andrey Fradkin, Brad Larsen, Erik Brynjolfsson

We study the effects of occupational licensing on consumer choices and market outcomes in a large online platform for home services. We exploit exogenous variation in the time at which licenses are displayed on the platform to identify the causal effects of licensing information on consumer choices. We find that licensing status is not valued by consumers and corroborate this finding in a survey of consumers. Next, we use variation in licensing stringency across states and occupations to measure the effect of licensing on the market equilibrium. We find that more stringent licensing leads to less competition and higher prices, but does not improve customer satisfaction.

Pricing and Assortment Problems in E-commerce

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Jacob Feldman, Olin Business School, Saint Louis, MO, 63108-1291, United States

1 - Click-based MNL: Algorithmic Frameworks for Modeling Click Data in Assortment Optimization

Ali Aouad, London Business School, London, NW64TG, United Kingdom, aaouad@london.edu, Jacob Feldman, Danny Segev, Dennis Zhang

We introduce the click-based MNL choice model, a novel framework for capturing the customers' purchasing behavior in e-commerce settings. In this setting, we assume that the click behavior within product recommendation or search results pages provides an exact signal regarding the alternatives considered by the customers. Our main algorithmic contribution comes in the form of a polynomial-time approximation scheme (PTAS) for the resulting assortment optimization problem. Using data from a large online retailer, we quantify the benefits of incorporating click behavior within choice models.

2 - Multi-product Price Optimization under a General Cascade Click Model

Huanan Zhang, Penn State University, State College, PA, 16803, United States, huz157@psu.edu, Xiangyu Gao, Stefanus Jasin, Sajjad Najafi

We consider a pricing problem for a set of products displayed on a list. We assume a general cascade click model, in which customers examine the products in decreasing order of display, from the top to (potentially) the bottom of the list. At each step, customers can decide to either purchase the current product, forego the current product and continue examining the next product, or simply terminate the search without purchasing any product. We develop online algorithms that jointly learn the unknown parameters and optimize the prices of the products. We provide theoretical performance guarantees for the algorithms and test their empirical performance using numerical experiments.

3 - Pricing under Choice Model with Consideration Set

Ruxian Wang, Johns Hopkins University, Carey Business School, Washington DC, DC, 20036, United States, ruxian.wang@jhu.edu

In this paper, we study the pricing problems in discrete choice models with consideration set.

4 - Dynamic Pricing under Consumers Sequential Search

Sami Najafi-Asadolahi, Santa Clara University, Santa Clara, CA, United States, snajafi@scu.edu, Sajjad Najafi, Chi-Guhn Lee, Steven Nahmias

In this paper, we consider a seller offering several vertically differentiated perishable products over multiple periods. In each period consumers sequentially search for and buy the product maximizing their utilities. We show that a perishable product's price can increase over time, which goes against the common intuition from the classic revenue management literature.

Sequential Decision Making in Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Garud N. Iyengar, Columbia University, New York, NY, 10027, United States

Co-Chair: Min-hwan Oh, Columbia University, New York, NY, 10027, United States

1 - Managing Customer Search: Assortment Planning for a Subscription Box Service

Yuan Guo, Duke University, Durham, NC, United States, yuan.guo1@duke.edu, Fernando Bernstein

Subscription box services provide customers a personalized selection of products from multiple stores delivered to the customers' homes. Customers first decide whether to order from such service or to actively shop at stores by considering their search cost and the expected utility of the search outcome. They then choose the product (or the no-purchase option) that provides the highest realized utility in the searched set. We consider the search box companies' problem to optimally select a set of products for each customer. We apply a cross-nested logit framework to model the interaction between the assortment contained in a box and the stores included in the consideration set under active search.

2 - Diffusion Approximations for Sequential Experiment Design

Rene A. Caldentey, The University of Chicago, Booth School of Business, Chicago, IL, 60637, United States, rene.caldentey@chicagobooth.edu, Victor Araman

We propose diffusion approximations for a class of sequential experiment design problems in which experimentation opportunities coincide with the epochs of a Poisson process. We illustrate our methodology in the context of a new product selection problem in which experimentation is driven by the outcome of a customer voting process governed be an MNL choice model.

3 - Shrinking the Upper Confidence Bound: A Dynamic Product Selection Problem for Urban Warehouses

Li Wang, Massachusetts Institute of Technology, Cambridge, MA, United States, li_w@mit.edu, Rong Jin, David Simchi-Levi, Xinshang Wang, Sen Yang

The recent rising popularity of ultra-fast delivery services on retail platforms fuels the increasing use of urban warehouses, whose proximity to customers makes fast deliveries viable. The space limit in urban warehouses poses a problem for the online retailers: the number of products (SKUs) they carry is no longer “the more, the better”, yet it can still be significantly large, reaching hundreds or thousands in a product category. In this paper, we study algorithms for dynamically identifying a large number of products (i.e., SKUs) with top customer purchase probabilities on the fly, from an ocean of potential products to offer onretailers’ ultra-fast delivery platforms.

4 - Thompson Sampling for Multinomial Logit Contextual Bandits

Min-hwan Oh, Columbia University, New York, NY, 10027, United States, m.oh@columbia.edu, Garud N. Iyengar

We study a dynamic assortment selection problem where the goal is to offer a sequence of assortments that maximizes the expected cumulative revenue. The feedback here is the item that the customer picks from the assortment, which is given by a multinomial logit model. The utility of each item is a dynamic function of contextual information of both the item and the user. We propose Thompson sampling algorithms which simultaneously optimize assortment selections and learn customer’s preference, balancing between exploration and exploitation.

Operations Management/Marketing Interface IV

Contributed Session

Chair: Sreejith Kumar Krishnakumar, State University New York at Buffalo, Atlanta, GA, 30339, United States

1 - Physical Showrooms vs. Virtual Showrooms: Optimal Information Provision Strategies in Online and Offline Competition

Haozhen Deng, Xi’an Jiaotong University, Xi’an, China, dhz0202@126.com, Gengzhong Feng, Kwai Sang Chin

Due to frictions caused by product fit uncertainty, online retailers are at disadvantage when selling products with nondigital attributes. Online retailers can invest to disclose product fit information to strategic consumers through physical showrooms or virtual showrooms. We develop a game-theoretical model to investigate an online retailer’s optimal information provision strategies confronting the competition from a traditional retailer. It shows that physical and virtual showrooms have distinct effects on the two competing retailers’ interplay. We also derive some insights about physical showrooms location decisions.

2 - Retailer Financing vs. Crowdfunding: Impacts of Consumer Valuation Uncertainty and Influencer Marketing

Zhixin Chen, University of Technology and Science of China, Hefei, China, chenzhix@mail.ustc.edu.cn, Xiang Ji, Jie Wu

Since more and more online retailers opening their own crowdfunding platforms, here emerges one issue, which is whether a retailer should finance a capital-constraint supplier or induce it to do crowdfunding. We show that a retailer can have more incentives to finance with a more uncertain or less communication markets.

3 - Strategic Implications of Binge Consumption for Entertainment Goods: An Analysis of Network Television

Franco Berbeglia, Carnegie Mellon University, Pittsburgh, PA, United States, fberbegl@andrew.cmu.edu, Timothy Derdenger, Kannan Srinivasan, Joseph Xu

With the broadcast television industry facing new forms of competition, networks have searched for new methods to distribute shows. Through the networks’ online interfaces shows are able to match the new competitors and offer all-at-once releases rather than follow the traditional linear strategy. This lowers consumers’ viewing costs, but also diminishes the viewer’s responsiveness to advertising. This paper studies the impact of this new channel on network shows with a signaling model. We find the adoption of this channel is highly profitable for low quality shows, reducing the necessity of costly signaling through advertising for the high quality shows, which results in a more efficient market.

4 - Pricing and Advertising under Spillover Effect of Product Harm Crisis

Arka Mukherjee, Concordia University, Montreal, QC, Canada, ar_mukh@live.concordia.ca, Satyaveer Chauhan

Aftereffects of a product harm crisis of a firm often spill over to the firm’s competitors. Under a game theoretic framework, we study the variations in pricing and advertising decisions for a firm and its rival in the pre-crisis and the post-crisis regimes. Our findings highlight the importance of crisis likelihood and damage on which the firms’ decisions depend.

5 - The Value of Opaque Selling When Consumers Are Heterogeneous in Their Horizontal Preferences for a Given Product

Yi Liu, Penn State University, University Park, PA, United States, yml5188@psu.edu, Nicholas C. Petruzzi

We consider a firm that sells a product defined by both vertical and horizontal attributes to consumers characterized by heterogeneous preferences for the horizontal attribute. We explore the extent to which the firm should be transparent versus opaque in describing its product’s horizontal attribute. Accordingly, we establish the value of opaque selling by comparing the firm’s optimal expected profit against the benchmark expected profit associated with full transparency. We find that opaqueness should increase as the vertical attribute increases. Moreover, we find that opaque selling could yield a win-win in the sense that it could increase both the firm’s profits and consumer surplus.

6 - Individual and Organizational Determinants of Firm Omni-channel Capability Development

Sreejith Kumar Krishnakumar, State University New York at Buffalo, Buffalo, NY, United States, sk374@buffalo.edu, Suresh Nallan C, Rajiv Kishore

The retailing landscape has changed dramatically in the last decade and customers can interact with a firm through several channels. This has entailed many firms to pursue omni-channel (OC) capability development. This pursuit requires firms to undertake a series of tasks over time and chief executive officers (CEOs) differ in their attentional foci. In this study we examine key impacts of external and internal foci on OC capability development. We also examine the moderating roles of these foci with other important variables. Data for the study comes from firm annual reports, the Standard and Poor (SP) and Compustat databases for the years 2009 to 2017.

Joint Session PSOR/Practice Curated: Managing Welfare Delivery Supply Chains

Sponsored: Public Sector OR

Sponsored Session

Chair: Sripad K Devalkar, Indian School of Business, Hyderabad, 500032, India

1 - Using Mobile Pantries to Improve Food Bank Distribution Equity and Capacity

Manoj Vanajakumari, University of North Carolina Wilmington, 601 S. College Rd, 3367 Tamu, Wilmington, NC, 28403, United States, Jon M. Stauffer, Subodha Kumar

Food banks provide food assistance to millions of food insecure people every year in the United States and other countries around the world. We examine how regional food banks can use mobile pantries to supplement their distribution network for more equitable food distribution. In addition, mobile pantries can be used to facilitate faster distribution of perishable foods, such as produce and dairy products. We use parameters taken from real-world food bank operations to determine the additional mobile pantry cost required to achieve near-perfect equity and reduce perishable food spoilage.

2 - Supply Chain Interventions to Mitigate Health Commodity Stock-outs: An Empirical Study

Amir Karimi, University of Minnesota, Minneapolis, MN, 55408, United States, karim100@umn.edu, Karthik V. Natarajan, Kingshuk K. Sinha

Public health supply chains in developing countries commonly use two types of distribution channels in order to deliver health commodities from upstream warehouses to health facilities in the last-mile, namely pull and push distribution channels. We use data from the field to develop contingencies of pull-push strategies.

3 - Impact of Introducing Coarse Cereals in the Indian Public Distribution System

Sripad K. Devalkar, Indian School of Business, Hyderabad, 500032, India, sripad_devalkar@isb.edu, Sarang Deo, Bhavna Jha

Coarse grains such as sorghum and other millets are rich in micro-nutrients and resilient to climate change. Distributing coarse grains through the Public Distribution System (PDS), India's food security program, can incentivize their production and target the main consumers of these grains. We show that introducing coarse grains can lead to up to 17% reduction (~ INR 115 billion) in operational costs, with coarse grains comprising 15% of the total volume of food grains distributed. Beyond reduction in operational costs, including coarse grains in the PDS can also reduce reliance on a few states for food grain procurement and ensure a better match of PDS supply with household consumption patterns.

4 - Fair and Efficient? A Data-driven Approach to Capacity Allocation of Mobile Family Planning Services in Uganda

Philippe Blaettchen, INSEAD, Boulevard de Constance, Fontainebleau, 77305, France, philippe.blaettchen@insead.edu, Andres Alban, Harwin de Vries, Luk N. Van Wassenhove

Modern contraceptive methods are still out of reach for 225 million women, which has immense consequences for health and development. We study mobile service teams providing contraceptive services in rural communities of developing countries. Drawing on diffusion theory, we develop a model to optimize team allocations that captures both fairness and efficiency considerations. To this aim, we need to maximize a sum of sigmoidal functions, which has received little attention in literature so far. We further calibrate the model based on data from over 300,000 client interactions in Uganda, allowing us to make relevant contributions to practitioners in this highly important field.

Big Data VI

Contributed Session

Chair: Xueqi Zhao, Penn State University, State College, PA, 16801, United States

1 - The Effect of Future Launch on Spot Market: Evidence from Bitcoin

Zheshi Chen, Harbin Institute of Technology, Harbin, China, Bin Fang, Qiang Ye, Wenjun Sun

The launch of Bitcoin futures in 2017 provides us a unique opportunity to investigate the effect of the future market on spot market. Employed with the high-frequency data collected from Binance Exchange, we leverage the weighted moving average of Bitcoin return to measure volatility. Results suggest that the Bitcoin's volatility significantly increased after the introduction of the future. Moreover, Bitcoin futures account a very small fraction of determinant of volatility of both Bitcoin's volatility and price. By contrast, Google Trend search volume's explanation ability is 10 times larger than that of the futures. This study extends the informed traders' theory on the Fintech area.

