Over the past decades, an axiomatic approach to fair resource allocation has led to the general acceptance of a class of alpha-fair utilities parametrized by a single non-negative parameter alpha. The maximization of alpha-fair utilities is typically considered subject to positive linear (packing) constraints. In this talk, I will present distributed and width-independent first-order methods for solving general alpha-fair packing problems and their minimization counterparts — alpha-fair covering problems. The convergence times of these algorithms scale as Õ(1/eps2) and Õ(1/eps), greatly improving upon Õ(1/eps5) and Õ(1/eps4) previously known only for the alpha-fair packing problems.

4 - On Sufficient and Necessary Conditions for Rank-1 Generatedness Property of Cones

Fatma Kilinc-Karzan, Associate Professor of Operations Research, Carnegie Mellon University, Pittsburgh, PA, United States, fkilinc@andrew.cmu.edu, CJ Argue

A convex cone K that is a subset of the positive semidefinite (PSD) cone is rank-one generated (ROG) if all of its extreme rays are generated by rank 1 matrices. ROG property is closely related to the characterizations of exactness of SDP relaxations, e.g., of nonconvex quadratic programs. We consider the case when K is obtained as the intersection of the PSD cone with finitely many linear (or conic) matrix inequalities, and identify sufficient conditions that guarantee that K is ROG. In the case of two linear matrix inequalities, we also establish the necessity of our sufficient condition.

On Prediction and Optimization

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Fatma Kilinc Karzan, Carnegie Mellon University, Pittsburgh, PA, 15217, United States

Co-Chair: Nam Ho-Nguyen, Carnegie Mellon University, Pittsburgh, PA, 15213, United States

1 - Risk Guarantees for End-to-end Prediction and Optimization Processes

Nam Ho-Nguyen, Carnegie Mellon University, Tepper PhD Program, Pittsburgh, PA, 15213, United States, Fatma Kilinc Karzan

In real-world decision-making, prediction models are often used to estimating parameters of optimization models. While it is usually believed that good prediction performance should result in good subsequent optimization performance, formal theoretical guarantees on this are lacking entirely. We provide two sufficient conditions on the prediction loss function that good prediction results in good optimization, and derive explicit relations between the two. In a preliminary computational study on fractional knapsack problems, we compare the optimization performance of using several Fisher consistent prediction loss functions with a provably inconsistent loss function.

2 - Generalization Bounds in the Predict-then-Optimize Framework

Paul Grigas, University of California, Berkeley, CA, 94720-1777, United States, pgrigas@berkeley.edu, Othman El Balghiti, Adam Elmachtoub, Ambuj Tewari

In the predict-then-optimize environment, the parameters of an optimization task are predicted based on contextual features. A natural loss function in this setting, called the Smart Predict-then-Optimize (SPO) loss, is to consider the cost of the decisions induced by the predicted parameters, in contrast to the prediction error of the parameters. We provide an assortment of novel generalization bounds for the SPO loss function, including initial bounds based on a combinatorial complexity measure and substantially improved bounds under an additional strong convexity assumption.

3 - Statistically-Consistent Identification of Switched Linear Systems

Pedro Ivo Bastos Hespanhol, UC Berkeley, Berkeley, CA, 94709, United States, pedrohespanhol@berkeley.edu, Anil Aswani

Consider a set of linear autonomous systems with bounded process noise, where the system dynamics are unknown. A question is how to estimate the system dynamics given that measurements of each system are nonsequential. Though seemingly straightforward, existing proof techniques for statistical consistency of system identification fail when measurements are nonsequential. Here, we provide an estimator that leverages boundedness of the process noise, and we prove its statistical consistency holds even when measurements are nonsequential. We illustrate the almost sure convergence of our estimator by using it to construct a stabilizing policy for a learning-based switched control application.

4 - Differentiable Optimization Based Modeling for Machine Learning

Brandon Amos, Carnegie Mellon University, Pittsburgh, PA, United States, brandon.amos.cs@gmail.com

Domain-specific modeling priors and specialized components are important for machine learning to integrate specialized knowledge into the model. We argue that optimization methods provide an expressive set of operations that should be part of the machine learning practitioner's modeling toolbox. We will present the OptNet architecture that integrates optimization problems as layers in larger trainable networks. We then show how this can be used to combine model-free and model-based reinforcement learning. Lastly we will present a way of rapidly prototyping differentiable optimization layers with cvxpy.

Robust Optimization: Theory and Applications

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Vineet Goyal, Columbia University, New York, NY, 10027, United States

1 - On the Optimality of Affine Policies for Budgeted Uncertainty Sets

Omar El Housni, Columbia University, New York, NY, 10027, United States, oe2148@columbia.edu, Vineet Goyal

We study the performance of affine policies for two-stage adjustable robust optimization problem under a budget of uncertainty set. The two-stage adjustable robust optimization problem is hard to approximate within a factor better than $\Omega(\frac{\log n}{\log \log n})$ for budget of uncertainty sets where n is the number of decision variables. We show that surprisingly affine policies provide the optimal approximation for this class of uncertainty sets that matches the hardness of approximation; thereby, further confirming the power of affine policies. We also provide a faster algorithm to compute near-optimal affine policies.

2 - Optimal Monitoring with Limited Information

Dan Andrei Iancu, INSEAD and Stanford University, Stanford, CA, 94107, United States, daniancu@stanford.edu, Do Young Yoon, Nikolaos Trichakis

We consider problems where a system can only be stopped at a limited set of monitoring times, which must be chosen in conjunction with the stopping policy. In a framework where only limited information is available — namely, ranges of future values — and where monitoring reduces uncertainty, we show that the worst-case rewards under static and dynamic monitoring are the same, under broad conditions. We show how this allows recovering an optimal dynamic policy by resolving static problems, and discuss cases when the latter problems are tractable, highlighting conditions when simple monitoring schedules (e.g., with equi-distant times) are optimal.

3 - A First-order Method for Robust Optimization Problems

Shimrit Shtern, Technion - Israel Institute of Technology, William Davidson Faculty of Industrial E, Haifa, 32000, Israel, shimrits@technion.ac.il, Krzysztof Postek

In this work, we suggest a first-order saddle-point approach for solving large-scale robust optimization problems where each constraints is convex in the decision variables and concave in the uncertain parameters. This method does not require boundedness of the primal variables and enables dealing with complex uncertainty sets. The suggested method has an O(1/T) convergence rate with both optimality and feasibility guarantees.

Two-Stage Distributionally Robust Optimization and its Applications in Power Systems

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Chaoyue Zhao, Oklahoma State University, Stillwater, OK, 74075, United States

1 - The Supermodularity in Two-stage Distributionally Robust Optimization

Aiqi Zhang, The Chinese University of Hong Kong, Hong Kong, aqzhang@se.cuhk.edu.hk, Daniel Zhuoyu Long, Jin Qi

In this paper, we solve a class of two-stage distributionally robust optimization problems equipped with the property of supermodular. We derive the exact worst-case distribution in the robust counterpart which leads to the tractability of this class of problems. We further provide a necessary and sufficient condition to check if any given two-stage optimization problem has supermodular property. We apply this framework to classical problems, including multi-item newsvendor problems, general assemble-to-order systems and the appointment scheduling problem. While typically these problems are computationally challenging, they can be solved efficiently with our approach.

2 - A Data-driven Model of Virtual Power Plants in Day-ahead Unit Commitment

Sadra Babaei, Oklahoma State University, 322 Engineering North, Industrial Engineering & Mgmt, Stillwater, OK, 74078, United States, sadra.babaei@okstate.edu

Due to the increasing penetration of Distributed Energy Resources (DERs), power system operators face challenges of ensuring effective integration of DERs. The Virtual Power Plant (VPP) enables DERs to provide their services by aggregating them and participating in the wholesale market as a single entity. However, the available capacity of VPP depends on its DER outputs, which is time-varying and not exactly known when the independent system operator runs the day-ahead unit commitment engine. This talk proposes a data-driven model to evaluate the physical characteristics of the VPP, i.e., maximum capacity and ramping capabilities, given the uncertainty in wind power output and load consumption.

3 - Distributionally Robust Reliability Assessment for Transmission System Hardening Plan under N-k Security Criterion

Ali Bagheri, Oklahoma State University, Stillwater, OK, 74075-5757, United States

Hardening and reliability assessment of power transmission networks have become very important to make power systems less vulnerable to cascading failures. To do a reliability assessment, the information of contingency probabilities are required. However, such information is usually unknown and cannot be estimated precisely. Thus, we assume the probability of contingencies unknown and ambiguous. Besides, the commonly used N-1 security criterion does not guarantee the system reliability against possible cascading failures. In this study, given a hardening plan, we develop two distributionally robust models to evaluate the reliability of transmission system under N-k security criterion.

4 - Distributionally Robust Distribution Network Configuration under Random Contingency

Chaoyue Zhao, Oklahoma State University, Stillwater, OK, 74075, United States

Topology design is a critical task for the reliability, economic operation, and resilience of distribution systems. This work proposes a distributionally robust optimization (DRO) model for designing the topology of a new distribution system facing random contingencies. The proposed DRO model optimally configures the network topology and integrates distributed generation to effectively meet the loads. As compared with a classical robust optimization model, the DRO model explicitly considers the contingency uncertainty and so provides a less conservative configuration, yielding a better out-of-sample performance.

Round Table - Discussion

Sponsored: Railway Applications

Sponsored Session

Chair: Jeremiah Dirnberger, GE Transportation, Jacksonville, FL, 32217, United States

Moderator

Jeremiah Dirnberger, Wabtec Corporation, 7572 Old Kings Road South, Jacksonville, FL, 32217, United States, jeremiah.dirnberger@wabtec.com

Positive Train Control (PTC) is one of the largest infrastructure projects ever undertaken by a single industry. Mandated by the U.S. government, PTC aims to further reduce the risk of accidents on the nation's rail network. The amount of data collected for the operation of this system is unprecedented and the industry is looking to leverage it to create the backbone of a digital railroad. In these panels, experts from several leading will discuss the potentials within this new data, how it is already being used, the opportunity for data scientists and operations researchers, and its role in the path toward automation in the rail industry.

Panelist

- Larry Chalmers
- Marty Schlenker, BNSF Railway, Fort Worth, TX, United States
- Patricia Randall, Princeton Consultants, Greenville, SC, 29605, United States
- Steven Harrod, Technical University of Denmark, Lyngby, 2800, Denmark

Primal-Dual First-Order Methods

Sponsored: Optimization/Nonlinear Programming

Sponsored Session

Chair: Renbo Zhao, ORC, MIT, Cambridge, MA, 02142, United States

1 - On the Convergence of Primal-dual First-order Methods for Min-max Non-convex Optimization

Songtao Lu, AI Resident, IBM Research, Yorktown Heights, NY, 55414, United States, lus@umn.edu

In this work, we consider a general block-wise one-sided non-convex min-max problem, in which the minimization problem consists of multiple blocks and is non-convex, while the maximization problem is (strongly) concave. We propose a class of simple algorithms named hybrid block successive approximation (HiBSA), which alternatingly performs gradient descent-type steps for the minimization blocks and one gradient ascent-type step for the maximization problem. For the first time, we show that such simple alternating min-max algorithms converge to first-order stationary solutions, with quantifiable global rates.

2 - Radial Duality

Benjamin Grimmer, Cornell University, Ithaca, NY, 14850, United States, bdg79@cornell.edu

Recently Renegar introduced a radial transformation which turns generic convex optimization problems into unconstrained, uniformly Lipschitz continuous ones. We generalize this transformation to avoid any reliance on convexity and thus apply to a variety of nonconvex functions. Our alternative construction shows this transformation is dual (i.e., self-inverse), which gives structural insights relating primal and radially dual problems. We characterize when the radially dual problem is uniformly Lipschitz or smoothness. Hence, this radial duality provides a strong foundation analyzing radial variations of the subgradient and accelerated methods for both convex and nonconvex problems.

3 - A Unifying Framework for Variance Reduction Algorithms for Finding Zeroes of Monotone Operators

Xun Zhang, PhD Candidate, National University of Singapore, Singapore, e0225088@u.nus.edu, Zhi-Sheng Ye, William Haskell

A wide range of optimization problems can be recast as monotone inclusion problems. We propose a unifying framework for solving the monotone inclusion problem with randomized Forward-Backward algorithms. Our framework covers many existing deterministic and stochastic algorithms. Under various conditions, we can establish both sublinear and linear convergence rates in expectation for the algorithms covered by this framework. In addition, we consider algorithm design as well as asynchronous randomized Forward algorithms. Numerical experiments demonstrate the worth of the new algorithms that emerge from our framework.

4 - Optimal Stochastic Algorithms for Convex-Concave Saddle-Point Problems

Renbo Zhao, MIT, Cambridge, MA

We develop stochastic first-order primal-dual algorithms to solve a class of convex-concave saddle-point problems. When the saddle function is strongly convex in the primal variable, we develop the first stochastic restart scheme for this problem. When the gradient noises obey sub-Gaussian distributions, the oracle complexity of our restart scheme is strictly better than any of the existing methods, even in the deterministic case. Furthermore, for each problem parameter of interest, whenever the lower bound exists, the oracle complexity of our restart scheme is either optimal or nearly optimal (up to a log factor). The subroutine used in this scheme is itself a new stochastic algorithm developed for the problem where the saddle function is non-strongly convex in the primal variable. This new algorithm, which is based on the primal-dual hybrid gradient framework, achieves the state-of-the-art oracle complexity and may be of independent interest.

Linear Optimization

Contributed Session

Chair: Richard Forrester, Dickinson College, Department of Mathematics, College and Louther Street, Carlisle, PA, 17013, United States

1 - Equitable Partitions and Linear Programming

Ethan Jedidiah Deakins, University of Tennessee, Knoxville, TN, United States, edeakins@vols.utk.edu

Exploiting the symmetric structure of certain linear programming instances can offer insights into a new method for solving such instances. By means of equitable partitions, we can construct an algorithm that is a combination of both interior point and active set methods. This algorithm attempts to reduce the computational cost of crossover.

2 - On Two Dimensional Search Directions for Linear Programming

Fabio Vitor, Assistant Professor, University of Nebraska at Omaha, Omaha, NE, United States, ftorresvitor@unomaha.edu

This talk will present strategies to derive two search directions for linear programming two dimensional search algorithms. Either within the context of a simplex framework or an interior point framework, two dimensional search algorithms move between solutions by solving a two dimensional subproblem at each iteration. This subproblem is defined by the intersection of the two search directions and the feasible region of the linear program. The talk will present a comparison of the computational benefits such as a reduction in the number of iterations and solution time when different strategies are implemented to enlarge the feasible region of the two dimensional subproblem.

3 - A Strongly Polynomial-time Algorithm for Linear Programming

Hsin-Der Chen, Associate Professor, Providence University, Shalu Taichung, Taiwan

In this paper, we propose an optimization mechanism for linear programming problems. We show that linear programming problems with n variables and m general constraints in canonical form can be solved in O(m) pivoting iterations. Further specified, in the proposed algorithm we keep both an interior primal feasible point and a dual corner point in each iteration, and it runs at most 2m dual simplex steps. Therefore, the complexity of the total running time is in O(mn(m+n)).

4 - Highs: A High-performance Linear Optimizer

Julian Hall, University of Edinburgh, Edinburgh, United Kingdom, jajhall@ed.ac.uk

This talk will present HiGHS, a growing open-source repository of high-performance software for linear optimization based on award-winning computational techniques for the dual simplex method. The talk will give an insight into the work which has led to the creation of HiGHS and then set out the features which allows it to be used in a wide range of applications. Plans to extend the class of problems which can be solved using HiGHS will be set out.

5 - On the Balanced Minimum Evolution Polytope

Daniele Catanzaro, Professor of Operations Research, Université Catholique de Louvain, Louvain-la-Neuve, Belgium, Raffaele Pesenti, Laurence A. Wolsey

Recent advances on the polyhedral combinatorics of the Balanced Minimum Evolution Problem (BMEP) enabled the characterization of a number of facets of its convex hull (also referred to as the BMEP polytope) as well as the discovery of connections between this polytope and the permutoassociahedron. We extend here these studies, by presenting new results concerning some fundamental characteristics of the BMEP polytope, new facets defining inequalities in the case of six or more taxa, a number of valid inequalities, and a polynomial time oracle to recognize its vertices.

6 - Improving a Linear Formulation of the 0-1 Cubic Knapsack Problem via Variable Reordering

Richard Forrester, Professor of Mathematics, Dickinson College, Carlisle, PA, United States, forrestr@dickinson.edu, Lucas Waddell

The 0-1 cubic knapsack problem can be written in linear form using a repeated application of Glover's method for 0-1 quadratic programs. We present a simply preprocessing step to improve the strength of the linear programming relaxation based upon a variable reordering strategy. Extensive computational tests demonstrate the effectiveness of this technique.

Cluster Detection in Networks

Sponsored: Optimization/Network Optimization

Sponsored Session

Chair: Mohammad Hosseinian

1 - Detecting K-plexes in Sparse Graphs

Mohammad Javad Naderi, Oklahoma State University, Industrial Engineering & Manag, stillwater, OK, 74078, United States, Austin Buchanan

Finding cohesive subgroups in real-life networks (e.g., social networks) is an important task. Cohesive subgroups are often modeled as a clique, which requires a node to neighbor all other nodes in the cluster. A k-plex is a more realistic alternative that allows for a small number of nonneighbors. Existing integer programming (IP) formulations for k-plexes have a dense constraint matrix even when the input graph is sparse, making them difficult to apply directly. We craft new, equally strong IP formulations for the k-plex detection problem that use significantly fewer nonzeros, allowing them to directly handle large, sparse graphs. Experiments on real-life instances show their effectiveness.

2 - Parallel Russian Doll Search: Applications to Hereditary Structures

Mykyta Makovenko, Texas A&M University, College Station, TX, United States, Eugene Lykhovyd, Sergiy Butenko

In this work, we revisit the implementation of a general-purpose combinatorial algorithm for the maximum (weight) hereditary subgraph problem, called Russian Doll Search. The parallel shared-memory and distributed-memory versions are developed. We provide an extensive computational study for s-defective clique, s-plex, forest, chordal graph, independent union of cliques, and biclique, as the subgraphs of interest, which reveals the merit of the proposed method. For the last two structures, we present new verifiers that run in linear and constant time, respectively.

3 - Evolutionary Algorithms for the Maximum Edge Weight Clique Problem

Dalila B. M. M Fontes, INESC TEC, Universidade do Porto, INESC TEC, Rua Dr Roberto Frias, Porto, 4200-465, Portugal, dfontes@inesctec.pt, Jose Goncalves, Fernando A. C. C. Fontes

This work addresses the maximum edge weight clique problem (MEWC), an important generalization of the well-known maximum clique problem, which can be used to model applications in many. We propose a random key genetic algorithm capable of finding good quality solutions. Computational experiments on a set of benchmark problem instances show our algorithm to be both effective and efficient, as for most of the problem instances tested we were able to match the best known solutions with very small computational time requirements.

4 - Polyhedral Properties of the Induced Cluster Subgraphs

Seyedmohammadhossein Hosseinian, Texas A&M University, TX, 77843-3131, United States, hosseinian@tamu.edu, Sergiy Butenko

Given an undirected graph G, a subset of vertices inducing a cluster graph is called an Independent Union of Cliques (IUC). We study the facial structure of the IUC polytope associated with G, spot its similarities with the vertex packing and clique polytopes, and present a complete description of this polytope for certain classes of graphs. We establish computational complexity of the separation problems for the identified valid inequalities, and explore the effectiveness of employing the corresponding cutting planes in an integer (linear) programming framework for the Maximum IUC problem, which finds applications in unsupervised data analysis, through computational experiments.

Bayesian Optimization

Sponsored: Computing

Sponsored Session

Chair: Peter Frazier, Cornell University, Ithaca, NY, 14853, United States

1 - Bayesian Optimization of Combinatorial Structures

Matthias Poloczek, Uber AI Labs & University of Arizona, San Francisco, CA, 85721, United States, Ricardo Baptista

The optimization of expensive-to-evaluate black-box functions over combinatorial structures is an ubiquitous task in machine learning, engineering and the natural sciences. The combinatorial explosion of the search space and costly evaluations pose challenges for current techniques and critically require new algorithmic ideas. In this talk we will propose Bayesian optimization of combinatorial structures (BOCS), that takes a novel approach to overcome these challenges. We will also discuss a comprehensive experimental evaluation that demonstrate that BOCS consistently outperforms other methods from combinatorial and Bayesian optimization.

2 - Bayesian Optimization of Composite Functions

Raul Astudillo, Cornell University, Ithaca, NY, United States, Peter Frazier

We consider optimization of objective functions of the form f(x)=g(h(x)), where h is a black-box expensive-to-evaluate vector-valued function, and g is a cheap-to-evaluate real-valued function. While these problems can be solved with standard Bayesian optimization, we propose a novel approach that exploits the structure of the objective function to substantially improve sampling efficiency. Our approach models h using a multi-output Gaussian process and uses as acquisition function the expected improvement under the implied non-Gaussian posterior on f. Numerical experiments show that this approach outperforms standard Bayesian optimization benchmarks by several orders of magnitude.

3 - Knowledge Gradient with Locally Quadratic Beliefs for Policy Search

Warren B. Powell, Princeton University, Dept of Operations Research and Financial Engr, Princeton, NJ, 08544, United States, powell@princeton.edu, Nana Aboagye

A common problem is optimizing smooth functions using noisy samples without derivatives. We assume the function is smooth (ideally unimodular) but without a known parametric structure. We propose a knowledge gradient policy that maximizes the value of information using a locally quadratic belief model. The resulting policy, KGLQ, has the desirable behavior of encouraging sampling away from the current estimated optimum, but not too far away, capturing the property that the best way to learn a linear model is with observations that are far from the optimum, but not too far, since this is where the modeling errors are highest.

1 - Improving Feature Selection in Data Mining with Simulation Optimization

Kimia Vahdat, North Carolina State University, Raleigh, NC, 27695-7906, United States, kvahdat@ncsu.edu, Sara Shashaani

In many data mining applications where the number of features is large, identifying the most informative features remains a challenge. We develop a Simulation Optimization framework to search for the best subset of features with genetic algorithms. We study the effect of fixed versus variable replication size in the outcome and compare the results with some of the existing feature selection methods on a number of datasets. Investigations on computation time and overall accuracy in our preliminary results reveal that SO based approaches can provide cost-effective improvements in the predictive power of such data mining models.

2 - PAC-Bayesian Approach to Proving Risk Bounds on Neural Nets

Anirbit Mukherjee, Johns Hopkins University, Baltimore, MD, United States, amukhe14@jhu.edu, Pushpendre Rastogi, Daniel Roy, Jun Yang

Explaining deep-learning is emerging to be a fundamental mathematical challenge of our times. The core technical question is to be able to explain as to why deep learning algorithms manage to minimize the risk function while at the same time also fitting the training data arbitrarily accurately. In recent times there have been found increasing amounts of evidences that PAC-Bayesian approaches can help understand this. In this talk we will explain our new PAC-Bayesian risk bounds on nets and give experimental evidence on standard test cases for it being the state-of-the-art. (If time permits we will also present some glimpses of our recent theorems about neural net training algorithms.)

3 - Semidefinite Optimization with Hyperspherical Constraints for Metric Learning Between Sets

Abhinav Maurya, Carnegie Mellon University, Pittsburgh, PA, United States, ahmaurya@cmu.edu

We present an approach for learning a distance metric between sets based on semidefinite optimization with hyperspherical constraints. We find that this approach leads to a very efficient learning procedure called the conditional mixing method. We demonstrate its superiority compared to the dominant approach of (minibatch) gradient descent commonly used in optimization-based machine learning.

4 - Post-Separation Classifier Feature Reduction

John W. Chinneck, Carleton University, Systems and Computer Engineering, Ottawa, ON, K1S 5B6, Canada, chinneck@sce.carleton.ca

Feature reduction seeks the smallest set of features that allows acceptable separation of the data. A new approach: (i) find a separating hyperplane by any method, using all features, then (ii) find a new hyperplane giving the same separation using fewer features. The correctly classified points from the first step are used to construct a feasible LP by transforming each retained point into a linear inequality in variables representing the feature weights. A new heuristic for finding sparse solutions to LPs is then applied. The heuristic is derived from methods for solving the maximum feasible subsystem problem (maxFS).

First-order Methods for Saddle Point Problems

Sponsored: Optimization/Nonlinear Programming

Sponsored Session

Chair: Necdet Serhat Aybat, University Park, PA, 16802, United States

1 - Oracle Complexity of a Trust Region Method for Non-Convex Min-Max Problem

Hassan Rafique, University of Iowa, Iowa City, IA, United States, Qihang Lin

We consider minimizing the maximum of finitely many non-convex, twice continuously differentiable functions. This type of min-max problems has applications in portfolio optimization and robust machine learning. We propose a trust region method based on a QCQP oracle and analyze the number of calls to that oracle for the trust region method to find a second-order stationary point of the min-max problem.

2 - Lower Complexity Bounds of First-order Methods for Bilinear Saddle-point Problems

Yangyang Xu, Assistant Professor, Rensselaer Polytechnic Institute, Department of Mathematical Sciences, Troy, NY, 12118, United States, xuy21@rpi.edu, Yuyuan Ouyang

On a convex-concave bilinear saddle-point problem (SPP), many works have studied the complexity results of first-order methods (FOMs). They are all about upper complexity bounds, which can determine how many efforts to guarantee a solution of desired accuracy. In this talk, I will show lower complexity bounds of FOMs on large-scale SPPs. For convex-concave SPP, the lower bound is $O(1/\epsilon)$ to obtain an ϵ-solution, and when the primal objective is strongly convex and the dual objective is concave, it would be $O(1/\sqrt{\epsilon})$. Both results match with existing upper complexity bounds. Hence, the established bounds are tight and indicate the optimality of existing FOMs.

3 - A Primal-Dual Parallel Method with 1/T Convergence for Constrained Composite Convex Programs

Michael Neely, University of Southern California, CA, United States

Please check the mobile app for this abstract.

4 - Iteration Complexity of Randomized Primal-dual Methods for Stochastic Convex-concave Saddle Point Problems

Erfan Yazdandoost Hamedani, Pennsylvania State University, University Park, PA, 16801, United States, evy5047@psu.edu, Afrooz Jalilzadeh, Necdet Serhat Aybat, Uday Shanbhag

In this paper, we propose a class of randomized primal-dual methods to contend with stochastic saddle point problem of minimizing over a large-scale primal variable and maximizing over a dual variable of a convex-concave function. We analyze the convergence rate of the proposed method under the settings of mere convexity and strong convexity in primal variable. In particular, under some Lipschitz assumptions of gradients, the ergodic sequence generated by the algorithm achieves the O(1/k) convergence rate in a suitable error metric.

Furthermore, assuming a uniformly strong convexity of primal variable, and linearity in dual variable, the scheme displays convergence rate of O(1/k2).

Sponsored Session

Chair: Venktesh Pandey, University of Texas-Austin, Austin, TX, 78712, United States

1 - A Holistic Approach to understand Traveler Route Choice Behavior and Satisfaction under Real-time Travel Information Provision

Dong Yoon Song, Purdue University, West Lafayette, IN, United States, song50@purdue.edu, Srinivas Peeta

This study proposes a comprehensive framework to understand the key factors influencing traveler's route choice behavior and satisfaction with travel experience under real-time travel information provision. It analyzes the roles of travel time savings and psychological gains. A structural equation model is estimated to capture latent variables for human factors in information perception and multiple psychological dimensions of information provision. Data for traveler behavior and information perception are collected through interactive driving simulator experiments and the associated surveys.

2 - Risk Evaluation for Route Guidance under Recurrent and Randomized Sensing Attacks

Li Jin, New York University, Brooklyn, NY, United States, Qian Xie

This research studies the security risk of real-time route guidance. We consider a dynamic flow network with feedback routing. We formulate a sequential game between attackers and a defender, where attackers recurrently compromise sensors and/or inject malicious data at random times and random locations, and the defender allocates security resources. We will characterize the equilibrium strategies of the attackers and the defender and estimate the security risk under various attacking and defending capabilities.

3 - Adaptive Park-and-Ride Choice on Time-Dependent Stochastic Multimodal Transportation Network

Pramesh Kumar, University of Minnesota, Minneapolis, MN, 55414, United States, Alireza Khani

This research proposes a model describing the adaptive behavior of commuters who opt for park-and-ride when going from low-density areas to a high-density area depending upon the realized state of the traffic. The problem is formulated as a stochastic shortest path problem. The objective is to find a path which minimizes the expected cost between an origin and destination.

4 - Sensitivity Analysis for User Equilibrium Models with Recourse

Venktesh Pandey, University of Texas-Austin, Austin, TX, 78712, United States, Tarun Rambha, Stephen Boyles

Static user equilibrium with recourse (UER) models are used for predicting the long-term traffic behavior on networks with supply-side uncertainty where a traveler may change their route in real-time based on the information received at a node. In this research, we conduct a sensitivity analysis of UER models where we calculate the derivatives of expected travel time between two nodes, with respect to the demand between them, assuming that the flow distributes in a way that the equilibrium is maintained. This sensitivity analysis is then used for network contraction of acyclic managed lane networks with toll and travel time uncertainty.

TSL Air/AAS: Drones in Logistics

Sponsored: Transportation Science & Logistics/Air

Sponsored Session

Chair: Haitao Li, Univ. of Missouri-St Louis, St Louis, MO, 63121-4400, United States

1 - Economic and Environmental Impacts of Drone Delivery

Juan Zhang, University of Missour-St. Louis, St. Louis, MO, United States, jzmq3@mail.umsl.edu, James F. Campbell, Donald Sweeney

Using drones for last-mile/home delivery may reduce costs and lower emissions. In this presentation, we focus on assessing the cost and emissions tradeoffs in drone delivery from a strategic perspective. We develop and optimize continuous approximation models for expected costs and greenhouse gas (GHG) emissions. We compare the costs and GHG emissions of drone-only, hybrid truck-drone and truck-only systems under various operational conditions. We show how the cost-efficiency and environmental-friendliness of drone delivery depends on the relative operational parameters and the carbon intensity of fuels.

2 - Drone Delivery in Global Healthcare: Optimizing the Vaccine Supply Chain

Deng Pan, University of Missouri - St. Louis, St. Louis, MO, United States, dpkq8@mail.umsl.edu, Haitao Li, James F. Campbell, Donald C. Sweeney

We present two models for optimizing a hierarchical vaccine delivery network for children in less developed regions, with application to the Republic of Vanuatu. The first model, for nation-wide distribution, optimizes the use of long-range drones in a multi-modal distribution system serving 60 islands. The second model optimizes local vaccine deliveries within a single health zone (often several neighboring islands) using shorter range drones, with synchronization of drone deliveries and healthcare worker routes. Both problems require maintaining the vaccine cold chain. Preliminary results show that drones can offer important savings and improve vaccine availability.

3 - A Framework to Transform Truck-and-Drone Coordination Problems into Traveling Salesman Problems

Stefan Poikonen, University of Colorado Denver, Denver, CO, 80202, United States, Adriano Masone, Bruce L. Golden

We show that a broad range of truck-and-drone coordination problems may first be recast as an equality generalized TSP (E-GTSP) and subsequently as an asymmetric traveling salesman problem (ATSP), where the number of nodes in the ATSP is equal to the number of non-dominated operations. We then leverage the capabilities of exact or heuristic TSP solvers to solve the ATSP. Whenever we solve the ATSP exactly, we can extract an optimal solution to the original truck-and-drone coordination problem. We also extend this transformation framework to multi-truck variants. Computational experiments will be presented.

4 - Mission Planning for UAVs

Liu Yang, Assistant Professor of Supply Chain Management, Purdue University, New Albany, IN, 47150, United States, lyang@purdue.edu, Haitao Li

We consider a group of heterogeneous UAVs to be assigned and scheduled to accomplish multiple military missions. UAVs have varying capacities and must take off from and return to the same launch and recovery stations (LRS), and be controlled by ground control stations (GCS) during flight. Missions have different weapon load requirements with specific time windows and generalized precedence relationships with minimum time lags. Missions accomplished by different UAVs lead to different rewards. A mixed-integer programming (MIP) approached is developed to maximize the total rewards.

Healthcare Payment and Incentives

Sponsored: Manufacturing & Service Oper. Mgmt/Healthcare Operations

Sponsored Session

Chair: Elodie Adida, University of California-Riverside, Riverside, CA, 92521, United States

1 - Too Much? Too Little? Economic Modeling of Physician Testing Decisions

Tinglong Dai, Johns Hopkins University, Baltimore, MD, 21202, United States, dai@jhu.edu

Few issues in the healthcare ecosystem are more salient than the utilization of medical tests. By some estimates, up to 30% of medical-testing decisions are deemed inappropriate, which may entail either over- or under-testing. All too frequently, the public attention has centered on over-testing. By comparison, under-testing has received little media coverage, but frequently appears in the medical literature. In addition, contrary to popular belief, the US trails most OECD countries in terms of the utilization of medical tests.In this talk, I discuss several recent modeling efforts aimed at understanding physician decision-making leading to over- and under-testing.

2 - Yardstick Competition, Credence Goods, and the Design of Diagnosis Related Groups

Nicos Savva, London Business School, Regent's Park, London, NW1 4SA, United Kingdom, Laurens Debo, Robert Shumsky, Nicos Savva

Hospitals throughout the developed world are reimbursed on the basis of diagnosis related groups (DRGs), a patient classification system first developed at the Operations Research department of Yale University. Under this scheme, the hospital receives a fixed fee per patient episode that is set based on yardstick competition (the fee is set to the average cost of providing care to similar patients in other hospitals). In this paper, we show that this payment system may give rise to incentives to "cherry pick" and/or "upcode" patients, and examine potential solutions to this problem involving yardstick competition based on output statistics.

3 - Outcomes-based Reimbursement Policies for Chronic Care Pathways

Sasa Zorc, Assistant Professor, University of Virginia, Darden School of Business, Charlottesville, VA, 22903, United States, Stephen E. Chick, Sameer Hasija

We develop an outcomes-based model of contracting in care for chronic patients, using data from United Kingdom's NHS. The government contracts with healthcare providers in effort to maximise population health minus the cost. We consider the decision of whether to contract with individual healthcare providers or groups of such providers, as well as which contract type to use. Individual contracts fail to provide the desired incentives if providers under such contracts cooperate (collusion), however so do group contracts if group members fail to coordinate (free-riding). We demonstrate that individual outcomes-adjusted capitation contracts are the most resistant to these adverse effects.

4 - Outcome-based Pricing for New Pharmaceuticals via Rebates

Elodie Adida, University of California - Riverside, School of Business Administration, Riverside, CA, 92521, United States, elodie.goodman@ucr.edu

We study the effect of outcome-based pricing for new pharmaceuticals via rebates. Under this payment scheme, the pharmaceutical firm is paid only when the drug treatment achieves a pre-specified goal. We consider heterogenous, price-sensitive, risk-averse patients, a payer, and a pharmaceutical firm producing a drug with uncertain effectiveness. We find that outcome-based pricing is unlikely to solve the issues of high drug prices and high payer expenditures. However, supplementing outcome-based pricing with a transfer payment between firm and payer can make patients, payer and firm better off than under uniform pricing.

CC- Room 618

Joint Session TSL/Urb/Practice Curated: Renewable-energy Driven Mobility: Infrastructure Design and Management Strategies

Sponsored: Transportation Science & Logistics/Urban Transportation

Sponsored Session

Chair: Leila Hajibabai, North Carolina State University, Raleigh, NC, United States

1 - Static and Dynamic Approaches to Modeling Electric Vehicle Use and Charging Behavior

Yanbo Ge, National Renewable Energy Laboratory, Golden, CO, United States, Don MacKenzie

We compare two approaches to modeling drivers' decisions about whether to use their battery electric vehicle (BEV) or an alternative vehicle for a long-distance trip, and when and where to charge their BEV: a traditional static discrete choice model that treats all decisions as independent; and a dynamic discrete choice model that is more behaviorally realistic, but also more computationally intensive.

2 - Self-rebalancing Electrical Vehicle Sharing Management

Wang Xin, University of Wisconsin-Madison, Madison, WI, United States, Yuguang Wu

We investigate a dynamic fleet management problem (DFLP) for an electric vehicle (EV) sharing system who faces time varying random demand and electricity price. Demand in each time period reacts to the announced price. To maximize the revenue, the EV fleet optimizes operations, charging decisions as well as the pricing decisions. We use a value function approximation with convex neural networks to generate near-optimal solutions. Base on the structure of DFLP, we propose multiple improvements in the design and the training of NN. We compare it with standard ADP methods and develop insights regarding the interaction between the EV fleet and the power grid.