2 - Clustering Transportation Companies' Trajectory Data

Mohammad Ali Alamdar Yazdi, Johns Hopkins University, Baltimore, MD, United States, yazdi@jhu.edu, Amirhossein Alamdar Yazdi

Transportation companies usually keep a database of trajectory data of their trucks, sampled very frequently every day. Such databases, in their raw formats, are very large and difficult to be used for optimization and statistical analysis. In this paper, we used some innovative big data mining methods to analyze and cluster the trajoctory data of an american transportation company with the size of 1.5 billion data points.

3 - Using Big Data on Fan Base Growing and Loyalty Building – A Case Study on San Jose Earthquakes

Hongwei Du, California State University-East Bay, Hayward, CA, United States, hongwei.du@csueastbay.edu

Big data in sports industry has been gaining momentum since at least 2008. Sports fans are becoming much more than just sports consumers. They no longer just watch—they participate, analyze, critique, fantasize and connect with their favorite players and teams in real time. Indeed, fans are increasingly becoming true brand partners. Utilizing Big Data can help advance the sports fans' experience as teams and ticket vendors compete with the at-home experience. The better they know their fans, the better they can cater to them. Big data and analytics capabilities can provide insights into fan preferences. This paper takes a look on how the San Jose Earthquakes have incorporated the analytics of Big Data.

4 - Predicting In-patient Discharges to Identify Bed Availability for Housekeeping During Emergency Department Surge Using Machine Learning Algorithms

Tahera Yesmin, PhD Student, University of Toronto, Ontario, ON, Canada, tahera.yesmin@mail.utoronto.ca, Michael W. Carter

Prolonged patient waiting time in the Emergency Department (ED) for an inpatient bed after the admission decision, is considered a global crisis and the most cited reason for ED crowding. When a hospital operates close to capacity and has hospital-wide inefficiencies in patient flows, ED boards the admitted patients until the inpatient bed is available.Housekeeping is crucial in patient-flow from ED to inpatient bed. A delay in bed cleaning causes a delay in patient flows and thus, contributes to ED crowding. Therefore, this research aims to apply machine learning algorithms to identify the number of beds available by predicting number of in-patient discharges during ED surge.

5 - Distributional Clustering: A Distribution-preserving Clustering Method

Arvind Krishna, Georgia Institute of Technology, Atlanta, GA, United States, akrishna39@gatech.edu, Simon Mak, Roshan Joseph

One of the key uses of clustering is to identify representative points from a dataset of interest via cluster centers. However, a drawback of k-means clustering is that it induces a distortion between the distribution of its cluster centers and that of the underlying data. To address this shortcoming, we propose a new clustering method called 'distributional clustering', where cluster centers capture the distribution of the underlying data. We first prove the asymptotic convergence of the proposed cluster centers to the data generating distribution, then propose an algorithm for computing them in practice. Finally, we demonstrate the effectiveness of our method on synthetic and real datasets.

6 - Intrinsic Geometrical Methods for Statistical Process Control of Complex Data Objects

Xueqi Zhao, Penn State University, State College, PA, United States, xuz206@psu.edu

Complex and not only big data are everywhere in industry and how to control and optimize systems based on these data types is an important aspect of modern Quality Engineering. We present a new approach for statistical process monitoring of point cloud, mesh and voxel data based on intrinsic geometrical features of the 2-D manifold (surfaces) of scanned manufactured parts. Monitoring intrinsic properties avoids computationally expensive registration pre-processing of the data sets. Our proposal brings SPC closer to computer vision and computer graphics methods.

Sponsored Session

Chair: Hongyue Sun, University at Buffalo, Buffalo, NY, 14260, United States

Chair: Chen Kan, University of Texas-Arlington, University of Texas-Arlington, Euless, TX, 76039-6215, United States

1 - Robust Tensor PCA with a Novel Subspace Regularization Algorithm

Bo Shen, Virginia Tech, Blacksburg, VA, 24061, United States, Zhenyu Kong

In this work, a robust tensor PCA (RTPCA) formulation is proposed to obtain the subspace. The robustness is justified by providing the equivalence between Lp-norm based formulation and sample weighted L2-norm formulation. In addition, a subspace regularization algorithm is developed to obtain the solution for RTPCA and the convergence of this algorithm is investigated. The experiments demonstrate the robustness of our formulation and effectiveness of the proposed algorithm

2 - Sequential Design Using Stochastic Kriging

Yiming Che, Binghamton University, Binghamton, NY, United States, Changqing Cheng

Process design plays a paramount role in manufacturing quality assurance and enhancement. In this talk, we present the optimal sequential design considering both intrinsic and extrinsic uncertainty. While intrinsic uncertainty is quantified by generalized polynomial chaos, it is oftentimes tedious to evaluate this type of uncertainty for stochastic simulation. The sequential design based upon stochastic Kriging provides a guideline to distribute computational resource in the design space.

3 - Individualized Degradation Modeling and Prognostics in a Heterogeneous Group via Incorporating Static Covariate Information of Units

Minhee Kim, University of Wisconsin–Madison, 1513 University Avenue, Madison, WI, 53706, United States, mkim555@wisc.edu, Changyue Song, Kaibo Liu

In this study, we propose a generic framework which handles the heterogeneity across units by effectively leveraging the covariates of each unit, i.e., the distinct individual characteristics, which are closely related to each individual unit's degradation process. The significant advantage of this approach is to enable us to efficiently transfer the information among units according to the covariates' similarities. In this way, the collected degradation signals from one unit can be shared with the entire heterogeneous group, enhancing degradation modeling and prognostics of other units.

4 - Real-time Data-driven Quality Assessment for Continuous Manufacturing of Carbon Nanotube Buckypaper

Xinran Shi, Georgia Institute of Technology, Atlanta, GA, 30329, United States, xshi80@gatech.edu, Xiaowei Yue, Jianjun Shi, Zhiyong Liang

Carbon nanotube buckypaper (CNT BP) has great potential as a multifunctional platform material. However, the mass applications have run into significant bottlenecks with the large variability in quality during fabrication. Producing high-quality CNT BP at an industrial scale is urgent. Although Raman spectroscopy has been applied to study CNT BP's characteristics, a systematic method for CNT BP quality assessment is needed. We propose a real-time data-driven quality assessment method to quantify CNT BP's quality during fabrication. The proposed method reflects CNT BP quality regarding consistency and uniformity. A case study shows the method demarcates CNT BP quality in a unified manner.

1 - Estimating Product-choice Probabilities from Sequences of Page Views

Naoki Nishimura, Recruit Lifestyle Co., Ltd., Tokyo, Japan, nishimura.n.ab@gmail.com, Noriyoshi Sukegawa, Yuichi Takano, Jiro Iwanaga

Understanding customers' product-choice behavior is an important issue for companies that operate e-commerce sites. This talk presents a method to estimate the customers' product-choice probabilities from sequences of their page views (PVs). Our method calculates the product-choice probabilities under shape restrictions reflecting properties of PV sequences. Computational results illustrate the efficacy of our method by comparison with standard methods for product-choice analysis.

2 - Reading Less in Haze the Impact of Air Pollution on Digital Reading Market

Yongjun Li, USTC, Hefei, China, lionli@ustc.edu.cn, Lizheng Wang

We adopt a regression discontinuity design approach to identify the impact of air quality on the digital content market and reveal the underlying mechanism. Identification results show that people reduce their reading time by 4.3 minutes each day when the air is polluted. In addition, people reduce their willingness to pay by 5.9% simultaneously. The results show that the impact of air pollution on us far exceeds our perception. For marketers, this study provides insights on how to conduct real-time air pollution based promotion strategies for a wider product range.

3 - Preferences Estimation under Bounded Rationality: Identification of Attribute Non-Attendance using SYM

Veronica Díaz Gómez, Universidad de Antofagasta, Antofagasta, Chile, veronica.diaz.gomez@uantof.cl
Veronica Díaz Gómez, Universidad de Chile, Santiago, Chile, veronica.diaz.gomez@uantof.cl, Ricardo Montoya

There is a growing interest in Economics regarding estimating preferences when consumers partially ignore the information provided in a choice experiment. This problem was introduced as attribute non-attendance by Scarpa et al. 2009. We propose a machine learning approach based on Support Vector Machines to identify non-attendance attributes at an individual level and to predict consumer choices in a conjoint experiment. We compare the performance of our proposed approach to different benchmarks from the literature. Our simulation study results show a higher performance in terms of the identification of non-attended attributes that improve the predictive ability of consumers' choices.

4 - Debunking False Health Information: A Text-Mining Approach

Jiexun Li, Western Washington University, Bellingham, WA, United States

In recent years, a lot of false health information has emerged and spread over the Internet. This study investigates this problem by analyzing data collected from two fact-checking websites, Snopes and PolitiFact. Topic analysis reveals frequent words and common topics occurring in these claims spread online. Furthermore, using text-mining and machine-learning techniques, this study builds prediction models for detecting false information and shows promising performance. Several textual and source features are identified as good indicators for true or false information in medical and health care.

5 - Teacher-school Assignment with Forward-looking Stability

Navid Matin Moghaddam, Arizona State University, Tempe, AZ, United States, nmatinm@asu.edu, Jorge Sefair, Margarita Pivovarova

Teacher retention has been identified as a pressing problem for Arizona's public schools. In this study, we analyze a longitudinal census of teacher data and develop supervised learning methods to identify rate of movements based on the characteristics of the teachers and schools in each assignment. Utilizing the results of the analysis, we model the movement as a stochastic process and develop a method that recommends stable assignments. Major outcome of the project is creating a tool for schools and school districts that would help them to make better hiring decisions resulting in long-term stable employment thus reducing both monetary costs and non-pecuniary costs.

Data-Driven Modeling and Monitoring in Smart Manufacturing System

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Yifu Li, Virginia Tech, Blacksburg, VA, 24061, United States

Co-Chair: Ran Jin, Virginia Tech, Blacksburg, VA, 24061, United States

1 - Family Learning: A Process Modeling Method for Cyber-additive Manufacturing Network

Lening Wang, Virginia Tech, Blacksburg, VA, 24061, United States, wangln@vt.edu, Xiaoyu Chen, Daniel Henkel, Jeffrey Burdick, Jingran Li, Ran Jin

A Cyber-manufacturing system (CMS) poses significant challenge in data-driven modeling for mass personalization, primarily due to limited sample sizes. As a results, most existing data-driven models may not provide satisfactory prediction accuracy, which motivated us to propose a new method called family learning. In this research, the similar-but-non-identical selective laser melting (SLM) processes are modeled as family members. Similarities among family members are quantified by designs and settings. The similarities are further used to penalize the differences among model coefficients of family members. A simulation and a real case study in SLM validate the proposed method.

2 - Filtering and Distributed Modeling in Smart Manufacturing Systems

Yifu Li, Virginia Tech, Blacksburg, VA, 24061, United States, Xinwei Deng, Hao Yan, Ran Jin

A smart manufacturing network collects high-volume data for process modeling and monitoring, and it is important to ensure data quality through filtering. Therefore, we propose an unsupervised data filtering algorithm and a filtering information criterion, which determines the appropriate proportion of data to preserve. Furthermore, to model multiple similar-but-non-identical manufacturing systems in a network, we proposed a multi-task learning framework by decomposing the variation among systems into explainable variation and latent variation. The simulation and case studies in crystal growth manufacturing demonstrate the superior computational performance of the proposed method.

3 - Adaptive Compressive Sensing for Anomaly Detection

Xinyu Zhao, Arizona State University, Tempe, AZ, United States, xzhao119@asu.edu, Hao Yan, Chen Zhang

Online anomaly detection is essential in various scenarios to ensure the system is in a healthy condition. Some practical information acquiring techniques are necessary when the sensing resources are limited. Compressive sensing is well known for its ability to reconstruct the signal with a limited amount of information. Here, we propose a Bayesian compressive sensing framework for online change detection, hypothesis testing, and active learning to select the sensing matrix adaptively. The proposed framework is validated through both simulation and case study.

4 - Causality Assessment in Industry 4.0 Applications

Ron S. Kenett, Senior Research Fellow, KPA, Raanana, Israel, ron@kpa-group.com

Judea Pearl, the 2011 Turing Award winner who developed Bayesian networks and causality networks, calls for a "causality revolution". Causality has been treated by statisticians since the work of R. A. Fisher at Rothamsted agricultural station on designed experiments. The gold standard for determining causality has been the randomized controlled trial (RCT). A general framework for handling causality, from observational data, is based on propensity score methods developed by Donald Rubin. The talk will review such tools and discuss applications to condition-based maintenance (CBM) and Industry 4.0.

5 - Distributed Family Learning in Cyber Manufacturing Modeling

Yutong Zhang, PhD. Student, Virginia Tech, Blacksburg, VA, 24060, United States, Lening Wang, Xiaoyu Chen, Ran Jin

Due to high volume data in cyber manufacturing systems (CMS), traditional centralized computing (e.g., Cloud computing (CC)) has problems in latency and reliability. Thus, advanced data-driven models cannot be efficiently utilized in centralized computing. This work proposed to adopt alternative direction method of multipliers to decompose penalized regression models (e.g., family learning) into a distributed manner in Fog-Cloud computing (FCC). The simulation result indicates that the method on FCC shows better redundancy and latency than CC with identical accuracy. The method can contribute to responsive decision-making for CMS compared with current centralized computing systems.

Predictive Maintenance

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Yan-Fu Li, Tsinghua University, Tsinghua University, Beijing, 100084, China

1 - Integration of Crack Detection and Probabilistic Fatigue Damage Prognosis

Yan-Fu Li, Tsinghua University, Haidian District, Beijing, 100084, China, Shan Jiang

The uncertainties of material properties and loading condition are discussed. A second-order polynomial regression model is developed for fatigue crack detection. The Paris law is employed to predict fatigue crack growth behavior. Moreover, the likelihood function is built, which incorporates the regression crack detection model and the Paris law. The posterior distribution of parameters can be estimated by Bayesian updating. The fatigue crack growth is recalculated by using the posterior distribution of parameters. The proposed approach can precisely predict fatigue crack growth.

2 - Degradation Based Optimization of Operating and Maintenance Schedule in Smart Grids

Chengwu Shao, Tsinghua University, Beijing, China, scw18@mails.tsinghua.edu.cn, Tarannom Parhizkar, Yan-Fu Li

Power flow optimization in smart grids depends on maintenance schedule of distributed generation (DG) systems. In order to achieve maximum profit, power flow and maintenance schedule of DGs should be optimized simultaneously. Another significant factor in optimization procedure is component degradation. Component degradation rate depends on DG type and its operating conditions, affecting fuel cost and maintenance schedule of the DG. In this paper, a framework for degradation based optimization of power flow and maintenance schedule in smart grids is developed.

3 - Predictive Maintenance for Infrastructure Assets under Environmental Risks

Zhenglin Liang, PhD, Tsinghua University, Beijing, China, zhenglin_liang@sina.com

We propose a novel approach to predict the remaining useful life for concrete infrastructure that exposes to the risk of the changing environment. The stochastic aging of concrete infrastructure is modelled by a continuous-time semi-Markov chain. To reduce the computational burden, we combine hypo-exponential approximation and phase-type prediction to forecast the remaining useful life with uncertain inspected information about the infrastructure condition and its surrounding environment. Then, we investigate the impact of different types of environmental risks. The overall approach is implemented on bridge predictive maintenance to gain resilience against environmental risks.

4 - Optimal Predictive Maintenance for a Deteriorating K-out-of-N: G Warm Standby System

Hui Wu, Tsinghua University, Beijing, 100084, China, wuh18@mails.tsinghua.edu.cn, Yan-Fu Li

This paper investigates a novel predictive maintenance policy with multi-level decision-making for an n-component deteriorating system with a k-out-of-n: G structure, where economic dependence, structural dependence and failure dependence are all considered. Decisions are made based on the remaining useful lifetime of the components and the system. Furthermore, a mathematical cost model of reliability-based opportunistic predictive maintenance strategies is developed to obtain the optimal maintenance decisions by minimizing the long-run average cost per time unit. Illustrative examples are provided.

Appointment Scheduling in Healthcare Systems

Sponsored: Health Applications

Sponsored Session

Chair: Mohammad Dehghanimohammadabadi, Northeastern University, Boston, MA, 02115, United States

1 - A Multi-objective Outpatient Appointment Scheduling: A Data-Table Input Simulation-Optimization Approach

Mohammad Dehghanimohammadabadi, Northeastern University, Boston, MA, United States, Mandana Rezaeiahari, Javad Seif

Appointment scheduling is one of the key factors to enhance patient satisfaction in healthcare services. A robust appointment scheduling pattern allows clinics to utilize medical assets, equipment, and resources in an efficient manner. This study proposes a practical appointment scheduling of patients using an integrated simulation-optimization framework. In this multi-objective simulation-optimization problem, the concept of data-table input experiments (appointments table) is applied in a simulation environment, to determine the most preferred appointment scheduling pattern for an outpatient clinic system with stochastic parameters including patient-no-show and service time.

2 - A Stochastic Programming Approach for Chemotherapy Appointment Scheduling

Nur Banu Demir, Wayne State University, Detroit, MI, United States, demir.nb@gmail.com, Melih Celik, Serhat Gul

Chemotherapy appointment scheduling is a challenging problem due to uncertainty in pre-medication and infusion durations. We formulate a two-stage stochastic mixed integer programming model for the chemotherapy appointment scheduling problem under limited number and availability of nurses, and infusion chairs. The Progressive Hedging Algorithm is implemented and improved with a penalty update method, cycle detection and variable fixing mechanisms, and linearization of the objective function. We conduct experiments to compare our algorithm with several scheduling heuristics. Finally, we estimate the value of stochastic solution to assess the significance of considering uncertainty.

3 - Modeling Healthcare Operations: Utilizing a Simulation Model to Predict Future Capacity Needs at a High Volume Surgical Center

David P. Grace, Hospital for Special Surgery, New York, NY, United States, graced@hss.edu

The landscape of healthcare is rapidly changing. Across the industry, we are seeing reduced inpatient LOS and shifts from inpatient to outpatient care (e.g., knee and hip replacements) requiring new care models. Given that these types of changes can result in multiyear, multimillion dollar capital projects and major shifts in resource planning, estimating the impact of these changes over the next 5 - 10 years is critical. At our high volume surgical center we utilized discrete event simulation to assess how the changing environment may impact long-term capacity needs.

4 - Stochastic Policies for Scheduling Customer Preference-based Fields Visits

Yanlu Zhao, ESSEC Business School, Paris, France, Felix Papier

Motivated by the sales force operations of a B2B payment services company in Belgium, we develop a model for scheduling customer appointments for a team of sales agents. The appointments are made by a call center and subject to uncertain customer approval. We aim to maximize the number of sales appointments per agent. We formulate the model as a Markov decision process, demonstrate the existence of an optimal policy, develop an upper bound on optimal performance, and derive sensitivity properties on several parameters. Since the problem suffers from curse of dimensionality, we develop two scheduling policies that dynamically decide which clients to call and which time slots to propose to each client.

Inverse Optimization in Healthcare Applications

Sponsored: Health Applications

Sponsored Session

Chair: Taewoo Lee, University of Houston, Houston, TX, 77204-4008, United States

1 - Inverse Optimization for Multi-objective Linear Programming

Masoud Zarepisheh, Memorial Sloan Kettering, New York, NY, 10017, United States, Mostafa Naghavi, Ali Asghar Foroughi

This work generalizes inverse optimization for multi-objective linear programming where we are looking for the least problem modifications to make a given feasible solution a weak efficient solution. This is a natural extension of inverse optimization for single-objective linear programming with regular "optimality" replaced by the "Pareto optimality". This extension, however, leads to a non-convex optimization problem. We prove some special characteristics of the problem, allowing us to solve the non-convex problem by solving a series of convex problems.

2 - Data-driven Objective Selection in Multi-objective Optimization

Temitayo Ajayi, Rice University, Houston, TX, 77004, United States, Taewoo Lee, Andrew J. Schaefer

A challenge in IMRT planning is selecting which clinical objectives to use in the optimization. We use inverse optimization with a cardinality constraint to infer important objectives from historical data. We use two methods to efficiently select a subset of objectives. The first method is a greedy algorithm, and we provide theory, a generalization of results by Nemhauser (1978), to support our results. The second method is a heuristic that selects objectives based on user-prescribed similarity metrics. We compare the proposed methods to the cardinality-constrained inverse problem and show our method efficiently finds a small set of objectives that generates clinically viable treatment plans.

3 - Multi-point Inverse Optimization for Constraint

Kimia Ghobadi, Johns Hopkins University, Baltimore, MD, United States, kimia@jhu.edu, Houra Mahmoudzadeh

Consider an LP for which we know a set of observed solutions (i.e., a set of feasible points; e.g., provided by an expert). We may not know the exact constraints that shape the feasible region of the problem. We would like to find the exact feasible region. To this end, we propose a multi-point data-driven inverse optimization framework for recovering the full set of constraints. We focus on LP models in which the objective function is known but a subset of the constraint matrix is unknown. Our inverse framework recovers the entire constraint matrix such that all the past observations are feasible, and the best-observed solution becomes optimal or near-optimal.

4 - Learning Hidden Action Principal-Agent Models

Sema Nur Kaynar Keles, University of California-Los Angeles, Los Angeles, CA, 90024, United States, Auyon Siddiq

We propose a method for estimating principal agent models from historical data on contracts and associated outcomes. We show that the estimator is statistically consistent and can be formulated as a mixed integer linear program. We then introduce a solution technique based on hypothesis testing and column generation, and show that it produces an asymptotically optimal solution.

5 - Quantile Inverse Optimization: Improving Stability in Inverse Linear Optimization

Taewoo Lee, University of Houston, Houston, TX, 77204-4008, United States, tlee20@central.uh.edu, Zahed Shahmoradi

Inverse linear programming can be very sensitive to inconsistency, noise, and measurement errors in input data. We develop a new inverse linear programming approach that determines a set of objective functions of a linear program by addressing quantile statistics of optimality error. We show that the proposed inverse model improves on the previous models in terms of stability against noise and inconsistency in data. We propose an efficient algorithm to approximate the model by exploiting its connection to maximum clique problems.

Product and Process Innovation in Healthcare

Sponsored: Health Applications

Sponsored Session

Chair: Zhili Tian, Coastal Carolina University, Florida International University, Conway, SC, 33327-2444, United States

1 - Adaptive Learning of Drug Quality and Optimization of Patient Recruitment for Clinical Trial with Dropouts

Zhili Tian, coastal Carolina Univ, Mt. Pleasant, SC, 33327-2444, United States

Clinical trials represent the largest cost in drug development, and has long been recognized as an important problem in operations management. The research challenge requires modeling the physical process of enrolling patients and belief about the efficacy of a new drug and a placebo, and the accurate modeling of the decision process. We develop an optimal policy for determining when to cancel, continue, or stop and go to market, for new drugs. Our model considers uncertainty in the performance of a new drug and a placebo, and characterizes the enrollment process. Our model captures the benefits of making decisions early to extend the time to market a drug under patent.

2 - What Information Do Health Information Consumers Seek Online?

Lina Zhou, The University of North Carolina at Charlotte, Charlotte, NC, 28223, United States

Patients increasingly use online questioning and answering sites to meet their health information needs. Despite existing analyses of user-generated content on questioning and answering sites, there is a lack of understanding of health information seekers from the perspective of information sharing. Additionally, empirical comparisons of different platforms are scarce. This research investigates the information sharing behavior across two types of platforms.

3 - The Determinants of Process Innovation

Ivan Lugovoi, HEC Paris, 1 Square Theodore Judlin, Jouy-en-Josas, 75015, France, ivan.lugovoi@hec.edu

Utilizing a unique dataset of the process-patent expert evaluations merged with the sales of 50 generic pharmaceutical products, we explore in depth the link between technological diversification in related/unrelated products and process innovation including its dimensions: novelty and scope. We find that diversification in related products negatively affects process innovation, novelty, and scope. Likewise, diversification in unrelated products has a negative association with process innovation and scope but positive effect on novelty. Moreover, experience with a focal product positively influence process innovation and scope but has a negative association with novelty.

Healthcare Analytics

Sponsored: Health Applications

Sponsored Session

Chair: Eric Park, University of Hong Kong, Hong Kong

1 - Decision Making under Compliance Uncertainty

Kyohong Shin, KAIST, Yuseong-gu, Daejeon, 34141, Korea, Republic of, Taesik Lee, Yoorim Song

In many decision making problems in healthcare, decision makers are different from those who perform them, and compliance with optimal solution is often a concern; optimal policy is not followed and it results in suboptimal outcomes. Based on a conjecture that compliance with optimal decisions is influenced by preferences (or biases) of the decision performer, we formulate a sequential decision making problem that accounts for decision performers' preferences. A policy solution from this formulation is sub-optimal to the original decision problem, but yields better outcome under less than full compliance environment. Characteristics of the policy solutions are illustrated with examples.

2 - Unintended Consequences of Hospital Regulation: The Case of the Hospital Readmissions Reduction Program

Christopher J. Chen, Indiana University, London Business School, Bloomington, IN, NW14SA, United States, cch3@iu.edu, Nicos Savva

We study the impact of the Hospital Readmissions Reduction Program on admissions decisions. Exploiting variation in hospitals' financial exposure to the program, we show that hospitals tried to reduce readmission rates by increasing the number of patients that were classified as admitted for "observation," which avoided potential penalties associated with a regular admissions.