3 - Infrastructure Design and Dynamic Pricing of Electric Vehicle Charging Facilities with User-equilibrium Behavior

Leila Hajibabai, North Carolina State University, Department of Civil Engineering, Raleigh, NC, 11794, United States, lhajiba@ncsu.edu, Amir Mirheli

This research develops a bi-level mathematical program with EV charging facility design and demand-driven pricing scheme in the upper level and user decisions considering electricity pricing and travel time in the lower level. The model is converted into an equivalent single-level formulation using Karush-Kuhn-Tucker conditions. A hybrid technique is developed that (i) determines strategic decisions on EV charging facility design using an iterative active-set based method, (ii) establishes a relationship between occupancy and capacity of each facility using a stochastic queuing theory, and (iii) estimates arc travel times using a macroscopic fundamental diagram concept.

4 - Viability of Electric Taxis: Impact on Charging Infrastructure and Competition with Non-electric Taxis in New York City

Jae Young Jung, Ford Motor Company, Dearborn, MI, 48120, United States, jjung22@ford.com, Joseph Y. J. Chow

Electrification of taxi fleets would be a major investment to reduce CO2 emission for cities and regions. However, due to the limited driving range of electric vehicles, there is a need to better understand the fleet operation efficiency and the impact on charging infrastructure. This study conducts simulation experiments to evaluate electric vehicle taxi operation and investigate impacts on charging infrastructure in New York City. The result reveals potential revenue competition between electric and non-electric vehicles and addresses resources allocation trade-offs in subsidizing electric vehicle taxis and investing in electric charging infrastructure.

Spatial Analysis in Transportation and Logistics

Sponsored: Transportation Science & Logistics/Facility Logistics

Sponsored Session

Chair: EunSu Lee, New Jersey City University, Jersey City, NJ, 07311, United States

1 - Spatial Modeling for Backup Service Coverage of Rural Emergency Medical Service

EunSu Lee, Associate Professor, New Jersey City University, Jersey City, NJ, 07311, United States, elee3@njcu.edu, Melanie McDonald

This study visualizes the statewide service coverage of Emergency Medical Service (EMS) in rural areas and discusses the backup coverage using multiple service levels and various response time in study areas.

2 - Location Prediction Using Recurrent Neural Network

Ali Rahim-Taleqani, Doctoral Student, North Dakota State University, Fargo, ND, 58305, United States

Spatial and temporal contextual information plays a vital role in analyzing shared mobility user behaviors and helps predict the next visiting locations. Given the increasing volume of data from dockless scooter/bike programs, the more spatiotemporal information is collected in systems, the harder the location prediction problem becomes. Recurrent Neural Networks (RNN) model shows promising performance. Hence we proposed a novel RNN model considering the spatial and temporal scooter/bike data. Experimental results show that the proposed model yields significant improvements over similar methods.

3 - Spatio-temporal Analyzes of Traffic Accidents Using ArcGIS

Poyraz Kayabas, Purdue University, Fort Wayne, IN, 06517, United States

In this study a spatio-temporal model is developed to understand how location and time characteristics influence the likelihood of motor vehicle crashes. Creating a space-time cube, finding temporal trends, and the limitations of the study will be discussed.

4 - Spatial Analysis in the Decision Making of CEP Crowd-sourced Last-mile Delivery

Mingwei Guo, Doctoral Student, North Dakota State University, Fargo, ND, United States, mingwei.guo@ndsu.edu

With the recent soaring of the sales from E-commerce and other last-mile delivert needs, increased number of packages have put pressure on traditional delivery modes. Crowd-Sourced Last-Mile Delivery can be served as an efficient role in the development of Carrier, Express and Parcel (CEP) services. Utilizing citizen workers as part of the scenario, crowd-sourced delivery would bring potential impacts to the location selection of warehouses and package hubs. This research will utilize spatial analysis tools to look into cases of CEP last-mile needs and provide reference for further study.

CC- Room 620

Joint Session AAS/TSL Air: Air Traffic Management Initiatives

Sponsored: Aviation Applications

Sponsored Session

Chair: Alexander Stewart Estes, University of Minnesota, Minneapolis, MN, 55414, United States

1 - Slot Allocation: Algorithms and Implementation at Guarulhos Airport

Nuno Antunes Ribeiro, Singapore University of Technology and Design, Portugal, Singapore, Singapore, nuno_r_@hotmail.com, Diana Jorge, Alexandre Jacquillat, António Pais Antunes, Amedeo R. Odoni

Airport slot allocation involves finding flight schedules that minimize displacement from airline requests, while complying with the Worldwide Slot Guidelines. This talk outlines three recent advances. First, we develop an algorithm based on large-scale neighborhood search to optimize slot allocation at the busiest airports. Second, we perform extensive comparisons with existing practices based on real-world data. Third, we report results from an implementation in support of coordination practices in real time at Guarulhos in Sao Paulo— the busiest airport in Latin America.

2 - Airline-Driven Ground Delay Programs

Chiwei Yan, Uber Technologies, San Francisco, CA, 94103, United States and University of Washington, Seattle, WA, United States, Prem Swaroop, Michael O. Ball, Cynthia Barnhart, Vikrant Vaze

We propose an airline-driven decentralized approach for designing ground delay programs (GDPs). The motivation for an airline-driven approach is the ability to incorporate the inherent differences between airlines when prioritizing, and responding to, different GDP designs. We design a mechanism based on a voting theory called Majority Judgment and assess its benefits over centralized approaches.

3 - Relative Trajectory Cost Prediction for Applications in Collaborative Trajectory Options Program

Ivan Tereshchenko, University of California-Berkeley, Berkeley, CA, 94709, United States, terivan2006@berkeley.edu

Increasing air traffic volume makes en route Traffic Management Initiatives (TMIs) more important than ever before. The effective execution of en route TMIs depends on accurate predictions of airspace demand. Precise forecasts of airspace demand require causal models of route choice. Previous research shows that obtaining such models is difficult, due to the complex nature of the airspace system. In this paper, we propose two methods for demand prediction in the context of Collaborative Trajectory Options Program (CTOP). The testing was done using simulated CTOP data. We show that CTOP offers data structures that allow us to achieve higher quality airspace demand predictions.

4 - Alternative Resource Allocation Mechanisms for the Collaborative Trajectory Options Program (CTOP)

Alexander Stewart Estes, University of Minnesota, Minneapolis, MN, 55414, United States, este0100@umn.edu, Michael O. Ball

We identify two weaknesses in the design of the collaborative trajectory options program (CTOP) traffic management initiative. First, CTOP may issue excessive quantities of delay even when the parameters of the program are chosen correctly. Second, CTOP's current design can discourage airlines from accurately disclosing trajectory options. We propose new mechanisms that address these design flaws. We also provide computational results that demonstrate that our proposed mechanisms would reduce delay costs and encourage greater participation in CTOP.

Interaction of Social Media with Revenue Management & Pricing

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Pelin Pekgun, University of South Carolina, Columbia, SC, 29205, United States

Chair: Sanghoon Cho, Columbia, SC, 29206, United States

1 - Discrete-choice Model for The Hotel Room Demand by Heterogeneous Guests

Sanghoon Cho, University of South Carolina, Columbia, SC, 29206, United States, Sanghoon.Cho@grad.moore.sc.edu, Andrew Vakhutinsky, Pelin Pekgun, Mark Ferguson

We develop a new approach to model the demand for the hotel rooms based on the individual booking attributes of each hotel guest as a combination of multiple multinomial logit models, which involves soft clustering of the guests followed by building a discrete choice model for each cluster. The demand model parameters are estimated using the EM algorithm. We demonstrate our model performance on the booking data from a medium-size hotel chain and show how varying the price for each room category affects the total revenue.

2 - How Important is Design for the Automotive Value Chain?

Hallie Cho, INSEAD, Singapore, 138676, Singapore, Manuel Sosa, Sameer Hasija

By using online customer ratings, this paper disentangles the role of different dimensions of perceived product quality in influencing consumer choice in the context of the U.S. automobile industry. We use a structural estimation model with endogenous prices and heterogeneous customer preferences to show that design is the most salient factor of perceived product quality in determining an automobile's market share. Our results have important implications for an automobile manufacturer's internal resource allocation strategy. We also highlight the changing role of on-line product review forums in the automobile industry's value chain.

3 - The Effects of Social Learning on Product Assortment and Pricing Strategy

Sanghoon Cho, University of South Carolina, Columbia, SC, 29206, United States, Pelin Pekgun, Michael Galbreth

To alleviate the uncertainty of new experience products, consumers in later purchase periods can combine user review into their decision process. Such social learning not only allows customers to gradually learn about the quality of the new experience products but also enables firms to dynamically change their optimal policy. We consider a monopolist that sells two vertically quality differentiated products over two periods to consumers who are Bayesian social learners. In the presence of two types of user reviews for both products, consumers decide on which products to purchase to maximize their utility.

4 - E-word of Mouth (WoM) on Action: Analysis of Operational Decisions in Online Retail

Bahar Cavdar, Middle East Technical University, Universiteler Mah, Dumlupinar Bulv, Ankara, 06800, Turkey, bcavdar@metu.edu.tr, Nesim K. Erkip

In this study, we consider an online shopping system with both premium and regular customers. We model customer preferences based on the perceived service quality indicated by WoM and integrate this into the retailer's operational problem to determine a shipment policy. We show that (i) beating the competition in market may not always benefit the company as it can result in undesired customer switching behavior, (ii) relaxations in operational constraints may hurt profitability due to the associated difficulties of perception management, and (iii) seeking a stationary policy can lead to suboptimal solutions, therefore cyclic policies should also be considered when appropriate.

Networks, Mechanism Design, and New Markets — II

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Ozan Candogan, University of Chicago, Chicago, IL, 27708, United States

1 - Homophily is (Not) Bad for Learning

Mohamed Mostagir, University of Michigan, Ann Arbor, MI, 48109, United States, James Siderius

The common view in the social learning literature is that homophily is not conducive to learning. We investigate this claim using a random network formation model. Agents in a population try to learn a state of the world (like for example, whether a product if of high or low quality) and a firm tries to manipulate the learning process towards a particular outcome. We show that the presence of homophily —generally a negative force when it comes to social learning— can sometimes shield a population from being manipulated, making agents overcome the attempts of distortion by the principal and instead leading them to learning the true state of the world.

2 - Shapley Meets Uniform: An Axiomatic Framework for Attribution in Online Advertising

Raghav Singal, Columbia University, New York, NY, United States, rs3566@columbia.edu, Omar Besbes, Antoine Desir, Vineet Goyal, Garud N. Iyengar

A central challenge in online advertising is attribution, namely, assessing the contribution of individual ads to product purchase. We develop an axiomatic framework for attribution in online advertising. Under a Markovian model for user behavior, we illustrate limitations of existing heuristics and propose a novel framework motivated by causality and game theory. Furthermore, we establish that our framework coincides with an adjusted ``unique-uniform" attribution scheme. This scheme is efficiently implementable and can be interpreted as a correction to the commonly used uniform attribution scheme. We supplement our theory with numerical experiments inspired by a real-world dataset.

3 - Optimal Data Acquisition for Statistical Estimation

Juba Ziani, Caltech, Pasadena, CA, 91106, United States, jziani@seas.upenn.edu, Yiling Chen, Nicole Immorlica, Brendan Lucier, Vasilis Syrgkanis

We consider a data analyst's problem of purchasing data from strategic agents to compute an unbiased estimate of a statistic of interest. Agents incur private costs to reveal their data and the costs can be arbitrarily correlated with their data. We design an IR and IC mechanism that optimizes the worst-case mean-squared error of the estimation, where the worst-case is over the unknown correlation between costs and data, subject to a budget constraint. We characterize the optimal mechanism in closed-form. We further extend our results to regression analysis, when private costs can correlate with the values of the dependent variable but not with the values of the independent variables.

4 - LP-based Approximation for Personalized Reserve Prices

Mahsa Derakhshan, University of Maryland, College Park, MD, United States, mahsa@cs.umd.edu, Negin Golrezaei, Renato Paes Leme

We study the problem of computing personalized reserve prices in eager second price auctions without having any assumption on valuation distributions. Here, the input is a dataset that contains the submitted bids of n buyers in a set of auctions, and the goal is to return personalized reserve prices r that maximize the revenue earned on these auctions by running eager second price auctions with reserve r. We present a novel LP formulation to this problem and a rounding procedure which achieves a 0.684-approximation. This improves over the 0.5-approximation algorithm due to Roughgarden and Wang. We further bound the integrality gap of the LP, which bounds the performance of any algorithm based on this LP.

Recent Topics in Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Victor Araman, American University of Beirut, American University of Beirut, Beirut, 1107-2020, Lebanon

Co-Chair: Dragos Florin Ciocan, INSEAD, Fontainebleau, France

1 - Using Distributionally Robust Optimization to Sharpen Mixed Integer Programming Formulations for Trained Neural Networks

Will Ma, Columbia University, New York, NY, United States, Ross Michael Anderson, Joseph Huchette, Christian Tjandraatmadja, Juan Pablo Vielma

We consider the fundamental problem of given a trained Neural Network NN, finding the input vector x within some domain D which maximizes the output NN(x). We attack this problem using Mixed-Integer Programming, and develop strong formulations for high-dimensional piecewise linear functions which represent the non-linearities in the NN. The formulations are derived using the Marginal Distribution Model from Distributionally-Robust Optimization, and shown to be sharp/ideal in various setting. We discuss many general applications of this Neural Network maximization procedure, including DNA sequencing and high-dimensional pricing.

2 - Pricing of Access Services

Ozlem Yildiz, University of Virginia, Darden School of Business, Charlottesville, VA, United States, yildizo@darden.virginia.edu, Dana G. Popescu

In access services such as shared work spaces and parking lots, the consumers pay for the privilege of accessing the firm's facilities. The service capacity is often limited and the firms typically face a mix of consumers with different needs in terms of the time they need to use those facilities as well as different willingness to pay for service. In this paper, we study different pricing strategies for access service systems. We compare the performance of a price-per-service strategy scheme to that of a price-per-unit-time scheme and give insights into the factors that might influence a firm's adoption of one pricing strategy over the other.

3 - A Logarithmic Bound for the Multi-class Dynamic Knapsack Problem

Jiawei Zhang, New York University, New York, NY, 10012, United States, Jiashuo Jiang

We consider the dynamic knapsack problem over T discrete time periods with multiple class of items. In each time period, an item arrives according to a class-dependent probability with known class-dependent reward and the weight is drawn from a class-dependent distribution function. As soon as its weight is revealed, an online decision has to be made whether or not to accept the item. The objective is to maximize the total reward collected subject to the capacity constraint. We present that an algorithm that enjoys a log(T) regret bound, which generalizes a recent result by Arlotto and Xie.

4 - Dynamic Pricing and Demand Learning with Returns

Sahar Hemmati, University of Maryland, College Park, MD, United States, Wedad Jasmine Elmaghraby, Ozge Sahin

Due to customers' uncertainty about product fit prior to purchase, retailers have been dealing with huge amount of returned products. In spite of competitive pressure for offering free returns, online retailers have the possibility to explore the demand via tools such as promotional pricing. Also, online retailers possess more flexibility in offering a variety of return policies, while banning returns over final sales or framing the non-refundable portion of paid price as shipping fee. In this paper, we are considering a seller who has limited knowledge of demand for his product and conducts dynamic pricing to learn the demand and extract as much profit as possible, considering the returns.

Analytics in Humanitarian Operations Management

Sponsored: Public Sector OR

Sponsored Session

Chair: Gloria Urrea

1 - Scalability of Follower Bases on Social Media Platforms for Humanitarian Operations

Elliot Rabinovich, Arizona State University, W. P. Carey School of Business, Department of Supply Chain Management, Tempe, AZ, 85287, United States, elliot.rabinovich@asu.edu, Eunae Yoo, Bin Gu

Humanitarian organizations aim to increase their follower bases on social media platforms to share information efficiently. Our study studies the mechanisms that drive the growth of humanitarians' follower bases. Using Twitter data from one week before and after a recent earthquake, we find that the retweeting of humanitarians' content helps to increase the organizations' number of followers. We also formulate a structural model to evaluate why users choose to follow an organization on Twitter after they have read a retweet of content by the same organization. We find that users are motivated by faster and more complete access to humanitarian organizations' content, especially after a disaster.

2 - Coopetition in First Response Operations to Global Disasters: Case of UNHRD Network

Hasti Rahemi, University of Colorado Boulder, Boulder, CO, 80303, United States, hasti.rahemi@colorado.edu, David F. Drake

We propose a coopetition model between humanitarian organizations in preparing for sudden onset disasters. While many studies show the importance of cooperation in humanitarian relief response operations, they mostly overlook the competitive nature of these operations. We implement the model on the United Nations Humanitarian Response Depot (UNHRD) that tries to incentivize cooperation among humanitarian organizations in pre-positioning stockpiles of relief supplies.

3 - Analysis of Trade Credit for Life-saving Medical Devices in Emerging Markets

Olumurejiwa Fatunde, Massachusetts Institute of Technology, Cambridge, MA, 02140, United States, Jarrod D. Goentzel

In emerging markets, health facilities often lack capital and bank financing to purchase life-saving medical devices. Distributors can increase access to essential goods through trade credit but must manage payment uncertainty to survive. We develop working capital policies to maximize the survival probability for distributors that offer trade credit for life-saving medical devices.

4 - Volunteer Management in Charity Storehouses: Experience, Congestion and Operational Performance

Gloria Urrea, University of Colorado Boulder, Boulder, CO, 47408, United States, gloria.urrea@colorado.edu, Alfonso J. Pedraza-Martinez, Maria Besiou

Volunteers are the backbone of humanitarian operations. We investigate how volunteer experience and storehouse congestion affect the preparation of orders (food and hygiene items) at a charity storehouse. Our multi-method approach begins with a field study to collect primary data on volunteers' work. Next, we estimate the effects of volunteer experience and storehouse congestion on the order processing times empirically. Finally, we simulate operational decisions—volunteers' pairing in teams and whether to allow or impede storehouse congestion—and their effect on on-time order preparation rate and additional time to prepare the orders, in steady and disaster conditions.

Joint Session PSOR/DEI: Community-Based Operations Research II

Sponsored: Public Sector OR

Sponsored Session

Chair: Michael P Johnson, University of Massachusetts-Boston, Boston, MA, 02125-3393, United States

Co-Chair: Wilkistar A. Otieno, University of Wisconsin-Milwaukee, Industrial Engineering Department, Milwaukee, WI, 53201, United States

1 - Spontaneous Emergence of Community or via Social Media

Leroy White, University of Warwick, Warwick Business School, Scarman Road, Coventry, CV4 7AL, United Kingdom, Mike Yearworth

Recently we develop a new constitutive definition of Community OR as a self-initiating, self-organising Community actor network emerging spontaneously in response to an unsettling event. We also found evidence of non-codified OR behaviours that lead to action to improve the problem situation. Here, we examine further how social media afford new possibilities for community empowerment and participation, with consequences for civil society. We draw on data arising from the community response to a devastating flooding event - the UK Carlisle floods of December 2015, and on sentiment analysis We explore the question of the OR practitioner negotiating entry to offer support.

2 - Potential Applications of Community-based Operations Research for Climate Change in the United States.

Maria Manuella Pache de Athayde, University of Massachusetts Boston, Boston, MA, 02125-3393, United States, M.PachedeAthayde001@umb.edu

Community-based operations research (CBOR) is an analytical method that is well suited to explore the interests of underrepresented communities in local settings especially when communities have limited access to the policy process. CBOR also has the potential to allow communities to make better decisions using formalized processes through the formal and informal implementation of organizational programs. This paper provides a synthesis of CBOR applications for climate change in the U.S. and proposes an application of CBOR for community resilience in urban settings.

3 - CBOR for Urban Mobility: A Social Analytics Approach to Complex Planning Issues

Tristan Stull, MS, University of Massachusetts-Boston, Boston, MA, 02125-3393, United States

In the 21st century, urban mobility is a "wicked problem" in its complexity and elusiveness of solutions. Concerns about sustainability concatenate with short-term problems of congestion, accessibility, and equity. Traditional OR has fallen short by failing to apply social theory congruently in sufficient depth and holism to drive effective optimization. The principles of community-based operations research synthesized with data science and design will inform a new kind of analytics that is both data-driven and socially complete. A well-designed approach supports both planning and public participation. This paper suggests how a CBOR-inspired solution landscape will evolve for this domain.

4 - Effective and Equitable Technology in the Digital Era

Michal Tzur, Tel Aviv University, Tel Aviv, Israel, tzur@eng.tau.ac.il, Peter Glynn, Adi Sarid

Recently there is evidence that advanced technology such as sophisticated algorithms and infrastructure planning exhibit a "discrimination" nature that can have a negative social impact. In this research, we discuss some causes for this phenomenon and present examples for its existence. Then, we suggest a general framework that includes possible remedies and ways to prevent it. Our model and framework use the notion of deprivation costs, borrowed from the literature on humanitarian logistics, as well as an equity measure based on the Gini index.

Improving Operations and Allocation Policies for Organ Transplantation

Emerging Topic: Policy & Government

Emerging Topic Session

Chair: Nikolaos Trichakis, MIT, Cambridge, MA, 02143, United States

1 - Size Based Exception Points for Fair Liver Allocation

Mustafa Akan, Associate Professor of Operations Management, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, akan@cmu.edu, Musa Eren Celdir, Sridhar R. Tayur

Patients on the waiting list for liver transplants receive priority based on their Model for End-Stage Liver Disease (MELD) scores, which reflect the severity of liver disease. Recent studies have shown that for patientw with Hepatocellular Carcinoma (HCC), shorter candidates and women (which may relate to smaller stature) have longer wait times and lower probability of liver transplant. Using a queueing model and data from the Scientific Registry of Transplant Recipients (SRTR), we investigate whether additional MELD exception points would help equalize the sizebased disparity in organ access.

2 - Organ Procurement and Information Process Optimization

Paola Martin, University of Texas at Austin, Austin, TX, United States, paola.martin@mccombs.utexas.edu, Diwakar Gupta, Timothy Pruett

In the US there is a severe shortage of kidneys available for transplant. Although Organ Procurement Organizations (OPOs) receive a large number of death or imminent-death referrals from donor hospitals, the actual number of referrals that become donors is much smaller. A referral may not turn into a donor because of medical reasons, family consent or timing of the referral. In addition, there are operational and information processing related factors that may influence this outcome. The purpose of this talk is to identify all factors that affect decision-making at OPOs and develop optimization models and computer algorithms to increase the number of authorized donors and the number of transplants.

3 - Balancing Efficiency and Fairness in Liver Transplant Access: A Boundaryless Model of Organ Distribution with Implications for National Transplant Policy

Nikolaos Trichakis, MIT, Cambridge, MA, 02143, United States, ntrichakis@mit.edu, Dimitris Bertsimas, Theodore Papalexopoulos, Yuchen Wang, Ryutaro Hirose, Parsia Vagefi

Current distribution policies have resulted in persistent geographic disparity in access to donated livers for waitlisted candidates. Using mathematical optimization and simulation, the following organ distribution concepts were assessed 1) current policy, 2) proposed alternative models, and 3) a novel continuous distribution model. A number of different scenarios for each concept were generated. Continuous distribution allowed both for the greatest reduction in patient deaths and for the most equitable geographic distribution across comparable organ transportation burden.

4 - Fair Liver Transplant Allocation: A Scalable Optimization Model

Shubham Akshat, University of Maryland, College Park, MD, United States, sakshat@umd.edu, S. Raghavan, Sommer E. Gentry

U.S. Department of Health and Human Services is interested in increasing geographic equity in liver transplants. Organ supply/demand ratio can be viewed as a good proxy for evaluating access to organs by patients. We develop a nonlinear integer programming model that allocates supply in order to maximize the minimum supply/demand ratio across all transplant centers. We reformulate it as a set-partitioning problem. Our results indicate that the worst supply/demand ratio across transplant centers is improved upon significantly. Simulation studies suggest reduced geographic disparity and an annual saving of more than 70 lives (on average) compared to the current 11 region system with full sharing.

Vendor Tutorial

1 - Optimization Modeling Tools from LINDO Systems

Mark A. Wiley, LINDO Systems Inc, 1415 No Dayton Street, Chicago, IL, 60622, United States, Gautier Laude

Exceptional ease of use, wide range of capabilities, and flexibility have made LINDO software the tool of choice for thousands of Operations Research professionals across nearly every industry for over 30 years. LINDO offers solvers to cover all your optimization needs. The Linear Programming solvers handle million variable/constraint problems fast and reliably. The Quadratic/SOCP/Barrier solver efficiently handles quadratically constrained problems. The Integer solver works fast and reliably with LP, QP and NLP models. The Global NLP solver finds the guaranteed global optimum of nonconvex models. The Stochastic Programming solver has a full range of capabilities for planning under uncertainty. Get the tools you need to get up and running quickly. LINDO provides a set of intuitive interfaces to suit your modeling preference. · What's Best! is an add-in to Excel that you can use to quickly build models that managers can use and understand. · LINDO has a full featured modeling language for expressing complex models clearly and concisely, and it has links to Excel and databases that make data handling easy. · LINDO API is a callable library that allows you to seamlessly embed the solvers into your own applications. Pick the best tool for the job based upon who will build the application, who will use it, and where the data reside. Technical support at LINDO is responsive and thorough - whether you have questions about the software or need some modeling advise. Get started today. Visit our booth or www.lindo.com to get more information and pick up full capacity evaluation licenses.

2 - Improvements in the Gurobi Python Interface

Greg Glockner, Gurobi Optimization, Bellevue, WA, United States, Ed Rothberg

Our new release brings with it several significant improvements to our Python interface. We'll give you an overview of what was possible before, and what is possible now. We'll also present several examples that demonstrate the new capabilities.

Industry Job Hunting Session

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Kaibo Liu

Chair: Abdallah A Chehade, University of Michigan-Dearborn, Dearborn, MI, 48128, United States

Moderator

Abdallah Chehade, University of Michigan-Dearborn, Dearborn, MI, United States, achehade@umich.edu

The goal of this session is to help students better prepare for industry job hunting. The session provides a forum where participants can share their experience in job hunting, recruitment opportunity, industry interview process, and do's and don'ts associated with the job search.

Panelists

- Na An, Amazon, Bellevue, WA, 98006, United States
- Ji Liu
- Zuzka Bodik, Facebook, Seattle, WA, United States
- Mojtaba Khanzadeh

1 - Limited Attention and Asymmetric Overnight Return Puzzle in Chinese Stock Markets

Fei Su, Nanjing University of Aeronautics and Astronautics, Nanjing, China, sufei@126.com

In this paper, we reinvestigate an interesting puzzle that the average overnight return on market portfolio is significantly negative in China's stock market. Furthermore, we find that the overnight return puzzle only appears on days with lagged negative daytime returns, which is termed "Asymmetric Overnight Return Puzzle". Empirical evidence reveals that the limited attention theory can at least partially explain this phenomenon, namely, investors with limited attention would response more strongly to bad news than to good news, which may lead to short-term momentum in the overnight period on days with negative information shocks.

2 - Price Discovery of Steel Commodities on the Supply Side Structural Reform Period

Wen Fang, Xidian University, Xi'an, China, az-moju@163.com

This study focuses on price discovery of steel commodities during the supply-side structural reform period. After using two different futures contracts for three kinds of steel commodities, we found that price discovery function of futures market is stronger than the spot market by applying the most active futures contracts. However, if the data of nearby contract is used, price discovery of futures is weaker than spot market in the pre-reform and post-reform study periods. By applying multivariable time-varying research model, our findings show that if we neglect closely related steel futures, we would draw to different conclusions about steel spot and futures price discovery function.

3 - Share Pledge Transactions, Investor Sentiment and Volatility

Hengzhen Lu, Nanjing University of Aeronautics and Astronautics, Nanjing, China, Luhengzhen@nuaa.edu.cn

This paper examines how share pledge transactions affect stock price volatility. We developed an investor overconfidence model about the impact of share pledge transaction on stock price. We find that share pledge trading can lead to emotional bias and consequently affect investment decisions. We studied the relationship between investor sentiment indicators including share pledges transaction factors and stock price volatility. We find that the impact of share pledge trading on investor sentiment has a positive impact in the long term. It shows that pledge trading does have accelerating effect on stock price cyclical fluctuation through investor sentiment effect.

4 - Modeling and Measuring Systemic Risk

Faraz Dadgostari, University of Virginia, Charlottesville, VA, United States, fd4cd@virginia.edu, Peter A. Beling

We propose a novel mathematical framework to model financial markets as complex systems of economic interactions and contractual and legal obligations aiming to understand, measure and mitigate systemic risk exposure of economy from the perspective of the policymakers and regulators. The proposed mechanism exploits the systemic structure of contractual dependencies of the financial institutions in a competitive market where banks maximize their individual share of the financial market/profit. The resulting framework would be ideal for developing alternative regulatory technologies to mitigate aggregate systemic risk exposure of the economy, subject to minimum intervention.

QSR International Activities I: QSR Research in Asia

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Nan Chen, National University of Singapore, 117576, Singapore

Co-Chair: Xi Zhang, Peking University, Beijing, 100871, China

Co-Chair: Chen Zhang, Tsinghua University, Singapore, 117576, Singapore

Co-Chair: Xiao Liu

1 – QSR Research and Funding Opportunities in Singapore

Nan Chen, National University of Singapore, Department of Industrial and System Eng, 1 Engineering Drive 2, Singapore, 117576, Singapore

In this presentation, we will briefly introduce some funding schemes and opportunities, especially for international collaborations in the research areas related to QSR. We will also introduce some major research initiatives and undergoing research projects to explore possible collaborations.

2 - Online Monitoring of Pipeline Corrosion Process via Machine Learning Methodsonline Monitoring of Pipeline Corrosion Process via Machine Learning Methods

Chen Zhang, Assistant Professor, Tsinghua University, e1-07-26, 3 Engineering Drive, beijing, 117576, China, zhangchen01@tsinghua.edu.cn

We present an online monitoring algorithm for tube wall corrosion process based on FBG sensors. We first develop a spatio-temporal model for FBG signal extraction. The model can remove environmental influence and extract FBG features that relate to tube thickness. Then model residuals can be regarded as features caused by sensors' own properties, such as its local thickness and local system vibrations. Consequentially, we can use the regression residuals for thickness feature extraction. Then taking the physical principle as guideline, we construct a nonlinear model to describe the relationship between residual feature and the tube thickness and use the relationship for online monitoring.

3 - Some Research Collaboration Opportunities in Data Analytics in Mainland China

Xi Zhang, Peking University, Beijing, China, xi.zhang@pku.edu.cn, Jianguo Wu

In recent years, some interesting opportunities have emerged for the development of engineering data analytics and associated disciplines, with the growth of IT technologies in China. In this talk, the speaker would like to review some previous and ongoing projects related to engineering data analytics, and also would share some thoughts regarding the future directions.

1 - Repeatedly Estimating Correlated and Normally Distributed Parameters of an Expensive and Highly Nonlinear Model

Chuljin Park, Hanyang University, KAIST ISYSE, Yuseong-gu, Seoul, Korea, Republic of, chuljini@gmail.com

We consider a problem of repeatedly estimating parameter vectors of a highly nonlinear and expensive model, where the parameter vectors of the model are sampled from a multivariate normal distribution. The mean vector and covariance matrix of the parameter distribution are assumed to be pre-known or can be estimated. We propose a new framework, called the distribution-guided heuristic search, which can be combined with any heuristic algorithm to solve the target problem. The framework was tested in simulation studies and was applied to measuring the critical dimensions of a 2-D high aspect ratio structure of a wafer in semiconductor manufacturing.

2 - Maximum Feasibility Estimation

Sungil Kim, Ulsan, 44919, Korea, Republic of, sungil.kim@unist.ac.kr

This paper proposes a novel parameter estimation method called the maximum feasibility estimation(MFE). The MFE does not rely on any assumption about parametric family of probability densities from which a random observation is drawn. Instead, we assume that constraints are imposed on observations and some of constraints are a function of a parameter of interest. The proposed estimator maximizes the feasible region, a set of all possible observations that satisfy those constraints. The method proposed is validated by using synthetic data as well as real streaming event log data.

3 - Statistical Modeling and Analysis of K-layer Coverage of Two-dimensional Materials in Inkjet Printing Processes

Jaesung Lee, University of Wisconsin-Madison, Madison, WI, United States, lee826@wisc.edu, Shiyu Zhou, Junhong Chen

Two-dimensional(2D) materials have been receiving great attention in electronics fabrication due to their intriguing properties. The k-layer coverage area of printed flake pattern significantly impacts on the properties of the printed electronics. We constructed a statistical model to describe the k-layer coverage of randomly distributed 2D materials, providing the expectation and variance of coverage area. An approximated statistical testing approach is also developed to detect abnormal coverage patterns. The case studies based on simulated data and real flake images obtained from the inkjet printing process show the accuracy and effectiveness of the proposed model and analysis methods.

4 - Hierarchical Bayesian Kernel Model: Prediction Using Small Data

Hiba Baroud, Vanderbilt University, Nashville, TN, 37235, United States, hiba.baroud@vanderbilt.edu, Jinzhu Yu

Various research applications suffer from small data and require highly predictive models. A major challenge in predicting the recovery rate of communities after disasters is that recovery data are often scarce due to the nature of extreme events. To address this challenge, we propose a new model called the Hierarchical Bayesian Kernel Model (HBKM). This model integrates the Bayesian property of improving predictive accuracy as data are dynamically accumulated, the kernel function that can make nonlinear data more manageable, and the hierarchical property of borrowing information from different sources in scarce and diverse data samples. Model performance is evaluated using sample data.

5 - Repeatedly Estimating Correlated and Normally Distributed Parameters of an Expensive and Highly Nonlinear Model

Chuljin Park, Hanyang University, Seoul, Korea, Republic of, chuljini@gmail.com, Hyungjin Kim

We consider a problem of repeatedly estimating parameter vectors of a highly nonlinear and expensive model, where the parameter vectors of the model are sampled from a multivariate normal distribution. The mean vector and covariance matrix of the parameter distribution are assumed to be pre-known or can be estimated. We propose a new framework, called the distribution-guided heuristic search, which can be combined with any heuristic algorithm to solve the target problem. The framework was tested in simulation studies and was applied to measuring the critical dimensions of a 2-D high aspect ratio structure of a wafer in semiconductor manufacturing.

Data-driven Decisions in Healthcare

Sponsored: Health Applications

Sponsored Session

Chair: Vishal Ahuja, Southern Methodist University, Dallas, TX, 75275, United States

1 - Optimizing Interventions in Health Care Settings

Margret V. Bjarnadottir, University of Maryland, College Park, MD, 112, United States, margret@rhsmith.umd.edu, Weiguang Wang, Gordon Gao, Leila Zia

Risk prediction models are increasingly common in the health care system. The implementation of these models in clinical settings includes a choice of which intervention programs, if any, to offer and to which members in order to improve outcomes. We model two applications and report the results.

2 - Estimating the Attributable Cost of Physician Burnout in the United States

Shasha Han, National University of Singapore, NUS Business School, Biz 2 Building B1, 1 Business Link, Singapore, Singapore, shashahan@u.nus.edu, Tait Shanafelt, Christine Sinsky, Joel Goh

Even though physician burnout is known to be associated with negative clinical and organizational outcomes, the economic costs associated with burnout are poorly understood. Consequently, leaders in healthcare cannot properly assess the financial benefits of initiatives to remediate physician burnout. In the study, we provide a model to estimate burnout-associated costs related to physician turnover and physicians reducing their clinical hours at national (U.S.) and organizational levels.

3 - An Analytics-driven Approach for Optimal Individualized Diabetes Screening

Hossein Kamalzadeh, Southern Methodist University, Dallas, TX, 75206, United States, Michael Hahsler, Vishal Ahuja, Michael Bowen

About 10% of the US adult population has diabetes, and almost 40% are at risk of developing diabetes. Guidelines suggest population-based screening, however, in resource-restricted settings (e.g., for safety-net providers), prioritizing whom to screen and when is essential. We combine analytics methods (hidden Markov models and predictive analytics) with partially observable Markov decision process models to derive the optimal screening policy customized to the characteristics of the provider's subpopulation. We will present results for electronic health record data from the Parkland Health & Hospital System.

4 - Outcome-adaptive Iterative Elastic Net: A Tool for Causal Inference in the Observational Setting

Ashkan Farahani, UT Arlington, Arlington, TX, United States, ashkan.aliabadifarahani@mavs.uta.edu, Victoria C. P. Chen, Nilabh Ohol, Jay Michael Rosenberger

We focus on the adaptive treatment regime in the observational setting where the dynamic nature of the problem causes a bias called endogeneity or time-varying confounding. While previous studies handled one treatment case, we are focusing on the "multiple correlated treatment" case where the aim of the study is to "uncover the true underlying outcome model" at each stage. We propose the "Outcome-Adaptive Iterative Elastic Net" that augments (1) the consistent selection of true outcome-predictors, true confounders and more importantly causal "treatments". (2) adjusting for time varying-confounding by IPTW method for "multiple treatments". (3) Inclusion of the correct effect-modifiers.