3 - Integrating New Diagnostic Tests into Emergency Department Workflow

Pengyi Shi, Purdue University, West Lafayette, IN, 47907, United States, shi178@purdue.edu, Jonathan Helm, H. Sebastian Heese, Alice Mitchell

In medical research, new diagnostic tests are evaluated solely on their efficacy in detecting an illness. However, ignoring the workload impact of introducing new tests into existing workflow can create barriers to adoption. In collaboration with an ED physician, we develop an analytical framework for evaluating the workload impact of adopting new tests. We derive useful structural properties and develop an efficient decomposition algorithm for settings with multiple patient classes. As a showcase, we apply our framework to a new test, D-dimer, for diagnosing Pulmonary Embolism to understand what characteristics make adopting it feasible and how to best integrate it into the ED workflow.

4 - Does Limiting Time on Ambulance Diversion Reduce Diversions? A Data-driven Analysis on the Role of Paramedic Compliance and Network Effect

Eric Park, University of Hong Kong, Pokfulam Road, Hong Kong, ericpark@hku.hk, Sarang Deo, Itai Gurvich

We study the effect of a policy intervention intended to reduce ambulance diversions in LA County, CA. The intervention succeeded in its purpose of reducing the time EDs spent on diversion but did not reduce ambulances being diverted. A possible explanation for this outcome, identified by our empirical analysis, is a combination of the ambulance operator's imperfect compliance to the ED diversion signals and the decrease in frequency of ambulances facing EDs on diversion. We build a simulation model to investigate the efficiency of such policy intervention limiting ED time on diversion in ED networks with varying level of congestion and operator compliance to the ED diversion signals.

1 - L1 Splines with Optimized Knot Locations for Data Approximation and Application in Change Point Detection

Ziteng Wang, Northern Illinois Universtiy, DeKalb, IL, United States, zwang3@niu.edu

Spline-based models can be a very useful tool in modeling time series data, sensor collected data, urban and natural terrain data and in recognizing patterns and objects of problem-specific interest. Recent development of L1 splines show robustness and computational efficiency over conventional ones. To further expand the modeling capability of L1 splines, this research optimizes the location of spline knots which allow the spline to more accurately capture the data shape. Application on change point detection is demonstrated.

2 - Design of Usage-based Preventive Maintenance under Two-dimensional Warranties

Shizhe Peng, Shanghai Jiao Tong University, Shanghai, China, pengshizhe@sjtu.edu.cn

This paper, from the manufacturer's perspective, considers the problem of designing a usage-based preventive maintenance service in the context of a two-dimensional warranty. We use dynamic programming to show that the optimal policy is characterized by a time threshold and a sequence of failure rate thresholds. Specifically, the manufacturer performs preventive maintenance up to the time threshold, to bring the failure rate of the product back to its lowest level once it exceeds the corresponding failure rate threshold. Interestingly, we find that the time threshold is a random variable which depends on the usage rate and that the failure rate thresholds are functions of the cumulative usage.

3 - QSR Research and Activities in HK

Yao Cheng, The University of Hong Kong, Hong Kong, Hong Kong, yao.cheng.ise@gmail.com

HongKong is the center of logistics and smart manufacturing of east Asia; to guarantee the operation efficiency of the logistics networks and manufacturing systems, extensive research has been done on quality, statistics and reliability (QSR) in universities and research institutions in HK. In this talk, we will introduce the development of research and knowledge exchange (KE) activities on QSR in different domains in HK.

4 - Economic Design of Repetitive Inspection Plans via the Expectation-maximization Algorithm

Young H. Chun, Louisiana State University, Baton Rouge, LA, United States

We first propose a new multiple inspection plan under which each item is tested repeatedly until we have a sufficient number of positive or negative test results. We then deal with the problem of estimating three model parameters: the type I and II errors of a testing device and the fraction defective of incoming items. Because of computational difficulties in maximizing the likelihood of the three parameters, we propose the use of the expectation-maximization (EM) algorithm as an easy alternative. In a numerical analysis, we demonstrate the outstanding performance of our new inspection plan over previous ones.

5 - Stochastic Modeling of Multiple Corrosion Pits Growth

Changxi Wang, Rutgers University, Piscataway Township, NJ, United States, rucxwang@gmail.com, Elsayed Elsayed

Corrosion growth modeling is important in structure maintenance planning. Existing methods mainly model maximum corrosion pit depth growth. However, other features of corrosion growth such as corrosion volume growth may also lead to failures but have not been investigated. We develop a stochastic model that characterizes both corrosion volume and depth growth. The multiple corrosion pits growth and propagation are captured by a physics-based model and a degradation branching model. Field corrosion data are used for models validation. These models result in accurate prediction of the remaining lives and provide more characteristics such as the distribution of the failure time and its variance.

1 - Design of Diversified Package Tours for the Digital Travel Industry: A Branch-cut-and-price Approach

Yanlu Zhao, ESSEC Business School, Paris, France, Laurent Alfandari

We consider the design of a fixed number of package tours offered to customers in digital travel industry. This can be formulated as a Team Orienteering Problem (TOP) with restrictions on budget and time. Our work introduces controlled diversity between tours. This enables the OTA to offer tourists a diversified portfolio of tour packages, each customer choosing a single tour in the selected set, rather than multiple independent tours as in the TOP. Tuning the similarity parameter between tours enables to trade off between individual preference and economies of scale. We propose compact and extended formulations and solve the master problem by a branch-and-price, and an branch-cut-and-price method.

2 - Solving A Real-world Multi-period Petrol Replenishment Problem with Complex Loading Constraints: A Branch-and-price Heuristic

Abderrahman Bani, PhD Student, Polytechnique de Montreal & GERAD, Montreal, QC, Canada, abderrahman.bani@polymtl.ca, Issmail El Hallaoui

In this paper, we solve a rich real-word Multi-Period Petrol Replenishment Problem (MPPRP) with a Branch-and-Price heuristic. The underlying network consists of five distinct depots, a group of five private carriers with heterogeneous fleets of tank-trucks and five types of gas to replenish three main groups of clients on a weekly basis. Due to the hazardous nature of the products carried, some complex handling rules apply and are addressed in the column generation sub-problem as an Elementary Shortest Path Problem with Resource Constraints. Acceleration strategies are discussed. Numerical results on some real-world data show the effectiveness and high potential of the proposed approach.

3 - Syntactical Circuits for Combinatorial Optimization Using Extensions of Dynamic Programming

Michal Mankowski, King Abdullah University of Science and Technology, Jeddah, Saudi Arabia

We developed an algorithmic framework for combinatorial optimization using Extensions of Dynamic Programming based on the circuit model which provides algorithms for series of single-criteria optimizations and bi-criteria optimization (construction Pareto front). A syntactical circuit is a new tool to work with problems where the optimal solution for subproblem might be an optimal solution for the initial problem. We will introduce an application of this tool to multi-objective 0/1 Knapsack problem.

4 - Comparison of the Number of Nodes Explored by CBFS-depth and BFS

Wenda Zhang, University of Illinois at Urbana-Champaign, Urbana, IL, United States, wzhang95@illinois.edu, Jason Sauppe, Sheldon H. Jacobson

When using Branch-and-bound (B&B) algorithms, a new search strategy called Cyclic Best First Search with depth contour (CBFS-depth) has been shown to consistently process fewer nodes than Best First Search (BFS) on several combinatorial optimization problems. In this paper, we study the conditions of the search tree that may lead to CBFS-depth outperforming BFS in terms of average number of nodes expanded to prove optimality. We propose a search tree model for B&B algorithms based on the distributions of nodes with different lower bounds and use it to compare the performance of both search strategies. Several problems are used to verify the conclusion from the generated search trees.

5 - Multi-period Set Covering Problem: Formulations, Applications, and Solution Methods

Hadi Farhangi, Savannah State University, Savannah, GA, United States

Set covering problem and its extensions to multiple periods of planning are studied in this work. Particularly, we studied different formulations of multi-period set covering problems and exact column generation approach for solving this class of problems.

Manufacturing and Neural Networks

Contributed Session

Chair: Alireza Aghasi, Georgia State University, Atlanta, GA, 30303, United States

1 - Development of Graphical User Interface GUI for Dimensional Accuracy Prediction on 3D Printing Process

Honglun Xu, The University of Texas at El Paso, El Paso, TX, United States, hxu3@miners.utep.edu, Carlos Garcia Rosales, Tzu-Liang (Bill) Tseng

A dimensional accuracy prediction using a Graphical User Interface (GUI) is presented. An artificial neural network (ANN) is developed for modelling dimensional error on 3D printed specimens. ANN training and testing phases using stereolithography (SL) historical data and results are compared for several variants of the ANN architecture. ANN results obtained will be compared using maximum Pearson correlation during testing.

2 - Automatic Alignment and Quickest Change Detection in Additive Manufacturing under a Multi-resolution Framework

Yu Jin, University of Arkansas-Industrial Engineering, Fayetteville, AR, United States, Haitao Liao

The in-situ layer-wise inspection of geometric accuracy is essential for wide application of Additive Manufacturing (AM). The shape of a layer can be described by a two-dimensional point cloud, which must be aligned with the corresponding base-truth model before evaluating its geometric accuracy. In this work, a multi-resolution framework is proposed for alignment and error quantification. Moreover, a quickest change detection algorithm is applied to identify the layer where the earliest systematic deviation distribution change occurs during the printing. A sample part with different featured layers is provided to illustrate the effectiveness and efficiency of the proposed methods.

3 - The Role of Stochastic Gradient Descent Algorithms in Generalization of Deep Learning

Navid Azizan, California Institute of Technology, Pasadena, CA, United States, Babak Hassibi

Stochastic descent methods have a long history in optimization, and have gained tremendous popularity as the workhorse of deep learning. It is widely believed that the success of deep networks is not just due to their special deep architecture, but also due to the behavior of the stochastic descent methods used. In an attempt to shed some light on why this is the case, we study some minimax properties of stochastic gradient descent and general stochastic mirror descent algorithms, from an $H\infty$ estimation theory perspective. This theory can be used to explain the convergence and “implicit-regularization” properties of such algorithms when the problem is highly over-parametrized, as in deep learning.

4 - On the Use of Multi-objective Optimization in Deep Learning Models

Alireza Aghasi, Georgia State University, Atlanta, GA, United States

There has been an increasing attention towards using deep learning models to simulate physical phenomena or address inverse problems. In many problems (e.g., the training of generative adversarial networks) model training is hard and often requires a careful selection of the minimization parameters. In this talk we discuss some multi-objective minimization schemes which could be used across different areas of deep learning. The proposed algorithms are more robust, showing favorable convergence properties, and require minimum parameter fine-tuning.

Joint Session Telecom/TSL Urban: Multi-level Optimization in Network Applications

Sponsored: Telecommunications and Network Analytics

Sponsored Session

Chair: Changhyun Kwon, University of South Florida, Tampa, FL, 33620, United States

1 - Pessimistic Evasive Flow Capturing Problems

Changhyun Kwon, IMSE department, University of South Florida, Tampa, FL, United States, Aigerim Bogyrbayeva

The evasive flow capturing problem is to locate a set of law enforcement facilities to intercept unlawful flows and is typically formulated as a bilevel optimization problem. While optimistic bilevel formulations are studied in the literature, we consider pessimistic formulations by relaxing the assumption on the optimizing behavior of unlawful travelers. Such pessimistic formulations introduce another level in the optimization problem. We introduce a cutting plane algorithm for the pessimistic formulations.

2 - A New Bilevel Approach for the K-vertex Cut Problem

Ivana Ljubic, ESSEC Business School of Paris, Paris, 95021, France, Fabio Furini, Enrico Malaguti, Paolo Paronuzzi

The k-vertex cut problem is to find a subset of vertices of minimum weight, deletion of which separates the graph into at least k connected components. The problem is highly relevant for applications in networks analytics.

We provide a new ILP formulation, derived from the perspective of a two-phase Stackelberg game in which a leader deletes the vertices in the first phase, and in the second phase a follower builds connected components in the remaining graph. Our computational study demonstrates that this new ILP model (extended with variables and inequalities to model representatives of each component) significantly outperforms the state-of-the-art exact methods from the literature.

3 - Multilevel Approaches for the Critical Node Problem

Margarida Carvalho, University of Montreal, Montreal, QC, Canada, carvalho@iro.umontreal.ca, Andrea Baggio, Andrea Lodi, Andrea Tramontani

Network safety is modeled through a defender-attacker-defender game. It encompasses three phases: prevention, attack and recovery. This game is formulated as a trilevel mixed-integer program for which an exact algorithm is proposed. The computational results highlight the advantage of simultaneously integrating these three game stages on the determination of the defender’s optimal strategy.

4 - Modeling Defender-attacker Problems as Robust Linear Programs with Mixed-integer Uncertainty Sets

Juan S. Borrero, Oklahoma State University, Stillwater, OK, United States, juan.s.borrero@okstate.edu, Leonardo Lozano

We study a class of uncertain defender-attacker optimization problems where the defender has uncertainty about the data but can represent her limited knowledge by a mixed-integer uncertainty set. Given that the defender hedges against the worst possible data realization, the robust optimization problem becomes a bilevel bilinear problem with a mixed-integer lower level. We discuss two applications and reformulate the problem using semi-infinite and convex optimization. These reformulations are the basis for a cut generation and a Frank-Wolfe based algorithms. We provide theoretical convergence bounds for each algorithm and discuss their performance on numerical experiments.

Accounting & Vehicle Routing

Contributed Session

Chair: Yongsen Zang, Tsinghua University, Tsinghua Yuan,Haidian, Beijing, 100084, China

1 - Sustainability of Social Enterprises and Acquiring Resources by Sending Market Signals

Junseok Goh, Seoul National University, Seoul, Korea, Republic of, junsgoh@gmail.com, Dan Hong

Social Enterprises solve societal issues by both pursuing economic and social returns and operating their business to create values for the society and for stakeholders. The survival of social enterprise is contingent upon their ability acquire capital and resources to sustain. The information asymmetry problem arises when principals who make investments to social enterprises (agents) do not observe social value being created. Drawing from signaling theory, this paper proposes that a third party, institutions who evaluate overall performances of social enterprises, can be a promising signal to investors. Firms engaged in a third party support shows easier access to debt financing.

2 - Flexibility Structure Evaluation and Routing Policy with Human Resource Considerations

Fengming Cui, Tsinghua University, Beijing, China, cfm16@mails.tsinghua.edu.cn

Most of organizations consist of staffs who can deal with multiple types of tasks. The multiskill agents provide structural flexibility to the organizations. This study examines several structure flexibility indices and routing policies from an organizational behavior perspective by incorporating human resource factors like emotional exhaustion. The objective of the study is to help design an effective flexibility structure and routing policy in organization operations management.

3 - Variable Tact Times for Mixed-model Assembly with Random Customization

Tobias Moench, WHU - Otto Beisheim School of Management, Vallendar, Germany, Arnd Huchzermeier

In case of a fixed tact system, raising the number of products to be assembled on a single line results in increased idle time as well as utility work and often requires an expansion of the line. To the contrary, a variable tact time approach is able to eliminate such line inefficiencies altogether, and diminishes the computational effort associated with line balancing and sequencing. We present a benchmark study of a global manufacturer of agricultural machinery where models differ greatly in assembly times and each product is uniquely customized.

4 - The Electric Vehicle Routing Problem Considering Different Battery Depreciation Strategies

Yongsen Zang, Tsinghua University, Beijing, China, zysthu@163.com

A growing body of work has shown that Electric Vehicle Routing Problem (EVRP) engenders greater benefits than VRP in the long run. Battery depreciation cost is one of the important key factors making against the benefits. We adopt three battery depreciation methods to pursue the influence for EVRP model: 1) charge-discharge cycles depreciation; 2) total driving distance depreciation; 3) battery depreciation with nonlinear function. To deal with the complexity of the models, a Column Generation algorithm relies on different labeling algorithms is designed. After computational studies and comparison of three models, several managerial insights are deduced for the better operation of EVRP fleet.

1 - Product Recall Delay and Product Cycle

Hsiao-Hui Lee, National Chengchi University, Taipei, Taiwan, hsiaohui@nccu.edu.tw, Wenzheng Mao, Zhanyu Dong

When a safety defect occurs, manufacturers often use product recalls to mitigate potential consequences. Our empirical observation on large recalls in the automobile industry suggests that the timing of a recall is a key decision in this recall process, as we find that only recalls made in an early stage of a product cycle significantly influence future product sales. Our model confirms that when a product defect is discovered at an early stage of the product cycle, a firm may strategically delay the timing of a recall to mitigate the negative shock evoked by this recall. To avoid long-delayed recalls, governments need to note this behavior and design penalty/incentives accordingly.

2 - Product Remanufacturing in the Presence of Secondary Market Implications of Recollection Policy

Chang Dong, Hong Kong University of Science and Technology, Hong Kong, Hong Kong, cdongad@ust.hk, Qian Liu

We analyze the impact of strategic customers' p2p used goods transaction in a two-period model where a profit-maximizing firm successively sells two generations of a product in a market. A key message of our study is that due to strategic customers' inter-temporal purchase decision, the existence of p2p used goods market could either improve or reduce the benefit of the trade-in remanufacturing policy: the p2p used goods market acts as a double-edged sword. Moreover, in the stochastic depreciation case where there is uncertainty concerning the quality level of a used product, a trade-in program amounts to an intervention by the firm in the used goods "lemon" market.

3 - Preventing Free Riders in Collaborative Logistics: How to Share Joint Profits with Partners

Minyoung Yea, Korea University, Seoul, Korea, Republic of, ymy99@korea.ac.kr, Daeki Kim, Taesu Cheong

This study investigates a mechanism for sharing profits of horizontal cooperation in transportation. Collaborative logistics, which generates benefit by resources utilization, increases social welfare unless it approves inefficient acts. The proposed allocation rule is designed to mitigate "the tragedy of the commons" in shared logistics.

4 - Offering Trade-ins for Competitor's Used Products

Narendra Singh, Indian School of Business, Mohali, India, narendra_singh@isb.edu

Firms increasingly offer trade-ins for their competitors' used products. While such trade-ins may allow a firm to compete more aggressively, they may also increase resale value of competitors' products. I study the implications of a firm offering trade-ins to consumers who own used products sold by a competing firm.

5 - Evaluation of Trade-in-to-upgrade Policies as a Marketing Strategy for Smart Product Recovery

Ozden Tozanli, University of Bridgeport, Bridgeport, CT, United States, Elif Kongar, Surendra M. Gupta

Trade-in programs offer remarkable opportunities to manufacturers from environmental and economic standpoints. These programs while may be a significant asset to organizations, if not tailored properly, become a financial burden for producers who rely on qualified disassembly yields that would compensate for product acquisitions cost. Addressing this issue, this study presents the use of intelligent products in a blockchain-enabled disassembly-to-order (DTO) system to determine the optimal trade-in offer. A discrete-event simulation model is developed to obtain the expected cost of the DTO system. An optimal offer for varying product qualities is computed by utilizing the proposed model.

1 - An Empirical Analysis of the Role of Banner Ads in Mobile Games

Jiaying Deng, University of Washington, Seattle, WA, 98105, United States, jydeng2@uw.edu, Stephanie Lee, Yong Tan

Freemium games dominate the mobile game market and revenues from mobile games account for almost 90% of total app revenue on Google Play. However, in-game purchases rate is formidably low and most game publishers still rely on advertisement. On the other hand, there is a trade-off between advertisement revenue and gamers' nuisance cost. This paper investigates how the introduction of banner ads affects players' activities. The result shows that there is no significant change in players' daily playing frequency or session duration after the launch of banner ads. Second, gamers' intention to make no-ads purchase is significantly increasing.

2 - A Smart Solution to Rush-hour Traffic Congestion: Effects Dockless Bike-sharing Entry on Ride-sharing

Juan Qin, Harbin Institute of Technology, WA 98105, Seattle, WA, 98105, United States, jqin@uw.edu

We examine whether dockless bike-sharing can offer a technology-enabled smart solution to the traffic congestion problem by offering an environmentally-friendly, cost-effective, and sustainable mode of transportation. We exploit the natural experiment setting to examine the effect of dockless bike-sharing entry on the demand for ride-sharing car-travels during rush-hours. Using a difference-in-difference framework, we find that the entry of dockless bike-sharing reduces rush-hour ride-sharing orders, especially at congested regions.

3 - Can Match-funding Really Double Your Impact? Crowding Out in Donation-based Crowdfunding

Zhen Fang, University of Washington, Seattle, WA, United States, zhenfang@uw.edu, Shengsheng Xiao, Yong Tan

Match-funding has become a new measure of philanthropic marketing for large companies to match donation from individual donors dollar-for-dollar. Leveraging an open dataset from a large classroom crowdfunding platform, we conduct a natural experiment to examine the impact of match-funding and moderating effects of campaign progress. Our results show that match offers will significantly crowd out part of donations but accelerate the financing process by lowering actual objective amount and mitigating negative effect of donated percentage. Our findings have important implications for crowdfunding platforms and project owners on how to succeed in the presence of match-funding.

4 - Helpfulness of Video Reviews: A Study of Product Reviews on Youtube.com

Kyungmin Park, University of Washington, Seattle, WA, 98105, United States, Stephanie Lee, Yong Tan

This research explores the determinants of the helpfulness of online video review. By analyzing 10219 reviews from YouTube.com, we found the heterogeneous effect of review contents on the helpfulness of review by reviewer popularity. For popular reviewers, review subjectivity has a positive effect on review helpfulness. However, the effect is opposite for less popular reviewers. For both reviewer types, the level of information concentration has a positive effect on review helpfulness, but the reviewer type moderates the effect of the level of information concentration on review helpfulness.

Chair: Sam Ganzfried, Ganzfried Research, Miami Beach, FL, 33139, United States

1 - Online Channel Choices of a Farmer with Pick-your-own Operations

Bing Xu, Prof., Nanchang University, Nanchang, China, xu_bing99@sina.com

Nowadays, farmers are increasingly adopting pick-your-own (PYO) operational method in which consumers can pick agriculture products by themselves on the farm. In the context of e-commerce, farmers need to consider whether or not to operate online sales channels. To address this challenge, we investigate online channel choices of a farmer. Particularly, we consider three scenarios: No online channel; operating online channel itself; operating online channel via an e-tailers. The results show that the product freshness and online operation cost affect the farmer' choices among three scenarios.

2 - An Evolutionary Game Theory Approach to the Role of Government in Technology Transitions

Camila Apablaza, PhD Student, Georgia Institute of Technology, Atlanta, GA, United States, capablaza@gatech.edu, Valerie Thomas

The widespread adoption of alternative fuels and alternative fuel vehicles (AFVs) could have an important role in the task of curbing future emissions. The mass adoption of AFVs depends on a network of interactions between regulators, vehicles manufacturers, fuel providers, and consumers. This study uses an evolutionary game theory approach to model the network of stakeholders involved in the process of adopting AFVs in the transportation sector. This approach allows studying the changes in strategy chosen by each one of the game's players when a change in the environment happens. We examine the effect of regulation targeting AFVs in the strategy adopted by the stakeholders.

3 - An Algebraic Method About Power Asymmetry in the Graph Model for Conflict Resolution

Haiyan Xu, Nanjing University of Aeronautics and Astronautics, Nanjing, China, xuhaiyan@nuaa.edu.cn, Dequn Zhou, Zhihong Tu

An algebraic approach is proposed to implement the conflict analysis with asymmetric power based on the graph model for conflict resolution. The follower decision maker would like to take consensus preference with the leader decision maker and the leader may choose positive, negative or indifferent attitude towards the follower. The stability definitions for decision makers with asymmetric power are presented and the algebraic presentation is provided to implement algorithms efficiently. The energy pipeline conflict in the Central Asian Caspian is utilized to show how the proposed method work.

4 - Quality Improvement and Product Recall

Tulika Chakraborty, John Molson School of Business, Concordia University, Montreal, QC, Canada, jum.tulika@gmail.com, Satyaveer S. Chauhan

We consider a dynamic model of one-manufacturer purchasing a specific part from one-supplier to produce a finished product. Both members invest in product quality. The supplier is prone to product recall during the planning horizon. Our goal is to investigate the impact of the recall on pricing and quality decisions.

5 - Bounded Rationality with Information Cascading in Social Media

Guanxiang Yun, University of Central Florida, Orlando, FL, United States, Qipeng Phil Zheng

Social media have been popular platforms for people to share information. Expanding the connections can help commercial users make more influences. In order to optimize their network connections, we have a three-level math model to simulate behaviors of other users within the target user's network. We apply the linear threshold propagation model to determine the action of re-post. In addition, the action of following or un-following is restricted by boundedly rational user equilibrium (BRUE). We tackle this problem by using the heuristic large neighborhood search algorithms. We discuss the reasons why the BRUE model may be a more accurate simulation of users' actions compared to game theory.

6 - Optimization-Based Algorithm for Evolutionarily Stable Strategies Against Pure Mutations

Sam Ganzfried, PhD, Ganzfried Research, Miami Beach, FL, United States

Evolutionarily stable strategy (ESS) is an important solution concept in game theory which has been applied frequently to biology and even cancer. Finding such a strategy has been shown to be difficult from a theoretical complexity perspective. Informally an ESS is a strategy that if followed by the population cannot be taken over by a mutation strategy. We present an algorithm for the case where mutations are restricted to pure strategies. Our algorithm is based on a mixed-integer non-convex feasibility program formulation, which constitutes the first general optimization formulation for this problem.

1 - The Effect of Distribution Center Processes on Supply Chain Inventory

James Bradley, Hays T. Watkins Professor, College of William and Mary, Williamsburg, VA, United States, james.bradley@mason.wm.edu

We show that the picking sequence in a distribution center, which serves downstream retail stores, affects the inventory in the supply chain when a common "ship-when-full" trailer dispatching policy is used. Further, we develop an effective heuristic picking sequence policy for minimizing inventory.