Topics in Hospital and Patient Management

Sponsored: Health Applications

Sponsored Session

Chair: Pengyi Shi, Purdue University, West Lafayette, IN, 47907, United States

1 - Platelet Inventory Sharing in a Two-hospital System

Can Zhang, Duke University, Durham, NC, 27708, United States, c.zhang@duke.edu, Turgay Ayer, Chelsea C. White

Motivated by a platelet inventory management problem in a local hospital network, we present one of the first analysis of perishable inventory sharing in a two-location system. We derive structural properties of the optimal policy and present managerial insights that significantly differ from those in existing studies for non-perishable products.

2 - Design of Incentive Programs for Optimal Medication Adherence

Joel Goh, NUS Business School, Mochtar Riady Building, Singapore, 119245, Singapore, Sze-chuan Suen, Diana M. Negoescu

We consider how to design a schedule of incentive payments to induce optimal treatment adherence levels with heterogeneous patient preferences for adherence. A unique challenge in this problem is that any prior commitment that a patient makes to a given level of treatment adherence cannot be contracted upon, rendering existing contract-theoretic approaches ineffective. We develop new models and analyses to capture this feature and conduct a numerical study using representative data in the context of the tuberculosis epidemic in India.

3 - Surgical Case-Mix and Discharge Decisions: Does Within-Hospital Coordination Matter

Vanitha Virudachalam, University of Illinois at Urbana-Champaign, Urbana-Champaign, IL, 19104, United States, vanitha@wharton.upenn.edu, Hessam Bavafa, Lerzan E. Ormeci, Sergei Savin

We study the problem faced by a hospital that controls patient inflows by designing a case-mix of elective procedures and patient outflows via patient discharges. Our model analyzes the impact of patient flow decisions on the utilization of two classes of resources, front-end (e.g. operating rooms), and backroom (e.g. recovery beds). We assess the benefit from coordinated decision-making, where portfolio and discharge decisions are made in tandem, when compared to two decentralized approaches: front-end (both decisions are made based only on front-end costs) and siloed (discharge decisions are made based on backroom costs, and the case-mix is the optimal match for the discharge policy).

4 - How to Elicit Physician Judgment to Improve Surgery Duration Prediction Algorithms

Song-Hee Kim, University of Southern California, Los Angeles, CA, 90089, United States, songheek@marshall.usc.edu, Rouba Ibrahim, Jordan D. Tong, Joan Brown

Increasingly, hospitals are trying to use algorithms to predict surgery duration times. These algorithms may use both observable data and physician judgmental forecasts. Using field data, we find that physician forecasts add significant predictive value when included in algorithms — so it is desirable to incorporate their judgment. We then study how to best elicit physician judgment when these judgments are not used directly, but rather indirectly as inputs for algorithms. Through behavioral models and controlled experiments, we conjecture and find evidence that there are better ways to elicit physician judgment than directly asking physicians for their surgery duration forecast.

1 - Big Data and the Precision Medicine Revolution

Wallace J. Hopp, University of Michigan, Ann Arbor, MI, 48109-1234, United States

The big data revolution is making vast amounts of information available in all sectors of the economy including health care. One important type of data that is particularly relevant to medicine is observational data from actual practice. In comparison to experimental data from clinical studies, observational data offers much larger sample sizes and much broader coverage of patient variables. However, because it is high dimensional and uncontrolled, observational data presents unique challenges. This talk will describe some recent results and some future opportunities for addressing these challenges.

2 - Perspectives on Successful Healthcare Analytics Projects

Turgay Ayer, Georgia Institute of Technology, School of Industrial and Systems Engineering, Atlanta, GA, 30332, United States, ayer@isye.gatech.edu

In this talk, I will i) provide an overview of multiple research projects on healthcare analytics, ii) present my perspectives on key ingredients of successful healthcare analytics papers/projects, and iii) discuss the potential growth of healthcare analytics within the INFORMS community.

Application of Operations Research Models to Staffing in Healthcare System

Sponsored: Health Applications

Sponsored Session

Chair: Jacqueline Griffin, Northeastern University, Boston, MA, 02115, United States

Co-Chair: Ann Suhaimi, Northeastern University, Boston, MA, 02115, United States

1 - Effective Methods for Solving a Large-scale Resident Block Scheduling Problem with Multi-criteria Objectives

Junhong Guo, University of Michigan, 1205 Beal Avenue, Ann Arbor, MI, 48109-2117, United States, jhguo@umich.edu, Amy Cohn

Each year, program directors must construct block schedules for their residency programs. Residents submit their prioritized preferences with respect to vacation times and electives, which introduces multiple objective criteria. This problem is often formulated as an integer programming (IP) and is solved through a hierarchical procedure. However, these IPs often suffer from long run times; the generated schedule is not always satisfactory to each individual resident; and there is no guarantee of fairness across all residents. To address these issues, we propose several methods to speed up the construction process, as well as new approaches to address the multi-criteria objective function.

2 - Determining Nurse Staffing to Maximize Patient Safety and Nurse Satisfaction

Anna Svirsko, United States Naval Academy, Annapolis, MD, 15217, United States, ACS167@pitt.edu, Bryan A. Norman, Bo Zeng

In the emergency department, nurses are an important part of the team that administers care to patients. However, the nurses rely not only on the physicians in the emergency department, but also on the external services of consults, radiology, labs, and pharmacy to aid in providing care. The staffing levels of physicians and the external services can affect the nurse's ability to progress the care of the patient. In addition, emergency departments are frequently understaffed, increasing the difficulty to determine appropriate staffing levels. We use robust optimization to help determine nurse staffing levels with regards to patient safety and nurse satisfaction.

3 - Evaluating Residents and Physicians Assignment Policies in an Outpatient Dermatology Clinic using Discrete-Event Simulation

Ann Suhaimi, Northeastern University, Boston, MA, 02115, United States, nmsuhaimi@gmail.com, Jacqueline Griffin

Productivity of providers are measured differently based on the role of the provider in the clinic. For physicians, the focus is to maximize number of patients seen while for residents, it is to maximize learning objectives both when they are interacting with patients, and with physicians. We present a discrete-event simulation model based on the daily operations of a dermatology clinic located to evaluate the provider assignments and suggest new policies to maximize their productivity. Criteria such as patient waiting time, provider idleness, and clinic closing time is incorporated in the model.

4 - Optimized Planning of School Operations at Hospitals

Jens Brunner, University of Augsburg, Faculty of Business and Economics, Augsburg, 86159, Germany, jens.brunner@unikat.uni-augsburg.de, Markus Seizinger, Sebastian Kohl

The shortage of nurses is one of the most urgent problems in health services and finding well-trained nurses is a big challenge. In Germany, the vocational training system closely combines theoretical and practical education and is highly regulated by federal legislation. Nurses rotate through vocational school-blocks followed by assignments to hospital units. We develop two mixed integer programming models for this problem. The first model determines the number and length of school- and work-blocks on a class level whereas the second model finds an individual unit-assignment for every nurse. Our approach enables vocational schools to solve this complex planning problem efficiently.

5 - Integrating Standardization and Optimization Based Simulation in Staffing Model Development for Care Management

Gene Shan, University of Houston-Clear Lake, Houston, TX, United States, shan@uhcl.edu, Zhanting Gao, Silei Shan, Mohammad Khasawneh

As the population that lives in the United States ages and has longer life spans, more people are living with chronic diseases. Therefore, there is a significant demand for the efficient operations of care management organizations to support them and improve their quality of life. In this paper, we integrate process improvement with simulation-based optimization. Our results show significant improvements could be achieved with both approaches.

Personalized Medicine II

Emerging Topic: Personalized Health

Emerging Topic Session

Chair: Jennifer Mason Lobo, University of Virginia, Charlottesville, VA, 22902, United States

Co-Chair: Hyojung Kang, University of Illinois at Urbana-Champaign, Mahomet, IL, 61853, United States

1 - Analysis of Temporal Patterns of Sepsis-related Cellular and Physiological Responses to Inform Personalized Prediction of Mortality

Muge Capan, Drexel University, Philadelphia, PA, United States, Ali Jazayeri, Christopher Yang, Min Chi, Julie Simmons Ivy, Jeanne Marie Huddleston, Ryan Arnold

Sepsis is a multi-stage health condition with high mortality rate. While sepsis-related cellular and physiological responses have been utilized as independent factors to predict outcomes, temporal dependencies between these factors are understudied. Using electronic health records data from 13,367 unique patients, we model sepsis progression developing novel co-failure networks and association rule algorithms. Key results show that proximity and frequency of cellular and physiological co-failures are sepsis stage-specific and there are significant proximate failures that play a major role in predicting in-hospital mortality in a personalized manner.

2 - Subtree Decomposition for Multistage Stochastic Integer Programs

Rahman Khorramfar, North Carolina State University, Raleigh, NC, 27606, United States, rkhorra@ncsu.edu, Osman Ozaltin

Real life instances of multistage stochastic integer programs are often solved using scenario decomposition due their extensive size. In scenario decomposition subproblems are formulated for scenario clusters. We develop a decomposition approach in which subproblems are formulated for scenario tree node clusters. This approach generalizes scenario decomposition. We present numerical experiments using well-known test problems.

3 - Dynamic Prediction of Patient Outcomes: A Deep Learning Approach

Erkin Otles, University of Michigan, Ann Arbor, MI, United States, eotles@umich.edu, Haozhu Wang, Jon Seymour, Jenna Wiens, Brian T. Denton

Physicians are awash in a sea of data. Machine learning (ML) methods could help power clinical decision support tools, however classical ML methods dictate the need for data transformations that destroy important clinical signals, such as temporality and high dimensional categories. We present a novel clinical data transformation platform paired with a recurrent neural network architecture. In tandem these methods allow for prediction of patient outcomes with respect to complex clinical information observed over time. Discussion of this approach will include results from the task of dynamically predicting patient recovery from occupational injuries.

4 - Subgrouping of Patient Trajectories for Personalized Care: Evidence from Low Back Pain

Stefan Feuerriegel, ETH Zürich, Weinbergstr., Zürich, 8092, Switzerland, sfeuerriegel@ethz.ch, Christof Naumzik

Personalizing healthcare via subgrouping promises to translate clinical data into subgroup-specific disease management that is more effective. Yet a rigorous clustering framework and a study of its cost-effectiveness is lacking. As a remedy, our work thus proposes a mixture hidden Markov model that leverages the actual illness progression for clustering. This allows us to compare costs from a one-treatment-fits-all scheme with the cost of providing subgroup-specific care. We demonstrate our subgrouping technique based on a longitudinal study across patients suffering from non-specific low back pain.

5 - Optimal Treatment Strategy for Patients with Severe Emphysema

Maryam Alimohammadi, University of Arkansas, Fayetteville, AR, United States, malimoha@email.uark.edu, Shengfan Zhang, Art Chaovalitwongse

Emphysema is a chronic lung disease that has two main treatment options: medical therapy and lung-volume reduction surgery (LVRS). This study proposes a Markov decision process model to identify the optimal treatment strategies for patients with severe emphysema, considering the cost of the treatments and quality-adjusted life expectancy of the patients. We present both the long-term and short-term results to evaluate patient outcomes under different timing for LVRS considering patients characteristics.

Sample Average Approximation

Sponsored: Simulation

Sponsored Session

Chair: Dashi Singham, Naval Postgraduate School, Monterey, CA, 93943, United States

1 - Robust Importance Sampling for Loss Minimization under Covariate Shift

Henry Lam, Columbia University, New York, NY, 10027, United States, henry.lam@columbia.edu

In empirical loss minimization problems where only partial information is revealed from a data set and the remaining information is revealed from another set under a different distribution (a setting known as covariate shift), common approaches such as kernel mean matching rely on estimating the importance sampling weights between the two distributions, which can sometimes add substantial variance to the solution estimates. We present a scheme to reduce variance and enhance robustness in these contexts based on a systematic use of control variates. We provide theoretical bounds and demonstrate our approach in several common statistical learning tasks.

2 - Retrospective Approximation for Stochastic Optimization

David Newton, Purdue University, Department of Statistics, West Lafayette, IN, 47907, United States, newton34@purdue.edu

The Stochastic Gradient Descent (SGD) recursion is the ``workhorse" recursion for machine learning. For smooth, strongly convex objectives, the SGD recursion achieves the Cram\'{e}r-Rao lower bound when the learning rate is chosen optimally. Such choice, however, depends on unknown curvature constants, and mis-choice leads to degraded rates. There is indication that this situation is not merely ``theoretical." As a remedy, we present Retrospective Approximation (RA) —- a sequential SAA framework that facilitates embedding the best deterministic solvers, e.g., BFGS with line search, leading to excellent finite-time performance. We show when RA achieves the Cram\'{e}r-Rao lower bound.

3 - Uniform Convergence of Sample Average Approximation with Adaptive Multiple Importance Sampling

Ben Feng, University of Waterloo, Waterloo, ON, N2J 4Y3, Canada, ben.feng@uwaterloo.ca, Alvaro Maggiar, Jeremy C. Staum, Andreas Waechter

We study sample average approximations under adaptive importance sampling in which the sample densities may depend on previous random samples. Based on a generic uniform law of large numbers, we establish uniform convergence of the sample average approximation to the function being approximated. In the optimization context, we obtain convergence of the optimal value and optimal solutions of the sample average approximation.

4 - Sample Average Approximation for Univariate Functions

Dashi Singham, Naval Postgraduate School, Operations Research Department, Monterey, CA, 93943, United States, dsingham@nps.edu

Most sample average approximation methods are applied when the set of decision variables is finite. This research develops methods of finding optimal solutions to infinite-dimensional optimization problems when the decision variable is a well-defined continuous univariate function defined over the space of a random variable. We approximate the problem and apply sample average approximation to find a discrete solution, which we interpolate to approximate the continuous function.

Topics in Cloud Computing

Emerging Topic: Sharing Economy & Crowdsourcing

Emerging Topic Session

Chair: Ishai Menache, Microsoft, Redmond, WA, 98052, United States

Chair: Sebastian Perez Salazar

1 - Heavy-traffic Analysis of Queueing Systems with No Complete Resource Pooling

Siva Theja Maguluri, Georgia Institute of Technology, Atlanta, GA, United States, siva.theja@gatech.edu

Resource Allocation problems in Stochastic Processing Networks arise in a variety of systems. Exactly characterizing the performance of these systems is intractable and so, these systems are studied in various asymptotic regimes, such as heavy-traffic. When the so-called complete resource pooling (CRP) condition is satisfied, these systems usually have a single bottleneck resource in the heavy-traffic limit and so behave like a single queue. There are many systems such as the Input-queued switch and the bandwidth sharing system that do not satisfy the CRP, and so, their heavy-traffic behavior is not completely understood. Recent results in such systems using the Drift method will be presented.

2 - Resource Allocation in a Parallel World

Mor Harchol-Balter, Carnegie Mellon University, Computer Science Dept, Pittsburgh, PA, 15213, United States, harchol@cs.cmu.edu, Benjamin Berg, Rein A. Vesilo

Today's cloud computing workloads are typically parallel jobs which are designed to run across multiple servers. These jobs are often flexible, in that they can be run on many servers (in a short time) or on few servers (in a longer time). We are interested in the question of how to allocate servers between jobs in the case where there are several jobs and a limited total number of servers. This is a wide open problem. It is made difficult by the fact that the speedup experienced by allocating more servers to a job is often sublinear with diminishing returns. We present the first results on optimal allocation of servers to jobs for a set of jobs which all follow the same speedup function.

3 - Striking the Right Utilization-availability Balance in WAN Traffic Engineering

Ishai Menache, Microsoft Research, Redmond, WA, 98052, United States, ishai@microsoft.com

A key challenge in Wide Area Networks is striking a good balance between network utilization and availability, as these are inherently at odds; a highly utilized network might not be able to withstand unexpected traffic shifts resulting from link/node failures. We advocate a novel approach to this challenge that draws inspiration from financial risk theory: leverage empirical data to generate a probabilistic model of network failures and maximize bandwidth allocation to network users subject to an operator-specified availability target. Our approach enables network operators to strike the utilization availability balance that best suits their goals and operational reality.

4 - Dynamic Resource Allocation in the Cloud with Near-optimal Efficiency

Sebastian Perez-Salazar, Georgia Institute of Technology, Atlanta, GA, 30309, United States

A goal in cloud computing is to share a resource among users with distinct and unpredictable demands. Cloud offerings often come with a service level agreement (SLA) specifying the amount of resource a user can utilize. In many cases providers try to operate resources at high utilization while simultaneously satisfy SLA. There is a tradeoff in these 2 goals; e g, a static policy only ensuring SLA can lead to poor usage of resources. In this work we design a model that captures basic properties of cloud systems: SLA, limited feedback and arbitrary demand. We design simple algorithms that achieve near optimal utilization of a resource compared to offline dynamic solutions while satisfy SLAs up to a small error.

1 - Could Have Been a Contender Factors Driving Competitiveness in the NCAA Mens Basketball Tournament

Stephen Hill, University of North Carolina-Wilmington, Wilmington, NC, 28403-5611, United States, hills@uncw.edu

In this work we discuss characteristics that may predict whether a team is competitive in the NCAA Mens Basketball tournament. This work is inspired by a Kaggle competition launched for the 2019 tournament. We begin by defining competitiveness and then applying analytical techniques to identify teams that have demonstrated competitiveness.

2 - Can Twitter Data Improve the Stock Price Predictions for Sports Clubs? Case of Turkish Soccer League

Altug Tanaltay, Sabanci University, Istanbul, Turkey, Amirreza Safari-Langroudi, Raha Akhavan-Tabatabaei, Nihat Kasap

Finance literature in sports focuses on three main methods of stock price prediction in soccer: based on match results, pre-match expectations or match importance. For pre-match expectations, betting odds is commonly used as the indicator of investors' sentiments. We propose to include Twitter data as another indicator of this variable, and analyze the links between soccer match results, sentiments, and stock returns of the four major Turkish soccer teams. Our results show that social media can be a strong indicator of pre-match expectations and investors' sentiments in stock price prediction.

3 - Team-specific Ticket Options: An Empirical Analysis of the Online Marketplace for College Football.

Ovunc Yilmaz, University of Notre Dame, Notre Dame, IN, 46617, United States, oyilmaz@nd.edu, Matthew Gartenhaus

Team-specific ticket options have recently gained popularity in the sports industry. Using a unique data set from a company selling these options, we investigate the main drivers of the option prices and transaction volumes in primary and secondary markets.

4 - Analysis of Chris Davis's Hitless Streak

Matthew Hanson, Student, University of North Carolina at Wilmington, Wilmington, NC, United States, mh7240@uncw.edu, Christian Gay

In this project we investigate the struggles of Baltimore Orioles First Baseman Chris Davis. He recently gained notoriety for setting the record for most consecutive plate appearances (for a non-pitcher) without registering a hit. We analyze other hitless streaks in his career, his performance over his career, and commonalities among players who have also experienced long hitless streaks.

Theories and Applications of Interpretable Machine Learning

Sponsored: EBusiness

Sponsored Session

Chair: Dokyun Lee, Carnegie Mellon University, Pittsburgh, PA, 15213, United States

1 - Interpretable Neural Networks for Computer Vision

Cynthia Rudin, Duke, LSRC / Box 90129, Durham, NC, 27708, United States

I will discuss our work on interpretable neural networks for computer vision. These networks use case-based reasoning. Their network architecture augments any standard black box neural architecture with a special prototype layer that allows the network to provide explanations for each prediction. This is not posthoc analysis, the network actually explains its own reasoning process for reaching a prediction. So far, these interpretable neural networks seem to be approximately as accurate as their black box counterparts.

2 - Explainable AI for Science and Medicine

Scott Lundberg, University of Washington, Seattle, WA, United States, slund1@cs.washington.edu

Understanding why a machine learning model makes a certain prediction can be as crucial as the prediction's accuracy in many applications. Here l will present a unified approach to explain the output of any model. It connects game theory with local explanations, uniting many previous methods. I will then focus specifically on tree-based models, such as random forests and gradient boosted trees, where we have developed the first polynomial time algorithm to exactly compute classic attribution values from game theory. Based on these methods we have created a new set of tools for understanding both global model structure and individual model predictions (http://github.com/slundberg/shap).

3 - Understanding Your Model's Errors with Errudite

Marco Tulio Ribeiro, Microsoft Research, Seattle, WA, United States

Even though error analysis is crucial to understanding and improving NLP models, the common practice of manual, subjective categorization of a small sample of errors can lead to biased and incomplete conclusions. I will present Errudite, an interactive tool for scalable, reproducible, and counterfactual error analysis. Errudite provides an expressive DSL for extracting relevant features of linguistic data, which allows users to visualize data attributes, group relevant instances, and perform counterfactual analysis at scale. User studies and case studies demonstrate that Errudite enables users to perform high quality, reproducible error analyses with less effort.

4 - Quantifying Persuasive Dialogue via Belief Hierarchies

Emaad Manzoor, Carnegie Mellon University, Pittsburgh, PA, United States, emaad@cmu.edu

Argumentation forms the grease of human decision-making machinery, enabling progress via consensus. However, many arguments result in deadlock without progress. In this work, we introduce a computational method grounded in theories of argumentation to quantify and explain successful persuasion. Our method infers a network of beliefs from argumentative text and formalizes persuasion strategies via graph-theoretic properties. We demonstrate our method on a large-scale dataset of debates on several pressing issues (such as immigration and gun control) containing ground-truth labels of argument persuasiveness to uncover several insights on the efficacy of different persuasion strategies.

Behavioral Cost Accounting in OM

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: James Fan, Naval Postgraduate School, Monterey, CA, 93940, United States

1 - Performance of Queuing Systems with Strategic Customers and Servers

Hung Do, PhD, University of Vermont, Burlington, VT, United States, hdo@uvm.edu

In this project, we study the impact of strategic behavior of customers and servers on the performance of queuing systems under different queue designs and incentive systems.

2 - Wait and See or Pay Now

Lijia Tan, Dr., Eindhoven University of Technology, Eindhoven, Netherlands, Rob.J.I. Basten

In business and our personal life, we usually have to make a decision on whether and when to pay a cost to avoid an unexpected loss, such as in the context of machinery maintenance and preventive healthcare. This study addresses on such individual decision in a degradation process. A dynamic cost-loss game is considered as a theoretical benchmark. We develop an experiment Our experimental results from lab show that either risk aversion or risk seeking cannot explain the overall behavior. The decision maker's behavior fall in to a specific pattern, which would be explained in this study.

3 - Social Norms in Customer-operated Service Systems

James Fan, Assistant Professor, Naval Postgraduate School, Monterey, CA, 93940, United States, james.fan@nps.edu, Mirko Kremer, Laurens G. Debo, Chen Jin

We study experimentally whether and how social norms evolve in, and affect the performance of, customer-operated service systems, where service times are (partially) endogenously determined by the customers. Our data shows that service times are positively serially correlated. We explore several boundary conditions of this phenomenon, as well as managerial levers to mitigate its adverse impact on system level metrics. Our results complement a growing literature that demonstrates the effect of system load on service times in server-operated systems.

Advanced Data Analytics for Business Applications

Sponsored: Information Systems

Sponsored Session

Chair: Yuheng Hu, University of Illinois-Chicago, Chicago, IL, 60607, United States

1 - One Side Does Not Fit All: Personal Match and Marketing Message Effectiveness on Social Networks

Yuan Qu, Rutgers University, Newark, NJ, 07102, United States, yuan.qu@rutgers.edu, Jingyuan Yang

The goal is to improve participation and eventually marketing effectiveness of this kind of marketing (group marketing) according to user-article match. Technique-wise, this is a new problem compared to existing work. A traditional problem setting usually looks for a good match between users and product, and the goal is to maximize user interest in the product. Here our problem is the user and product match which leads to marketing effectiveness.

2 - Which Startup to Invest in: A Personalized Portfolio Strategy

Hao Zhong, Rutgers University, Harrison, NJ, 07029, United States

The screening and evaluation of startups for investment largely depends on investors' personal experiences, social relationships, and qualitative evaluation on firms. It thus has a strong call for quantitative and methodologically sound study. In this paper, we aim to develop a personalized portfolio strategy for assisting investors to target right startups and determine proper amount of capital to invest. Specifically, we develop a Probabilistic Latent Factor model to estimate investors' investment preferences in a collaborative way. Then we apply modern portfolio theory to optimize the investment strategy by considering both investment returns and potential risks.

3 - The Impact of Airbnb's Entry on Financial Delinquency

Jinan Lin, University of California, Irvine, CA, United States, Tingting Nian, Vijay Gurbaxani

We study the impact of Airbnb's entry on financial delinquency, and to the best of our knowledge, we are the first study investigating how the income shocks generated by a sharing economy platform relax liquidity constraints. By exploiting the entry of airbnb to each zip-code level, we estimate the causal effects on reducing mortgage loans, auto loans as well as bankcard loans delinquency. This paper evaluates the income shocks by utilizing excess housing capacity via an online platform, and demonstrates the economic impacts of sharing economy platform at the intersection among technology, finance and society. Our research implies that the entry of Airbnb can bring 3.99% and 2.68% reduction of mortgage loans and auto loans delinquency, and supports evidence from dynamic structures among loans delinquency and impulse-response analysis. This investigation stands with other studies supporting the welfare brought from online platform, and provides policy implication especially under the environments that U.S. households generally owe debts and remain low-liquidity assets.

Scheduling with Batching, Gaming and Dynamic Appointment

Emerging Topic: Project Management & Scheduling

Emerging Topic Session

Chair: Zhixin Liu, University of Michigan-Dearborn, Dearborn, MI, 48126-4100, United States

1 - Pareto Optimization of Two Agents Scheduling on Parallel Batch Machines

Guoqiang Fan, Northwestern Polytechnical University, Xi'an, SN 29, China, pacpos.gqfan@gmail.com, Jun-Qiang Wang, Zhixin Liu

This paper considers a Pareto optimization problem of scheduling jobs of two competing agents on parallel batch machines with non-identical capacities. The objective is to find Pareto optimal schedules to trade-off makespans for both agents. We recognize an approximate Pareto region that covers all Pareto optimal points, and prove that any obtained point in the approximate Pareto region is 2-approximate Pareto optimal. We design an algorithm to find approximate Pareto optimal points. The computational study shows that, our obtained set of approximate Pareto optimal points is very close to the set of all Pareto optimal points, and is even equal to the set of all Pareto optimal points.

2 - Parallel Batch Machine Scheduling: Impact of Allowing Job Compatibility

Jun Xu, Northwestern Polytechnical University, Xi'an, 710072, China, pacpos.jxu@gmail.com, Junqiang Wang

We consider the scheduling problems on identical parallel batch machines with family jobs to minimize the makespan and total completion time, respectively. When jobs from incompatible families are allowed to be compatible, the impact of compatibility on each scheduling objective is investigated. We measure such impact by a ratio indicator and further prove the bound of the indicator. We investigate the cost-effective choice of allowing incompatible families to become compatible families. Furthermore, an algorithm is proposed to capture the trade-off between the value of scheduling objective and the cost of allowing compatibility.

3 - Maximizing the Number of on Time Jobson Identical Machines

Hairong Zhao, Purdue University Northwest, 2200 169 Street, Hammond, IN, 46323, United States, hairong@pnw.edu

We study the scheduling problem on identical machines. There are n jobs and each has a due date. A job has one or more tasks. The tasks can't be preempted and different tasks of the same job can be scheduled concurrently on different machines. A job is on time if all of its tasks finish before its due date; otherwise, it is tardy. The problem is to find a schedule of these jobs so that the number of on time jobs is maximized; or equivalently, the number of tardy jobs is minimized. We show that when the jobs have common due date, one can get a schedule with small absolute error. We also conduct computational experiment when the jobs have distinct due dates.

4 - Dynamic Appointment Scheduling with Random Number of Requests

Yan Zhu, Hong Kong University of Science and Technology, Hong Kong, Hong Kong, yzhubp@connect.ust.hk

We propose a new appointment policy, different from the traditional first-come-first-serve policy, for trading off between server idle time and customer waiting time. We assume that both customer service durations and the number of customers in a period are uncertain. We first use dynamic programming algorithms to construct lower and upper bounds under the first-come-first-serve policy. Then we recognize an optimality property when adding incoming customers into an existing appointment schedule. Combining the property and the bounds, we develop a branch and bound algorithm.

Theoretical Issues in DEA

Emerging Topic: Productivity, Efficiency and Data Envelopment Analysis

Emerging Topic Session

Chair: Andrew Johnson

1 - Technology, TFPG and Employment: A Panel Data Analysis

Arup Mitra

Please check the mobile app for this abstract.

2 - The Impact of the Facet Structure in Piecewise Linear Technologies on the Incidence of Congestion

Ole Bent Olesen, University of Southern Denmark, Denmark, ole@sam.sdu.dk, Niels C. Petersen

Estimating congestion in DEA involves the radial input contraction of a DMU towards technology with strong and weak disposability. No congestion is present if this ratio is one. With two inputs and one output and CRS all DMUs in the cone spanned by strongly efficient DMUs will be congestion free. However, this result is no longer valid when we increase the number of inputs and outputs. Sufficient conditions for this to hold in higher dimensions are presented. An example from the literature illustrates this problem.

3 - Production Functional Estimation Imposing the Regular Ultra Passum Law with Homothetic Isoquants

Xun Chen, Texas A&M University, College Station, TX, United States, xchen@tamu.edu, Yining Chen, Daisuke Yagi, Andrew L. Johnson

Nonparametric shape constrained estimators can preserve the flexibility in capturing the nuances of the data and satisfy the basic properties from theories at the same time. While global concavity is generally imposed in production function estimation, our approach generalizes this constraint by imposing Regular Ultra Passum law instead. Input isoquants are assumed to be convex and homothetic. Statistical properties are well introduced, as well as a two-step estimation algorithm.

4 - Shape Constrained Functional Estimation: Bridging Parametric Estimators and Nonparametric Estimators

Andrew Johnson, Texas A&M University, College Station, TX, United States, ajohnson@tamu.edu

Parametric estimators of production functions have been the workhorse for modeling productivity to quantify economic growth over time. The development of shape constrained nonparametric estimators have allowed researchers to relax strong parametric assumptions while still maintaining some structure on the estimator. I will review some of the existing estimators emphasizing their relationship to each other and the economic principles the shape constraints model. I will identify areas where alternative models could capture existing economic concepts and the potential benefits of research in these areas.

5 - A Revised Dynamic Data Envelopment Analysis Model with Budget Constraints

Dong-Joon Lim, Sungkyunkwan University, Suwon, Korea, Republic of, tgno3@skku.edu, Kyu-Won Lee, Moon-Su Kim

This presentation points out an unintended limitation in the conventional specification of budget constraints in dynamic DEA. It is particularly discussed that the existing model tends to underestimate the production possibilities owing to misleading assumptions, and consequently it yields overstated efficiency measures. Besides addressing the relevant issues, a revised dynamic DEA model is developed whereby one can properly take budget constraints into account in a dynamic setting while preserving the major principles of the activity analysis. An empirical case of operational assessment in fire departments is demonstrated as an example.

Agriculture 4.0: Digital Revolution in Farming

Emerging Topic: Agriculture

Emerging Topic Session

Chair: Oskar Marko

Co-Chair: Vladimir Crnojevic

1 - Data Fusion for Real Time Agricultural Information Systems

Berk Ustundag, Istanbul Technical University, Istanbul, Turkey

Data has an increasing role in agricultural production and management at all scales depending on raising importance of yield efficiency and sustainability. Field level precision agriculture and basin level agricultural management are based on evaluation of various types of data and the knowledge. Remote sensing systems provide spatial information at some observation instants and real time terrestrial monitoring systems provide temporal information at some observation points. Machine Learning based Data fusion methods appear as the way of multi-temporal mapping of information and QoS management for agricultural information platforms and the services.

2 - Internet of Things (IoT)-Inspired Platform for Precision Dairy Farming

Ivan Andonovic, Strathclyde University, Glasgow, United Kingdom, Christopher Davison, Andrew Hamilton, Craig Michie, Christos Tachtatzis, Robert Atkinson

In this talk, an IoT-inspired platform will be presented that targets the provision of dairy animal health services and comprises a robust, wirelessly enabled, high node-count sensor network, gathering data from individual animals. Besides that, a cloud-based environment manages on-farm data and informs the supply chain in real time, on key operational and management interventions. These include the indicators of health state: onset of heat, important in fertility increase and hence the overall productivity, and the time spent eating and ruminating. The classifier algorithms reached the accuracy of over 98% for heat detection and >90% for the time spent eating and ruminating.

3 - Agriculture in the Big Data Era: Paradigms, Tools and Skills

Ioannis Athanasiadis, Wageningen University and Research, Wageningen, Netherlands

The agricultural digital footprint is increasing at unprecedented speed, bringing opportunities for data-driven innovation in food production. Decision-making processes are heavily influenced by big data. This talk goes through the new paradigms introduced; offer a comparative presentation across several big data applications in precision agriculture and livestock farming; and the skills needed for digital agriculture. In the big data era, the peers of agrifood chains need to change their roles and outreach beyond disciplinary silos. Teams mastering both domain expertise and data science skills are needed; but also with capabilities to communicate with stakeholders and local farmers.

4 - Data Revolution in Agricultural Insurance

Vladimir Crnojevic, BioSense Institute, Dr Zorana Djindjica 1, Novi Sad, 21000, Serbia

Agricultural insurance has an extremely important role in agri-business. While there are various insurance schemes in different countries, insurance in agriculture is still not utilizing the full potential of state-of-the-art information technology. Images coming from European Space Agency's satellites, weather parameters, artificial intelligence and big data are giving us an opportunity to estimate the true state of crops based on observations. By fusing the aforementioned technologies, we provide decision support system that dramatically improves traditional insurance and erases border between indemnity-based and index-based insurance in agriculture.

TIMES Doctoral Dissertation Award

Sponsored: Technology, Innovation Management & Entrepreneurship

Sponsored Session

Chair: Pascale Crama, Singapore Management University, Singapore, 178899, Singapore

1 - Crowdfunding

Daniel Blaseg, Goethe University, Frankfurt, Germany

The overarching aim of this dissertation is to provide insights into crowdfunding beyond the time of the crowdfunding campaign. Specifically, I aim to (1) critically investigate the regulatory challenges and approaches currently applied to crowdfunding, (2) investigate the circumstances in which entrepreneurs use crowdfunding that ultimately might lead to failure, and (3) provide a reproducible data-generating process that should enable further scientific inquiry on the topic.

2 - Entrepreunerial Operations Management

Evgeny Kagan, University of Michigan, Ann Arbor, MI, United States

This dissertation examines entrepreneurship and innovation not as "phenomena", but rather as collections of more micro-level, operational or process-related questions. Addressing these questions is particularly important given the explosion of training and educational resources for fledgling entrepreneurs. Devoid of answers (or frameworks), much of the advice directed at entrepreneurs is derived from individual success stories and popular press, often driven by singular experiences of founders, and not validated by data. The purpose of this dissertation is to take some initial steps to close this gap.

■ MC81

Optimization in Petrochemicals

Sponsored: Energy, Natural Res & the Environment/Natural Resources Petrochemicals

Sponsored Session

Chair: Zukui Li, PhD., University of Alberta, AB, Canada

1 - Optimization of Linepack in Natural Gas Pipelines under Supply Uncertainty

Kody Kazda, Queen's University, Kingston, ON, Canada, 17kk18@queensu.ca, Asgeir Tomasgard, Vibeke S. Nørstebø, Xiang Li

We propose a two-stochastic programming model for optimization of linepack in gas pipeline networks under future supply uncertainty. Traditionally, the nonlinear relationships among linepacks, gas flow rates, and pressures are described with polynomial, fractional, and exponential functions, but in the proposed model, they are describe with piecewise linear functions. Case study results demonstrate that, compared to the traditional linear or nonlinear model, the proposed model can achieve higher model precision as well as better computational performance.

2 - Biorefining and Machine Learning: Towards a Universal Kinetic Model of Wood Deconstruction

Yankai Cao, University of British Columbia, Vancouver, BC, 53706, Canada, yankai.cao@ubc.ca, Heather Trajano, Edward Wang, Genpei Cai, Riley Ballachay

Hemicellulose is a major component of lignocellulosic biomass and be hydrolyzed into monomers to support biorefining transformations. Hemicellulose hydrolysis has been studied extensively, yet there lacks a universal model of this process that can be applied to multiple species and reactor conditions. In this project, the literature on hardwood hemicellulose hydrolysis is mined and used to build machine learning models. The kinetic and machine learning models (e.g. linear regression, support vector regression, and deep neural networks) are assessed on their ability to predict xylose yield.

3 - Distributionally Robust Chance Constrained Optimization with Wasserstein Distance for the Process Scheduling under Uncertainty

Yuan Zhihong, Tsinghua University, Beijing, China, zhihongyuan@mail.tsinghua.edu.cn, Botong Liu

Distributionally robust chance constrained programming (DRCCP) is a framework containing a set of uncertain probabilistic constraints which are supposed to be satisfied a specified value under distributions of uncertain variables. In the present work, the ambiguity set employed was the Wasserstein metric centered at the empirical distribution. We derived a tractable dual reformulation of the DRCCP problem when proper norm spaces were chosen for the Wasserstein metric. The effectiveness of the proposed reformulation was demonstrated by scheduling cases of batch chemical plant.