2 - The Influence of Franchisee Loss on Logistics Network: A New Perspective from NK Model

Yihang Feng, Huazhong University of Science and Technology, Wuhan, China, Bin Hu, Changying Ke

The development of Internet of Thing and new information technology makes the repaid expansion of their logistics network become possible. As the management of franchisee cannot keep pace with the speed of logistics network expansion, this mode has led to many management problems such as franchisee loss. We introduce NK model to launch our analysis from the perspective of vulnerability. In addition, efficacy and efficiency are proposed to measure the performance of logistics network. Results show that relatively small networks should focus on the enhancement of efficacy, while relatively large networks should make efforts in efficiency. Corresponding cases are introduced to confirm our results.

3 - The Selection of the Optimum Location for Wind Farms by MAUT and AHP: A Case Study

Behnaz Malaei, Graduate Assisstant, Binghamton University, Binghamton, NY, United States, bmalaei1@binghamton.edu

These days, the greater part of the world, unfortunately, depends intensely on non-renewable fossil fuels; meanwhile, wind energy continually self-renews. Diverse social and local criteria are as vital as the wind for the optimal location of wind power generation-transmission plants. Building wind farms requires a high investment. Therefore, location selection for wind farms has special importance. Since different methods present different results, decision-makers significantly apply more than one technique. This paper applies Multi-Attribute Utility Theory and Analytical Hierarchy Process methods with six different decision criteria to identify the optimum location for wind plants.

4 - Welfare Impacts of Optimal Virtual Bidding in a Multi-settlement Electricity Market with Transmission Line Congestion

Hyungkwan Kim, Lawrence Berkeley National Laboratory, Berkeley, CA, United States, hyungkwankim@lbl.gov, Paul V. Preckel, Douglas Gotham, Andrew Lu Liu

The objective of this research is to understand the effect of virtual transactions on electricity market efficiency using a model that explicitly includes the network as well as relationships that reflect the physical properties of electricity flows through a network (i.e. loop flow). The core research question is; what impact does network congestion have on the welfare shifts caused by the participation of financial virtual traders? Results indicate that optimal virtual bidding tends to decrease consumer welfare when the expected spot price is equal to the cleared forward price, and congested lines in the network can magnify the welfare changes while virtual traders essentially always benefit.

5 - When Do Acquirers' Absorptive Capacity Have Better Performance?

Yunjae Bae, Seoul National University, Seoul, Korea, Republic of, jaybae4606@gmail.com, Taewoo Roh

This study cumulates the importance of absorptive capability and future performance after obtaining extrinsic resources by acquiring other firms. Using United States International M&A transaction toward foreign companies during 2000-2014, we propose that the higher level of absorption capacity, the more likely to have better firm performance. In addition, this study used four moderate variables that would further effect on firm's future performance. From acquiring the firm's M&A information, we find that the firm's payment method of cash and past M&A experience positively creates a higher firm performance.

6 - A Matheuristic for Large-scale Capacitated Clustering

Mario Gnägi, University of Bern, Bern, Switzerland

Capacitated clustering problems consist of assigning a set of weighted objects to clusters such that the total weight of the objects in each cluster does not exceed a cluster-specific capacity. The objective is to minimize the total distance between the objects and their respective cluster centers. Typical applications include facility location and customer segmentation. State-of-the-art approaches for capacitated clustering problems scale up to instances with 10,000 objects. Here, we present a new type of matheuristic for instances with up to 100,000 objects.

7 - The Value of Blockchain in Smart City Energy Management

Pranathy Enamela, University of North Texas, Denton, TX, United States, pranathyenamela@my.unt.edu, Abdulrahman Habib, Victor R. Prybutok

This study explores the use of blockchain by smart cities to increase the likelihood of sustaining an uninterrupted supply of electricity. Review of theory allowed development of a conceptual model that supports the value of data processing in smart grids. The posited model supports the need for better integration between platforms and providers to enhance city wide distribution of energy.

Bayesian Approach & Retail Management

Contributed Session

Chair: Kyle Maclean, Ivey Business School

1 - Bayesian Business Analytics

Adam Jason Fleischhacker, University of Delaware, Newark, DE, United States

We introduce an R package, causact, that provides an intuitive, yet powerful, interface into probabilistic programming. Causact's goal is to accelerate the complete Bayesian business analytics workflow - including strategy elicitation with c-level execs, creating/visualizing probabilistic graphical models, computing posterior distributions with Hamiltonian Markov Chain Monte Carlo, and data visualization to persuade stakeholders to take action.

2 - Consumer Response Behavior: A Cross-Category Targeting Perspective

Sri Devi Duvvuri, Assistant Professor, University of Washington Bothell, Bothell, WA, United States, duvvuris@uw.edu

Very often retailers are in situations where they have to target customers who have not made a purchase in the categories under consideration. Are there methodologies that can help generate response sensitivities for customers with no purchase histories? In this research, we propose a multivariate probit framework that derives consumer response sensitivities for such customers. We use scanner panel data across multiple categories to calibrate the model. We validate model results and derive marketing metrics using survey data from the same panel of customers. We use Hierarchical Bayesian methods (MCMC) to infer model parameters.

3 - An Optimal Assortment for Complements and Category Coordination

Xi Shan, Boston College, Boston, MA, United States, Chenglin Zhang, Dorothee Honhon

Using complements is common practice in assortment planning: Restaurants offer meals with drinks or a music environment and even allow consumers to bring their own wine. Department stores use one category as a complement to the other categories to stimulate purchases.

4 - Assortment Planning with Satisficing Consumers

Forough Pourhossein, Sauder School of Business, University of British Columbia, Vancouver, BC, Canada, forough.pourhossein@sauder.ubc.ca, Woonghee Tim Huh, Steven Shechter

We consider an assortment optimization problem in which consumers have a satisficing behavior rather than being utility maximizers. Satisficers do not necessarily investigate all items; they stop searching and make a purchase when an acceptability threshold is met. We incorporate search budgets in our optimization model too; customers leave without purchase if they are not satisfied with certain number of items they investigated. We prove our problem is NP-hard, demonstrate some structural properties and reformulate it as a MIP problem. We discuss the firm's expected revenue loss if they wrongly assume their consumers are utility maximizers or ignore search budgets.

New Product Development

Contributed Session

Chair: Lili Shangguan, Xiamen University, Xiamen, 361005, China

1 - A Cooperative Game Based Method to Setting Target Values of Engineering Characteristics in Quality Function Deployment

Ping Ji, The Hong Kong Polytechnic University, Dept. of Industrial and Systems Engineering, Kowloon, Hong Kong, Yunwen Miao

Quality function deployment (QFD) is a systematic tool to mapping customer requirements (CRs) into engineering characteristics (ECs) in product design. In this paper, a mixed integer non-linear programming is established to determine target values of ECs to maximize overall customer satisfaction, whose objective is a Nash bargaining function among fulfillment degrees of CRs. These fulfillment degrees are expressed by a quantitative Kano's model. Finally, an example of a notebook computer design is used to demonstrate the feasibility and effectiveness of the proposed model.

2 - The Influence of Starting Configuration in Customer Co-design

Heejoo Lim, Korea University, Seoul, Korea, Republic of, hlim@korea.ac.kr

Customers can enjoy added value through co-design by possessing a unique product with a better fit reflecting their self-expression. While they might be confusing due to the complicated co-design process. The complexity level is differently perceived by different customers and it makes some of the potential customers give up to purchase a co-design product. Providing a starting configuration can attract them who are not accustomed to co-design of a certain product and the firm can avoid a situation to lose potential customers. This study analyzes the influence of starting configuration on the choice of process.

3 - Robust Product Line Design by Protecting the Downside While Minding the Upside

Tan Wang, The University of Texas at Austin, Austin, TX, United States, tanwang@utexas.edu, Genaro J. Gutierrez

Robustness approaches are useful when decisions must be made before uncertainties resolve. Two major approaches to robustness are: 1) maximizing the value of the worst outcome and 2) minimizing the ex-post regret of the decision made. We examine performance tradeoffs between the two approaches in the product line design problem, and we construct an efficient frontier for robust designs obtained by both approaches. Our findings indicate that it is possible to find robust designs that mitigate downside risk while limiting ex-post opportunity losses.

4 - Interactions Between Trade Promotion and Product Line Design under Demand Uncertainty

Yu Jiang, University of Science and Technology of China, Hefei, China, jiangyu1@mail.ustc.edu.cn, Jie Wu, Xiang Ji, Zhixin Chen

This paper studies a manufacturer's optimal decisions on trade promotion and product line design when the manufacturer sells through an independent retailer to uncertain market. The two major types of trade promotion, off-invoice and scan-back, are taken into consideration. We show that, when consumers have discrete demand uncertainty, a manufacturer may prefer scan-back to off-invoice no matter selling a product or a product line. In addition, a manufacturer can have more incentives to extend its product line when using off-invoice than scan-back in trade promotion.

5 - Drop-shipper or Re-seller: Analysis for Online Distribution Strategies with Demand Uncertainty and Off-line Retailing

Wei Lu, University of Science and Technology of China, Hefei, China, luw@mail.ustc.edu.cn, Jie Wu, Xiang Ji

We use a game-theoretical model to tackle the issue how the demand uncertainty and off-line retailing affect online distribution strategies. Our results show that the impact of online demand uncertainty on manufacturer's drop-shipping strategy is nonmonotonic. In addition, we show that both the manufacturer and the etailer prefers drop-shipping when aggressive off-line retailing exists.

6 - Manufacturer's Product Differentiation and Pricing Strategies in Different Channels

Lili Shangguan, Xiamen University, Xiamen, China, Yongquan Lan, Zhaowei Miao, Jiguang Chen

We learn how a manufacturer, who sells products through different channel, designs his product differentiation together with pricing strategies. By taking the horizontal and vertical dimensions of product differentiation into consideration, we divide the product differentiation strategies into four cases, establish game theory models for each case and derive related optimal pricing strategies. The results show when uniform/differentiated pricing strategies in different channel will be adopted under given product differentiation strategy and how the manufacturer designs his horizontal and vertical product differentiation strategies in different channels for given pricing strategy.

Chair: Yang Yang, Kellogg School of Management, Evanston, IL, 60208, United States

1 - People, Process and Products: An Analytical Perspective

Iddrisu Awudu, Quinnipiac University, Hamden, CT, United States, iddrisu.awudu@quinnipiac.edu, Mariama Yakubu

In this work, we consider a clinic access scheduling system in the US to be replicated in a Polyclinic in Ghana where patients (including pregnant women) wait for hours to be attended to by a healthcare provider. We consider two modeling frameworks from bed allocation/scheduling and optimization perspectives. We identify parameters that determine open clinic access and scheduling. We develop an optimization model using data for patient scheduling in an open clinic setting. We propose a novel solution to the proposed open clinic scheduling problem to reduce waiting times based on the data used. Finally, we outline the importance of decision support tool for patient scheduling in an open clinic setting.

2 - An Organic Web Intelligence Architecture Based on Micro-services and Data Processing Pipelines

Bram Steurtewagen, Ghent University, Ghent, Belgium, Bram.steurtewagen@ugent.be, Dirk Van den Poel

Keeping up with data streams on different media has become a challenge for researchers, communications experts and content producers alike. Web Intelligence tools tackle these vast amounts of data. In this study, we put forward an architecture based on the principles of micro-services, containers, and distributed frameworks in order to attain a media tracking platform. We show it possible to implement multiple trackers, analytics pipelines, and visualizations on one system that is fed by a common fabric. This allows for tracking viral phenomena over different media. In the study, we highlight the architectural fit of our proposal to data processing pipelines while being modular and scalable.

3 - The Emotional Response of the Public to the Development of Artificial Intelligence – Emotional Analysis Method Based on Microblog Text

Ma Liyi, Beijing Union University, Beijing, China, maryliyi@126.com

The existing studies on the impact of technological progress on employment effect mainly focus on phenomenal description, detail analysis and trend prediction, and there is no research that can accurately quantify the impact of the development of artificial intelligence (AI) on the public sentiment.Based on social media, this study builds a sentiment analysis model based on support vector machine using machine learning, sentiment analysis and other related methods, and carries out a quantitative evaluation on the psychological impact of artificial intelligence on the public, and finally verifies the effectiveness of this model.

4 - Research on Value Evaluation System of Online Literature Adapted for TV Drama

Dan Xiao, the Communication University of China, Beijing, China, Jinluan Ren

Based on the comprehensive analysis of the research status of online literature, this paper summarizes the factors that affect the value of online literature, and establishes the value evaluation system of online literature adapted for TV drama. On the basis of collecting 684 sample data, the weights of evaluation indicators are calculated by combined Analytic Hierarchy Process, experts scoring and entropy evaluation method. The value evaluation model of online literature adapted for TV drama is constructed and 18 samples are empirically analyzed and ranked according to content value, operational capability of publishing platform, derived value and comprehensive value respectively. This article provides a methodological support for selecting materials of TV dramas from online culture literature.

5 - Clinical Text Deidentification in the Era of Big Data

Ioana Danciu, Oak Ridge National Laboratory, Oak Ridge, TN, United States

Clinical notes offer invaluable insights into patients' health, but transforming the text into a research-ready form is no easy task. We present our approach to scrubbing billions of notes of protected health information (PHI) as defined by HIPAA. We used Apache Spark and worked with the National Library of Medicine (NLM) to adapt their PHI scrubber to our big data framework. The framework is generalizable to other natural language processing tasks. The results are supporting the Million Veterans Program (MVP) and are available to Veterans Affairs (VA) and Department of Energy (DOE) researchers.

6 - Media and Public Access to Science

Yang Yang, Kellogg School of Management, Evanston, IL, 60208, United States, Yuan Tian

Public opinion about science has become increasingly polarized in the past decade. While scientists are viewed central to scientific communication and literacy, we argue that the changing media environments play an increasingly important role in shaping public perception of science. We combined data of 160 million research articles, 63 million news reports, and 53 million tweets to describe how the mainstream media and the social media influence public access to scientific knowledge. We further address the causal impact of media using an IV2SLS approach.

1 - Does Clean Heating Improve Air Quality? Evidence from Chinese Cities

Tong Feng, Tianjin University, China, Tianjin, China, fengtong@tju.edu.cn, Huibin Du, Ning Zhang

To improve the air quality in winter, clean heating policy was implemented in "2+26" pilot cities of China in 2016. Using a difference-in-differences method, we estimate the impact of clean heating policy on air quality. We find this policy improves the daily air quality index by 6% and increases the number of days with good air quality. The health and economic co-benefits of clean heating are huge. We also find the consumption growth of clean coal does not lead to the deterioration of air quality. There is suggestive evidence revealing the advanced coal-fired boilers for heating will be helpful for air quality improvements. It is more in line with China's coal-rich and gas-short resource endowment.

2 - Quantitative Evaluation of the Feasibility of Meeting Emission Targets with a Chance Constrained Energy System Model

Hansung Kim, Pohang University of Science and Technology (POSTECH), Cheongam, Pohang, Korea, Republic of, willhomehs@postech.ac.kr, Hyungkyu Cheon, Daeho Kim, Dong Gu Choi

Recently, researchers have incorporated uncertainties into energy system models with stochastic programming-based models. Most studies focused on meeting greenhouse gas (GHG) reduction targets considering various uncertainties. However, meeting targets leads to dramatic cost increases. At the same time, there is a risk to fail to meet the targets if enough uncertainties are not considered. Therefore, it is important to find a balance between cost and risk. In this study, we define the risk as to the feasibility of meeting GHG reduction targets and evaluate the risk by using a chance-constrained model. We apply the model to South Korea and analyze the trade-off between total cost and the risk.

3 - Optimal Management of a Demand Response Aggregator in a Small-scale Electricity Market

Jong-hyun Ryu, Hongik University, Sejong, Korea, Republic of, jhryu@hongik.ac.kr

Demand response (DR) resources have been more discussed as grid flexibility becomes more important. In order to cost effectively manage scattered DR resources in a small-scale electricity market, a DR aggregator needs to determine an optimal operating policy. This study develops an optimization model for a DR aggregator. To promote DR programs, we also provide a guideline on designing an effective subsidy policy considering the uncertainty of market prices and balancing requirements.

4 - A Bi-level Program Approach to Utility Estimation for Price-responsive Electricity Consumers

Arnab Roy, University of Louisville, Louisville, KY, United States, arnab.roy@louisville.edu, Lihui Bai, Bo Zeng

We present a bi-level optimization model for estimating utility parameters for price-responsive electricity consumers in a demand response environment. The lower level problem is for the user to maximize his/her total utility by determining the optimal curtailed load daily on multiple event days. The upper level problem minimizes the difference between the optimal consumption induced from the lower level and the actual consumption data by determining proper utility parameters. Computational results on the model and a fast trust-region algorithm will be reported.

5 - Dynamic Programming Model for Optimal Policy Supports Driving Renewable Energy Technology Development

Hao Ding, Nanjing University of Aeronautics and Astronautics, Nanjing, China, dding2009@nuaa.edu.cn, Dequn Zhou, Peng Zhou

Renewable energy technologies (RETs) are undergoing rapid developments globally. One of the main contributors is policy supports. The expenditure and efficiency of policy supports have to be considered with such a great market scale for RETs. This study aims to offer a model to search optimal policy supports for RETs integrating forces of technology push and demand pull. A dynamic programming model with the objective of minimizing policy expenditure is constructed. The results show that policy supports would be the main force for RETs' developments during their initial development periods. Policy supports should be reduced faster than the cost decline in order to improve their efficiency.

Chair: Jing Ma, Nanjing University of Aeronautics and Astronautics

1 - An Agent-based Model of Miscommunication in Complex System Engineering Organizations

John Meluso, PhD Candidate, University of Michigan, Ann Arbor, MI, United States, jmeluso@umich.edu, Jesse Austin-Breneman, Lynette Shaw

A recent study of a Fortune 500 firm demonstrated widespread "miscommunication"—communication with deficient outcomes—about the definition of "an estimate" in complex system design. We show via agent-based model and Monte Carlo simulation that design process miscommunication may affect system performance. Each run created and designed a unique 1000-artifact system through generative networks and optimization. Systems employing "current" design estimates outperformed "future" design projections ($p<0.001$). Fractional usage of each definition varied system performance and uncertainty. With estimates and generally, organizational miscommunication may affect system performance.

2 - Simulation-based Queueing Inference of the True Arrival, Balking, and Reneging Processes from Censored Transactional Data

Ashkan Negahban, Assistant Professor, The Pennsylvania State University, Malvern, PA, United States

Transactional data collected on queueing systems often censor unsuccessful arrivals due to balking and/or unserved entities due to reneging. In many situations, the true arrival, balking, and reneging events are unobservable, making it virtually impossible to collect data on these stochastic processes - information that is crucial for capacity planning and process improvement decisions. In this work, the estimation problem is formulated as an optimization model and an iterative simulation-based inference approach is proposed to find appropriate input models for these stochastic processes. The efficacy of the proposed approach is illustrated in a real-world application in a call center.

3 - A Data-driven Simulation Platform of Microscopic Road Behaviors and Macroscopic Traffic Flows

Cong Zhao, Roman Roads, Inc, San Jose, CA, United States, czhao27@wisc.edu

Carmakers and traffic regulators are faced with issues of decision making in operation and planning and it can be alleviated by utilizing a simulated environment. AI technologies can be leveraged to address issues of system modeling of driver's intention and behaviors, traffic capabilities. The speaker presents that have been used to build and train an AI-powered simulation. Data-driven approaches are exploited to learn real human road behaviors and produce simulated traffic scenes, trajectories, and intentions of road users. System-level architectures are also described on how to take into account the correlations among the road users in macroscopic traffic flow simulations.

4 - Rumor Spreading in Online Social Networks by Considering the Group and Individual Differences

Jing Ma, Nanjing University of Aeronautics and Astronautics, Nanjing, China, Chi Li, He Zhu, Xiaoyu Guo, Jiao Yan

In this study, we explore the impact of the group and individual differences on the rumor spreading process. Under the basis of the mean-field theory, we formulate the mathematical expression of the rumor spreading model, and theoretically analyze the spreading threshold. With the help of the Monte-Carlo simulation method, the theoretical analysis is explicitly verified. According to the numerical simulation, we find that the final density of spreaders is in positive correlation with both the group and individual difference coefficients. However, the impact of these two factors are not the same: the effect of the group difference is more significant.

1 - Relationships in Heart Rate Variability Measures and Their Ability to Predict Physical Performance

Michael Tolston, Ball Aerospace and Technologies, Fairborn, OH, United States, mtolston@ball.com, Nickolas Mackowski, Maegan O'Connor, Adam Strang

The ubiquity of wearable heart rate monitoring devices has both simplified the collection of heart rate data and added confusion regarding the large number of proprietary algorithms related to heart rate variability (HRV). In this work, we show how some of these proprietary metrics are related to traditional measures of HRV and compare their ability to predict performance in strenuous physical activities. We show that various metrics are related in predictable ways and that traditional metrics of HRV can be used to predict performance outcomes in repeated measures data.

2 - Can Learning-by-doing Hurt Profit? The Case of Outsourcing and Supplier Encroachment

Yaqin Sun, Drexel University, Philadelphia, PA, United States, ys523@drexel.edu, Wenjing Shen

In this paper we consider an OEM's outsourcing decision when CM can learn to reduce production cost and when CM can enter the market. We want to study how this learning affects CM's encroachment decision. We will further discuss how OEM adjusts its outsourcing quantity when CM can encroach the end market.

3 - Application of Data Science Techniques to Transform Public Investment Management

Martin M. Spollen, Queens University Belfast, Belfast, United Kingdom, m.spollen@qub.ac.uk

This session will examine the development and application data science techniques for consumer choice analysis to inform public investment management. These approaches focus attention on the network effects of investment on total portfolio performance. Application to a major regional schools investment and rationalisation programmes is demonstrated.

Chair: Troy Tong, Tsinghua University, Tsinghua University, China

1 - Predicting Carbon Abatement Outcomes Using Text Analysis

Christian Blanco, Ohio State University, 640 Fisher Hall, 2100 Neil Ave, Columbus, OH, 43210, United States, blanco.58@osu.edu

Are firms strategic in disclosing carbon emissions reduction projects? We explore this question by comparing carbon emissions reduction projects with partial and full information. We use data from over 40,000 carbon abatement opportunities reported to CDP from 2011-2016.

2 - Administrative Environmental Innovations, Supply Network Structure, and Environmental Disclosure

Marcus A. Bellamy, Boston University, Rafik B. Hariri Building, 595 Commonwealth Avenue, Boston, MA, 02215, United States, bellamym@bu.edu, Suvrat Dhanorkar, Ravi Subramanian

Using supply chain relationship (SPLC) and environmental, social, and governance (ESG) data from Bloomberg, we test our hypothesized relationships between focal firms' adoption of administrative environmental innovations and their extent of environmental disclosure, with supply network structure as a moderating factor.

3 - How Resource Scarcity Affects Environmental Performance?

Suresh Muthulingam, The Pennsylvania State University, Smeal College of Business, 460 Business Building, University Park, PA, 16803, United States, Charles J. Corbett, Suvrat Dhanorkar

Using econometric techniques, we examine the impact of resource scarcity on the environmental performance of Texas manufacturing plants.

4 - An Analysis of Subsidy Policies for the Adoption of Electric Vehicles

Runyu Tang, Tsinghua University, Beijing, China, try15@mails.tsinghua.edu.cn, Saed Alizamir, Foad Iravani

Electric vehicles(EV) are good alternatives to the traditional gas vehicles in case of reliving global warming. Governments around the world try to promote EV adoption and develop EV infrastructures to protect the environment. The charging station deployment has a strong network effect on EV consumers, so the government needs to distribute the subsidy to the EV consumers and to charging station investors efficiently to boost the adoption process. We construct an analytical model which capture the network effect and the government's cost-benefit trade-off, and and the optimal subsidies structure under different scenarios.

5 - Impact of Geographic Water Stress on Operational Sustainability

Dustin Cole, Michigan State University, Sriram Narayanan, Elizabeth Connors

We examine the impact of geographically local water stress on operational sustainability, focusing on reduction in greenhouse gases, water and solid waste in operational outcomes. Using context theory we theorize that having water stress occur in the geographic area around the organization will provide a number of contextual cues that will cause the organization to improve the sustainability of its operational outcomes.

Voltage and Transient Stability in Modern Electric Power Systems

Sponsored: Energy, Natural Res & the Environment/Electricity

Sponsored Session

Chair: Andy Sun, Georgia Institute of Technology, Atlanta, GA, 30332-0205, United States

1 - Stability Properties of the Equilibrium Points in Power System Swing Equations

Amin Gholami, Georgia Institute of Technology, Atlanta, GA, 30080, United States, Andy Sun

Swing equations are a set of ordinary differential equations that model the dynamic behavior of power grids. Although swing equations have been extensively used in various contexts such as transient stability assessment for a long time, several basic questions on the stability of these equations have still remained unanswered. In particular, when a power system with nontrivial transfer conductances is stable? What is the relation between the underlying graph of a power system with the stability of its equilibrium points? In this talk, we address these questions. Moreover, we present a set of sufficient and necessary conditions for power system transient stability.

2 - Model-free Real-time Optimal Power Flow for Voltage Regulation

Andrey Bernstein, NREL, 15013 Denver West Parkway, Golden, CO, 80401, United States, andrey.bernstein@nrel.gov

We consider the problem of real-time optimal voltage regulation in distribution network with high penetration of distributed energy resources (DERs). Classic approaches rely on solving optimal power flow (OPF) that requires accurate network model. In high-penetration scenarios, this approach might fail to address system uncertainties. We propose a model-free algorithm that optimizes grid objectives using real-time measurements. It uses a quasi-stochastic approximation approach to estimate the gradients and solves the OPF by a gradient-based approach. It is adaptive to variable conditions, such as topology reconfigurations, faults, and variability of renewables.