4 - Adaptive Nonlinear Robust Optimization of Water Treatment Network Design under Uncertainty

Zukui Li, University of Alberta, Edmonton, AB, T6G1H9, Canada, zukui@ualberta.ca, Sanjula Kammammettu

We present a nonlinear robust optimization method for the optimal design and operation of the wastewater treatment network under uncertainty. The problem is formulated as a two-stage mixed-integer nonlinear optimization problem under uncertainty, where the variables are classified into design, state and control variables. The solution method is based the linearization with respect to uncertain parameters and the application of decision rule to control variables. Applications on water treatment network for in-situ oil sands extraction process shows that the method can lead to robust water network design and adaptive operation policies for different ranges of uncertainty.

Sustainability and Social Responsibility in Commodity Supply Chains

Sponsored: Energy, Natural Res & the Environment/Environment & Sustainability

Sponsored Session

Chair: Jan C. Fransoo, Kuehne Logistics University, Hamburg, 20457, Germany

1 - Reveal the Supplier List? A Trade-off in Capacity vs. Responsibility

Basak Kalkanci, Georgia Institute of Technology, 815 Creekgarden Court, Atlanta, GA, 30339, United States, Erica Plambeck

Some buying firms, facing scrutiny regarding social and environmental violations in their suppliers' operations, have recently made commitments to publish the identities of their current and/or terminated suppliers. In this paper, we study the trade-offs faced by a buying firm in deciding whether or not to make such transparency commitments. We identify the conditions under which a buying firm should commit to publish its supplier list, and the conditions under which the buying firm should make complementary investments to help the supplier become more productive.

2 - Social Equity in Supplier-Buyer Relationships in Smallholder Agri-food Supply Chains

Nayeli Hernandez-Martinez, Eindhoven University of Technology, Eindhoven, Netherlands, n.hernandez.martinez@tue.nl, Nevin Mutlu, Jan C. Fransoo

We study supplier-buyer relationships in smallholder agri-food supply chains with equity concerns and under stakeholder engagement. We develop a Stackelberg game model to study the impact of these socially responsible practices in investment and pricing decisions. We provide closed form expressions for the optimal prices and characterize the structure of the optimal investment. We numerically study the effect of the model parameters and the price of ignoring equity concerns. We show that equity concerns may reverse the advantage of the game leader and that, under the right circumstances, the introduction of socially responsible practices can increase the total supply chain profit.

3 - Do Policies with Limited Enforcement Reduce Harm? Evidence from Transshipment Bans

Joann de Zegher, MIT Sloan, Cambridge, MA, 02142, United States, jfz@mit.edu, Hamsa Sridhar Bastani

To mitigate environmental and social harm in supply chains, buyers often provide incentives or impose sanctions to suppliers. Such policies are often implemented with limited monitoring and enforcement, which may lead to strategic behavior by suppliers and unintended consequences. We study empirically if a policy with limited enforcement can reduce harm, leads to strategic behavior, and increases raw material costs. We combine modeling with remote sensing data, and exploit variation over time and space to develop a conservative estimate of the effect of a ban on seafood transshipments. Our results inform the debate on such bans, which is hoped to mitigate forced labor and illegal fishing.

4 - The Impact of Animal Welfare Regulation on Firms' Product Offerings: Humane or Organic Product

Yen-Ting (Daniel) Lin, University of San Diego, School of Business Administration, San Diego, CA, 92110, United States, linyt@sandiego.edu, Wenli Xiao, Yinping Mu

We consider two competing supply chains with a supplier and a retailer. We examine the retailers' choice between offering an organic product and a humane product, when an animal welfare regulation is introduced. By offering an organic product, the retailer improves both animals' living conditions and the product's nutritional benefits, while offering a humane product only improves animals' living conditions. We provide the conditions under which the retailer would choose to offer the organic versus humane product. In addition, we show that subsidies offered by regulators to encourage the consumption of humane product in general hurts social welfare.

The Challenges of Going Green: Solutions for Utilities and Firms

Sponsored: Energy, Natural Res & the Environment/Energy

Sponsored Session

Chair: Benjamin D. Leibowicz, University of Texas-Austin, Austin, TX, 78712-1591, United States

1 - Black-box Optimization for Design of Photovoltaic and Concentrating Solar Power Hybrid Systems

William T. Hamilton, Graduate Student, Colorado School of Mines, Golden, CO, 80218, United States, whamilton@mines.edu, Alexandra M. Newman, Robert J. Braun

Concentrating solar power (CSP) technologies capture thermal radiation from the sun. When paired with thermal energy storage (TES), CSP systems are a dispatchable renewable energy source. The hybridization of photovoltaic (PV) and CSP with TES systems has the potential to provide continuous energy production at a lower cost than a PV or CSP system alone. We evaluate hybrid system designs using a black-box optimization solver, and optimize corresponding dispatch decisions for a given geographic location and electricity market structure. We present preliminary results with an emphasis on system design trade-offs based on system requirements.

2 - Optimizing the Design and Dispatch of Combined Heat and Power Technologies

Joshua Pearson, Colorado School of Mines, Golden, CO, 80226, United States, jpearson@mines.edu, Alexandra M. Newman, Tulay Flamand, Josiah Pohl, Alexander Zolan

We enhance a model developed by the National Renewable Energy Laboratory to incorportate combined heat-and-power technologies with existing photovoltaics, batteries and wind. The model determines a cost-minimizing collection of technologies subject to load, operational, and logical constraints. We develop methodologies to improve tractability of this mixed-integer program, and analyze results for a set of regions within the United States.

3 - Harvesting Solar Power Foments Prices in a Vicious Cycle: Breaking the Cycle with Price Mechanisms

Metin Cakanyildirim, The University of Texas at Dallas, Jindal School of Management, 800 W. Campbell Road Sm 30, Richardson, TX, 75080, United States, metin@utdallas.edu, Fariba Farajbakhsh

Growth of residential solar power in a market benefits the environment but not necessarily the (utility or transmission) firms. It reduces the residential power demand and hence hinders the coverage of fixed part of generation and transmission costs with reasonable prices. The firms tend to raise the retail prices and make electricity less affordable for their consumers. We provide a novel revenue maximization formulation for a regulated firm and analytically reveal the connection between price increases and solar penetration. We also extend this formulation to take into account new price structures that mitigate price increases by allowing for the coverage of fixed costs in part or full.

4 - Meeting Corporate Renewable Power Targets

Danial Mohseni-Taheri, College of Business, University of Illinois at Chicago, Chicago, IL, 60610, United States, smohse3@uic.edu, Selvaprabu Nadarajah, Alessio Trivella

Prominent companies have committed to procuring a percentage of their power demand from renewable sources by a future date. We study procurement portfolios to achieve this target based on two dominant strategies: Long-term procurement of power and short-term purchases. We analyze a two-stage model to understand the behavior of procurement costs when using popular corporate power purchase agreement (CPPA) variants employed in practice. Finding the optimal multi-stage procurement portfolio gives rise to an intractable Markov decision process. To overcome this intractability, we develop a novel dual reoptimization heuristic and highlight the benefits of using CPPAs to meet a renewable target.

Economic Development, Energy and Climate

Sponsored: Energy, Natural Res & the Environment/Energy Sponsored Session

Chair: Yongyang Cai, Ohio State University, Columbus, OH, United States

1 - Modeling the Feed-in Tariff and Renewable Energy Certificates Schemes in U.S. Electricity Market

Ziyu Guo, The Ohio State University, Columbus, OH, United States, guo.645@buckeyemail.osu.edu

In the U.S., feed-in tariffs (FITs) and renewable energy certificates (RECs) are two main policy tools to encourage electricity generation from renewable energy. FITs offers a specific amount of payment to renewable energy producers for the electricity they produce. RECs requires electricity producers to supply a specific percentage of their electricity generating from renewable resources by a specified year. To compare the effects of the two schemes, this paper builds a dynamic model to simulate the electricity generations under two systems. The results indicate that, FITs can induce more renewable energy production than RECs. But the total production of electricity is uncertain over time.

2 - Geospatial Optimization of Infrastructure for CO2-based Geothermal Electricity Generation

Marcos Miranda, Ohio State University, Columbus, OH, United States, Jeffrey M. Bielicki, Jonathan Ogland-Hand, Stephen Maldonado, Christina Howard, Benjamin Adams, Martin Saar, Richard Stephen Middleton

Carbon dioxide (CO_2) based geothermal electricity production can simultaneously isolate CO_2 from the atmosphere and generate dispatchable baseload electricity. We investigated the viability of this approach by adapting an engineering-economic geospatial optimization model, SimCCS, to investigate the optimal deployment of infrastructure for systems that capture and transport CO_2, inject that CO_2 into sedimentary basin geothermal resources, and circulate that stored CO_2 to extract geothermal heat and convert it into electricity. We found a few regions in the United States that may be viable, if amenable by policy.

3 - Forecasting of Durable Consumer Goods under Uncertainty: A Non-standard Difference Numerical Scheme

Hongbo Duan, University of Chinese Academy of Sciences, Beijing, China, hbduan@ucas.ac.cn

The discretization method of these diffusion models becomes one of critical techniques to affect the effect of parameter estimation and product prediction. In this paper, a nonstandard finite difference numerical scheme is developed to approximate stochastic differential models and generate the one-step ahead conditional transition density, which finally contributes to achieve better parameter estimations and predictions than the traditional Euler-Maruyama discretization scheme. We attempt to predict the future sales of China's electric vehicles in the context of proposed discretization scheme, and we obtain more accurate predications as compared to the traditional methods.

4 - Climate Policy under Spatial Heat Transport: Cooperative and Noncooperative Regional Outcomes

Yongyang Cai, Ohio State University, Columbus, OH, 43210, United States, cai.619@osu.edu, William Brock, Anastasios Xepapadeas, Kenneth Judd

We build a novel stochastic dynamic regional integrated assessment model of the economy and climate system with spatial heat transport from the Equator to the Poles, sea level rise, permafrost thaw and tipping points. We study optimal policies under cooperation or noncooperation between two regions (the North and the Tropic-South) in the face of risks and recursive utility. We find that ignoring elements of climate science leads to serious biases in important policy variables such as the regional social cost of carbon (SCC) and adaptation. We also find the regional SCC is significantly smaller in the feedback Nash equilibrium than in the social planner's problem for each region.

5 - Effect of Coal Transportation Inefficiencies on Indian Wholesale Power Generation

Jevgenijs Steinbuks, The World Bank, Washington, DC, United States, JSteinbuks@worldbank.org, Puneet Chitkara, Shefali Khanna

This study assesses the effect of inefficiencies in coal transportation by Indian Railways on the productivity of Indian wholesale power generation. The stochastic frontier analysis is applied to the plant level electricity generation data to determine electricity generation efficiency. Using the state-level data of passenger and coal freight schedules and tariffs, we optimize the coal dispatch to thermal generators accounting for the railroad route capacities and interstate transmission constraints. The optimal coal dispatch is used as an instrumental variable to obtain the econometric identification of the causal effect of coal transportation on thermal generation efficiency.

Towards Fully Integrated Energy Systems: From Long-term Planning to Short-term Operations

Sponsored: Energy, Natural Res & the Environment/Energy Sponsored Session

Chair: Stefanos Delikaraoglou

Co-Chair: Conor Malley

1 - Thermostatically Controlled Loads as Demand Response Providers: A System and Aggregator Perspective

Kenneth Bruninx, KU Leuven, Celestijnenlaan 300, post box 2421, Leuven, B3001, Belgium, kenneth.bruninx@kuleuven.be

The flexibility of thermostatically controlled loads may hold significant value for the power system and be monetized by aggregators, acting as mediators between consumers and the electricity market. We study (i) this flexibility from a power system perspective and (ii) the strategic interactions between an aggregator, its consumers and the wholesale market. In both cases, the demand response resources' limited controllability is accounted for via chance constraints. The presented methodology may be used to assess the value of DR in a deregulated power system.

2 - Unlocking Linepack Flexibility from Natural Gas and District Heating Networks: Convexification Approaches

Anna Schwele, Technical University of Denmark, Kgs Lyngby, Denmark, Charlotte Vervaeren, Adriano Arrigo, Jalal Kazempour, François Vallee

We model an integrated energy dispatch to reveal the maximum potential of linepack, i.e., energy storage in natural gas and district heating pipelines, to provide operational flexibility for the power system. Accounting for dynamics of natural gas flow and time delay of heat transport introduces nonlinearities and nonconvexities. We explore mixed-integer convex quadratic relaxations for linepack modeling and recast the original MINLP as a MISOCP. Ex-post analysis ensures feasibility of the heat dispatch while keeping the relaxation of the gas flow model tight. Flexibility is quantified in terms of system cost compared to a dispatch model neglecting the natural gas and district heating networks.

3 - Benders Decomposition with Adaptive Oracles for Large Scale Optimization

Nicolo Mazzi, University of Edinburgh, Edinburgh, United Kingdom, nicolo.mazzi@ed.ac.uk, Andreas Grothey, Ken McKinnon

We propose an algorithm to solve large stochastic investment planning problems for power system expansion, where subproblems differ in right-hand side and cost coefficients. Similar problems are often tackled using cutting-plane algorithms, which may slow down severely when solving subproblems is computationally expensive. We propose two adaptive oracles that yield inexact information much faster than solving the subproblem. The first oracle generates inexact but valid cutting planes, and the second oracle gives a valid upper bound of the true optimal objective. These adaptive oracles are embedded within a Benders algorithm to substantially reduce the effort to obtain a -optimal solution.

4 - Primal Decomposition of Gas and Electric Network Optimization

Conor O. Malley, ETH Zurich, Physikstrasse 3, Zurich, 8092, Switzerland, omalleyc@eeh.ee.ethz.ch

The increasing use of natural gas-fired generators in power systems can cause an interdependency between the electrical network operation and the gas network operation. In order to choose an optimal dispatch for both the gas and electric systems a combined optimal gas and optimal power flow problem can be solved. The complexity of this problem, and hence the solution time, for this problem can grow with the size of the networks and the number of time-steps that are considered. To overcome this problem, recent literature has proposed the use of dual decomposition strategies, but in this work a primal decomposition strategy is investigated and compared with the dual decomposition approaches.

1 - Last-mile Delivery: Optimal Locker Location under Multinomial Logit Choice Model

Yunhui Lin, National University of Singapore, Singapore, linyunhui@u.nus.edu, Yuan Wang, Loo Hay Lee

In today's E-commerce, locker systems for last-mile delivery have drawn intense attention from logistics companies. Recently, Singapore Post has launched a "Locker Alliance", which offers an access delivery network comprising of parcel lockers and collection points to enable customers to collect parcels at their convenience. In this work, we study the location of locker stations, considering the preference of customers, with the objective to minimize the walking distance. The customer's preference is modeled by a multinomial logit choice model. We conduct a case study based on the existing locker system of Singapore and derive managerial implications.

2 - A Three-stage Heuristic Algorithm for the Capacitated Vehicle Routing Problem

Maryam Abdirad, Wichita State University, Wichita, KS, United States, Krishna Krishnan

Industry 4.0 focuses on mobility and real-time integration and is a good framework for a Dynamic Vehicle Routing problem (DVRP). VRP problems are computationally intensive and often infeasible. In order to find the best solution for a scheduling system for delivery vehicles, a hierarchical approach consisting of three-stage solution with "cluster-first route-second" is proposed. The results of this approach confirmed the proposed methodology is applicable.

3 - Integrated Supply Chain Network Design for Perishable Products

Gang Wang, University of Massachusetts-Dartmouth, North Dartmouth, MA, United States

This paper studies a multi-echelon supply chain design considering production scheduling and lead times. We propose a mixed-integer linear programming model and a two-phase solution approach. Furthermore, we perform computational experiments on the randomly generated datasets and assess computational performance regarding network size, demand variability, and relative penalty costs.

4 - A Dual Sourcing Inventory Model for Modal Split Transport: Structural Properties and Optimal Solution

Chuanwen Dong, ESCP Europe, Berlin, Germany, cdong@escpeurope.eu, Sandra Transchel

We generalize the classical tailored base-surge dual sourcing inventory model by introducing a fixed cost in the slow mode (rail), adding an extra decision in its delivery frequency, and relaxing the assumption of the base stock control of the fast mode (road), to support firms' modal split transport optimization. We obtain properties of this problem, which allows to find the optimal solution using stochastic dynamic programming with realistic computing effort. Finally we analyze the sensitivity and robustness of our model using values suggested by a consumer goods firm.

5 - Effect of Flexible Delivery Windows During Multi-period Vehicle Routing

Aliakbar Izadkhah, Carnegie Mellon University, Pittsburgh, PA, United States, aizadkha@andrew.cmu.edu, Anirudh Subramanyam, Jose M. Lainez-Aguirre, Jose M. Pinto, Chrysanthos E. Gounaris

We study the effect of flexible delivery day windows on the optimal solutions of multi-period vehicle routing problem (MPVRP) under customer order uncertainty. We develop a simulation engine that supports multiple decision policies, including myopic policies often practiced in real life, as well as more sophisticated, look-ahead policies (both deterministic and robust). The engine addresses weekly snapshots using an exact MPVRP solver, adopts the routes for the first day, and repeats the procedure in a rolling horizon fashion. Computational studies on literature benchmarks allow us to quantify the overall distribution cost savings that customer flexibility in delivery windows provides.

6 - The Last Mile Flying- An Improved Approximation Algorithm for the Traveling Salesperson Problem with Drone

Rupei Xu, The University of Texas at Dallas, Richardson, TX, United States, rupei.xu@utdallas.edu, Andras Farago

With the development of new delivery technologies, drones are adopted to provide faster and more cost-efficient home delivery services, which leads to an innovative approach—the last-mile delivery. The combination of a traditional truck, which can release drones for the "last mile," and then recaptures them, defines the novel optimization problem called Traveling Salesperson Problem with Drone (TSP-D). In the existing literature, some heuristic methods are presented to find solutions for practical settings. However, there exists only a very limited theoretical performance analysis. This paper provides an improved approximation algorithm, along with theoretical analysis.

1 - Spillover Effects of Participating in Contests in Online Health Communities

Zhijun Yan, Beijing Institute of Technology, Haidian DistrictBeijing, 100081, China, yanzhijun@bit.edu.cn, Han Yang, Lin Jia, Lini Kuang, Chenxi Guo

Nowadays, crowdsourcing contest has become an efficient channel for people to seek for help. We focus on crowdsourcing contest section of a focal online health community, in which doctors are no longer anonymous and provide services in different sections other than crowdsourcing contests. This allows us to explore the spillover effect of doctors' participation in contests on their reputation and performance. The results indicate that doctors' participation will increase their online consulting performance, online ratings, and number of fans. On average, their participation does not affect their number of offline appointment.

2 - Software Development Kit Network and Mobile App Success

Xia Yu, City Univeristy of Hong Kong, Hong Kong, yuxia25-c@my.cityu.edu.hk, Chen Hailiang

The adoption of third-party Software Development Kits (SDKs) in mobile app development is becoming increasingly popular. While the impact of SDKs on app success has not been well examined. This study aims to quantify the effect of SDK adoption on mobile app performance and in particular focuses on the role of SDK network. Our dataset covers all mobile apps released on both Apple App Store and Google Play from 2008 to 2018. Mobile app performance is measured by the number of app downloads and revenues. We use the number of apps that install two SDKs at the same time to denote the strength of the SDKs' connection. Our findings would help app developers better understand the role of SDKs in mobile app development.

3 - Investigating Value Co-creation in Outdoor Adventure Mobile Apps

Hossein Kalantar, University of Colorado Denver, Denver, CO, United States, hossein.kalantar@ucdenver.edu

There are certain types of mobile applications that guide users for outdoor activities. These applications provide a crowdsourcing platform where users can find, create, and share related contents such as maps, photos, directions, and reviews of hiking, running, and biking trails. Although the primary geospatial data is provided in these platforms, their success is highly tied to the active participation of users. In this study, we conduct an empirical analysis to determine the main factors that lead to users' participation and value co-creation in these platforms.

4 - Effect of Gamification Elements on Activities of Stack Overflow

Jaewan Lim, University of North Carolina at Charlotte, Charlotte, NC, United States, jlim13@uncc.edu, Dongsong Zhang

Collective intelligence plays a critical role in developing a wide range of knowledge in the online community. Particularly, user spontaneity has a great impact on scaling the network of collective intelligence. If users do not contribute efforts spontaneously to the online community, the quantity and quality of Q&A will worsen. To date, Stack Overflow hosts more than 16M questions and 24M answers. One of the strategies that the site motivates users to be spontaneous is gamification. In the study, we mainly explore how gamification elements affect user's Q&A activities in the Stack Overflow.

5 - Measuring User Experiences of Techfin Mobile Apps from the Cognitive Science Perspective

Songhyun Kim, Yonsei University, Seoul, Korea, Republic of, hci.researcher.kim@gmail.com, Junseok Goh

In a dynamic environment where Internet Primary bank and other Techfin services keeps growing and technology evolves, financial mobile applications have gained popularity. With advent of technology and the changes in the perceiving UX/UI, this paper looks into the altering process of how users trust and adopt financial apps. Especially millennials make transaction and manage their asset in daily life, using apps. Thus, we examine Techfin service users from the cognitive science perspective, unveiling the purpose and the patterns of usage UI/UX of millennials. Methodology will primarily be based on archival data, survey data with Lab testing of individual's usage and evaluations of the apps.

6 - An Active Choice Inbox Management System to Reduce Email Clutter

Nicholas Brown, Doctoral Student, Virginia Tech, Blacksburg, VA, United States, nichb15@vt.edu

This study deals with email clutter inside an inbox. Email users have indicated that email overload can become a source of strain. The aim of this study is to create an artifact that will help reduce email clutter. The Vinish artifact is an active choice inbox management system that uses colored labeling inside Gmail, along with the active choices of "keep" and "later" to help users manage their inbox more effectively. Based on a preliminary qualitative study, the results show that the use of active choice labeling can be useful in reducing the number of emails within inboxes.

1 - Study on Smart Factories and Services: Korea Cases

Chang Won Lee, Hanyang University, School of Business, Seoul, 133-791, Korea, Republic of, leecw@hanyang.ac.kr, kijun Lee

We will analyze the level of smart factories in the current market by analyzing the theoretical review and actual cases of implementation and implementation of smart factories in Korea.

2 - Emergency Medical Services' Impact on Brand Equity

Sungyong Choi, Associate Professor, Yonsei University, Wonju, Korea, Republic of, sungyong.choi@yonsei.ac.kr, Ki-Young Kim, Yunsik Choi, Jiyeon Choi

This empirical study gauged the impact of the public's perception of the relationship between the emergency medical service, public health system, and level of system governance in South Korea. We developed a survey to measure how the key activities of the emergency medical service (EMS) are perceived. First, the public's perception of the EMS affected the development of brand equity in the public health system. Third, the public perception of governance played a moderating role on the relationship between EMS activities and the brand of the public health system.

3 - Are Proactive Services Beneficial?: An Event Study

Youngmi Han, Korea University Business School, Seoul, Korea, Republic of, 55835729@hanmail.net, Chulok Ahn, Hosun Rhim

Customer needs are constantly increasing. While reactive behavior of enterprise does not satisfy the changing customer needs, proactive behavior prevents potential problems and creates values. Previous study defined proactive services, and classified them into three types. In this study, we analyze event data to empirically study consequences of implementing proactive services.

4 - Designing and Managing Wastewater Treatment Planning for River-Basin in Developing Countries

Kwon Gi Mun, Fairleigh Dickinson University, Teaneck, NJ, United States, kgmun@fdu.edu, Jiyong Eom, Yao Zhao

Designing and managing wastewater treatment for riparian states has become a highly controversial policy issue since their asymmetric externality relationships and vulnerability positions. The problem is particularly pronounced in low-income countries facing tight public budgets and development uncertainties. We develop the concept of wastewater management by proposing a spatially, temporally, and technologically explicit optimization model using the case of Ganga river in India.

Keynote: Alleviating Poverty & Inequity: Fresh Challenges for Business Model Innovation

Emerging Topic: Keynote

1 - Alleviating Poverty & Inequity: Fresh Challenges for Business Model Innovation

Kamalini Ramdas, London Business School, Regent's Park, London, NW1 4SA, United Kingdom

Poverty and inequity remain two of the most pressing challenges in today's world. Meanwhile, business model innovation is transforming business across the globe, creating new wealth by combining innovative operational thinking, data and analytics to unleash previously untapped sources of value. This talk will examine the opportunity for business model innovation to alleviate poverty and inequity, showing how our community can play an important role. I will discuss how business model innovations can alleviate poverty by simultaneously empowering women, increasing incomes, and creating low-cost, high-quality and environmentally sustainable products or services. I will highlight opportunities for high-impact research that require different forms of modelling expertise, including econometrics and data science.

Keynote / MSOM Fellow: The New Age of Healthcare Delivery

Emerging Topic: Keynote

1 - The New Age of Healthcare Delivery

Linda Green, Columbia University, New York, NY, United States

The U.S. healthcare system is undergoing one of the most rapid periods of change ever. The confluence of new payment systems, technological innovations, greater data availability and higher consumer expectations is resulting in a new focus on increasing access and convenience, particularly for high-risk, high-needs patients, while controlling costs through greater reliance on evidence-based care and increasing productivity. While hospitals and physicians have dominated the healthcare delivery system in the past, new models of healthcare delivery employ a variety of locations and types of providers, raising questions about the best means to deliver cost-effective care. In this talk I'll describe these operational and organizational innovations and the critical research questions that must be addressed to create higher quality, lower cost healthcare systems in the future.

Keynote: Zero Carbon Analytics (IFORS Distinguished Lecture)

Emerging Topic: Keynote

1 - Zero Carbon Analytics (IFORS Distinguished Lecture)

Andy Philpott, University of Auckland, Dept of Engineering Science, Private Bag 92109, Auckland, New Zealand

Climate change from global warming is the most critical problem currently facing mankind. The deleterious effects of global warming have already been felt in 2019 in terms of storms, heatwaves and forest fires. Climate-based natural disasters in the longer term threaten to be much worse. Policies to deal with this problem must combine efforts to reduce global warming by eliminating greenhouse gas emissions with actions that adapt to worsening climate outcomes. Determining the best policy settings is a highly complex decision problem, involving complex interacting systems and markets, many stakeholders, many decision criteria, and huge uncertainty. In other words, it is a major opportunity for operations researchers. This talk will illustrate some of the analytics challenges in planning a net-zero carbon economy with a focus on electricity systems. Models range from short-term operations (like dealing with intermittent renewable energy) to long-term investment planning to ensure security of energy supply in an uncertain future. Planning models are complemented with equilibrium models that represent the effects of risk-averse agent behaviour. The models will be illustrated with a New Zealand case study based on our recent work for the New Zealand Interim Climate Change Committee in planning a 100% renewable electricity system.

Keynote: INFORMS AI Strategy: Opportunities at the Intersection of AI and Operations Research

Emerging Topic: Keynote

1 - INFORMS AI Strategy: Opportunities at the Intersection of AI and Operations Research

Ramayya Krishnan, Carnegie Mellon University, Pittsburgh, PA, United States; Pascal Van Hentenryk, Georgia Tech University, Atlanta, GA, United States

From driverless cars to deep learning, from AlphaGo to poker, from health care diagnosis and delivery to smart operations, applications of Artificial Intelligence (AI) have captured public imagination and become an active topic of discussion among leaders in all sectors. The Trump administration released an executive order on AI (see https://www.whitehouse.gov/ai/) and held a White House summit in September 2019 on "Public Sector Implementation of AI" (https://www.whitehouse.gov/wp-content/uploads/2019/09/Summary-of-White-House-Summit-on-AI-in-Government-September-2019.pdf). As a community and discipline that has long focused on developing solutions to important societal and business decision problems, what should our posture as a society be to these developments in AI? In this keynote presentation, we will present the key ideas underlying the AI strategy for INFORMS and the work already underway that will find ways for members to benefit from the rise of AI. This will draw on the work done by the board, the AI strategy committee, and countless members of INFORMS.

Data Mining, Machine Learning, and Artificial Intelligence in Banking, Financial Services, and Insurance (BFSI) Sector: Concepts, Cases and Applications

Sponsored: Data Mining

Sponsored Session

Chair: Darshan Desai

1 - Art and Science of Designing Machine Learning and AI Applications in Financial Services

Rahul Bedi, Berkeley College, New York, NY, United States, rbe@berkeleycollege.edu, Debasish Das, Darshan Desai

As the science of harnessing intelligence from data ("information insights") evolves rapidly, due to emergence of superior, faster and cheaper computing resources, it is now imperative that the artists within us are powered with the right tools and frameworks for creating the narrative which evokes positive socio-economic response from the beneficiaries of Machine Learning (M/L) and AI based applications. This paper discusses potential areas of M/L and AI based applications in financial services industry and outlines key design considerations for building solutions leveraging power of data science and providing artistic freedom for driving responsible innovation.

2 - Use of Artificial Intelligence to Enhance Fiduciary Duties of International Financial Institutions by Incorporating Text Mining Into Audit Planning

Kitty Kay Chan, Professor of Professional Practices, Columbia University, New York, NY, United States

International Financial Institutions (IFIs) often provide loans to member countries to fund projects that advance economic and social development. To ensure the funds are used for the intended purposes, IFIs conduct audits of the financed projects. It is important to be able to identify high-risk areas as it is not possible to examine all projects at a reasonable cost. To help address this challenge, this presentation will discuss the application of text mining techniques in audit planning.

3 - Risks Associated with Deep Learning Algorithms: Implications on BFSI Sector

Darshan Desai, Berkeley College, New York, NY, United States, Om Desai

The use of deep learning algorithms, like the algorithms used in some autonomous cars, can influence risk profiles of BFSI customers. Many of the firms in this sector are facing challenges in identifying risks associated with deep learning algorithms in an effective and timely manner. Additionally, these risks can manifest in unfamiliar ways and may evolve over time, sometimes very rapidly, as deep learning models learn and evolve. This presentation discusses methods of identifying the risk-parameters and developing risk-classification associated with deep learning models.

Teaching Data Mining to Business Students

Sponsored: Data Mining

Sponsored Session

Chair: Vijay Mehrotra

1 - Planting Analytics: A Journey Through Creating a Business Analytics Curriculum.

Majid Karimi, California State University, San Marcos, San Marcos, CA, United States

We present our experience with designing a curriculum to meet the demand of the ever-growing number of students and industry partners for a robust Business Analytics Program. We were faced with many challenges such as teaching R to students with little to no coding background, bringing big business real-world data into classrooms, making the program accessible to full-time students as well as part-time students, and most importantly creating an influential capstone project which spans across three courses of Descriptive Analytics, Predictive Analytics, and Prescriptive Analytics.

2 - Designing Data Mining Course for Business Data Analytics

Zinovy Radovilsky, California State University, East Bay, Hayward, CA, United States, zinovy.radovilsky@csueastbay.edu, Vishwanath Hegde

The interdisciplinary nature of the data mining (DM) subject poses a number of challenges while teaching this subject in a business program. A DM course can be introduced by a variety of departments/disciplines including statistics, computer science and business; within business it can be taught by faculty from multiple disciplines. The DM course may emphasize various dimensions, i.e., machine learning algorithms, statistical methods, and business applications. The DM course may be also taken by students from multiple programs, and thus a student preparedness along the specified dimensions varies. We explain how the DM course should be designed given the complexity of its dimensions.

3 - Business Analytics Programs at William & Mary's Mason School

James Bradley, College of William and Mary, Williamsburg, VA, United States, james.bradley@mason.wm.edu

William & Mary's Raymond A. Mason School of Business has reinvented its undergraduate operations management major as a business analytics major. It has also introduced two new Masters of Science in Business Analytics programs, one of which is a traditional in-residence program and another of which is online. This talk describes the design approach and structures of these new programs.

4 - **Teaching Data Mining to MBA Students: Some Lessons and Some Questions**

Vijay Mehrotra, University of San Francisco, School of Business and Professional Studies, San Francisco, CA, 94117, United States, vmehrotra@usfca.edu

In teaching Predictive Modeling and Data Mining to a non-technical population of MBA students, I have evolved my course content and teaching approach significantly over the past several years. In this presentation, I describe my journey, share some lessons learned, and solicit input from audience members about how to make the course more effective and relevant.

1 - **The Predictive Power of Discrete Emotions in Microblogging Messages: An Empirical Study in the Movie Industry**

Yifan Yu, University of Washington, Seattle, WA, United States, Jinghua Huang, Yong Tan

This paper generates daily box office prediction by conducting discrete emotion analysis on microblogging messages. Eight kinds of discrete emotions are empirically found to be predictive to box office. We also find discrete emotions have higher predictive power than valence, indicating that discrete emotions can better delineate consumer sentiment than valence can. Love, disgust, expect and anxiety are the four emotions with the highest predictive power. Each of them can individually produce higher prediction accuracy than valence. This study also proposes a methodology for automatic domain-specific emotion lexicon construction with Word2Vec model.

2 - **Impact of Live Streaming on Online Sales: A Deep Learning Approach**

Cheng Chen, University of Illinois-Chicago, University Hall, Chicago, IL, 60607, United States, cchen224@uic.edu, Yingda Lu, Yuheng Hu

Recent years have witnessed an explosive growth in online live video streaming. With the rise of live streaming in popular culture, it has begun to attract interest from the research community. Recent research has shown that the adoption of live streaming has an impact on online selling. Live streaming, reducing product uncertainty by providing rich information, significantly increases online product sales. The literature, however, remains unanswered regarding the mechanism of the effect of adopting live streaming on online sales. In this study, we propose to analyze the content of live streaming and analyze the effect of the factors during live streaming on online product sales.

3 - **A Latent Class Model of Player Reward Ads Watching Behaviors in Online Mobile Games**

Jiaying Deng, University of Washington, Seattle, WA, 98105, United States, jydeng2@uw.edu, Stephanie Lee, Yong Tan

This paper investigates an emerging monetization mechanism - reward ads. Specifically, a latent class model is proposed to examine what factors affect player reward ads watching behavior and how it relates to player engagement to the game. We identify three levels of player engagement, and find that all players are more likely to watch incentivized ads when in need of coins or have a lower nuisance cost. Challenge level of the game is helpful to motivate high and medium engagement players, but deters gamers with low engagement level from watching. On the other hand, low-engagement players are prone to view reward ads as their tenure increasing, while medium gamers reduce their tendency in this situation.

4 - **Artificial Intelligence and Human Intelligence - A Field Experiment Based on A College Application Assistance Program**

Xue (Jane) Tan, Indiana University, Kelley School of Business, Bloomington, IN, 47405, United States, janetan@iu.edu, Mochen Yang

This paper leverages an online platform that provides both artificial intelligence and human intelligence to aid high school graduates with college application. A unique field experiment was conducted to understand the complementarity of artificial and human intelligence. In a course of three days, messages were sent to students who used only one type of assistance. By examining students' response to the message, we observed interesting findings.

1 - **Globally-consistent Rule-based Summary-explanations for Machine Learning Models: Application to Credit-risk Evaluation**

Yaron Shaposhnik, University of Rochester, Simon Business School, Rochester, NY, 14627, United States, yaron.shaposhnik@simon.rochester.edu, Cynthia Rudin

We develop a method for interpreting specific predictions made by predictive models by constructing (local) models tailored to each specific observation. Unlike existing work that ``explain" specific observations by approximating global models in the vicinity of these observations, we fit models that are globally consistent with predictions made by the global model on past data. We focus on rule-based models and design multiple algorithms to extract such rules from discrete and continuous datasets. Finally, we apply these algorithms to a variety of credit-risk models trained on data from FICO and demonstrate that our approach produces sparse summary-explanations of these models.

2 - **Optimal Planning and Decision Making with Learned Neural Network Transition Models**

Buser Say, PhD Candidate, University of Toronto, Toronto, ON, M5T 1K2, Canada, buser.say@mail.utoronto.ca, Ga Wu, Scott Sanner

Hybrid Deep MILP Planning (HD-MILP-Plan) is a two-stage data-driven framework for learning and solving automated planning and decision making problems. Given samples of state transition data, the first stage of HD-MILP-Plan learns the transition function using a NN. In the second stage, the learned NN is sequentially chained over a horizon, and compiled into a MILP for optimal decision making. In this talk, a base MILP encoding and an improved MILP encoding based on additional preprocessing will be presented. Both models will be empirically evaluated on challenging benchmark instances.