3 - Towards Robustness Guarantees for Feedback-based Optimization

Marcello Colombino, McGill University, Montreal, QC, Canada

Feedback-based optimization algorithms for real-time optimization of the distribution grid have gained traction in recent years because of their simple implementation, their ability to reject disturbances in real time, and their increased robustness to model mismatch. In this work, we propose a framework to systematically assess the robust stability of feedback-based online optimization algorithms. We leverage tools from monotone operator theory and classical robust control to obtain tractable numerical tests that guarantee robust convergence properties of online algorithms in feedback with a physical system, even in the presence of disturbances and model uncertainty.

4 - Optimization of System-level Performance and Resilience of Low-inertia Power Systems

Dominic Gross, ETH Zurich, Zurich, Switzerland

A consequence of the transition of power systems towards renewable generation is the loss of synchronous machines, their inertia, and frequency and voltage control mechanisms. This leads to critical challenges in maintaining system stability. This talk focuses on system norms as metric for transient stability, resilience, and performance. In particular, system norms can be use to obtain efficient optimization algorithm that can be used to optimize the placement and control parameters of power converters provide frequency and voltage regulation in in large-scale systems.

5 - Solvability of Power Flow Equations Through Existence and Uniqueness of Complex Fixed Point

Bai Cui, Argonne National Laboratory, , Lemont, IL, 60015, United States, bcui@anl.gov

Despite intensive study, some basic properties of power flow equations still remain elusive. In particular, under what condition these equations admit a solution is one of the most fundamental questions. This question bears great theoretical and practical significance as it is intimately related to the stability of largescale power grids. In this presentation, we provide a strong solution to this question by identifying a sufficient condition to certify the existence and uniqueness of power flow solutions. Our novel approach exploits a certain fixed-point form in the complex domain, which leads to much sharper conditions than previously achievable through analysis in the real domain.

Advanced Game-theoretic Models in Energy Systems

Sponsored: Energy, Natural Res & the Environment/Energy Sponsored Session

Chair: Jalal Kazempour, Technical University of Denmark, Kgs Lyngby, 2800, Denmark

Co-Chair: Spyros Chatzivasileiadis, Technical University of Denmark, Kgs. Lyngby, 2800, Denmark

1 - Market Design for Peer-to-peer Energy Trading and Distribution System Flexibility

Thomas Morstyn, Research Fellow, University of Oxford, Oxford, United Kingdom, thomas.morstyn@eng.ox.ac.uk

Power systems are undergoing a fundamental transition, due to the emergence of distribution network 'prosumers', proactive consumers with flexible energy resources and ICT infrastructure who actively manage their consumption, production and storage of energy. Networked matching market theory is proposed for designing decentralised digital market platforms that allow prosumers to engage in peer-to-peer energy trading, and offer flexibility services to their local distribution system operator. The proposed market designs allow prosumers to reach agreement on a set of economically efficient and game theoretically stable transactions.

2 - When Nash Meets Stackelberg

Sriram Sankaranarayanan, Polytechnique Montreal, Montreal, QC, Canada, sriram.sankaranarayanan@polymtl.ca, Felipe A. Feijoo, Andrea Lodi

We provide an algorithm to compute a mixed-strategy Nash equilibria of a Nash game where each player's (or leader's) pay off is given as a bilevel linear program. This leads to a situation where the leaders not only play a Nash game with other leaders but also a Stackelberg game with their own follower(s). The algorithm exploits the polyhedral structure in the game and our ability to solve mixed-integer linear program fast. We then use this model to solve for equilibrium in a Nash game among countries (leaders) where each country also plays a Stackelberg game with their indigenous industries (followers).

3 - Efficiency of Two-settlement Electricity Markets under Alternative Market Designs and Oligopolistic Conduct

Puneet Chitkara, Post Doctoral Fellow, Johns Hopkins University, Baltimore, MD, United States, puneetchitkara2903@gmail.com, Benjamin Field Hobbs, Jalal Kazempour, Kaiying Lin

This study seeks to assess the efficacy of flexible resources, including fast-start generators and demand response and financial participants (virtual bidders) in enhancing the efficiency of two-settlement electricity markets under alternative market designs and conduct of market players with different risk perceptions. The simulations are done on large real-world power systems using Alternative Directions Method of Multipliers (ADMM). The work is proposed to be an extension of Kazempour and Hobbs (2018) and Kazempour and Pinson (2016).

4 - Risk Trading in Energy Communities

Niklas Vespermann, PhD Student, Technical University of Munich, Munich, Germany, Jalal Kazempour, Thomas Hamacher

Volatile local market-clearing prices give rise to heterogeneous risk preferences of community members. To prevent welfare losses due to conservative trading decisions in the forward stage of a few highly risk-averse players, we propose risk trading in energy communities. The Conditional Value-at-Risk serves as our risk measure for players to study different degrees of risk market completeness. For incomplete risk markets we formulate a two-stage stochastic equilibrium problem, while relaying on optimization when the risk market is complete. Results indicate that system costs savings can be realized when players engage in risk trading and sufficient financial products are available.

5 - Electricity Market Equilibrium under Information Asymmetry

Vladimir Dvorkin, PhD Student, Technical University of Denmark (DTU), Kgs. Lyngby, 2800, Denmark, Jalal Kazempour, Pierre Pinson

We study a competitive electricity market equilibrium with two trading stages, day-ahead and real-time. The welfare of each market agent is exposed to uncertainty associated with renewable energy production, while agent information on the probability distribution of this uncertainty is not identical at the day-ahead stage. We show a high sensitivity of the equilibrium solution to the level of information asymmetry and demonstrate economic, operational, and computational value for the system stemming from potential information sharing.

Machine Learning for Energy System Operations

Sponsored: Energy, Natural Res & the Environment/Energy Sponsored Session

Chair: Yue Zhao, Stony Brook University, Stony Brook, NY, 11794, United States

Chair: Baosen Zhang, University of Washington, Seattle, WA, 94105, United States

1 - Learning to Infer Voltage Stability Margin using Transfer Learning

Yue Zhao, Stony Brook University, Stony Brook, NY, 11794, United States, yue.zhao.2@stonybrook.edu, Jiaming Li, Young-hwan Lee, Seung-Jun Kim

Preventing voltage collapse is critical for reliable operation of power systems. A challenging problem is that the voltage stability margin is very computationally intensive to obtain. A novel machine learning-based approach for real-time inference of voltage stability margin is developed, only needing a very small number of offline-computed voltage stability margin data. An accurate margin predictor is trained by first training a binary stability classifier and then transferring this pre-trained model to fine-tune on the small data set of margins. Numerical simulations demonstrate the superior performance of the proposed method.

2 - Optimal Transmission Switching under Uncertainty using Linear Decision Rule

Yuqi Zhou, The University of Texas at Austin, Austin, TX, United States, zhouyuqi@utexas.edu, Hao Zhu, Grani Adiwena Hanasusanto

Transmission switching is becoming a popular operational strategy for interconnected power systems to reduce congestion and generation costs. With growing level of renewable energy sources such as wind generation, it is of increasing importance to account for the uncertainty in power system operational tasks including transmission switching. We will present a two-stage stochastic mixed-integer programming formulation for the optimal transmission switching (OTS) problem using sample scenarios of random wind power. The technique of linear decision rule is leveraged to solve the proposed two-stage problem to accelerate the computational speed.

3 - Kernel-based Learning for Inverter Control Rules

Manish Singh, Virginia Tech, Blacksburg, VA, United States, Mana Jalali, Vassilis Kekatos

Smart inverters have been advocated as a fast-responding mechanism for voltage regulation in distribution grids. Nevertheless, optimal inverter coordination can be computationally demanding, and preset local control rules are known to be subpar. Leveraging tools from machine learning, the design of customized inverter control rules is posed here as a multi-task learning problem. Each inverter control rule is modeled as a possibly nonlinear function of local and/or remote control inputs. The function outputs interact to yield the feeder voltage profile. Inverter rules are designed jointly to minimize a voltage deviation objective based on anticipated load and solar generation scenarios.

4 - Power System Control and Decision-making via Deep Reinforcement Learning

Qiuhua Huang, Sr. Research Engineer, Pacific Northwest National Laboratory, Richland, WA, United States, qiuhua.huang@pnnl.gov

In this talk, Dr. Huang will first talk about reinforcement learning, particularly deep reinforcement learning (DRL), and how it could be applied to address some of critical control and decision-making problems in power systems. Reinforcement Learning for Grid Control (RLGC), an open-source platform for development and benchmark reinforcement learning algorithms for grid control, was developed. Experiments on generator dynamic braking and undervoltage load shedding problems show the adaptiveness and robustness (to uncertainties and noise) of the developed DRL-based control schemes, compared with conventional Q-learning, model predictive control and existing protection mechanisms.

5 - Learning Congestion Patterns in AC Optimal Power Flow

Line A. Roald, Assistant Professor, University of Wisconsin, Madison, WI, 87544, United States, roald@wisc.edu, S idhant Misra, Yee Sian Ng

In power systems operation, similar optimization problems are solved over and over and over again, with only slight variations in load and system topology. Interestingly, in many power system test cases, there seems to be only a limited number of limiting constraints (so-called active sets) that determine the optimal system operation - even across a wide range of operating conditions. Even more strikingly, only a few constellations of congested transmission corridors seem to be relevant to practical system operations. In this talk, I will discuss our work on learning active sets, active constraints and transmission congestion patterns in optimal power flow problem.

6 - Networked Synthetic Dynamic PMU Data Generation: A Generative Adversarial Network Approach

Dileep Kalathil, Texas A&M University, College Station, TX, United States, Xiangtian Zheng, Dongqi Wu, Le Xie

Due to the confidentiality of real PMU data and no public access to detailed real power systems model, the lack of credible PMU data becomes a growing concern for research and education purposes. In this paper, using partial power systems infrastructure information, we develop a GAN-based method to synthesize realistic networked PMU data, which satisfy basic physics laws and mimic dynamic behavior of simulated power system. We validate the realistic dynamic characteristics of networked synthetic PMU data via a modal analysis method.

1 - How Shall I Trust the Online Review Through the Different Channels? An Empirical Study in Australia B2C Marketplace

Cong Cao, Tutor, University of Wollongong, Wollongong, Australia, cong.cao@outlook.com, Jun Yan, Mengxiang Li

Due to the virtual nature of e-commerce, trust plays an indispensable role. Furthermore, viewing other consumers' reviews and information becomes an effective risk control method for consumers. In order to better understand its influence mechanism on consumers' trust intention, based on related research, this paper summarizes the definitions of online review and then discusses in detail the meaning of the channel of online review and the different channels. Moreover, with the experimental method and data analysis, this paper substantiates that online reviews perceived by consumers from different channels have a significant difference and further demonstrate the existence of heterogeneity.

2 - Strategies for Online Retailers to Counter Webrooming

Peng Wang, Xidian University, Xian, China, wangpeng7@stu.xidian.edu.cn, Zhe Zhang

Webrooming (searching for information online and ultimately purchasing products offline) has been recently witnessed in multi-channel retailing. We develop a game theoretic model to examine how webrooming affects the profits of online retailers. We find that the existence of webrooming reduces the online retailer's profit. We also reveal that the product exclusive strategy is available for online retailers to counter webrooming. Finally, we extend to consider the strategic role of the manufacture and find that the product exclusivity strategy can generate a win-win outcome.

3 - Analysis of Online Arbitrage and Increased Returns

Avinash Geda, University of Florida, Gainesville, FL, United States, Jingchuan Pu, Liangfei Qiu

We model the phenomenon of online arbitrage and the associated problem of increased returns in a game-theoretic setting. We propose a solution to alleviate this problem and analyze how consumer surplus is affected under different settings.

4 - Integrating Kansei Engineering Into Analysis of Customer Requirements from Online Opinions

Jian JIN, Beijing Normal University, Beijing, China, jinjian.jay@bnu.edu.cn, Danping JIA, Qian Geng, Ping Ji

Designers have to optimize products according to customer requirements (CRs). Besides functional features, products need to meet emotional aesthete designs and it is critical for designers to understand emotional CRs. To capture emotional CRs, in this study, Kansei engineering is integrated with the Word2vec model. It helps to generate a domain Kansei lexicon and a product feature dictionary. Also, a feature-Kansei model is developed to represent CRs. To evaluate the effectiveness, an empirical case study is conducted with phone reviews. It shows that the integration of Kansei engineering helps to capture emotional CRs from online opinions and provides more critical insights for designers.

5 - Understanding Quality of Crowdsourced Answers in Online Communities

Orcun Temizkan, Ozyegin University, Istanbul, Turkey, orcun.temizkan@ozyegin.edu.tr, Ram Kumar

Community-based question answering is becoming increasingly important for the ability of online crowdsourcing community to generate quality answers to questions. Crowdsourcing answers to questions represent online knowledge repositories. In this respect, the quality of answers is important. Therefore, we present a model to understand factors that influence the quality of a good answer using theories from the knowledge management, multitasking, and social networks literatures. Empirical results based on data from a crowdsourcing website (Stack Overflow) will be presented.