3 - **Data Driven Forecasting and Revenue Management with Exposure Dependent Reference Prices**

Opher Baron, University of Toronto, Toronto, ON, M5S 1L7, Canada, opher.baron@rotman.utoronto.ca

We use data on the retail business of TMall to consider scalable implementation of revenue management (RM) in the presence of reference prices (RPs). We introduce forecast based upon RP with exposure effect and establish that these are more accurate than forecast ignoring this effect for many items. We develop scalable, data driven methodologies to compare the effectiveness of forecasts; demonstrate these methodologies; introduce models capturing exposure effect on RP via sales or clicks; and formulate and study RM when forecasts are RP-dependent. The improved accuracy and robustness of RM with forecast based upon RP with exposure effects support their usage in practice.

4 - **Process Performance Analysis Using Temporal Network Representations of Event Logs**

Matthias Weidlich, Professor, Humboldt University of Berlin, Berlin, Germany, matthias.weidlich@hu-berlin.de

Sojourn times and remaining times of business processes may be assessed based on event logs. Yet, existing work considers control-flow and performance information separately, or relies on an ad-hoc selection of temporal relations between events. In this work, we introduce the Temporal Network Representation (TNR) of a log. Based on Allen's intervals, it captures the pairwise temporal relations of activity executions. We demonstrate the usefulness of the TNR for detecting (unrecorded) delays and for probabilistic mining of variants in performance modelling. Our experiments with real-life healthcare datasets show that the TNR yields an up-to 40% improvement in sojourn time estimation.

5 - **Modeling Provider Learning Curves using Real-Time Locating System Data**

Arik Senderovich, Postdoctoral Fellow, University of Toronto, Toronto, ON, Canada, sariks@mie.utoronto.ca, Petar Momcilovic, Nikolaos Trichakis, Jillian Berry Jaeker

The implementation of electronic medical records (EMR) has been noted to disrupt clinical workflows as providers acclimate to a new EMR. On May 30, 2015, Dana-Farber Cancer Institute (DFCI) implemented a new EMR. Using our Real Time Location System (RTLS), we sought to identify the time required to stabilize the experience for providers. We identified factors that may speed the stabilization rate to guide EMR implementations elsewhere.

Advances in the Area of Business Analytics: Teaching & Research

Sponsored: Data Mining

Sponsored Session

Chair: Sinjini Mitra

1 - Improving Returns from Search Engine Marketing Using Google AdWords and Clustering – A Joint Teaching Effort between Data Sciences and Marketing Departments of Marshall School of Business

Arif Ansari, University of Southern California, Los Angeles, CA, 90089-0809, United States, aansari@usc.edu

Search Engine Marketing (SEM) is used by almost all major corporations and small companies are investing substantial portion of their marketing budget in SEM. Small companies lack the skills and man power of major corporations and they are looking for an edge over the competition. In this paper, we show how Data Science and Marketing department can collaborate and bring new and effective methods for small companies to compete against the major corporations. In this paper we will show how a small player can use Clustering and ROI based approach to compete with the major Resort in Bahamas and bring traffic to its website and sell their timeshare apartments to price sensitive customers.

2 - Business Analytics Education Lessons Learned from Program Development and Roll Out

Stephen Hill, University of North Carolina-Wilmington, 601 South College Road, Wilmington, NC, 28403-5611, United States, hills@uncw.edu

In this work we discuss various lessons learned from the development and roll out of Business Analytics programs at the undergraduate and graduate levels. We identify challenges faced, unexpected pitfalls, and ongoing issues and concerns.

3 - Transitioning From Administration Back to Faculty: A Journey Well Earned

Andrew Urbaczewski, United States Air Force Academy, Colorado Springs, CO, 80208, United States, andrew@urbaczewski.com

This session will detail the journey from a long-term administration position back to a research and teaching position. This presentation will cover preparation for and actual re-entering the world of university faculty.

4 - Experiment. Fail. Learn. Repeat.

Aaron Burciaga, Analytics2Go, Tysons, VA, 22102, United States, adburciaga@gmail.com

During this session, Aaron Burciaga CAP, Co-Founder and Principle of DataPrime, will share recent advances, new methods, emerging technologies, and research that facilitates speedier innovation and business impact though Analytics, Data Science, Machine Learning, and AI Engineering. Having developed Analytics Centers of Excellence for Fortune 100 Companies, growing and leading teams of over 400 data scientists, and being key advisor to government officials on the establishment of AI programs, Aaron will share what has made a difference across the hallmark projects that have revolutionized industry.

5 - Predictors of Choosing Business Analytics Concentration and Consequent Academic Performance

Sinjini Mitra, Associate Professor, California State University-Fullerton, ISDS Department, SGMH-4113, Fullerton, CA, 92831, United States, smitra@fullerton.edu, Zvi Goldstein, Bhushan Kapoor

In this talk, we present a comprehensive study of factors that affect students' choice of Business Analytics as the field of study via statistical and data mining techniques. Factors considered include personality traits including the "dark triad" and external factors such as interest or passion, lucrative job market, advice of faculty, experts and family, among others. Moreover, we also investigate which factors, particularly those related to personality traits, affect students' performance in this field, once selected.

CC- Room 209

Joint Session DM/Opt: Interplay between Machine Learning and Optimization.

Sponsored: Data Mining

Sponsored Session

Chair: Hari Bandi

Co-Chair: Hussein Hazimeh

1 - Statistical Hypothesis Testing via Robust Optimization

Hari Bandi, MIT, Cambridge, MA, 02139, United States, hbandi@mit.edu, Dimitris Bertsimas, Rahul Mazumder

In this work, we develop a novel framework for designing statistical hypothesis tests when given access to i.i.d. samples drawn under the considered hypothesis. We construct uncertainty sets for a testing sample using the Wasserstein distance with respect to the empirical distribution of the given sample. Using these uncertainty sets, we formulate a Sample Robust Optimization problem to design tests that maximally separate the two hypotheses using an affine combination of statistics. We prove the framework has finite and asymptotic optimality guarantees and show that it empirically performs better than existing hypothesis tests under distributional misspecification.

2 - Solving Large Scale Linear Programs in Machine Learning Tasks

Rahul Mazumder, Massachusetts Institute of Technology, Sloan School of Management, Cambridge, MA, 02139, United States

We consider a collection of problems popularly studied in Machine Learning and highdimensional statistics that can be cast as solutions to Linear Programs. In many modern applications these LP problems involve millions of decision variables and/or constraints—posing computational challenges. Examples include SVMs with L1 penalty, sorted L1 penalty, the Dantzig Selector, total variation denoising, etc. I wi Winchester, VA, ll describe how classical methods in large scale LP (e.g, column and constraint generation), when combined with approximate solutions available from surrogate problems (amenable to first order methods); can be surprisingly effective to solve these class of problems.

3 - Online Parameter Selection for Web-based Ranking via Bayesian Optimization

Kinjal Basu, Staff Software Engineer, LinkedIn Corporation, Sunnyvale, CA, United States, kbasu@linkedin.com, Deepak Agarwal, Souvik Ghosh, Ying Xuan, Yang Yang, Liang Zhang

Web-based ranking problems involve ordering different kinds of items to be displayed on a website or a mobile app. Usually, there are multiple conflicting objectives that we would want to balance. Constructing a serving algorithm that achieves the desired tradeoff is quite challenging. In this talk, we first show how we can model the balance criteria as a composite utility function over the space of control parameters in the ranking model. We then use Bayesian Optimization to obtain the optimal parameter values and illustrate its efficacy in the context of LinkedIn Feed. We show the effectiveness of our method by using both offline simulations as well as promising online A/B testing results.

4 - Multivariate Nonparametric Convex Regression: Algorithms and Theory

Wenyu Chen, Massachusetts Institute of Technology, Cambridge, MA, United States, wenyu@mit.edu, Rahul Mazumder

In general, nonparametric convex regression allows for more flexibility in modeling compared to multiple linear regression. It is an important model in econometrics, machine learning and operations research with many applications, such as fitting concave utility functions and giving convex approximation of a function. However, the nonparametric convex regression problem, written as the solution to a quadratic program with O(n2) linear constraints (n being the sample size), is difficult to solve and does not scale well. We develop an algorithm with provable linear convergence, and it can scale to $n \approx 50{,}000$.

Joint Session DM/Practice Curated: Inter-Disciplinary Topics Related to Data Mining: Lessons and Examples

Sponsored: Data Mining

Sponsored Session

Chair: Christopher Grubb

1 - Embedding Open Source NLP Tools in Production Systems

Emily Bicks, Deloitte Consulting, Arlington, VA, United States, embicks@deloitte.com

It's getting easier and easier to build open-source machine learning models to understand natural language. But generally these models can't easily be integrated into enterprise systems. This presentation showcases how Deloitte is integrating a supervised text categorization model trained on millions of records into an enterprise email system at a large federal agency. We will present details of our approach, which converts the machine learning pipeline into ONNX and embeds it into the .NET framework production system.

2 - Assisting Federal Agencies Declutter Search Results through Content Type Metadata Tagging

Isaac Stevens, Deloitte, Arlington, VA, United States, isstevens@deloitte.com

In order to assist a large federal agency in handling their high volume of Freedom of Information Act (FOIA) requests, a text categorization, semi-supervised learning model was implemented to identify and tag non-relevant news emails, allowing analysts to filter out these emails from search and analysis. Because keywords in FOIA requests often parallel closely with current events, filtering out these news updates greatly reduces search time for FOIA analysts looking for records pertinent to requests. This presentation discusses the business impact of using open-source NLP tools for content filtering.

3 - Fundamental Equilibrium Models for Commodity Markets

Jai Gopal, Specialist Leader, Deloitte, Los Angeles, CA, United States, jagopal@deloitte.com

MarketBuilder (MB) is a software system used to build fundamental, dynamic, microeconomic market models and calculate market clearing prices and quantities combining supply, transportation, demand, and other key economic constructs in a spatial market network. MB simulates goal-seeking behavior in the market. MB can be used to answer key business questions, strategies, consumption and depletion of competing resources, mark to market existing flow/capacity, asses market risks and support trading and arbitrage activities. MB is based on a graphical nodal network for solving nonlinear supply and demand curves in time-dependent, spatially diverse networks.

4 - Presenter

Ande Barry, Data Scientist, Deloitte Consulting, Washington, DC, United States

Positive-unlabeled (PU) learning addresses the concern of training binary classifiers on data that is either positive (P) or unlabeled (U). In these situations, negative data (N) can become nearly impossible to label, or gathering an abstract sample set of only PU data is significantly easier by comparison. This talk will discuss an approach to using positive-unlabeled data in training a text classification machine learning algorithm by using two step sample expansion techniques with python's Scikit-Learn package. As well, potential and past use cases of this method will be illustrated.

5 - Strategies for the Database Record Linkage Problem

Christopher C. Grubb, Grubb, Fairfax, VA, 22030, United States, chrisgrubb@me.com

Integration of data across databases and tables is often complicated by a lack of unique identifiers that are common across databases and tables. These 'record linkage problems' can be partially solved using methods that classify pairs of records as likely matches, unlikely matches, or as pairs that require human reviews. This presentation reviews heuristics and machine learning methods applicable to record-linkage problems that use text strings as comparison features between records. Performance comparisons (including algorithm runtime and classification/misclassification metrics) are included.

Joint Session AI & ML/Practice Curated: Fairness and Bias in AI/ML

Emerging Topic: Artificial Intelligence & Machine Learning

Emerging Topic Session

Chair: Swati Gupta, Georgia Institute of Technology, Atlanta, GA, 30332, United States

Chair: Vijay Kamble, University of Illinois at Chicago, Chicago, IL, 60611, United States

1 - On Preserving Non-discrimination When Combining Expert Advice

Thodoris Lykouris, PhD Candidate, Cornell University, Ithaca, NY, 14853, United States, teddlyk@cs.cornell.edu, Avrim Blum, Suriya Gunasekar, Nathan Srebro

Understanding the trade-offs involved in optimizing performance and avoiding discrimination against protected groups is essential to inform societally responsible decision-making. Aiming to understand the effect of adaptivity on this tug-of-war, we focus on sequential decision making when samples arrive online and do not follow distributional assumptions. We address the most basic extension of classical online learning that takes into account the goal of non-discrimination: "Given a class of predictors that are individually non-discriminatory (with respect to a particular metric), how can we combine them to perform as well as the best predictor, while preserving non-discrimination?".

2 - An Information Theoretic Look at Fair Machine Learning

Flavio P. Calmon, Harvard University, Cambridge, MA, United States, flavio@seas.harvard.edu

Machine learning (ML) algorithms are at risk of inheriting and reinforcing social biases and discrimination patterns present in the training data, which may reflect discrimination patterns existent in society at large. In this talk, we present a few information-theoretic results that build on rate-distortion theory and estimation theory to characterize the fundamental accuracy cost of ensuring fairness in ML. We delineate a few fundamental limits of non-discrimination in classification by studying fairness-constrained estimators. This approach informs a practical and scalable method for training fair classifiers. Work done jointly with Hao Wang, Shahab Asoodeh, and Wael Alghamdi.

3 - Delayed Impact of Actions in Multi-armed Bandit

Yang Liu, University of California, Santa Cruz, CA, United States, yangliu@ucsc.edu

Algorithms have been increasingly involved in decision making in our daily life. Oftentimes these decisions have influences on the subsequent rewards and in turn invalidate the assumption. For example, the capability to pay back a loan for people in a certain group might depend on historically how frequently that group has been approved a loan application. If banks keep rejecting loan applications to most people in a disadvantage group, it could create a feedback loop and further damage the chance of getting loans for people in that group. We study the impacts of actions in the multi-armed bandit framework, the classical sequential decision making framework that is particularly suitable for our study.

4 - On the Compatibility of Privacy and Fairness

Rachel Cummings, Georgia Tech, Atlanta, GA, 30332-0205, United States, Varun Gupta, Dhamma Kimpara, Jamie Morgenstern

In this work, we investigate whether differential privacy and fairness can be simultaneously achieved by a single classifier, using statistical notions of fairness, namely Equality of False Positives and Equality of False Negatives (EFP/EFN). We show that even under full distributional access, the constraint of differential privacy can preclude exact EFP/EFN. We then show the existence of a PAC learner which is differentially private and approximately fair (EFP/EFN) with high probability. Finally, we give an efficient algorithm for classification that maintains utility and satisfies both privacy and approximate fairness with high probability.

1 - Goal-based Recommendation

Weijie Jiang, PhD, Tsinghua University, Beijing, China, jiangwj.14@sem.tsinghua.edu.cn, Qiang Wei, Zachary Pardos

Learners are often faced with the scenario: given a goal for the future, and what they have learned in the past, what should they do now to best achieve their goal? We utilize deep learning to make inferences about how past actions correspond to future outcomes. We apply this technique to datasets both from a university setting in which courses can be recommended towards preparation for a target course, and from MOOCs in which course pages can be recommended towards quiz preparation. The proposed algorithm is applied to recommend actions the learner can take to maximize a desired future achievement objective.

2 - Recurrent Neural Networks for Cross-domain User Modeling

Sheng Li, University of Georgia, Athens, GA, United States

Understanding and predicting user behavior is critical for providing seamless user experiences as well as increasing revenue of service providers. Recently, thanks to the remarkable success of recurrent neural networks (RNNs), it has been widely employed for modeling user behaviors from sequential data. In this talk, I will introduce our recent work on RNNs based cross-domain user modeling. First, we introduce a practical domain switch problem, and propose a holistic recurrent neural network approach. Second, we leverage auxiliary unstructured log-trace data and propose a recurrent semantics memory network for user modeling. Future research directions on this topic will be discussed as well.

3 - Explainable recommendation with attribute network

Guannan Liu, Beihang University

Please check the mobile app for this abstract.

4 - Bullet Screen Assisted Video Analysis

Hongfu Liu, Brandeis University, Waltham, MA, United States

Bullet screen surges as a new form of video comments, which enables the audience to interact with the video contents, and gradually becomes the crucial component of videos. Although bullet screen has drawn more and more attention in the real-world scenarios, the related research is still in the void stage. In this project, we aim to explore the rich information of the bullet screen for video analysis. Specifically, we will focus on the sentiment and mine the relationship between bullet screen and static comments.

Joint Session Analytics/Practice Curated: People Analytics

Sponsored: Analytics

Sponsored Session

Chair: Margret V. Bjarnadottir, Reykjavik, 112, Iceland

Co-Chair: David Anderson, CUNY Baruch, Hoboken, NJ, 07030, United States

1 - The Role of Operations Research in Revolutionizing the Human Resource Department

Margret V. Bjarnadottir, University of Maryland, College Park, MD, 112, United States, margret@rhsmith.umd.edu, David Anderson

Analytics are changing all aspects of business - including the HR department. In this talk we discuss the role of, and the opportunity for Operations Research methodology in human resource management. We provide an overview of the development of People Analytics and future research opportunities.

2 - Addressing the Gender Pay Gap in Practice

David Anderson, Villanova School of Business, Villanova, PA, 07030, United States, David.Anderson@Villanova.edu, Margret V. Bjarnadottir

Companies are facing increasing pressure from employees, shareholders, and customers to measure and address gender pay gaps. In this paper, we discuss how employers can take steps to close gender pay gaps as fairly as possible at as low of a cost as possible. We discuss the policy implications and unintended consequences of focusing on the "unexplained" pay gap, as currently measured, using regression analysis. We further discuss different methods of measuring pay gaps specifically, and gender equality more generally across an organization, and the varying pressures that different regulations place on employers.

3 - A Multi-stage Model for High-volume Recruitment

Qing Li, Hong Kong University of Science & Technology, Dept. of ISOM, Clear Water Bay, Kowloon, Hong Kong, imqli@ust.hk, Lilun Du, Peiwen Yu

The process to recruit a total of n workers consists of multiple stages, each of which corresponds to an application deadline. The qualification of applicants is known only after they have submitted their applications. The offer acceptance yield is random, and it is undesirable if the total yield in the end is different from n. What is the optimal number of offers given in each stage? We formulate the problem as a Markov Decision Process, explore its convergence properties when n and the number of applicants in each stage are large, and test it with a data set.

1 - Finding Structures Planted in Random Graphs

Laurent Massoulié, Inria, Paris, France

The problem of finding structures planted in otherwise random graphs arises in many applications and gives rise to rich mathematical phenomena: By varying the strength of the planted signal, the problem may go from feasible to infeasible (an information-theoretic phase transition), and from polytime-feasible to polytime-infeasible (a computational phase transition). In this lecture we will cover results of this kind first for planted structures consisting in a planted partition, for which we will describe efficient spectral algorithms. We will then discuss phase transitions for detection and reconstruction of structures consisting in a planted tree graph.

2 - Efficient Random Graph Matching: Algorithms and Theory

Jiaming Xu, Duke University, Durham, NC, 47907, United States, jiaming.xu868@duke.edu

Random graph matching refers to recovering the underlying vertex correspondence between two random graphs with correlated edges. It offers a rich set of problems involving the interplay of optimization, random matrix theory, and information theory. This talk will present an overview and our recent results on this topic.

3 - Discussant

Bruce Hajek, University of Illinois, CSL, 1308 W. Main Street, Urbana, IL, 61801, United States

Extensions of community detection beyond the stochastic block model will be discussed.

Chair: Shipra Agrawal, Columbia University, New York, NY, 10027, United States

1 - Recent Advances and Challenges in Counterfactual Learning for Long-Term Decision Making

Adith Swaminathan, Microsoft, Redmond, WA, 98052, United States

Off-Policy Reinforcement Learning offers a useful framework for counterfactual reasoning when re-using the logs of an interactive system to train new policies to engage with users. We will describe recent work (with Yao Liu, Alekh Agarwal and Emma Brunskill; https://arxiv.org/abs/1904.08473, UAI'19) that describes a new class of off-policy estimators that work well for these temporally-extended interaction settings and demonstrates successful off-policy policy optimization. We will conclude by sketching three open problems in learning from logged interaction data.

2 - Smooth Contextual Bandits: Bridging the Parametric and Nonparametric Regret Regimes

Nathan Kallus, Cornell University, New York, NY, 1004 4, United States, kallus@cornell.edu, Yichun Hu, Xiaojie Mao

We study a non-parametric contextual bandit problem where the arms are Holder functions with smoothness parameter β. We show how this interpolates between two extremes that were previously studied in separation: non-differentiable bandits ($\beta\leq1$) and parametric bandits ($\beta\to\infty$). We develop a novel algorithm that carefully adjusts to all smoothness settings and achieves rate-optimal regret in either extreme as well as in between. In this sense, our results bridge the gaps both between the existing literatures on parametric and non-parametric contextual bandits and between bandit algorithms that leverage global and local reward information.

3 - Discussion

Shipra Agrawal, Columbia University, Industrial Engnr and OR, 423 S. W. Mudd Building, New York, NY, 10027, United States

Load Balancing, Routing and Caching in Networks and Data Centers

Sponsored: Applied Probability

Sponsored Session

Chair: Siva Theja Maguluri, ISyE Ba Tech, Atlanta, GA, 30339, United States

1 - Achieving Zero Queueing Delay for Parallel Jobs

Weina Wang, Carnegie Mellon University, Pittsburgh, PA, 15213, United States

Zero queueing delay is highly desirable in large-scale load-balancing systems. Existing work has shown that it can be asymptotically achieved by using the celebrated power-of-d-choices policy with a probe ratio d = omega(1/(1-lambda), and it is impossible when d = O(1/(1-lambda)), where lambda is the load of the system. In this work, motivated by the predominant use of parallel computing, we study the model where each job consists of a batch of k parallel tasks. We show that in this model, zero queueing delay can be achieved with a probe ratio d = omega(1/((1-lambda)log(k)), which is smaller than the lower bound in the non-parallel model.

2 - Optimal Service Elasticity in Large Scale Distributed Systems

Debankur Mukherjee, Georgia Institute of Technology, Atlanta, GA, 02109, United States, debankur.mukherjee@isye.gatech.edu, Sem C. Borst, Souvik Dhara, Johan S.H. van Leeuwaarden, Aleksandr Stolyar

A fundamental challenge in large-scale systems is to achieve efficient server utilization and limit energy consumption, while providing excellent performance. We propose a joint auto-scaling and load balancing scheme, which does not require any global queue length info or explicit knowledge of system parameters, and yet provides near-optimal service elasticity. Specifically, we prove that both the waiting time of tasks and the relative energy consumed by idle servers vanish in the limit. At the same time, the scheme operates in a distributed fashion and involves only constant communication overhead per task, ensuring scalability in massive data center operations.

3 - Heavy-traffic Delay Optimality in Pull-based Load Balancing Systems: Necessary and Sufficient Conditions

Xingyu Zhou, The Ohio State University, Columbus, OH, United States, Jian Tan, Ness Shroff

In this talk, we consider a load balancing system under a general pull-based policy. In particular, each arrival is randomly dispatched to one of the servers with queue length below a threshold; if none exists, the arrival is randomly dispatched to one of the entire set of servers. We are interested in the fundamental relationship between the threshold and the delay performance in heavy traffic. To this end, we establish both necessary and sufficient conditions on the threshold for delay optimality in heavy traffic. In particular, the sufficient condition (i.e., a logarithmic growth rate of the threshold) resolves a long-standing open conjecture by Kelly and Laws.

4 - How to Achieve Delay Reduction with Near-zero Cache?

Fei Wu, The Ohio State University, Columbus, OH, United States, Ness Shroff

The fundamental challenge in achieving multicast gains is that although popular contents may be requested by multiple users, users may request popular contents at different times. In this work, we ask the following question: Can we achieve performance improvement even with very limited cache space? We develop a new analytical framework such that the asymptotic delay performance can be characterized given a load-adaptive caching and scheduling policy in the heavy-traffic regime. We show that even when the cache size is asymptotically zero in the heavy-traffic regime, predictive caching could achieve a significant delay reduction, compared with the optimal policies without predictive caching.

1 - Timely After-Sales Service and Technology Adoption: Evidence from the Off-Grid Solar Market in Uganda

Amrita Kundu, London Business School, Regent’s Park, PhD Office - MSO, London, NW1 4SA, United Kingdom, Kamalini Ramdas

In this paper, we examine to what extent timely after-sales service impacts technology adoption in emerging markets. Using detailed customer-level sales and service data from a leading solar distribution company operating in Uganda, we develop a fixed effects base specification and two geo-spatially based instrumental variables specifications. We find that timely after-sales service experienced by existing customers is a strong driver of purchase by first-time users. Further, the number of customers acquired through referrals from an existing customer depends on the referring customer’s service wait time. This provides evidence of a strong word-of-mouth channel of information sharing.

2 - Can Big Data Cure Risk Selection in Healthcare Capitation Programs?

Zhaowei She, Georgia Institute of Technology, Atlanta, GA, United States, Turgay Ayer, Daniel Montanera

We analyze the risk selection problem in Medicare Advantage (MA), the largest capitation payment program in the U.S. healthcare market. In practice and current literature, the observed risk selection in MA is primarily attributed to data limitations and low explanatory power (e.g. low R^2) of the current risk adjustment design. However, our study shows that MA cannot eliminate risk selection even if its risk adjustment design becomes informationally perfect (e.g. R^2 =1) in the age of big data. To address risk selection in capitation programs, payers should not solely rely on big data and advanced ML algorithms, but need to consider mechanisms other than pure statistical risk adjustment designs.

3 - Dynamic Learning and Pricing with Model Misspecification

Milashini Nambiar, Massachusetts Institute of Technology, Cambridge, MA, 02142, United States, David Simchi-Levi, He Wang

We study a multi-period dynamic pricing problem where demand depends on time-varying contextual information. We are especially interested in demand model misspecification and show that it can cause inconsistent price elasticity estimates and suboptimal pricing decisions. We thus propose a “random price shock” (RPS) algorithm that estimates price elasticity by dynamically generating randomized price shocks. RPS has strong theoretical performance guarantees, and offline simulations on a fashion retail dataset demonstrate average revenue gains of 8-20% over competing algorithms.

1 - Dynamic Learning and Rational Customers in Services

Nur Sunar, UNC, 1604 Village Crossing Drive, Chapel Hill, NC, 27517, United States, nur_sunar@kenan-flagler.unc.edu, Yichen Tu, Serhan Ziya

We consider a single-server queueing system where customers make joining and abandonment decisions when a service characteristic is unknown. We study different ways in which customers process service-related information, and how these impact the performance of a service provider. Specifically, we analyze forward-looking, myopic and naïve information processing behaviors by customers. There is a rich literature that establishes that forward-looking customers are detrimental to a firm in settings different than queueing. In contrast to this common understanding, we prove that for service systems, forward-looking customers are beneficial to the firm under certain conditions.

2 - Hospital Readmissions Reduction Program Does Not Provide the Right Incentives: Issues and Remedies

Kenan Arifoglu, UCL, London, United Kingdom, k.arifoglu@ucl.ac.uk, Hang Ren, Tolga Tezcan

The Hospital Readmissions Reduction Program (HRRP) reduces Medicare payments to hospitals with higher-than-expected readmission rates. HRRP has three distinct features, i.e., multiplier, capped penalty, and no-bonus payment. We use a principal-agent model to understand the impact of each of these features and show that: (i) HRRP over-penalizes hospitals with excess readmissions because of the multiplier; (ii) having a penalty cap can curtail the effect of financial incentives and result in a no-equilibrium outcome when the cap is too low; and (iii) not allowing bonus payment leads to many alternative symmetric equilibria, including one where hospitals exert no effort to reduce readmissions.

3 - Spatial Pricing: An Empirical Analysis of Taxi Rides in New York City

Nasser Barjesteh, University of Chicago, Chicago, IL, United States, barjesteh@chicagobooth.edu, Baris Ata, Sunil Kumar

We study how spatial pricing and search friction can impact the taxi market in NYC. We use a mean field model, in which taxi drivers strategically search for customers, taking into account the spatial and temporal distribution of supply and demand as well as the spatial prices. Our model captures the interplay between spatial pricing and search friction. Spatial pricing can incentivize relocation of taxis to a neighborhood while the use of mobile applications can alleviate search friction within that neighborhood. We fit our model to a dataset of taxi rides over four years and conduct counterfactual studies to explore how spatial pricing impacts supply, demand, consumer welfare, and drivers' profit.

4 - Optimal Scheduling of Proactive Care with Patient Deterioration

Yue Hu, Columbia Business School, New York, NY, United States, YHu22@gsb.columbia.edu, Carri Chan, Jing Dong

Healthcare is a limited resource environment where the most severe patients are typically prioritized. However, there has been a growing interest in preventative care. While providing care for patients when they are less critical could mean that fewer resources are necessary to return them to a healthy state, utilizing limited capacity for patients who may never need it also takes the capacity away from other more critical patients. To understand this tension, we propose a two-class queueing model where a moderate class patient who does not receive treatment may recover or deteriorate to an urgent class. In this setting, we characterize how moderate and urgent patients should be prioritized for care.

1 - User Privacy in Platforms

Ruslan Momot, HEC Paris, 1 Rue de la Liberation, Jouy-en-Josas, 78350, France, momot@hec.fr, Itay Fainmesser, Andrea Galeotti

We build an equilibrium model of platform privacy. The users experience direct utility from using the platform, however, they are also susceptible to strategic self-interested, criminals who use the information users put on the platform. The platform, in turn, chooses the amount of data it stores and shares with business partners, and its security level. We characterize the equilibrium activity levels of users and criminals, and the resulting privacy levels, as well as how these are affected by different attributes of the platforms, such as the strength of network effects. We also investigate the extent to which a competition among platforms might affect equilibrium privacy levels.

2 - A Risk-ratio Procedure for Consumer Choice-based Demand Estimation for Sales Transaction Data

Anran Li, London School of Economics and Political Science, Department of Management, New Academic Building, LSE, London, WC2A 2AE, United Kingdom, A.Li26@lse.ac.uk, Kalyan Talluri

We consider the estimation problem for a retailer who sells an assortment of products but records only sales transactions; i.e., the no-purchased alternative is never observed. Consumer choice is captured by the Multinomial logit discrete choice model. Out goal is jointly estimating arrival rate and the choice model parameters from sales transaction data without observing no-purchases. We propose a Two-Step estimation approach. Comparing with all the existing methods in the literature, our algorithm requires least amount of information. Moreover, in extensive numerical testing and comparison we find that our method is most robust, especially when the assortments are endogenized.

3 - Recommender Systems on Platforms

Renyu Zhang, New York University Shanghai, Shanghai, 200122, China, renyu.zhang@nyu.edu, Xuan Wang, Dennis Zhang

We study how a recommender system could match the demand and supply of a two-sided platform, which seeks to maximize the weighted number of transactions between consumers and producers. The traditional recommender system has been focusing on identifying and recommending the producers of the highest qualities. Albeit optimal when producers have unlimited capacities, such a recommender system may result in substantial optimality losses in the presence of producer capacity constraints and producer quality evolution, especially when the demand and supply are balanced.

4 - Optimizing Assortment Size and Variety in Online Platforms

Abhinav Sinha, Postdoctoral Researcher, Columbia University, New York, NY, 10027, United States, as5561@columbia.edu, Yash Kanoria, Fanyin Zheng, Zhenyu Lai

Many online marketplaces face the challenge of determining the right assortment size and variety. Using data from a large online e-retailer of diverse home goods, we develop a systematic structural estimation approach to estimate a discrete choice model of customer purchase behavior that also incorporates choice paralysis that customers may face on a platform with too many products. We quantify the causal impact of assortment size and product variety on likelihood of purchase and use the estimated model to infer the optimal assortment size and product variety for each category on the platform. Finally, we design and run an experiment to validate our estimated model, its predicted counterfactuals.

Environmental, Economic and Social Issues in Supply Chain

Sponsored: Manufacturing & Service Oper. Mgmt/Supply Chain

Sponsored Session

Chair: Greys Sosic, University of Southern California, Los Angeles, CA, 90089-0809, United States

Co-Chair: Hailong Cui, University of Southern California, Los Angeles, CA, 90089-0809, United States

1 - The Environmental Impact of the Advent of Online Grocery Retailing

Ekaterina Astashkina, INSEAD, Boulevard de Constance, Fontainebleau, 77305, France, ekaterina.astashkina@insead.edu, Elena Belavina, Simone Marinesi

To study the environmental impact of the advent of online grocery retailing, we build a stylized 3-tier model of geographically-dispersed traditional and online fresh grocery retail chains. We analytically compare food waste and transportation emissions before & after the advent of online grocery retail. We isolate three key factors that drive the difference: (i) which households switch to online shopping, (ii) their shopping patterns, and (iii) how the first two factors change where inventories are held. Numerical calibration using industry and demographic data reveals that in most US cities the advent of online grocery should be beneficial, leading to an eventual 8-41% reduction in emissions.

2 - The Resilience of Airline Networks to Severe Weather

Beverly Osborn, The Ohio State University, Columbus, OH, United States, osborn.259@osu.edu, Hyunwoo Park, Christian Blanco

Climate change can negatively impact the airline industry. We empirically study the relationship between airline network structure and the impact of severe weather events using data from the Bureau of Transportation Statistics from 2003-2017. We measure network concentration using the Herfindahl-Hirschman Index and compare the propagation of delays between different networks.

3 - Donor Funding for Drug Availability

Iva Rashkova, Washington University in St Louis, St. Louis, MO, United States, irashkova@wustl.edu

We study the decision of a donor subsidizing health programs in a developing country by allocating a fixed procurement budget between the public and private distribution channels. The donor's objective is to maximize consumption and funding can be a lump-sum disbursement to the public channel, per-unit subsidy to the private channel, or both. We show that that the two types of funding exhibit a risk-hedging synergy. Using real data from 48 African countries, we show that expected consumption could be improved by up to 24% if the budgets were reallocated to take advantage of this synergy.

4 - Rebound Effects under Manufacturer's Intervention into Secondary Market

Hailong Cui, University of Southern California, Marshall School of Business, Data Sciences and Operations, Los Angeles, CA, 90089-0809, United States, HailongC@marshall.usc.edu, Greys Sosic

We study the manufacturer's intervention in the used product market. Specifically, the manufacturer purchases used products from consumers in the form of trade-in, then refurbishes such products and resells them to consumers. We study the optimal pricing, quality of refurbishing, and the implications on firm's profit and consumer welfare.

1 - Service Provision in Distribution Channels

Haresh B. Gurnani, Wake Forest University, Winston Salem, NC, 27106, United States, gurnanih@wfu.edu, Shubhranshu Singh, Sammi Tang, Huaqing Wang

Consumers may need help using an inherently complex or information-intensive product after purchase. This paper studies the incentive for a manufacturer or a retailer to invest in pre-sales service effort that would reduce the consumer's likelihood of seeking after-sales support. Because providing pre-sales and after-sales support would incur costs for the provider, it is not evident whether the manufacturer or the retailer would be more effective in doing so, and whether both services should be provided by the same firm.

2 - Data-driven Menu Recommendation System of Meal-kit Services Using Machine Learning

Aysun Mutlu, McGill University, Montreal, QC, H2X2B7, Canada, aysun.mutlu@mail.mcgill.ca, Mehmet Gumus, Saibal Ray

Meal-kit services are a rapidly growing area in the food sector. This study empirically analyses recipe popularity in this sector from various perspectives of a particular meal-kit service provider. Main approaches exploited in the study are text and data analysis for relabeling, customer segmentation and recipe categorization. This study forms the backbone of building an improved menu recommendation system for the provider.

3 - A Model for Value Co-Creation with Multi-Producer Bundles

Hemant Bhargava, University of California, Davis, CA, United States, hemantb@ucdavis.edu

In many markets (e.g., in-home video entertainment), value is co-created by multiple producers and their outputs sold as a common bundle by a producer-consortium or a retailer. This paper develops an economic model to study demand, production, and revenue-sharing in such markets and examines market dynamics covering both the causes and effects of changes in industry structure.

4 - Membership Design for Subscription-based Retailing

Yiwei Wang, University of California-Irvine, Paul Merage School of Business, Irvine, CA, 92617, United States, willwangyiwei@gmail.com, Jeannette Song

An innovative trend, called subscription-based retailing (selling access of physical product, to members for a fixed fee) has gained increasing popularity. In this paper, we partner with Y-Closet, a leading fashion subscription provider, to explore the optimal design of membership structure under such business model. Our paper was motivated by real life observations and data analysis, and has both theoretical and practical impact.

Chair: Gangshu Cai, Santa Clara University, Santa Clara, CA, 95053, United States

1 - A New Firm Entry under Capital Constraint

Wenhui Zhao, Shanghai Jiao Tong University, 1954 Huashan Road, Shanghai, 200030, China, Guanmei Liu, Xuan Zhao

We study whether and how an entrant can enter a product market and compete with a dominant incumbent, when they both are capital constrained and need to borrow loans from a credit market. In the case that the credit market is monopolistic, the bank may reject the entrant's loan request, or "deter" her entry by providing the incumbent a lower interest rate. While a competitive credit market may favor a weak entrant, we show that a monopolistic credit market welcomes a strong entrant. Finally, we provide insights for the entrant on how to prepare working capital under a monopolistic credit market.

2 - The Effects of Stock-based Incentives on Inventory Management

Qi Wu, Case Western Reserve University, Cleveland, OH, 44122, United States, qxw132@case.edu, Guoming Lai

We develop a stylized model which shows that in the presence of an interest in the stock price, managers overinstall inventory when it can either inflate the sales or deflate the reported cost of goods sold (COGS) even if the market anticipates such actions. We analyze the joint as well as the marginal effect of stock-based incentives and the costs of using inventory to manage earnings, which may provide useful implications for the detection of inventory distortion and the design of management incentive plans. We then conduct an empirical analysis based on the financial data of the U.S. listed retailers and manufacturers.

3 - Strategic Financing and Information Revelation Amid Market Competition

Xinyi Zhao, Stern School of Business, New York University, 44 West 4 Street, New York, NY, 10012, United States, xzhao@stern.nyu.edu, Guoming Lai, Wenqiang Xiao

Under information asymmetry, a firm in financial need may have an incentive to either over-borrow or under-borrow due to financing effect and competition effect. We investigate the determinants of a firm's financing and information revelation strategy. First, under public financing, we discover that firm's decision is driven by its internal capital level and the market competition intensity. There exists a unique separating PBE under three regimes and the two averse incentives can be neutralized with some counter-intuitive results. Second, we find out the unique PBE under private financing. Last, we compare private financing with public financing and examine the equilibrium outcome.

4 - E-commerce Platform Finance for Small and Medium-sized Enterprises with Dual-channel

Xun Xu, California State University, Stanislaus, California State University-Stanislaus, One University Circle, Turlock, CA, 95382, United States, xxu@csustan.edu, Nina Yan, Zhineng Chen, Xiuli He

Through a game theoretical approach, taking consumers' channel preference into consideration, this study examines the supplier's optimal supply quantity for each channel and e-commerce platform's optimal interest rate and loan limit. We examine this in four scenarios based on supplier's financing needs and e-commerce platform's financing offering. We find supplier's channel strategy depends on her financial constraints, loans offered by platform, the channel's profit margin, and consumers' channel preferences. This study proves the value-added effect of e-commerce's financing service and provides important implications for supplier's distribution channel strategies.

1 - Inclusive Manufacturing: Maximizing Disability Diversity, Cultural Diversity and Productivity

Ying (Maggie) Zhang, Clemson University, Clemson, SC, United States, ying6@clemson.edu, Sriram Narayanan, Kalyanmoy Deb, Tharo Soun

In this study, the impact of employing individuals with disabilities in garment manufacturing cells on overall team productivity was examined. Specifically, a multi-objective assignment problem with precedence and skill constraints was used to optimize productivity, disability diversity and cultural diversity across multiple garment types that vary in complexity levels. The analysis sheds light on how firms can employ people with disabilities in their organizations, and realize superior productivity. The results are stable and replicable across multiple garments the firm manufactures.

2 - Extended Producer Responsibility and Supplier Selection

Yuqi Peng, University of South Carolina, Columbia, SC, United States, Yuqi.Peng@grad.moore.sc.edu, Yan Dong

With the increasing public consciousness of product recycling and waste management, firms are encouraged or required to take the responsibility of end-of-life products, a.k.a extended producer responsibility (EPR). However, implementing EPR initiatives such as take-back or E-waste reduction is costly and requires coordination in a supply chain. We consider that EPR initiatives may play an important role in a focal firm's supplier selection decision. In this study, we empirically test if a firm's EPR initiatives affect the likelihood to be chosen as a supplier.

3 - Consistent Allocation of Emission Responsibility in Energy Supply Chains

Sanjith Gopalakrishnan, University of British Columbia, Vancouver, BC, Canada, sanjith.gopalakrishnan@sauder.ubc.ca, Daniel Granot, Frieda Granot

Canada's federal government, since 2016, factors in upstream emissions during the environmental impact assessment of energy projects. Motivated by the regulation, we adopt a cooperative game model and propose the nucleolus as a mechanism to apportion upstream emissions. It avoids the distortionary effects of double counting and exhibits a consistency property that is significant in a context wherein energy supply chains span multiple legal jurisdictions. We develop a polynomial time algorithm and further derive it as the unique subgame perfect equilibrium to a non-cooperative game induced by two easily stated and verifiable policies thereby lending a self-implementing policy framework.

4 - Does Environmental Performance Predict Quality Performance at FDA-regulated Plants?

In Joon Noh, Ohio State University, Columbus, OH, United States, noh.69@buckeyemail.osu.edu, Christian Blanco, John Gray, Gopesh Anand

Does a plant's performance in one regulatory domain predict its performance in another? To study this, we merge pharmaceutical/medical device plant-level outcomes related to environmental performance (from the Environmental Protection Agency [EPA]) and quality performance (from the Food and Drug Administration [FDA]). We explore whether, when, and how these two dimensions of performance are related.

Decision Analysis Society Awards

Sponsored: Decision Analysis

Sponsored Session

Chair: Karen Jenni, U.S. Geological Survey, Wheat Ridge, CO, 80033, United States

1 - Student Paper Award

Asa Palley, Indiana University, Bloomington, IN, 47405, United States

The Student Paper Award is given annually to the best decision analysis paper by a student author, as judged by a panel of the Decision Analysis Society of INFORMS. Students who did not complete their PhD. prior to May 1, 2018 are eligible for the 2019 competition. The winner and finalists will be recognized and the winner will give a condensed presentation of their paper.

2 - Publication Award

Canan Ulu, Georgetown University, McDonough School of Business, Operations and Information Management Area, Washington, DC, 20057, United States

3 - Decision Analysis Practice Award

Michael C. Runge, USGS Patuxent Wildlife Research Center, 12100 Beech Forest Rd, Laurel, MD, 20708, United States

The Decision Analysis Practice Award is awarded jointly by DAS and the Society of Decision Professionals to the best example of decision analysis practice as judged by the Decision Analysis Practice Award Committee. The purpose of the award is to publicize and encourage outstanding applications of decision analysis practice. We will present the finalists and this year's winner.

4 - Frank P. Ramsey Medal

Jason R.W. Merrick, Virginia Commonwealth University, Richmond, VA, 23284, United States

The Ramsey Medal of the Decision Analysis Society is awarded for distinguished contributions in decision analysis. Distinguished contributions can be internal, such as theoretical and procedural advances in decision analysis, or external, such as developing or spreading decision analysis in new fields. We will introduce the 2019 Ramsey Medal winner, followed by a presentation by the winner.

Methodological Improvements and Innovative Applications in MCDM

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Cristiano Cavalcante, Universidade Federal de Pernambuco, Recife Pernambuco, 52070-080, Brazil

Co-Chair: Adiel Teixeira De Almeida, Universidade Federal de Pernambuco, Universidade Federal de Pernambuco, Recife PE, 50630-970, Brazil

1 - A Multicriteria Model to Support Decisions on Investments in Maintenance Quality

Alexandre Alberti, PhD student, UFPE, Recife, Brazil, alexandre.emc091@gmail.com, Cristiano Cavalcante

Maintenance quality can have a significant impact on the performance of a maintenance policy. The investment in higher quality maintenance can be done in different ways, for example by improving the quality of replacements or inspections. Previous works has shown how mathematical models can be used to obtain guidelines for such an investment, considering only the cost criterion. In this work, we present a multicriteria model based on cost and risk criteria, which can be used to obtain such guidelines. The results demonstrate that the multicriteria model can lead to different orientations.

2 - Solving Multicriteria Ranking Problems Based on Partial Information with FITradeoff Method

Eduarda Frej, PhD, UFPE - Universidade Federal de Pernambuco, Recife, Brazil, eafrej@cdsid.org.br, Adiel Teixeira De Almeida

This work aims to presented a methodological tool for solving multicriteria decision making/aiding (MCDM/A) problems in the scope of the ranking problematic using partialinformation about the decision maker's preferences with the FITradeoff method. The process is conducted throughout an interactive decision support system (DSS), and theranking of the alternatives is computed based on pairwise dominance relations, which are obtained throughout linear programming. The DSS presents graphical visualization ofpartial results at any step, in order to facilitate the process for the decision maker.

3 - Maintenance Planning for Electrical System: A Multicriteria Perspective

Cristiano Cavalcante, Universidade Federal de Pernambuco, Rua Antonio de Castro N. 61, Apartment 701, Recife Pernambuco, 52070-080, Brazil, cristianogesm@gmail.com, Augusto Rodrigues, Heldemarcio Ferreira

We propose a multicriteria decision model to support the definition of maintenance planning for electrical system. The model consider important criteria for the performance of substantion. The downtime indirectly measures the degree of undesirability of the duration of interruptions on the energy delivery service; The cost criterion takes into account aspects such as inspection cost, cost of system repair and cost arising from the failure; The probability criterion aims to reduce the chances of a failure occurring through maintenance actions, and also becomes a way to avoid serious consequences. The model allows the decision-maker takes decision with a broader perspective about the problem.

4 - Multi-criteria Decision Model to Support the Maintenance Policy for Circuit Breakears in an Electrical Substation

Rodrigo Sampaio Lopes, assistant Professor, Federal University of Pernambuco, Avenida Cicero Araujo 349, Caruaru-PE, 55021330, Brazil, rodrigoengep@gmail.com, Cristiano Cavalcante

The energy systems are composed of several protection systems that have the function of isolate a fault and protect critical components. In this study we describe the decision problem to establish the frequency of inspection and replacement actions for the circuit breaker. We propose a multi-criteria model considering the preference of the decision maker about the risk and cost criteria and addressing the veto for alternatives. The steps to implement the model are applied to a circuit breaker in a pilot substation in Brazil. The results show the advantages of considering more than one criterion and the preference of the decision maker.

Joint Session Not-for Profit/Policy and Gov't/Practice Curated: Operations Research in Public Education

Emerging Topic: Humanitarian and NotforProfit Operations

Emerging Topic Session

Chair: Sebastien Martin, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States

1 - Informal Mentoring and Teacher Turnover

Samantha Meyer Keppler, University of Michigan, Ann Arbor, MI, 48103, United States, Stefanus Jasin, Damian Beil, Minmin Zhang

It is well-established that novice teachers are more likely to stay at their school when they have colleagues who they can turn to for advice as informal or formal mentors. Combining the vast mentoring literature with workforce planning in operations, we show analytically that schools can be in a persistent state of high turnover when they cannot retain teachers long enough to become mentors, as high turnover means fewer mentors which means even higher turnover - a "turnover snowball." We provide managerial and policy insights as to where to focus retention efforts to get schools over the tipping point in teacher retention, so they can maintain enough mentors and reduce turnover further on their own.

2 - A Bounded Formulation for the School Bus Scheduling Problem

Liwei Zeng, Northwestern University, IEMS Department, Evanston, IL, 60208, United States, Karen Smilowitz, Sunil Chopra

This paper proposes a new formulation for the school bus scheduling problem (SBSP) which optimizes starting times for schools and associated bus routes to minimize transportation cost. Specifically, the problem determines the minimum number of buses required to complete all bus routes under the constraint that routes for the same school must arrive within a set time window before that school starts. We present a new integer linear programming (ILP) formulation for this problem which is based on a time-indexed formulation. We develop a randomized rounding algorithm based on the linear relaxation of the ILP that yields near-optimal solutions for large-scale problem instances.

3 - Optimizing Schools' Start Times

Sebastien Martin, Lyft, NYC, NY, 02139, United States, 92sebastien@gmail.com

Spreading start times allows school districts to reduce transportation costs by reusing buses between schools. However, assigning each school a time involves both estimating the impact on transportation costs and reconciling additional competing objectives. These challenges force many school districts to make myopic decisions, leading to an expensive and inequitable status quo. We propose the first algorithm to jointly solve the school bus routing and bell time selection problems. Our application in Boston led to $5 million in yearly savings and to the unanimous approval of the first school start time reform in thirty years.

Meet the Service-related Journal Editors

Sponsored: Service Science

Sponsored Session

Chair: Roland T. Rust, University of Maryland, College Park, MD, 20742, United States

1 - Meet the Service-related Journal Editors

Roland T. Rust, University of Maryland, Robert H. Smith School of Business, University of Maryland-College Park, College Park, MD, 20742, United States

This session features editors from four top journals that seek to publish the leading service research. The session features Saif Benjaafar (Editor-in-Chief of Service Science), Mike Brady (Editor-in-Chief of the Journal of Service Research), PK Kannan (Editor-in-Chief of the International Journal of Research in Marketing) and Rob Palmatier (Co-Editor of the Journal of Marketing). Each Editor will discuss what kind of articles his journal seeks, and will describe how best to craft a publishable service research article.

Panelists

- Robert W. Palmatier, PhD, University of Washington, WA, United States
- Saif Benjaafar, University of Minnesota, Department of Industrial and Systems Engr, Minneapolis, MN, 55419, United States
- Pallassana K. Kannan, University of Maryland-College Park, The Robert H. Smith School of Business, Department of Marketing, College Park, MD, 20742-1815, United States
- Michael K. Brady, PhD, Florida State University, FL, United States

Data-Driven Resource Planning

Sponsored: Service Science

Sponsored Session

Chair: Haitao Li, Univ of Missouri-St Louis, St Louis, MO, 63121-4400, United States

1 - Scheduling with a Maintenance Activity to Minimize the Maximum Late Work

Yao-Wen Sang, Northwestern Polytechnical University, Xi'an, China, Junqiang Wang

We schedule n independent jobs on a single machine with a flexible maintenance activity. The late work of a job is the amount of processing of the job that is performed after its due date. The objective is to minimize the maximum late work, Vmax. We prove the problem with maintenance activity is NP-hard and propose a pseudo-polynomial dynamic programming algorithm. For the approximability of the problem, we prove that there is no polynomial (1+)-approximation algorithm. After modifying the objective of our problem to Vmax+a, we can design a FPTAS for this modified problem. For the special case without maintenance activity, a polynomial time algorithm is provided.

2 - Data-Driven Optimization for Agile Project Operations

Chidu Subbiah, EdwardJones, Saint Louis, MO, United States, csubbiah@mail.umsl.edu, Haitao Li, Joseph Simonis, Andrea Hupman, Donald C. Sweeney, Joshi Kailash

In Agile IT Project Management practices, there is an important need to make better scheduling and resource allocation decisions to facilitate on-time and on-budget project deliveries. Our work contributes to the research literature and practice in service industry by providing a new data-driven analytical approach built upon predictive analytics for better estimating the project efforts, in conjunction with optimization-based prescriptive analytics using mixed-integer linear programing (MILP). A real-world application of the proposed models at a large services firm is showcased as part of the talk.

3 - Optimizing Large-Scale Stochastic Resource Planning

Haitao Li, Univ of Missouri-St Louis, College of Business Administration, St Louis, MO, 63121-4400, United States, lihait@umsl.edu, Vargas Marcos, Santos Cirpriano

A professional service organization (PSO) often needs to assign a myriad of workforce resources to project jobs, which is known as resource planning (RP). We develop an integrated stochastic resource planning (SRP) model to optimize the here-and-now multi-attribute resource-job assignment decision, while accounting for the expected costs of job loss and resource idleness. We tackle the large-scale SRP by transforming it to a minimum-cost matching problem in an unbalanced bipartite graph. Comprehensive computational experiments show first that our SRP solutions provide significant value over a deterministic certainty-equivalent approach.

4 - Clustering Analysis of Crash Report Data for Identifying and Characterizing Representative Scenarios of Vehicle Crashes

Yu Li, Missouri University of Science and Technology, Rolla, MO, 65401-4587, United States, ylkqm@mst.edu, Md. Al-Amin, Mohammad Karim, Ruwen Qin

Univariate data analysis for identifying causes of vehicle crashes is not sufficient in supporting decision-making. Assisting drivers in recognizing risk scenarios in a real-time manner is in a great need for the safety purpose, which requires a thorough understanding of causes of crash and the concise characterization of risk scenarios. This study retrieved crash report data from FARS and used descriptive analysis to identify risk factors that not only contribute to crashes but can be captured by a vision-based system.

Sharing Economy in Service Industry

Sponsored: Service Science

Sponsored Session

Chair: Paolo Roma, University of Palermo, Palermo, Italy

Co-Chair: Paolo Letizia, University of Tennessee, Knoxville, TN, 37996, United States

Co-Chair: Tiziana D'Alfonso, Sapienza University of Rome, Italy

1 - Manufacturing As a Service

Gokce Esenduran, Purdue University, West Lafayette, IN, 47907, United States, gesendur@purdue.edu, Alok R. Chaturvedi, Gaurav Nanda

We study Manufacturing-as-a-Service (MaaS) in a sharing economy context. Motivated by the Project Saksham that was implemented in the state of Jharkhand in India, MaaS brings mobile manufacturing as Factories on Wheels (FOWs) to low-income communities. Called labor firms, these communities have an opportunity to make/sell products and achieve economic growth and stability. To mainstream MaaS in the US, we model the interaction between a social planner, labor firms, and FOWs. Analyzing this problem, we identify how the total welfare progresses, under what conditions the business model would succeed, and what the breakeven point would be from social planner's, labor firms', and FOWs' perspective.

2 - Is Sharing Economy Green?

Paolo Letizia, University of Tennessee, Knoxville, TN, 37996, United States, pletizia@utk.edu, Paolo Roma, Esther Gal-Or, Fahimeh Rahmanniyay

We study the profitability and environmental impact of sharing economy, considering the different incentives of the manufacturer, sharing platform, and consumers. The environmental impact is characterized by the trade-off between the number of products sold and the usage of each product.

3 - The Impact of Sharing Economy on Incumbents' Price and Quality Decisions

Paolo Roma, University of Palermo, Viale delle Scienze, Palermo, Italy, Tiziana D'Alfonso

We study how the sharing economy influences incumbents' price and quality decisions. Specifically, we focus on the hospitality industry and on a duopoly of incumbents. We show that the entry of a sharing economy platforms may have nontrivial effects on both price and quality decisions, and in turn on profitability, of incumbents due to the two contrasting effects of competition and consumers' income increase.

Optimization in Matching Markets

Sponsored: Auction and Market Design

Sponsored Session

Chair: Peng Shi, University of Southern California, University of Southern California, Los Angeles, CA, 90064, United States

1 - Optimizing for Distributional Goals in School Choice Problems

Aaron Bodoh-Creed, PhD, University of California, Berkeley, CA, United States

I investigate three goals of school choice: welfare, encouraging neighborhood schools, and diversity. I use optimization problems to find the best stable and incentive compatible match for any combination of these objectives. I apply my framework to data from Boston Public Schools. If the mechanism conditions on demographics, the improvement (relative to the status quo) in student welfare is equivalent to moving 291 students (out of 3,479) to schools one rank higher in their preference lists. Improvements in the distributional goals can be made (e.g., increasing enrollment in neighborhood schools by 50%) without reducing welfare or diversity.

2 - Optimal Priority-Based Matching Mechanisms

Peng Shi, University of Southern California, Los Angeles, CA, 90064, United States, pengshi@usc.edu

I develop a tractable methodology for designing an optimal priority system for assigning agents to heterogeneous items while accounting for choice behavior. The space of mechanisms being optimized includes deferred acceptance and top trading cycles as special cases. The methodology is based on analyzing large market models of one-sided matching using techniques of network revenue management, and solving a certain assortment planning problem whose objective is social welfare. I apply the methodology to school choice and show that restricting choice may be beneficial to student welfare. Moreover, I compute optimized choice sets and priorities for elementary school choice in Boston.

3 - The Cutoff Structure of Top Trading Cycles in School Choice

Irene Lo, Stanford University, Stanford, CA, 94306, United States, ilo@stanford.edu, Jacob Leshno

We develop a tractable theoretical framework for the Top Trading Cycles (TTC) mechanism for school choice that can be used to quantify welfare and optimize policy decisions. Our framework relies on a novel characterization of the TTC assignment in terms of a cutoff for each pair of schools. We use our framework to compute welfare for TTC and Deferred Acceptance (DA) under different priority structures, and find that the choice of priorities can have larger welfare implications than the choice of mechanism. We solve for the welfare-maximizing distributions of school quality for parametrized economies, and find that optimal investment decisions can be very different under TTC and DA.

4 - Matching Algorithms for Blood Donation

John P. Dickerson, Assistant Professor, University of Maryland, College Park, MD, 20742, United States, john@cs.umd.edu, Duncan McElfresh, Christian Kroer, Sergey Pupyrev, Eric Sodomka

Managing perishable inventory, such as blood stock awaiting use by patients in need, has been a topic of research for decades. We develop policies for matching potential blood donors to donation centers under various constraints and donor preferences, and under simple models of demand shocks to the system. We provide preliminary experimental results in simulation using real data from a large, worldwide social network, and show that our system provides lift relative to the status quo allocation methods.

5 - Spatio-Temporal Pricing for Ridesharing Platforms

Hongyao Ma, Harvard University, MD 242, Cambridge, MA, 02138, United States, Fei Fang, David C. Parkes

A challenge in dynamic pricing in ridesharing platforms is to set prices that are appropriately smooth in space and time, so that drivers will choose to accept their dispatched trips, rather than drive to another area or wait for a better trip. We introduce the Spatio-Temporal Pricing (STP) mechanism, which is subgame-perfect incentive compatible for drivers, and also welfare-optimal, envy-free, individually rational and budget balanced from any history onward. We prove that there can be no dominant-strategy mechanism with the same economic properties, and show via simulation that STP achieves significantly higher social welfare than a myopic pricing mechanism, where drivers have high regret.

Health Care, Modeling and Optimization VIII

Contributed Session

Chair: Jian Hu, University of Michigan-Dearborn, Dept. of IMSE,, Dearborn, MI, 48128, United States

1 - Identifying Influential Individuals and Predicting Future Demand of Chronically Ill Patients

Zlatana Nenova, University of Denver, Denver, CO, United States, zlatana.nenova@du.edu, Valerie Bartelt

We develop a generalizable framework which (1) identifies high impact and stable-demand customers and (2) predicts the medium-term demand for services of stable-demand customers. Identifying high impact individuals can be used in (1) monitoring prioritization, (2) patients' motivation and (3) patients' stabilization. Predicting need for care of stable demand individuals up to three years into the future is critical for hospital management in identifying future hiring needs. We evaluate our method by leveraging a large electronic medical records' data set, which comprises of 48,344 chronic kidney disease patients treated across eleven geographically diverse VA hospitals.

2 - Optimization of Admission Policies with Dynamic Capacity in Inpatient Ward Units

Jorge Acuna, PhD Student, University of South Florida, Tampa, FL, United States, jorge@mail.usf.edu, Jose L. Zayas-Castro

Admission of patients plays a fundamental role in hospital overcrowding management as well as patient outcomes and quality of care. In this talk, we formulate and solve a Markov Decision Process (MDP) to optimize the admission of different classes of patients to hospital inpatient ward with dynamic capacity. We discuss how better admissions policies that consider the different patient length of stay (LOS) can help to improve access to care. At the same time, we provided two different methods to overcome the curse of dimensionality of the MDP model with embedded prediction techniques of LOS and demand. We conclude with insights for the model implementation and the primal and dual acceptance policies.

3 - Planning Response to Medical Needs During Mass Gatherings

Mohammadreza Torkjazi, West Virginia University, Morgantown, WV, 26505, United States, mt0055@mix.wvu.edu, Behrooz Kamali, Leily Farrokhvar

Medical response during mass gatherings (MG) requires detailed prior planning due to the presence of a large number of crowds in a relatively small area in a short window of time. Medical care is either provided on-site (e.g., temporary care facilities), off-site (e.g., nearby hospitals) or using a combination of both during MG events. We propose mathematical models to study the trade-offs between different care policies and identify optimal and near-optimal service strategies. We use simulation to compare and analyze the results from our models.

4 - Mean-Risk Two Stage Vaccine Allocation to Geographically Different Regions under Uncertainty

Amira Mahmoud Hijazi, NC State University, Raleigh, NC, United States, amhijazi@ncsu.edu, Osman Ozaltin, Maria Jansen

CDC estimated that 25 million people became infected in the U.S. during the 2015-2016 flu season. While most of these cases were mild, there were approximately 12,000 flu-related deaths and 310,000 related hospitalizations. The economic burden of influenza on the U.S. economy is estimated to be $10.4 billion annually in direct medical costs, and $16.3 billion in indirect costs such as lost earnings. Vaccination is the most effective way of preventing influenza. In this study, we consider a risk-averse two-stage stochastic vaccine allocation model, where we specify the conditional-value-at-risk (CVaR) as the risk measure. We apply The sample average approximation (SAA) method to distribute flu vaccines to North Carolina State counties over two time phases.

5 - Dynamic Surveillance and Contact-tracing Policies for Outbreaks

Soheil Eshghi, Postdoctoral Associate, Yale University, New Haven, CT, United States, soheil.eshghi@yale.edu, Wasiur R. KhudaBukhsh, Eben Kenah, Grzegorz A. Rempala, Forrest W. Crawford

Enhanced surveillance (ES) and contact-tracing (CT) are policies that find and treat infected individuals in outbreaks. ES augments baseline surveillance through random testing. Once an index case is found, CT finds and treats their infected contacts. Each policy has fixed and variable costs. Under a simple epidemic model, the optimal dynamic coordinated policy that balances a trade-off between disease burden and policy expenditure uses each of these policies at either their highest intensity or not at all, traces at a subset of the times it surveils, and only switches each on and off once. This structure suggests simple heuristic policies for real-world outbreaks.

6 - A Two-stage Resilient Dynamic Programming Model for Nurse Scheduling Problem under Uncertainty

Jian Hu, University of Michigan - Dearborn, Dearborn, MI, United States, jianhu@umich.edu

This study is to find the optimal resilient policies of nurse scheduling for both improving serve quality of hospitals and respecting nurses job satisfaction under workload uncertainty. Major challenges in nurse scheduling problems are three key factors of workload uncertainty: unforeseen patient demand, nurse absenteeism, as well as nurse willingness to volunteer to work additional hours. The research proposes a stochastic dynamic optimization model, where the here-and-now decision in the planning stage makes an initial schedule, and the wait-and-see decisions in the operation stage finds the optimal daily on-call policy to adjust the schedule for the realization of nurse workload.

Tutorial: Wasserstein Distributionally Robust Optimization: Theory and Applications in Machine Learning

Emerging Topic: Tutorials

1 - Wasserstein Distributionally Robust Optimization: Theory and Applications in Machine Learning

Daniel Kuhn, Ecole Polytechnique Federale de Lausanne (EPFL), Lausanne, 1015, Switzerland, Peyman Mohajerin Esfahani, Viet Anh Nguyen, Soroosh Shafieezadeh-Abadeh

Many decision problems in science, engineering and economics are affected by uncertain parameters whose distribution is only indirectly observable through samples. The goal of data-driven decision-making is to learn a decision from finitely many training samples that will perform well on unseen test samples. This learning task is difficult even if all training and test samples are drawn from the same distribution — especially if the dimension of the uncertainty is large relative to the training sample size. Wasserstein distributionally robust optimization seeks data-driven decisions that perform well under the most adverse distribution within a certain Wasserstein distance from a nominal distribution constructed from the training samples. In this tutorial we will argue that this approach has many conceptual and computational benefits. Most prominently, the optimal decisions can often be computed by solving tractable convex optimization problems, and they enjoy rigorous out-of-sample and asymptotic consistency guarantees. We will also show that Wasserstein distributionally robust optimization has interesting ramifications for statistical learning and motivates new approaches for fundamental learning tasks such as classification, regression, maximum likelihood estimation or minimum mean square error estimation, among others.

Military and Security (MAS) Society Awards

Sponsored: Military and Security

Sponsored Session

Chair: Andrew Hall, United States Army Cyber Research Institute, United States Army Cyber Research Institute

1 - Seth Bonder Scholarship

Nicholas Shallcross, DoD/University of Arkansas, Fayetteville, AR, 72701, United States

The recipient gives a presentation on the research thread for which this scholarship is bestowed. The award-winning research thread is titled, “Demonstrating Set-based Design Concepts in Support of U.S. Army Ground Combat Vehicle Acquisition Decisions.

2 - Koopman Prize

Miguel Lejeune, George Washington University, Washington, DC, 20052, United States

The recipients present their award-winning work from 2018, which was published in Management Science. The presented research focuses on “Aeromedical Battlefield Evacuation Under Endogenous Uncertainty in Casualty Delivery Times”.

3 - J. Steinhardt Prize

Jeffrey Kline, Naval Postgraduate School, Salinas, CA, 93908, United States

The recipient will share insights, observations, and professional wisdom from a highly-regarded, impactful career of contributions. Dr. Kline’s career has supported both the education of graduate military officer students and the informing of senior policy makers in the Navy and Department of Defense, all to plan and analyze military plans and operations.

4 - MAS Award Opportunities

Andrew Oscar Hall, United States Military Academy, West Point, NY, 10996, United States

The past president and awards chair for the Military and Security (MAS) Society will provide an overview of award opportunities within the society, host a discussion about how to apply for these opportunities, and share information about developing awards within MAS.

Operations Management II

Contributed Session

Chair: Henny van Ooijen, Eindhoven University of Technology, Eindhoven, 5600MB, Netherlands

1 - Swan or Ugly Duckling? An Investigation of Zero-waste Management

Mikeum Kim, Korea University, Seoul, Korea, Republic of, mkkim01@korea.ac.kr, Byung Cho Kim

This paper examines the viability of zero-waste model. We identify the conditions under which the firm’s zero-waste action brings profit in the presence of two types of consumers, including primary consumers and eco-conscious consumers. Our preliminary results show that the size of the eco-conscious consumer segment and the level of consumers’ perception influence on the viability of zero-waste model. We aim to make contributions to the operations management literature by incorporating consumer behavior into manufacturer’s decision-making.

2 - Effect of Balance of Quality Features on Business Performance

Hyunjung Kim, Prof., Sunchon National University, Suncheon-si, Korea, Republic of, hkim@scnu.ac.kr

The relationship between quality and business performance has attracted theoretical attention. The purpose of this study was to investigate the missing point between quality and business performance which might connect them more strongly. This study suggests decision stage which is positioned between perceived quality features and actual purchase. According to the different standard of decision, different choices can be made under the same perceived quality level. As a result, balanced features of quality performed better than unbalanced features of quality even though the former has lower average quality level.

3 - Age Replacement Policy under Presence of Cyber Threats

Anh Ta, University of North Texas, Denton, TX, United States, Hakan Tarakci

This study provides analytical models to deal with cyber-threats in a production system that utilizes the age replacement policy. Two different scenarios involving cyber-threats are proposed. First, cyber-attacks do not disrupt the physical production system. The broken components are replaced either when the system has a physical breakdown or when a predetermined amount of time elapses. Second, the system is replaced right after it suffers from a successful cyber-attack. We analytically provide optimal policies to minimize the expected cost for these scenarios. Finally, sensitivity analyses show the effect of model parameters on the value of a cyber security system.

4 - Valuing Decision Lead Time under Non-constant Residual Value

Lauri Saarinen, Assistant Professor, Aalto University, Espoo, Finland, lauri.3.saarinen@aalto.fi, Suzanne de Treville

The amount that a decision maker should be willing to spend to reduce the decision lead time depends on the residual value under the assumption that the residual value is constant. We develop a theoretical model to explore how the value of responsiveness changes when the residual value is stochastic: Not considering stochasticity will cause the decision maker to undervalue responsiveness. Data from a consumer goods company exemplifies different forms that the relationship between expected leftover inventory and residual value might take.

5 - Performance Analysis of Flow Lines with Planned Work Center Order Release Times: A Queueing Approach

Henny van Ooijen, Eindhoven University of Technology, Eindhoven, Netherlands, h.p.g.v.ooijen@tue.nl

Literature on setting planned lead times for flow lines often assumes that the throughput time distributions of the different work centers are known, for instance based on practical data. In this study we develop a queueing based approach to determine the throughput time distributions for flow lines with planned release dates.

Latest Developments in Optimization Software

Sponsored: Optimization/Computational Optimization and Software

Sponsored Session

Chair: Hans Mittelmann, Arizona State University, Tempe, AZ, 85287-1804, United States

1 - Latest Benchmark Results

Hans Mittelmann, Arizona State University, Mathematics and Statistics, PO Box 871804, Tempe, AZ, 85287-1804, United States, mittelmann@asu.edu

The latest results from our benchmarks of non-commercial and some commercial software for continuous and discrete optimization will be presented.

2 - Recent Improvements in the Gurobi Optimizer

Edward Rothberg, Gurobi Optimization, LLC, Beaverton, OR, 77027, United States, rothberg@gurobi.com

This talk will present the latest features and improvements in the new version of the Gurobi Optimizer.

3 - Latest Developments in the Artelys Knitro Optimization Solver

Richard Waltz, Artelys Corp, Los Angeles, CA, United States

Artelys Knitro is the premier solver for nonlinear optimization problems. Knitro offers both interior-point and active-set algorithms for continuous models, as well as tools for handling problems with integer variables and other discrete structure. This talk will highlight the latest developments and improvements in Knitro, i ncluding a new algorithm designed for second order cone constraints, and advances in mixed-integer nonlinear optimization.

4 - What's New in CPLEX

Roland Wunderling, IBM, Austria, roland.wunderling@at.ibm.com

We will present the performance improvements realized in the latest release of CPLEX and describe the ideas that helped achieve them.

Stochastic Optimization in Machine Learning

Sponsored: Optimization/Global Optimization

Sponsored Session

Chair: Zhengyuan Zhou, Stanford, CA, 94305, United States

1 - Algorithm Design Through the Lens of Optimal Transport

Zhaoran Wang, Assistant Professor, Northwestern University, Evanston, IL, United States, zhaoran.wang@northwestern.edu

Infinite-dimensional distributional optimization is prevalent in machine learning. Typical examples include Bayesian estimation, generative adversarial learning, distributionally robust optimization, and online & reinforcement learning. In fact, any (possibly nonconvex) optimization problem can be lifted into a linear infinite-dimensional optimization problem. In this talk, I will present a unified approach of dimensional optimization through the lens of optimal transport. (Joint work with Yongxin Chen and Zhuoran Yang)

2 - Randomized Alternating Directions Methods for Distributed Optimization

Mert Pilanci, Professor, Stanford University, Stanford, CA, United States, pilanci@stanford.edu

We consider large scale distributed machine learning problems where the data rows are split across different machines. We propose a novel randomized variant of the Alternating Direction Method of Multipliers (ADMM), where random projections are applied instead of sampling the data. On least squares problem, we prove that the randomized ADMM converges in constant number of steps, independent of the condition number, and how the data rows are split. Moreover, our method is always guaranteed to converge with no tuning parameters. In contrast, classical ADMM requires tuning parameters and can take an arbitrarily large number of steps depending on the local conditioning of the partitioned data.

3 - On the Parallel Complexity of Non-smooth Optimization

Aaron Sidford, Professor, Stanford University, Stanford, CA, United States, sidford@stanford.edu

In this talk I will discuss recent advances in designing parallel algorithms for minimizing non-smooth convex functions. In particular, I will present new upper and lower bounds on the parallel complexity of non-smooth convex function minimization. This talk will emphasize new stochastic accelerated methods for this problem and additional applications for solving large scale learning problems. This talk reflects joint work with Sebastien Bubeck, Qijia Jiang, Yin Tat Lee, and Yuanzhi Li.

4 - Understanding the Importance of Noise in Training Neural Networks

Tianyi Liu, Georgia Institute of Technology, School of Industrial and Systems Engineering, Atlanta, GA, 30332, United States, Mo Zhou, Yan Li, Dachao Lin, Enlu Zhou, Tuo Zhao

Empirical evidences have corroborated that the noise plays a crucial rule in effective and efficient training of neural networks. The theory behind, however, is still largely unknown. Our work studies this fundamental problem through training a simple two-layer convolutional neural network model. Although training such a network requires solving a nonconvex optimization problem with a spurious local optimum and a global optimum, we prove that perturbed gradient descent in conjunction with noise annealing is guaranteed to converge to a global optimum in polynomial time. This implies that the noise enables the algorithm to efficiently escape from the spurious local optimum.

5 - When Nonconvexity Meets Non-smoothness

Ju Sun, Stanford University, Stanford, CA, United States, sunju@stanford.edu

Most applied problems we encounter can be naturally written as nonconvex optimization, which in theory is hard to solve globally. In practice, however, simple methods often work surprisingly well in finding high-quality solutions. In this talk, I will describe recent efforts in bridging the mysterious theory-practice gap. I will highlight a family of smooth nonconvex problems that can be solved to global optimality using simple methods. The discovery does not cover nonsmooth functions, which are increasingly popular in modern applications. I will introduce tools from nonsmooth analysis, and show how nonsmooth, nonconvex problems can also be analyzed and solved in a provable manner.

Packing and Covering

Sponsored: Optimization/Integer and Discrete Optimization

Sponsored Session

Chair: Yuri Faenza, Columbia University, New York, NY, 10027, United States

1 - Mixed-integer Programming Techniques for Strategic Open-pit Mine Planning

Gonzalo Muñoz, Polytechnique Montreal, Montreal, QC, H3T 1N8, Canada, Orlando Rivera, Daniel G. Espinoza, Marcos Goycoolea, Eduardo Moreno

Computing production schedules for strategic open pit mine planning has proved to be an elusive problem. Using a block representation of the ore body, a schedule must specify which blocks should be extracted, when, and how will they be processed so as to maximize the value of a project. Given the size of real-world mines and the presence of knapsack and spatial constraints, among others, instances can have hundreds of millions of variables, and many times more constraints. In this talk, we describe a MIP methodology for finding an optimal schedule which combines preprocessing, cutting-planes, heuristics, and a branch-and-bound algorithm. We show extensive computational tests using real problem sets.

2 - Approximating Integer Programs with Monomial Orders

Akshay Gupte, Clemson University, Dept. of Mathematical Sciences, Clemson, SC, 29634-0975, United States, agupte@clemson.edu

We present an approach for creating primal and dual bounds for a general integer program using monomial orders on the integer lattice. We give approximation guarantees for these bounds with respect to the integer optimum. In particular, we show that for certain monomial orders, the dual bounds converge to the integer optimum of packing and covering 0/1 IPs, and the primal bounds converge for any 0/1 IP. The complexity of computing our bounds is also discussed. Some preliminary computational results for MIPLIB instances will also be presented.

3 - The Generalized Incremental Knapsack Problem

Lingyi Zhang, Columbia University, New York, NY, United States, lz2573@columbia.edu, Yuri Faenza

The Generalized Incremental Knapsack (GIK) problem is an extension of the classical Knapsack problem to a discrete, multi-period setting, naturally modelling scenarios where the available resources increase over time. GIK is strongly NP-Hard, hence strictly harder than the classical Knapsack. Special cases of this problem (IK, IIK) have recently been studied in literature. In this talk, we present new polyhedral and algorithmic results for GIK.

5 - Covering Problems: Pitch and Extended Formulations

Xuan Zhang, Columbia University, New York, NY, 10025, United States, Daniel Bienstock, Yuri Faenza

Consider covering problem Ax>=b with x binary. The pitch of a valid inequality cTx>=d is the minimum integer p such that the p smallest non-zero coefficients in c sum up to at least d. Pitch is therefore a way to measure complexity of inequalities. Pitch is connected to other relevant concepts in integer programming such as the Chvátal-Gomory closure. In this talk, we investigate bounded pitch inequalities for the minimum knapsack (aTx>=b) and the set covering (Ax>=1) problems. In particular, we investigate their relationship with inequalities of bounded coefficients and give bounds on the size of extended formulations for relaxations of covering problems when inequalities of bounded pitch are added.

Emerging Topics in Data-Driven Optimization

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Vishal Gupta, University of Southern California, Los Angeles, CA, 90026, United States

Co-Chair: Michael Huang, University of Southern California, Los Angeles, CA, United States

1 - Data-Pooling for Stochastic Optimization

Vishal Gupta, University of Southern California, Marshall School of Business, Los Angeles, CA, 90026, United States, guptavis@usc.edu, Nathan Kallus

When simultaneously solving many unrelated, data-driven stochastic optimization problems, optimization intuition suggests decoupling and solving them separately. We propose a novel data-pooling algorithm that combines data across unrelated problems and generally outperforms decoupling. We study causes of this phenomenon, when it holds, and prove our method learns the optimal amount of pooling in the small-data, large-scale regime. We propose refinements that leverage covariates and illustrate through real-world applications in inventory and vehicle routing.

2 - Interpretable Optimal Stopping

Velibor Misic, UCLA Anderson School of Management, Los Angeles, CA, 90095, United States, velibor.misic@anderson.ucla.edu, Florin Ciocan

Optimal stopping is the problem of deciding when to stop a stochastic system to obtain the greatest reward. State of the art methods for this problem rely on obtaining an approximate value function for use within a greedy policy. However, such policies are generally not interpretable, in that it is often difficult to see how the policy maps each system state to a decision. We propose a new data-driven method for optimal stopping that directly learns interpretable policies in the form of binary trees. We apply our approach to a canonical option pricing problem and show that it quickly obtains interpretable policies that outperform existing non-interpretable policies based on simulation-regression.

3 - Small-data, Large-scale Discrete Optimization

Michael Huang, University of Southern California, Los Angeles, CA, 90007, United States, huan076@usc.edu, Vishal Gupta, Paat Rusmevichientong

We propose a method for data-driven, discrete optimization problems in the small-data, large-scale regime, i.e., problems that depend on many uncertain parameters, each with highly imprecise estimates. The key idea is to use a novel decomposition approach to optimize out-of-sample performance. We prove our method achieves best-in-class performance for a variety of problems such as shortest path, minimum spanning tree, and weighted maximum independent set.

4 - Bounding Optimality Gaps via Bagging

Huajie Qian, Columbia University, New York, NY, 10027, United States, Henry Lam

We investigate a statistical method to assess the suboptimality of a given solution in data-driven stochastic optimization, via estimating the solution's optimality gap. Our approach is based on bootstrap aggregating, or bagging, resampled sample average approximation (SAA). We show how this approach generates valid statistical confidence bounds for non-smooth optimization, and demonstrate and compare its statistical efficiency and stability with some existing methods. We also present our theory by viewing SAA as a kernel in an infinite-order symmetric statistic, which leads to some generalizations of classical central limit results for SAA.

Applications of robust optimization

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Aurelie Thiele, Southern Methodist University, Dallas, TX, 75275-0123, United States

1 - Robust Continuous Optimisation for Project Portfolio Management under Uncertainty

Hedieh Ashrafi, Southern Methodist University, Dallas, TX, 75206, United States, Aurelie Thiele

We consider the management of projects under uncertainty in a firm's market entry, competitors' entry and product adoption dynamics. The company can adjust manpower staffing on a portfolio of projects (new products), which diversifies its portfolio but delays market entry for each product line, making it more likely a rival will launch a competing product first. We present a robust optimisation approach to balance those concerns and extend our framework to dynamic policies based on information revealed over time about competitors' products entering the market. We provide insights into when it is optimal for the manager to focus on a narrow range of new products.

2 - Determining Facility Locations under Distributionally Robust Decision-dependency

Beste Basciftci, Georgia Institute of Technology, H. Milton Stewart School, Atlanta, GA, 30332, United States, beste.basciftci@gatech.edu, Siqian Shen, Shabbir Ahmed

We study distributionally robust facility location problem under decision-dependent demand distribution, motivated by an example from a car sharing setting. We propose a moment-based ambiguity set that captures the underlying uncertainty based on the location decisions. Furthermore, we develop a mixed-integer linear programming reformulation under the proposed ambiguity set and strengthen the formulation by deriving valid inequalities. Our case study illustrates superior performance of the proposed approach in comparison to distributionally robust and stochastic programming methods which omit decision-dependency.

3 - Inverse Markov Decision Processes with Unknown Transition Probabilities

Zahra Ghatrani, University of Washington, Kirkland, WA, United States, Archis Ghate

Inverse optimization is a framework for inferring parameters of an optimization problem (cost coefficients, right-hand side vector, or the constraint matrix) given observed values of decisions. We study the problem of Inverse Markov Decision Processes (MDP) with unknown transition probabilities. We consider the inverse MDP problem under different assumptions about the observed solution. We show that in special cases we can use a variable transformation method which reduces solving the inverse MDP problem to a linear program (LP). Then, we extend our work to more general LPs and Semi-Definite programs.

4 - Understanding Distributional Ambiguity via Non-robust Chance Constraint

Shumin Ma, City University of Hong Kong, Kowloon Tong, Hong Kong, shuminma@cityu.edu.hk, William Cheuk Hang Leung, Qi Wu

The DRO formulation resolves distribution uncertainty in portfolio optimization but it's difficult to determine and interpret the ambiguity radius. We show that DRO problem is asymptotically equivalent to mean-deviation problem with investor's risk aversion controlled by radius. Theoretical and numerical analysis show there exists a radius threshold, crossing which optimal value/solution exhibit phase transition, and beyond which, distribution uncertainty takes effect. We also show, a DRO problem with bound constraint can be cast as a deterministic chance constrained optimization (CCO). Without boundedness, the CCO problem uniformly outperforms the DRO problem.

5 - Multi-stage Robust Optimization with Time-dependent Uncertainty Sets

Arkajyoti Roy, The University of Texas at San Antonio, San Antonio, TX, United States, arkajyoti.roy@utsa.edu, Shaunak Dabadghao, Victor Wu

Uncertainties that vary in time can limit the success of conventional robust optimization models, which assume invariant uncertainty sets. We develop a multi-stage robust optimization model that incorporates time-dependent uncertainty sets and provide tractable reformulations. Furthermore, we derive optimal schedules for the multi-stage robust model. An application in cancer radiotherapy is used to demonstrate the performance of the proposed methodology.

Theory and Applications in Distributionally Robust Optimization

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Zhenzhen Yan, Nanyang Technological University, Singapore, 637371, Singapore

1 - Data-driven Robust Optimization with Known Marginal Distributions

Rui Gao, University of Texas at Austin, Austin, TX, 78712, United States, rgao32@gmail.com

A key challenge in decision making under uncertainty is seeking robust solutions against high-dimensional data uncertainty. The joint distribution of the stochastic data can hardly ever be obtained exactly, even when estimation on their one-dimensional marginals is rather accurate. We propose a distributionally robust approach, which hedges against a family of joint distributions with known marginals and a dependence structure similar to that of a nominal joint distribution (e.g., the empirical or the independent product distribution). We obtain a tractable reformulation of this problem and demonstrated with portfolio selection and nonparametric density estimation.

2 - Robust Vehicle Allocation with Uncertain Covariates

Zhenyu Hu, National University of Singapore, Singapore, 119245, Singapore, bizhuz@nus.edu.sg, Zhaowei Hao, Long He, Jun Jiang

Motivated by a major taxi operator in Singapore, we consider the idle vehicle allocation problem, where the operator reallocates the idle vehicles to serve future uncertain demands. The main challenge lies in estimating demand distribution accurately from historical data. We employ a distributionally robust optimization approach that utilizes covariate information as well as the moment information of demands. We show that covariate information could alleviate the over-conservativeness of the robust solution. The resulting optimization problem can be tractably solved. We further validate our solution via a case study using trip and vehicle status data paired with rainfall data.

3 - Distributionally Robust Optimization with Confidence Bands for Probability Density Functions

Guanglin Xu, University of North Carolina at Charlotte, Charlotte, NC, 52242, United States

We study a stochastic program where the distribution is not completely known and only a set of historical data or some information of the shape of the distribution is available. We apply a data-driven approach to construct an ambiguity set consisting of all the probability density functions that could have generated the available data. The resultant distributionally robust optimization is computationally intractable due to the fact that it has both infinitely many constraints and infinitely many decision variables. We reformulate the problem into a semi-infinite program and propose an effective stochastic gradient method to solve it. The numerical results illustrate the strength of our approach.

4 - Allocation Inequality in Cost Sharing Problem

Zhi Chen, Assistant Professor, City University of Hong Kong, Imperial College Business School, Sout, Hong Kong, SW7 2AZ, China, Zhenyu Hu, Qinshen Tang

We consider the cost sharing problem where a coalition of agents, each endowed with an input, shares the output cost incurred from the total coalitional input. We bridge two important allocations—-average cost pricing and the Shapley value—-from the angle of allocation inequality. We use the concept of majorization to characterize allocation inequality and we derive simple conditions under which one allocation majorizes the other.

Chair: Hoi-To Wai

Co-Chair: Cesar A Uribe, MIT, Cambridge, MA, 02138, United States

1 - Stochastic Decentralized Nonconvex Optimization for Training Over Networks

Songtao Lu, AI Resident, IBM Research, Yorktown Heights, NY, 55414, United States, lus@umn.edu, Mingyi Hong

In this work, we propose a gradient-tracking based nonconvex stochastic decentralized (GNSD) algorithm for solving nonconvex optimization problems, where the data is partitioned into multiple parts and processed by the local computational resource. Through exchanging the parameters at each node over a network, GNSD is able to find the first-order stationary points (FOSP) efficiently. From the theoretical analysis, it is guaranteed that the convergence rate of GNSD to FOSPs matches the well-known convergence rate $\mathcal{O}(1/\sqrt{T})$ of stochastic gradient descent by shrinking the step-size.

2 - A Doubly Stochastic Surrogate Optimization Scheme for Non-convex Finite-sum Problems

Eric Moulines, Professour, Ecole Polytechnique, Dept TSI, France, eric.moulines@polytechnique.edu

Many constrained, nonconvex optimization problems can be tackled using the Majorization-Minimization (MM) method. For problems which minimize a finite sum of functions, a stochastic version of the MM method selects a batch of functions at random at each iteration and optimizes the accumulated surrogate. In many cases of interest, the surrogate functions are expressed as an expectation. We propose a doubly stochastic MM method based on Monte Carlo approximation of these stochastic surrogates. We establish non-asymptotic convergence of our scheme in a constrained nonconvex optimization setting. Several numerical examples are presented to illustrate the performance of the proposed scheme.

3 - Incremental Optimization with Smooth Inference for Structured Prediction

Zaid Harchaoui, University of Washington, Seattle, WA, United States

We present a framework to train a structured prediction model byperforming smoothing on the inference algorithm it builds upon.Smoothing overcomes the non-smoothness inherent to the maximum marginstructured prediction objective, and paves the way for the use of fastprimal gradient-based optimization algorithms. We illustrate theproposed framework by developing a novel primal incrementaloptimization algorithm for the structural support vector machine. Theproposed algorithm called Casimir blends an extrapolation scheme foracceleration and an adaptive smoothing scheme and builds upon thestochastic variance-reduced gradient algorithm. We establish itsworst-case global complexity bound and present numerical results innatural language process and computer vision applications.

4 - Bayesian Decision Making in Groups is Hard

M. Amin Rahimian, MIT, Cambridge, MA, United States, Elchanan Mossel, Jan Hazla, Ali Jadbabaie

We study the computations that Bayesian agents undertake when exchanging opinions over a network. The agents act repeatedly on their private information and take myopic actions that maximize their expected utility according to a fully rational posterior belief. We show that such computations are NP-hard for two natural utility functions: one with binary actions, and another where agents reveal their posterior beliefs. In fact, we show that distinguishing between posteriors that are concentrated on different states of the world is NP-hard. Therefore, even approximating the Bayesian posterior beliefs is hard. We also describe a natural search algorithm to compute agents' actions, which we call the elimination of impossible signals, and show that if the network is transitive, then the algorithm can be modified to run in polynomial time.

1 - Linear Programming Based Approach for Signal Separation

Mujahid N. Syed, KFUPM, Dhahran, Saudi Arabia, snumujahid@gmail.com

In this work, a novel optimization algorithm is proposed to solve a specific case of the blind signal separation problem.

2 - A Preordering Algorithm to Reduce Bit-lengths When Exactly Solving Sparse Linear Systems via Integer Preserving LU and Cholesky Factorizations

Christopher Lourenco, Texas A&M University, College Station, TX, United States, clouren@tamu.edu, Erick Moreno-Centeno

When exactly solving sparse linear systems via integer-preserving LU and Cholesky factorizations, a tradeoff exists between fill-in and bit-length (i.e., cost of operations) in the L and U factors. We propose a new algorithm, based on the widely used minimum degree heuristic, which adds node weights to the graph of the input matrix and generates an elimination ordering which both reduces fill-in and bit-length in the ensuing factorization. Associated computational results illustrate that the new algorithm dramatically reduces the worst case run time of the exact factorizations.

3 - A Novel Feature Selection Algorithm for Continuous Response Prediction with Interacting Variables

Maryam Nikouei Mehr, Iowa State University, Ames, IA, United States, Sigurdur Olafsson

This paper concerns a new feature selection method for multiple linear regression models. While common feature selection methods focus on the removal of redundant or irrelevant features, we show that such features may be important. We establish a computational framework for selecting a subset of features that have significant interactions with the response and a subset of features that may have little interactions with the response, but when combined with others, they can be strongly predictive of the response. Removal of these features can thus result in poor predictions. A mixed integer linear programming model is implemented to recognize feature interactions and their exact combinations.

4 - Porting an Open Source LP Solver to Web Assembly

Fabion Kauker, 3-GIS, Decatur, AL, United States, fkauker@3-gis.com

As new applications of optimization require different access methods to solvers new technologies must be explored. The evolution in browser technology has lead to WebAssembly (WASM) this enables code written for what was once server/local application code to be compiled and then run in the browser on the client side. By taking a solver written in C/C++ and porting the interface to be usable in the browser we examine the utility of the interface and example formulations.

Computational Challenges and Applications of Network Optimization

Sponsored: Optimization/Network Optimization

Sponsored Session

Chair: Minjiao Zhang, Kennesaw State University, Kennesaw, GA, 30144, United States

1 - Strict Quotas or Tariffs? Implications for Product Quality and Consumer Welfare in Differentiated Product Supply Chains

Dong Li, Babson College, MA, 02481, United States, dli@babson.edu, Anna B. Nagurney, Deniz Besik

We introduce a supply chain network equilibrium model with differentiated products where firms compete on product quantities and quality. We then extend the model to include trade policy instruments in the form of a strict quota or a tariff. We also establish the equivalence between the model with a strict quota and that with a tariff, when the quota constraint is tight. Illustrative examples as well as a case study on soybeans, an important global agricultural product, reveal interesting insights with accompanying suggestions for policy-makers. Specifically, although firms may benefit from the imposition of a quota or tariff, the consumer welfare in the country imposing the quota or tariff declines.

2 - Relay Network Design Problem under Uncertainty

Amin Ziaeifar, Southern Methodist University, 3002, Dallas, TX, 75231, United States, Halit Uster

We investigate designing a relay network for truckload transportation with uncertain demand. We propose a new two-stage stochastic program to model the problem. We devise an enhanced L-shaped method configured to efficiently solve large-size instances having significant number of scenarios. We present a computational study to demonstrate the performance of our algorithm on different test instance classes.

3 - Reformulation-linearization Technique Formulation and Gpu Acceleration for the Multidimensional Assignment Problem

Samhita Vadrevu, University of Illinois at Urbana Champaign, Urbana, IL, United States, samhita3@illinois.edu, Rakesh Nagi

This research is focused on reformulation and parallelization of multidimensional assignment problems. Strong lower bounds are obtained with Reformulation and Linearization Technique (RLT) and a dual ascent scheme. Efficient parallel algorithms are designed to accommodate the rapidly growing number of variables and tested for large instances with single and multiple GPUs.

4 - Quantifying Network Dissimilarities

Harshitha Meda, PhD. Candidate, North Carolina A&T State University, Greensboro, NC, United States, hmeda@aggies.ncat.edu, Chrysafis Vogiatzis

Quantifying network dissimilarity is a complex problem. In this talk, we focus on a specific part of quantifying how different two networks are based on their shortest path distribution. Specifically, we employ the set of shortest paths in two ways for every node: the first, which we call betweenness divergence, reveals the distance of a node to every shortest path, while the second, which we refer to as escape distribution, shows how diversely a node leads to every other path in the network. We present the mathematical derivation of these two terms and then use them to obtain a metric of network dissimilarity. We finish the talk with a series of computational results on real-world and synthetic instances.

5 - A Branch-and-cut Method for Dynamic Monopoly Problem

Minjiao Zhang, Kennesaw State University, Kennesaw, GA, 30144, United States, mzhang16@kennesaw.edu, Babak Moazzez

Dynamic monopoly (or dynamo for brevity) models the spread of influence in the context of graph theory. We study the polyhedral structure of the dynamic monopoly polytope that arises from integer programming formulations of dynamic monopolies in graphs. We present several families of valid inequalities for two alternative formulations. Our focus is to develop efficient separation algorithms for the proposed valid inequalities and generate branch-and-cut methods to solve the dynamic monopoly problems effectively. We demonstrate the efficacy of our branch-and-cut methods by conducting comprehensive computational study.

Co-Chair: Huseyin Ergin, Ball State University, Muncie, IN, 47304, United States

1 - Software Engineering for Research Software

Jeffrey Carver, University of Alabama, Tuscaloosa, AL, 35487, United States, carver@cs.ua.edu

Increasingly research advances are enabled by Research Software (i.e. software that enables research in various disciplines). The characteristics of this software and the fact that the researchers who develop it are often domain experts but not necessarily software engineering (SE) experts, results in a need to understand how to identify and apply appropriate SE practices for high-quality and sustainable software. This talk focuses on work done to advance this understanding through surveys and case studies. The talk will also describe the efforts of an ongoing project to design a US Research Software Sustainability Institute (URSSI), which includes a number of workshops and a large-scale survey.

2 - A Study of Software Development Practice in Operations Research

Huseyin Ergin, Ball State University, Muncie, IN, United States, hergin@bsu.edu, Mesut Yavuz

Software is a crucial part of research in many fields today. However, software development is not an easy task. Primarily it is harder in fields where researchers are not formally trained to produce better software systematically. In this talk, we will primarily share the results of a survey we have been conducting for the last ten months. The results of the survey will shed light on the software development practice in Operations Research (OR), reveal the relationship of the OR scholars with research software, and present the expectations and concerns of them regarding code and data sharing practices.

3 - 40 Years of Operations Research Software Development: Lessons Learned

John W. Chinneck, Carleton University, Systems and Computer Engineering, Ottawa, ON, K1S 5B6, Canada, chinneck@sce.carleton.ca

Advice and hard lessons learned during 40 years of developing algorithmic software for operations research. Things to consider when embarking on a new project: programming and modelling languages, basic numerical methods, solvers, software libraries, test sets, experiment design, etc.

4 - A New Computational Optimization Framework

Mesut Yavuz, University of Alabama, Alston Hall Box 870226, Tuscaloosa, AL, 35487, United States, myavuz@cba.ua.edu, Huseyin Ergin

We present a new framework consisting of libraries enabling faster development and experimentation in computational optimization. We demonstrate the use of the framework on a parallel-machine-scheduling problem and highlight the improvements obtained from using the framework.

Computational Advances in Production Planning and Inventory Management

Sponsored: Computing

Sponsored Session

Chair: Kartik Kulkarni, Blacksburg, VA, 24060, United States

Co-Chair: Manish Bansal, Virginia Tech., Blacksburg, VA, 24060, United States

1 - The Role of Robustness in Inventory vs. Timeliness Trade-off in Project Delivery

Arman Jabbari, University of California-Berkeley, 715 E. 19TH ST, Berkeley, CA, 94606, United States, jabbari@berkeley.edu, Philip Kaminsky

We explore the tradeoffs between inventory holding costs and project completion times in a variety of settings, across single and multiple projects, and we analyze how robustness affects these tradeoffs.

2 - M-natural-Convexity and its Applications in Operations

Menglong Li, UIUC, 164 Paddock DR E, Urbana, IL, 61874, United States, ml10@illinois.edu, Xin Chen

M-natural-convexity, one key concept in discrete convex analysis, possesses salient combinatorial properties and finds applications in discrete systems, operations research and economics. In this talk, we illustrate how this concept and its variants can be used to develop monotone comparative statics in parametric optimization problems, the existence of nonincreasing optimal solution in parameters, which is in sharp contrast to classical results in lattice programming on nondecreasing optimal solution. We present applications in operations and demonstrate that looking from the lens of M-natural-convexity may allow one to greatly simplify some complicated analysis in the literature.

3 - Dynamic Sourcing and Learning Strategies for Food Supply Systems with Quality Risk and Limited Traceability

Zhendong Pan, Purdue University, Hawkins Hall Room 0801, 430 Wood Street, West Lafayette, IN, 47906, United States, Zhan Pang

Motivated by food quality and safety issues in food supply chains with limited traceability, we consider a single-product supply system in the presence of multiple suppliers with unknown qualities. Based on the prior belief on the quality distributions, though sourcing to high-quality suppliers may lead to higher expected rewards, sourcing to some lower-quality suppliers may yield greater prospects. We demonstrate the trade-off between exploitation and exploration in dynamic sourcing decisions and show that the optimal sourcing policy can be characterized with a class of index policies. We also identify the value of information provided by food traceability systems.

4 - Evaluating Integer Programming Models for Solving Stochastic Inventory Problems

Ton de Kok, Eindhoven University of Technology, Eindhoven, 5600 MB, Netherlands, Bas Bluemink, Balan Srinivasan, Reha M. Uzsoy

We formulate integer programming models for the solution of finite horizon periodic review capacitated stochastic inventory models. The formulations require several approximations, but computational experiments show that they can yield near-optimal solutions in modest CPU times under a range of experimental conditions.

5 - Recent Advancements for Solving Generalizations of the Classical Lot-sizing Problem

Kartik Kulkarni, Virginia Tech, Blacksburg, VA, 24060, United States, kartikrf@vt.edu, Manish Bansal

In this talk, we present our recent advances on solving generalizations of the classical single-item economic lot-sizing problem where the total production capacity in each period can be the summation of some integer multiples of several capacity modules of different sizes.

Co-Chair: Wotao Yin

1 - Minibatch Stochastic Subgradient-based Projection Algorithms for Solving Convex Inequalities

Angelia Nedich, ASU, Tempe, AZ, 85281, United States, Angelia.Nedich@asu.edu, Ion Necoara

We consider a convex feasibility problem where the feasible set is given as the intersection of a (possibly infinite) number of closed convex sets. We assume that each set is specified algebraically as a convex inequality, where the associated convex function is general (possibly nondifferentiable). To find a feasible point for all the inequalities, motivated by the work of B.T. Polyak, we design and analyze random projection algorithms using special subgradient iterations and extrapolated stepsizes. For the minibatch stochastic subgradient-based projection methods, we prove asymptotic convergence results and prove linear convergence rates.

2 - Flexible Distributed Gradient Methods with Stochastic Errors

Ermin Wei, Northwestern University, Tech L310, Evanston, IL, 60208, United States, Fatemeh Mansoori, Charikleia Iakovidou

One of the most important problems in the field of distributed optimization is the problem of minimizing a sum of convex objective functions over a networked system. In such a network, each agent has access to a local objective function and works toward minimizing it, using potentially noisy local information and the information from its neighbors. We develop a class of communication aware distributed methods with minimal storage requirement, which can tradeoff computation and communication costs depending on the application. We analyze their respective convergence properties.

3 - Operator Splitting Methods in Decentralized Optimization

Wotao Yin, Alibaba US, Bellevue, WA, United States, Ming Yan

Many big-data problems must be solved in a decentralized manner, which uses short-distance communication between adjacent nodes to achieve the goal of the whole network. Decentralized methods are better for data privacy and more robust to failures. This talk overviews the formulations and methods of decentralized consensus optimization through a unified framework of operator splitting. The objective is that the variables of all nodes converge to the same vector that minimizes the sum of their objective functions. Naive decentralized algorithms are order-of-magnitude slower than their centralized counterparts. Recent methods based on duality have significantly narrowed this gap.

4 - A Stochastic Gradient Descent Ascent Method for Saddle Point Problems

Alireza Fallah, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, afallah@mit.edu, Sarath Pattathil, Asuman Ozdaglar

In this work, we study the strongly convex- strongly concave saddle point problem when the exact gradient is not available, and instead, we have access to its unbiased estimate at each iteration. In particular, we focus on Gradient Descent-Ascent method (GDA) and provide a characterization of rate and robustness in the presence of noise.

Chair: Omer Verbas, PhD, Argonne National Laboratory, Lemont, IL, 60439, United States

1 - Calibrating Large Scale Traffic Flow Simulation Models with Integrated Dynamic-Traffic-Assignment

Felipe A. de Souza, Postdoctoral Appointee, Argonne National Laboratory, Argonne, IL, United States, fdesouza@anl.gov, Omer Verbas, Joshua Auld

Commonly, traffic simulation models are calibrated based on road-specific sensors or vehicle trajectory data disregarding route-choice (DTA). We propose a simulation-based calibration technique to calibrate large-scale areas based on individual trajectories so as to (i) reproduce the individual links travel times from the observed trajectories, and (ii) no other alternative route yields significantly lower travel time to the same origin-destination than the observed route. We applied the proposed technique in the Chicago metropolitan area reaching accurate average travel times, despite larger deviation in localized areas of the network.

2 - A Distributed Gradient Approach for Cell Transmission Model-based System Optimal Dynamic Traffic Assignment

Mehrzad Mehrabipour, Washington State University, Pullman, WA, 27606, United States, mehrzad.mehrabipour@wsu.edu, Ali Hajbabaie

This study presents a distributed gradient algorithm to solve a system optimal dynamic traffic assignment problem modeled based on the cell transmission network loading concept. The algorithm distributes the problem into local sub-problems without requiring a central component. A sub-problem receives proposed values for common decision variables from all adjacent sub-problems, incorporates them with its offered values by weighted averaging, and enforces a gradient step to minimize its objective function. Then, the value is projected on the feasible region of the sub-problem. We show that the algorithm converges to the optimal solution.

3 - Traffic Flow and Speed Prediction on Freeways Using a Three-phase Model and Probe Data

Seiran Heshami, PhD. Candidate, University of Calgary, Calgary, AB, Canada, seiran.heshami@ucalgary.ca, Lina Kattan, Arash Afshar

In this research a traffic state prediction model is developed which includes two main modules: A) Online simulation, B) Data fusion and traffic state prediction. A stochastic microscopic model, based on three-phase traffic theory, is used to predict traffic flow and speed based on probe data. Predicted traffic parameters are fused with detector measurements through an Adaptive Kalman Filter to produce more accurate estimation of the traffic flow and speed for short time intervals.

4 - Ramp Meters as Control Variates for Freeway Simulations

William Alexander, University of Texas, Austin, TX, United States, Stephen Boyles

Simulation models are used extensively in transportation engineering to evaluate design changes. Previous work in variance reduction methods for roadway simulation includes common random numbers and antithetic variates. This study explores the application of control variates for variance reduction in the specific scenario of a freeway on-ramp with a ramp meter as the sole influencing control mechanism. Traffic dynamics are simulated using the cell transmission model. Using simulated arrivals and a fixed service time at the ramp meter, queueing theory provides a control variate to reduce variance and expedite the evaluation of ramp meter timing performance.

1 - Duopoly Pricing Strategy for Providing Digital Media Online: Subscription-only or Subscription-prior?

Jingpei Ma, Dalian University of Technology, Dalian, China, majingpei@mail.dlut.edu.cn, Wenli Li, Shuai Zhao

Many online media platforms offer prior content to subscribers, and also offer it for free with ads after a “windowing” period.This paper adopts a game theoretical approach to examine the impact of delay-ad-sponsored offering on the competition between two platforms. The platform can either offer a subscription-only strategy or a subscription-prior strategy with delay-ad-sponsored service. We will derive the market equilibria and present conditions under which the subscription-prior strategy outperforms the subscription-only strategy. We will find how the length of “windowing” period impact the platforms’ offering decisions and the equilibrium solutions.

2 - Pay as You Wish with Network Effect

Yutian Li, Assistant Professor, University of Science and Technology of China, HEFEI, China, liyutian@ustc.edu.cn, Can Sun

In this paper, we investigate the pricing strategy that are widely used by many live video stream firms. Under the pricing strategy, the audiences can pay the streamer as much as they like some of them are even watching for free. This policy is the so-called pay-as-you-wish pricing policy. On the other hand, the live video streaming exhibits network effect, which is different from pay-as-you-wish pricing literature. We find that when more people do not pay, firm’s profit may increase. We also compare the pay-as-you-wish pricing strategy with the subscription fee pricing strategy.

3 - YouTube Video Thumbnails: Do They Matter for Video Clicks?

Fuquan Cui, Korea university, Seoul, Korea, Republic of, cuifuquan0622@korea.ac.kr, Byungwan Koh

A recent AdWeek survey found 88% growth year over year in time spent watching videos on a smartphone. This high traffic on social media and video website has attracted the attention of many businesses. They extensively use social media and video website to deliver their ads, especially video ads. Consequently, how to be found and clicked among a large number of video ads available on the Internet is also gaining much attention from academia and industry. It is shown that nearly half of video ads on the Internet are, in fact, never clicked. This study investigates the impact of video thumbnails on video clicks.

4 - Optimal Platform Price Discrimination and the Measurement of Network Effects

Seth G. Benzell, Postdoctoral Associate, MIT, Cambridge, MA, United States, sbenzell@mit.edu, Avinash Collis

We propose an analytical model and practical procedure for a platform to exploit heterogeneous network effects. Using the example of Facebook, we evaluate profit maximization first order conditions. The relevant network characteristics are collected using surveys and choice experiments on a representative sample of the US online population. We find that Facebook could increase monthly profits by increasing the amount of advertising on some market segments, and decreasing it on others. Finally, we contrast the platform's profit maximizing strategy with a social welfare maximizing one.

5 - A Sampling Strategy for Unbundled Digital Contents – with a Different Quality and Price

Seul-ah Kim, Korea University, Seoul, Korea, Republic of, soelah1@korea.ac.kr, Byungwan Koh

To increase a digital content sales, three strategies can be implemented: bundling, unbundling and unbundling with sampling. This paper examines the most preferred strategy in terms of the firm's profit and customers' surplus, by restricting the distribution of the quality and the price on two unbundled contents. When the firm can change the quality and price allocation, regardless of the customer retention rate, unbundling strategy without a free sample can have an advantage over the bundling strategy. However, if the two conditions are restricted, as the sampling effect increases, the sampling strategy can have an advantage over other strategies.

1 - An Agent-based Simulation for Seasonal Guinea Worm Disease in Chad Dogs

Tyler Perini, Georgia Institute of Technology, Atlanta, GA, United States, perinita@gatech.edu, Julie L. Swann, Pinar Keskinocak, Adam Weiss, Ernesto Ruiz-Tiben

One obstacle to eradicating the Guinea Worm parasite in Chad is the infections of dogs, which far outnumber human infections. We present the first agent-based simulation that models transmission between a (shared) water source and a large population of dogs. By calibrating the infectivity parameters for several different hypothetical environmental factors, we find that a combination of temperature and rainfall best explain the seasonal infections. In addition, this tool can be used to forecast the effectiveness of potential intervention schemes, in order to inform program managers of the combination of interventions that is most likely to lead to eradication.

2 - Time Well Spent: A Metric to Improve Productivity and Quality in Health Care Services

Senthil Veeraraghavan, University of Pennsylvania, Philadelphia, PA, United States, senthilv@wharton.upenn.edu

Health care productivity has generally lagged behind other services. Waiting times are long, despite the service time has reduced over time, and resources have over-utilized. Based on data, we show how electronic health records (EHRs) have not assisted in improving productivity. We propose a time-based metric to reduce non-value adding activities and resolve the quality-speed conflict. We provide recent empirical evidence.

3 - Using Stochastic Decision Making Processes to Improve Alzheimer's Disease

Saeideh Mirghorbani, Assistant Professor, Binghamton University, Vestal, NY, United States, smirghorbani@binghamton.edu, Sharif Melouk, John Mittenthal

Genetics, high blood pressure and diabetes are some of the factors that place individuals at a higher risk of developing Alzheimer's disease (AD). To manage this risk in persons more susceptible to AD, we develop a partially observable Markov decision process model for individuals transitioning through different stages of AD.

4 - An Optimization Scheme for Malaria Intervention Methods

Johnny Gillings, NC State University, Raleigh, NC, United States

Malaria is a vector borne disease that affects millions throughout the world. The global fight against Malaria has been on-going for decades, and calls to use mathematics to optimize attempts to curb the disease's spread have intensified. In this paper we develop a model for optimally allocating malaria intervention resources within regions subject to budget and feasibility constraints. The outcome of the model is an intervention plan over a given time horizon. The model finds an optimal intervention policy by taking advantage of the problem formation and, if required by the objective function, considering states from differential equations models to determine intervention effectiveness.

1 - Courier Management in Crowd-sourced Food Delivery Operations

Ramon Auad, Ph. D. Student, Georgia Institute of Technology, Atlanta, GA, 30318, United States, rauad@gatech.edu, Alan Erera, Martin Savelsbergh

Recently, online restaurant aggregators with integrated meal delivery networks have substantially grown in popularity. Research efforts in this line have primarily focused on diners satisfaction. However, little research has been done on the satisfaction of couriers, also critical to guarantee the success of this business model. In this work, we additionally consider couriers' satisfaction, which we measure as the size of the region they operate in. We develop a rolling horizon policy that performs dynamic order assignments and region redefinition via bipartite matching, and show evidence of a positive effect from considering couriers satisfaction in the overall delivery operations.

2 - An Integrated Decomposition and Approximate Dynamic Programming Approach for On-demand Ride Pooling

Siqian Shen, Associate Professor, University of Michigan, Industrial & Operations Engineering, Ann Arbor, MI, 48109, United States, siqian@umich.edu, Xian Yu

Ride-pooling optimization, aiming to combine trips of multiple passenger groups with different origin-destination, is challenging and emerging. In this paper, we dynamically match available drivers to randomly arriving passengers over finite stages and also decide pick-up and drop-off routes for each driver. To solve large-scale problem instances, we develop both spatial and temporal decomposition schemes, where we solve each subproblem using Approximate Dynamic Programming (ADP) and couple the solutions. We test instances based on the New York City taxi data to show the positive impacts of pooling rides, computational efficiency of our approach, and empirical convergence of ADP.

3 - Congestion-aware Pricing on Ridesourcing: A Bayesian Optimization Approach

Qi Luo, PhD Candidate, University of Michigan, Ann Arbor, MI, United States, luoqi@umich.edu, Romesh Saigal, Zhiyuan Huang, Henry Lam

Despite the documented benefits of ridesourcing services, recent studies show that they can slow down traffic in the densest cities significantly. To implement congestion pricing policies upon those vehicles, regulators need to estimate how much their congestion effects are. This paper studies simulation-based approaches to address the two technical challenges arising from the representation of system dynamics and the optimization for congestion price mechanisms. This data-driven approach can potentially be extended to solve large-scale congestion pricing problems with unobservable states.

4 - Analyzing Ride-sourcing Systems Using a Fluid Model Framework

Zhengtian Xu, University of Michigan, Ann Arbor, MI, 48105-2540, United States, xzt@umich.edu, Yafeng Yin, Xiuli Chao, Jieping Ye

The popularisation of ride-sourcing services, such as Uber and Didi Chuxing, have attracted extensive research interests in service management. On these quests, there emerges a pressing need for a theoretical framework to capture the operational characteristics of a ride-sourcing system. With the framework, properties of the system performance can be discussed as well as controls and strategies to improve the performance. This study aims to address this need by establishing a fluid model framework. Our model closely follows the operational mechanism of a ride-sourcing system, and is leveraged to examine the system capacity as well as the efficiency of various control strategies.

1 - Scheduling for Order Picking in 3d AS/RS

Mingzhou Jin, University of Tennessee-Knoxville, 525D John D. Tickle Engineering Building, Industrial and Systems Engineering, Knoxville, TN, 37996, United States, jin@utk.edu, Wenquan Dong, Yanyan Wang

We focus on crane-based 3D automated storage and retrieval system (AS/RS) with shuttle-based depth movement mechanisms in this study. The optimization model focuses on the optimal assignment of shuttles, sequence of retrieval tasks and shuttle reallocation tasks. A mixed integer program is developed to minimize the cycle time for a given set of retrieval task and is proven NP-Hard. A genetic algorithm based on the feature of the problem is presented and compared to a commercial solver and the first-come first-serve rule. Numerical experiments are conducted to gain insights on the right number of shuttles.

2 - Optimal Maximum Coverage Location for Electric Vehicle Charging Stations under Uncertainty

Yue Guo, Beijing Institute of Technology, Beijing, China, guoyue16@126.com, Yuli Zhang, Ningwei Zhang, Bingjie Zhong

The deployment of electric vehicle (EV) charging stations is critical to mitigate the mileage anxiety and thus promote EV adoption. This paper considers the optimal EV charging stations location problem where charging demands are uncertain at the infrastructure planning stage. To provide robust location decisions, a two-stage distributionally robust maximum coverage location model is proposed where the uncertain demands are described by mean-covariance information. We provide an equivalent mixed 0-1 quadratic conic programming reformulation and present an efficient algorithm. Numerical experiments are conducted to validate the effectiveness of the proposed model and algorithm.

3 - Optimal Recharge Policy for Battery Electric Vehicles

Peng Li, Rutgers University, Piscataway, NJ, United States, peng.li.scm@rutgers.edu, Chunliu Zhou, Lian Qi

Recent years, Electric Vehicle (EV) has mitigated carbon emission and air pollution in many countries. However, the limited range, inconvenient recharge process and high battery cost of EV have greatly constrained customer adoptions. Although the battery exchange service can partially address these issues,how to optimize operations and reduce the high inventory cost of batteries should still be considered at each swapping station.We propose a navel policy to address these issues as follows 1) how to optimize operations and reduce the batteries inventory cost; 2) how many batteries should be stocked; and 3) how many swapping servers and charging bays should be implemented at each swapping station.

4 - A General Integer Replenishment Policy for Solving the VMI & CS Problem

Feng Liu, Dongbei Univeristy of Finance and Economics, AL, United States, drliufeng@mail.dlut.edu.cn, Ming-Jong Yao

In order to achieve maximum benefits, companies are trying to coordinate their supply chain members using various programmes. In practice, VMI and CS are often combined as a business partnership (VMI&CS). This paper focuses on the inventory management problem for a single-vendor and multiple-buyers supply chain under the VMI&CS and Centralized scenarios. It considers the vendor's setup time and assures that different buyers have different replenishment cycles following the general integer policy. A mathematical model is constructed, and the theoretical analysis on the inventory cost is carried out to design an optimal algorithm.

5 - Online Brands' Pricing and Showroom Decisions

Dincer Konur, Texas State University, San Marcos, TX, 78666, United States, d_k141@txstate.edu

In this study, we investigate two online brands' competitive pricing and showroom decisions. Equilibrium pricing and showroom decisions are characterized under sequential and simultaneous showroom expansion decisions. Then, shared showroom concept through cost- and revenue-sharing contracts is investigated. It is discussed that a brand can incentivize the other brand to share a showroom.

Chair: Reed Harder, Dartmouth, Hanover, NH, 03755, United States

1 - Primary Versus Secondary Mechanisms for Infrastructure Capacity Allocation when Users are Strategic

Vikrant Vaze, Dartmouth College, Murdough Center, Hanover, NH, 03755, United States, vikrant.s.vaze@dartmouth.edu, Alexandre Jacquillat, Weilong Wang

Two broad approaches exist to cope with information asymmetries in non-monetary capacity allocation for infrastructure systems. In a primary mechanism, the infrastructure manager directly determines the schedule. In a secondary mechanism, users can swap their service units following the initial schedule determination by infrastructure manager. The secondary mechanism provides flexibility to align the schedule with users' private preferences. However, this paper develops a bi-level capacity allocation game for multi-period operations, discrete service units and non-atomistic users to show that the secondary mechanism may not result in more efficient outcomes when users are strategic.

2 - Frequency Approximations for Two-stage Location Price Competition

Reed Harder, Dartmouth, Hanover, NH, 03755, United States, reed.haseltine.harder.TH@dartmouth.edu, Vikrant Vaze

In many critical industries, competing firms allocate resources across their networks by deciding service locations and pricing these services. For example, airlines competitively schedule and price flights across many origin-destination pairs. Solving for exact equilibrium service locations and prices can quickly become intractable. However, questions of practical interest are often more concerned with aggregate quantities of service within a market than exact service location decisions. With considerations in mind, we evaluate the effectiveness of approximating location decisions with service frequency decisions in firm profit functions.

3 - Predictive Models of Entry in the United States Airline Industry

Kang Hua Cao, Assistant Professor, Hong Kong Baptist University, Kowloon Tong, Hong Kong, kanghuacao@hkbu.edu.hk, Lei Kang, Chia-Mei Liu, Vikrant Vaze

Existing aviation demand forecasting methods maintain the so-called fixed network assumption. However, ignoring strategic effects among airlines in forecasting can lead to biased results. In this paper, we develop predictive game-theoretic models of entry for the U.S. airline industry. We use the structural model to identify the parameters that represent the strategic (competition) effects by the principle of revealed preference. We apply the model to predict the probabilities involved in an airline company entering or exiting a market.

4 - Quantity - Contingent Auctions for Airport Slot Allocation

Alexander Stewart Estes, University of Minnesota, Minneapolis, MN, 55414, United States, este0100@umn.edu

We propose a new type of auction, called a quantity-contingent auction, to allocate airport arrival and departure slots. A quantity-contingent auction determines both the number of items sold and an allocation of items to bidders. Since such auctions could be used by bidders to gain excessive market power we impose constraints limiting market power. We propose a continuous model and an integer programming model for the associated winner determination problem. Using these models, we perform computational experiments that lend insights into the properties of quantity-contingent auctions when used to allocate slots at an airport.

5 - Benefits of Airline Information Sharing During Airport Ground Delay Programs

Karthik Gopalakrishnan, Massachusetts Institute of Technology, Cambridge, MA, United States, karthikg@mit.edu, Hamsa Balakrishnan

Ground Delay Programs (GDPs) are used to delay flights on the ground at their origins in order to minimize airborne delays during periods of reduced arrival capacity at their destinations. Airlines do not share flight-specific delay costs with the system operator (e.g., the FAA) due to intra-airline competition and privacy concerns. Using simulations, we quantify the loss in system efficiency due to a lack of information-sharing, for different GDP formulations that have been proposed in the literature. This lack of information sharing, while affording the airlines more privacy, is found to have a significant cost in terms of efficiency. These results motivate the study of new approaches to GDPs.

RMP Practice Prize Session

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Guillermo Gallego, Hong Kong University of Science and Technology, Academic Concourse, Hong Kong, 852, Hong Kong

1 - Pricing Analytics for Reusable Resources

Adam Elmachtoub, Columbia University, New York, NY, 10027, United States, Omar Besbes, Yunjie Sun

We describe a comprehensive approach to pricing analytics for reusable resources in the context of rotable spare parts, which are parts that can be repeatedly repaired and resold. Pricing rotables presents unique challenges ranging from limited data, minimal demand information, and complex inventory dynamics. We prove that a static pricing policy is guaranteed to achieve at least 78.9% of the optimal dynamic pricing policy, and up to 95.5% in a special, practical case. We describe a multi-year, large-scale implementation at a major aircraft manufacturer, resulting in 3.9% profit improvement.

2 - Customer Choice Models versus Machine Learning: Finding Optimal Product Displays on Alibaba

Jacob Feldman, Olin Business School, Saint Louis, MO, 63108-1291, United States

We compare the performance of two approaches for finding the optimal set of products to display to customers landing on Alibaba's two online marketplaces, Tmall and Taobao. Both approaches were placed online simultaneously and tested on real customers for one week. The first approach we test is Alibaba's current practice. This procedure embeds thousands of product and customer features within a sophisticated machine learning algorithm that is used to estimate the purchase probabilities of each product for the customer at hand. The products with the largest expected revenue are then made available for purchase. Our second approach uses a featurized multinomial logit (MNL) model to predict purchase probabilities for each arriving customer. We use historical sales data to fit the MNL model and then, for each arriving customer, we solve the cardinality-constrained assortment optimization problem under the MNL model online to find the optimal set of products to display. Our experiments show that despite the lower prediction power of our MNL-based approach, it generates significantly higher revenue per visit compared to the current machine learning algorithm with the same set of features.

3 - Demand Learning and Dynamic Pricing for Varying Assortments: Algorithm Development and Implementation at Zenrez

Kris Johnson Ferreira, Harvard Business School, Boston, MA, 02163, United States

We develop a multi-product, attribute-based demand learning and dynamic pricing algorithm that efficiently learns customer demand to maximize revenue when a small number of price changes are allowed and when products may change over time. Our algorithm follows a learn-then-earn approach, using a novel adaptation of conjoint analysis in the learning phase. We validate the effectiveness of our algorithm through a three-month field experiment with an e-commerce company (Zenrez), where we change the price of products with daily assortment changes. Relative to a control group, our algorithm led to an 8.8% increase in average daily revenue.

4 - RMP Practice Prize

Guillermo Gallego, Hong Kong University of Science and Technology, Academic Concourse, Dept. of Industrial Engr. & Logistics Mgmt, Hong Kong, 852, Hong Kong

Interface of Marketing and Operations Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Spyros Zoumpoulis, INSEAD, Fontainebleau Cedex, 77305, France

1 - Optimization of Multi-channel Marketing Contacts

Kalyan Talluri, Imperial College Business School, United Kingdom, kalyan.talluri@imperial.ac.uk, Clint Ho, Sven Mikolon, Wolfram Wiesemann

We describe a dynamic-programming/machine-learning model to optimize marketing contacts across multiple channels that takes into account customer lifetime value, marketing costs and contact effectiveness. We describe implementation experience at a large telecommunications firm.

2 - Learning Targeting Models under Concept Shift

Spyros Zoumpoulis, INSEAD, Boulevard de Constance, Decision Sciences Area, Fontainebleau, 77305, France, spyros.zoumpoulis@insead.edu, Theodoros Evgeniou, Duncan I. Simester, Artem Timoshenko

A prominent challenge when using machine learning to target marketing actions to different customers is non-stationarity. We focus on concept shift - a form of non-stationarity that involves changes in the customer response function over time. We develop theoretical results on the learnability of targeting models under concept shift, and we develop practical targeting algorithms that perform well in practice. Overall, our findings characterize conditions on non-stationarity under which firms can train targeting models that perform well.

3 - Product Driven Questionnaire Design for Assortment Optimization

Jonathan Z. Amar, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, amarj@mit.edu, Nikolaos Trichakis, Chaithanya Bandi

We develop a novel question-design mechanism in order to improve healthcare plan recommendations. Our algorithm is based on accurately estimating the differences of utilities associated with every plan. Rather than being agnostic to it, our formulation is driven by available assortment, and therefore achieves better performance for plan recommendation. We establish theoretical justification for our algorithm which outperformed state-of-the-art methods on real datasets.

New Directions for Experimentation and Learning in OM

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Yonatan Gur, Stanford University, Stanford, CA, 94305, United States

1 - Sample-Based Optimal Pricing

Omar Besbes, Columbia University, Graduate School of Business, New York, NY, 10027, United States, ob2105@gsb.columbia.edu, Amine Allouah

Pricing is central to many industries and academic disciplines ranging from Operations Research to Computer Science and Economics. In the present talk, we will focus on data-driven optimal pricing in low informational environments. We analyze the fundamental problem of how to optimally price based on a single sample of the willingness-to-pay (WTP) of customers. The decision-maker's objective is to select a general pricing policy with maximum competitive ratio when the WTP distribution is only known to belong to some broad set. We characterize optimal performance across a spectrum of non-parametric families of distributions, α-strongly regular distributions.

2 - Adaptive Sequential Experiments with Unknown Information Flows

Ahmadreza Momeni, Stanford University, Stanford, CA, 94305, United States, amomenis@stanford.edu

We introduce a new, generalized multi-armed bandit (MAB) formulation in which additional information on each arm may appear arbitrarily throughout the decision horizon, and study the impact of such information flows on the achievable performance and the design of efficient policies. By obtaining matching lower and upper bounds, we characterize the (regret) complexity of this family of problems as a function of the information flows. We introduce an adaptive exploration policy that, without any prior knowledge of the information arrival process, attains the best performance that is achievable when the information arrival process is a priori known.

3 - Hedging the Drift: Learning to Optimize under Non-stationarity

Ruihao Zhu, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, rzhu@mit.edu, David Simchi-Levi, Wang Chi Cheung

We introduce general algorithms with state-of-the-art dynamic regret bounds for non-stationary bandit settings. Our main contribution is a general algorithmic recipe that first converts the rate-optimal Upper-Confidence-Bound algorithm for stationary bandit settings into a tuned Sliding Window-UCB algorithm with optimal dynamic regret for the corresponding non-stationary counterpart. Boosted by the novel bandit-over-bandit framework, it even permits us to enjoy, in a parameter-free manner, the (nearly) optimal dynamic regret. We further conduct extensive numerical experiments on the CPRM-12-001: On-Line Auto Lending dataset to show their superior dynamic regret performances.

4 - Towards Instance-optimal Regret in Online Learning

Varun Gupta, University of Chicago, Chicago, IL, United States, Marco Molinaro

The field of online learning and prediction is a rich area of research, with numerous performance metrics which aim to refine the classical notion of regret against a single best action/prediction. There is much less work on an axiomatic approach to defining optimal learners when the environment is non-stationary. In this talk we will discuss our first attempt at this problem for the task of online sequential prediction.

1 - Crowdsourcing Food Recovery Operations: A Platform Design Study

Vahideh Manshadi, Yale University, New Haven, CT, 06511, United States, vahideh.manshadi@yale.edu, Scott Rodilitz, Irene Yuan Lo

Over 60 billion tons of food goes to waste in the U.S. each year, while 40 million people—including 6.5 million children—live in food-insecure households. This mismatch is driven in part by the cost of last-mile transportation required to recover perishable food from local restaurants and grocery stores. In recent years, online platforms have emerged to facilitate crowdsourcing food recovery through volunteer or paid labor. In collaboration with one such platform, we aim to study and improve design decisions that influence the efficiency as well as the growth of the system, which crucially depends on volunteer engagement.

2 - Incentivizing Commuters to Carpool: A Large Field Experiment with Waze

Maxime Cohen, McGill University, Montreal, QC, 10012, Canada, maxccohen@gmail.com, Michael-David Fiszer, Avia Ratzon, Roy Sasson

What factors can persuade commuters to carpool? We run a field experiment on more than half a million users to encourage commuters to carpool using the Waze carpool service. Specifically, we investigate to what extent highlighting the commute time reduction (by using the HOV lane) is an effective incentive. We find that mentioning the HOV lane increases the click-through rate and conversion rate by 133-185% and 64-141%, respectively relative to a generic message. Our results ultimately suggest that users are more reactive to a commute time reduction than to earning compensation.

3 - SKU Proliferation: High-dimensional Choice Models and Online Retailing

Zoey Jiang, University of Michigan, Ann Arbor, MI, 48104, United States, jiangzh@umich.edu, Jun Li, Dennis Zhang

Online retailers are managing a great variety of products under vastly diversified consumer decision journeys. To improve retail pricing decisions, we need to understand the realistic substitution patterns among tons of products offered in the complex online environment. To address this challenge, we develop large-scale choice models that are not only scalable but also allow for flexible substitution patterns by leveraging customer clickstream information as well as econometric and machine learning methods.

4 - How Do Price Promotions Affect Customer Behavior on Retailing Platforms? Evidence from a Large Randomized Experiment on Alibaba

Dennis Zhang, Washington University in St Louis, St Louis, MO, 63130, United States, denniszhang@wustl.edu, Hengchen Dai, Lingxiu Dong

Dynamic pricing through price promotions has been widely employed by online retailers. We study how a promotion strategy—offering customers a discount for products in their shopping cart—affects customer behavior in the short and long term on a retailing platform. We conducted a randomized field experiment involving more than 100 million customers and 11,000 retailers with Alibaba Group, the world's largest retailing platform.

Nonprofit Operations Management: Focus on Resource Management

Sponsored: Public Sector OR

Sponsored Session

Chair: Telesilla Kotsi

Co-Chair: Alfonso J. Pedraza-Martinez, Indiana University, Bloomington, IN, 47405, United States

1 - Volunteers and Paid Workers in a Nonprofit Operation: Trade-offs and Social Outcomes

Lei Li, Purdue University, West Lafayette, IN, United States, leili2851@purdue.edu, Gemma Berenguer

A nonprofit organization offers activities run by workforce that can be composed of a mix of volunteers, part-time and full-time workers. We study this setting by designing a finite-horizon staffing problem to derive the organization's optimal hiring and assignment decisions. Our goal is to understand the key trade-offs between the three different type of workers and how our decisions impact social outcome. We demonstrate that a state-dependent hiring policy for part-time workers can be convenient and optimal under some conditions. We find that the budget has a significant impact on staff assignment policies, and we suggest useful heuristic policies.

2 - Improving Outcomes in Childcare Subsidy Voucher Programs Through Strategic Resource Allocation

Priyank Arora, University of Massachusetts-Amherst, Amherst, MA, 01003, United States, parora@isenberg.umass.edu, Senay Solak, Wei Wei

Childcare Resource and Referral Agencies (CCR&Rs) are tasked by the state governments with improving outcomes of childcare subsidy voucher programs. We analyze the optimal allocation of CCR&R's resources between outreach and engagement activities (with respect to childcare providers) to achieve socially-optimal outcomes across different regions in its service area.

3 - Allocation of Nonprofits' Funds Among Program, Fundraising, and Administration

Telesilla O. Kotsi, Kelley School of Business, Indiana University, Bloomington, IN, 47401, United States, tkotsi@indiana.edu, Goker Aydin, Alfonso J. Pedraza-Martinez

Nonprofits allocate their budget among three types of expenses: program spending to deliver services to beneficiaries; fundraising spending to raise donations; and administration spending to build infrastructure. We analyze how a nonprofit can balance the immediate reward of program spending versus the future reward of fundraising and administration spending. We complement our findings with a case study on foodbanks.

4 - Daily Tutor Scheduling Support at Hopeful Journeys Educational Center

Lucas A. Waddell, Assistant Professor of Mathematics, Bucknell University, Lewisburg, PA, United States, law038@bucknell.edu, Matthew D. Bailey

Hopeful Journeys Educational Center is a non-profit school whose mission is to "provide quality and individualized education to children with autism spectrum disorders and other developmental disabilities." This individualized education is implemented through hour-by-hour one-on-one scheduling of tutors to students five days a week. We present our optimization-based open-source decision support system discussing both the necessary formulation and implementation issues addressed. This DSS is in daily use and has reduced the daily scheduling process by over six hours.

Sponsored Session

Chair: Pieter van den Berg, RSM, RSM, Rotterdam, 3062 PA, Netherlands

Co-Chair: Jordan Srour, Lebanese American University, Beirut, 1102 2801, Lebanon

1 - Fire Truck Relocation During Major Incidents

Robert van der Mei, CWI & Vu University, Science Park 123, Amsterdam, 1098XG, Netherlands, Dmitrii Usanov, Peter van de Ven, Guido Legemaate

We propose an algorithm to compute the optimal relocations of idle fire trucks needed in order to regain good coverage in case of a major fire incident with many fire trucks involved. The algorithm makes relocations by solving a mathematical program that takes into account the location of the available fire trucks and the historic spatial distribution of incidents. We apply the algorithm to the operations of the Fire Department of Amsterdam-Amstelland. We demonstrate a substantial improvement over current practice, and show that not relocating during major incidents, or relocating based on flawed heuristics and intuition, may lead to significant performance degradation.

2 - Artificial Intelligence Techniques for Ambulance Travel Time Prediction

Abbas Tarhini, Lebanese American University, Beirut, Lebanon, Abbas.Tarhini@lau.edu.lb

In emergency medical services (EMS), a fraction of the response time is the time from the dispatch of an ambulance to its arrival at the scene of an emergency. A recognised problem of this domain is the assignment of ambulances from stations in a way that the travel time to the emergency scene is minimised. The purpose of this work is to propose artificial intelligence techniques based on artificial neural network to predict the travel time of ambulances from different stations to the emergency scene. The neural network is trained and tested with data sampled from ambulances run in Lebanon. Results are compared with those of another supervised machine-learning algorithm, Bayes classification algorithm.

3 - Improving Ambulance Coverage in a Mixed Urban-rural Region in Norway

Pieter van den Berg, RSM, Erasmus University, Burgemeester Oudlaan 50, Rotterdam, 3062 PA, Netherlands

In mixed urban-rural areas, this optimization of the ambulance distribution typically involves a trade-off between backup coverage in high-demand urban areas and single coverage in low-demand rural areas. This study applies the well-studied MEXCLP to a mixed urban-rural ambulance region in Norway to investigate how the optimal distribution of ambulances depends on the workload of the system. The results show that certain rural areas should only be covered if the workload allows to shift focus from back-up coverage in the urban areas towards single coverage in rural areas.

Political Redistricting and Public Policy

Emerging Topic: Policy & Government

Emerging Topic Session

Chair: Rahul Swamy, Champaign, IL, 61820, United States

1 - Airline Baggage Fees and Flight Delays

Pritha Dutta, University of Massachusetts-Amherst, Amherst, MA, 01002, United States, Amirhossein Alamdar Yazdi, Adams Steven

We examine the linkages between the implementation of baggage fees and late flights in the airline industry. We find that baggage fees policies result in improvements in ontime performance as assessed through late flights, directly through improvements in airport-side sorting and loading efficiencies, and indirectly through lower air travel demand. We further find that these relationships are contingent upon the presence of a hub airport on a route. Our findings have important managerial and public policy implications as baggage fees have often been cited as a driver of security queue, aircraft alley, and overhead bin congestion, and ultimately delayed flights.

2 - Redistricting in Virginia

Robert Hildebrand, Virginia Tech, Blacksburg, VA, 24061, United States, rhil@vt.edu, Peter Sforza, Laurel E. Travis, Nicolas Goedert, Matthew S. Pierson

Optimal redrawing of legislative districts is inherently multi-objective. Mandated criteria vary by state, but can include equal population, compactness, contiguity, and compliance with the Voting Rights Act. It can often be a challenge to define these criteria mathematically. Most notably, compactness has many different formulations, which may have a partisan bias. Various metrics have been used to judge whether a state's redistricting plan is the product of gerrymandering. We examine inherent bias in optimizing metrics, such as compactness measure, on partisan outcomes.

3 - Contiguity Constraints in Geographic Districting

Douglas M. King, University of Illinois at Urbana-Champaign, Urbana, IL, 61801, United States, Sheldon H. Jacobson, Edward C. Sewell

Geographic districting is often formulated as a graph partitioning problem. Each partite set corresponds to the geographic area composing a single district, which must typically be contiguous. This talk discusses how the geo-graph framework for districting can be used to efficiently enforce these contiguity constraints during local search.

4 - Using Simulated Annealing to Maximize Compactness of Congressional Districts in South Carolina

Blake Splitter, Clemson University, Clemson, SC, United States, bsplitt@clemson.edu

Ensuring that congressional districts are "compact" is of paramount importance for most states in the US. In particular, South Carolina's constitution requires that congressional districts be compact. In this presentation, we use simulated annealing to generate maps that seek to optimize Polsby-Popper compactness and other measures, subject to contiguity and population constraints while considering political boundaries. Understanding how compact a state's congressional districts could be might be valuable evidence in determining whether the state is gerrymandered or not.

5 - Transparency vs Fairness in Political Redistricting

Rahul Swamy, University of Illinois at Urbana-Champaign, Urbana, IL, 61801, United States, rahulswa@illinois.edu, Douglas M. King, Sheldon H. Jacobson

Political redistricting using fairness objectives has been an upcoming topic of interest. Prior research using optimization algorithms have studied this problem in a multi-objective setting. The presented work analyzes the extreme outcomes resulting from an optimization algorithm that focuses on one particular objective. A case study on congressional redistricting is presented, that highlights the need transparency in redistricting algorithms in addition to fairness considerations.

Vendor Tutorial

1 - End-to-End FICO® Xpress Insight Tutorial: From Data to Decisions for Non-Technical Business Users

James T. Williams, FICO, 2665 Long Lake Rd, Building C, Roseville, MN, 55113, United States

You have a team with a great analytics background. They've developed advanced analytical tools using Python, R, or your current optimization solver. They've derived crucial insights from your data and figured out how your decisions shape your customers' behaviors. Now it's time to put these critical analytical insights into the hands of your non-technical business users. In this tutorial, you'll learn how FICO's Xpress Optimization solutions (including Xpress Mosel, Xpress Workbench, Xpress Solver and Xpress Insight) make it possible to embed your analytic models in business user-friendly applications. See how to supercharge your analytic models with simulation, optimization, reporting, what-if analysis, and agile extensibility for your ever-changing business. Plus, you'll discover how to use the new View Designer to reduce GUI development times from minutes to seconds.

2 - Building Optimization Applications with MATLAB

Mary C. Fenelon, MathWorks, 3 Apple Hill Dr., Natick, MA, 01760-2098, United States

MATLAB makes it easy to build optimization applications that can be deployed royalty-free as standalone executables or as web apps. In this tutorial you will learn how to work with and clean Big Data, train machine learning models from that data, specify optimization models with an algebraic syntax, and build a web app that returns optimal decisions from the predicted outcomes.

Co-Chair: Xiao Liu

1 - Using Neural Networks in Condition Monitoring and Process Control

Nan Chen, National University of Singapore, Department of Industrial and System Eng, 1 Engineering Drive 2, Singapore, 117576, Singapore, isecn@nus.edu.sg, Rui Wang

In this talk, we introduce a few examples where we apply the deep learning approaches, particularly the convolutional neural networks, in various applications in condition monitoring and process control with complex data structures. We mainly discuss the characteristics of the data, and how to transform them meaningfully to suit the CNN architecture. Comparisons with other approaches are also carried out to demonstrate the effectiveness.

2 - Bayesian Cross Product Process Monitoring via Transfer Learning

Kai Wang, HKUST, Hong Kong, kwangai@connect.ust.hk, Fugee Tsung, Zhenli Song

Process control is essential for high quality. The traditional SPC, however, fails often in modern high-variety industrial cases since process data of one product become scarce. To solve this small data challenge, a novel Bayesian cross-product process monitoring scheme is proposed. In particular, a joint prior distribution is used to model the relatedness between similar products, through which information can be transferred between domains. The posteriors are derived in closed forms which lead to calculation efficiency for online monitoring. A user-specified parameter is also provided to enable a better understanding of transferability issue and a free control of transferred information.

3 - A Machine Learning Method for Tool Wear Evaluation

Luca Pagani, Huddersfield University, Huddersfield, United Kingdom, L.Pagani@hud.ac.uk, Paolo Parenti, Salvatore Cataldo, Massimiliano Annoni, Scott James Scott

Indirect classification of the tool wear based on chips' color allows fast detection of out of control parts. In this paper an artificial neural network able to monitor the condition of the tool is proposed. The algorithm takes as input the color histograms of the chips, the network is then trained in order to detected high tool's wear conditions.

4 - Integrating Pre-existing Knowledge to Improve Machine Learning for Additive Manufacturing Through a Graph-based Approach

Hari P.n. Nagarajan, Doctoral Student, Tampere University, Tampere, Finland, Hossein Mokhtarian, Suraj Panicker, Eric Coatanéa, Karl R. Haapala

Additive manufacturing (AM) serves as a melting pot of variables and data for machine learning to thrive. However, machine learning based models are case-specific black box models, which lack interpretability and require extensive testing and experimentation to represent a holistic system perspective. Integrating pre-existing domain knowledge would enable transparent and cost-effective development of grey-box machine learning models. This talk presents dimensional analysis conceptual modeling framework (DACM) framework as a graph-based tool for knowledge integration and a precursor for implementation of artificial neural networks and Bayesian networks for AM process modeling.

5 - Sieve Estimation for Warranty Data

Zhisheng Ye, National University of Singapore, Singapore, Yudong Wang

Product return data are usually subject to two layers of right censoring. The first layer applies to the product lifetime due to a fixed warranty limit. The second layer applies to the sum of the sales lag and the lifetime due to the end-of-study date for the data collection. This study develops a generic method for the two-layer censored data using acyclic phase-type distributions (APHDs) in the canonical form. Based on the property that the class of APHDs is closed under convolution, a dedicated expectation-maximization algorithm is proposed for parameter estimation. Two real examples are used to illustrate the proposed method.

1 - Robust Experimental Designs for Model Calibration

Arvind Krishna, Georgia Institute of Technology, Atlanta, GA, 30318, United States, Roshan V. Joseph, Shan Ba, William Brenneman, William Myers

A physics-based model can be used for predicting an output only after specifying the values of some unknown constants known as calibration parameters. The unknown calibration parameters can be estimated from real data by conducting physical experiments. This paper presents an approach to optimally design such a physical experiment by taking advantage of the information contained in the physics-based model. The main feature of the proposed design is that although it uses the physics-based model for its construction, it is to some extent robust to potential model biases.

2 - Simulation Parameter Calibration with Adaptive Stochastic Gradient Descent

Bingjie Liu, PhD Student, University of Michigan, Ann Arbor, MI, 48105, United States, bingjiel@umich.edu, Xubo Yue, Eunshin Byon, Raed Kontar

Parameter calibration is one of the widely used techniques to improve the performance of simulation model. We cast the problem into the stochastic optimization framework and provide its solution procedure based on the stochastic gradient descent approach. In particular, we apply the variance reduction technique to reduce the computational time. The estimation performance is validated through numerical examples and case study.

3 - BDRYGP: A New Gaussian Process Model for Incorporating Boundary Information Presenter

Liang Ding, HKUST, Academic Building Room 5568, Clear Water Bay, Kowloon, Hong Kong, China, ldingaa@connect.ust.hk

Gaussian processes (GP) are widely used for surrogate modeling, but existing GP methods largely ignore boundary conditions of the underlying system. We propose a new Boundary-Conditioned Gaussian process (BCGP) model, which integrates boundary conditions within GP modeling via a product Brownian bridge correlation function. This offers two important theoretical advantages for our model. First, the equivalence between BCGP and a specific Finite Element Method leads to matrix-free computation for the model. Second, the BCGP emulator enjoys convergence rates O(n-1) for fixed dimension. These greatly improve upon existing GP performance which neglect boundary conditions.

4 - Computer Model Calibration with Low Resolution Field Data and High Resolution Experimental Data

Wenbo Sun, Research Fellow, University of Michigan, Ann Arbor, MI, 48104, United States, sunwbgt@umich.edu, Matthew Plumlee

Computer simulations are commonly used to predict responses of physical systems. When simulation models are not accurate, physical experimental data are introduced to calibrate these simulation models. However, physical experimental data are often limited due to resources' constraints and give rise to low calibration performances. In this presentation, we will discuss the case when in addition to the physical experimental data, more noisy field test data but of a greater sample size are collected. We will show the effectiveness of introducing the field test data to the calibration problem. Both a numerical example and a case study in the vehicle safety application will be provided.

Applied Health Research by Bonder Scholars

Sponsored: Health Applications

Sponsored Session

Chair: Justin J. Boutilier, University of Wisconsin-Madison, Madison, WI, 53706, United States

1 - Optimizing Treatment Decisions under Strategically Reported Symptoms

Gian-Gabriel P. Garcia, University of Michigan, Ann Arbor, MI, 48105, United States, garciagg@umich.edu, Mariel Sofia Lavieri, Steven Broglio

Doctors rely on a broad range of information to assess patients' health and determine which treatments a patient should receive. A major challenge for doctors is to properly interpret subjective information - such as self-reported symptoms - when making treatment decisions. We model the patient's and doctor's dynamic decision problems as a multi-agent partially observable Markov Decision Process (mPOMDP). We derive structural properties of the mPOMDP and characterize its optimal policy. Then, we apply the mPOMDP to return-to-play decisions for patients with concussion.

2 - Proportionally Fair Organ Allocation Rules

Farhad Hasankhani, Clemson University, Clesmon, SC, United States, fhasank@g.clemson.edu, Amin Khademi

In this study we propose a new fairness measure into organ allocation rules and provide insights about the optimal policy with respect to this measure. We apply several policies and compare the results in terms of efficiency and fairness via a validated simulation model for heart transplantation.

3 - Ambulance Emergency Response Optimization in Developing Urban Centers

Justin J. Boutilier, University of Wisconsin-Madison, Madison, WI, 53706, United States, Timothy Chan

The lack of emergency medical transportation is viewed as the main barrier to the access and availability of emergency medical care in low and middle-income countries (LMICs). In this paper, we combine machine learning models with a robust optimization approach to determine both the location and routing of emergency response vehicles, accounting for uncertainty in travel times and spatial demand characteristic of LMICs. We then evaluate our solutions and provide an in-depth investigation into policy-related questions using a simulation model based on real data from Dhaka, Bangladesh.

4 - Risk-sharing Agreements For New Medical Treatments

Ozge Yapar, Indiana University, Bloomington, IN, United States, Stephen E. Chick, Noah Gans

Any estimate of a new treatment's value that relies only on clinical-trial data can have significant residual uncertainty. Post-marketing data, captured after the treatment has entered the market, can augment clinical-trial data to better validate the safety, efficacy, and economic value of the treatment. In fact, new risk-sharing contracts, in which a treatment's price is a function of post-marketing data, are under consideration around the world. We analyze several types of agreements that update the price according to a range of contract terms. An understanding of the equilibrium outcomes of different types of agreements is valuable to payers as they decide which contract forms to offer.

Joint Session HAS/MIF/Practice Curated: Causal inference and Applications in Healthcare

Sponsored: Health Applications

Sponsored Session

Chair: Gabriel Zayas-Caban, Madison, WI, 53706-1691, United States

Co-Chair: Toyya Pujol

1 - Almost Exact Matching for Causal Inference

Cynthia Rudin, Duke, LSRC, Durham, NC, 27708, United States

I will describe new matching algorithms for causal inference that match treatment and control units almost exactly, meaning that matches are made using as many covariates as possible. Machine learning on a training set is used to learn the distance metric for matching.

2 - Robust Statistical Learning Methods for Difference-in-Differences Designs

Toyya Pujol, Georgia Institute of Technology, Atlanta, GA, United States, pujol@gatech.edu, Sherri Rose

Typical methods for difference-in-differences (DID) analyses rely on parametric statistical models. Our project extends statistical machine learning methods to target a DID parameter while: considering a larger nonparametric model space that makes fewer assumptions and accounting for nuances commonly found in health care research questions. We develop this framework for healthcare DID designs that also allows researchers to estimate causal/statistical effect quantities using double robust machine learning. The method is demonstrated in simulation settings and a health care policy application estimating the effect of an episode-based bundled payment program on perinatal spending.

3 - Identification in Missing Data Models Represented by Directed Acyclic Graphs

Ilya Shpitser, John C. Malone Assistant Professor, Johns Hopkins University, Baltimore, MD, United States

Missing data is a pervasive problem in data analyses, resulting in datasets that contain censored realizations of a target distribution. Many approaches to inference on the target distribution using censored observed data, rely on missing data models represented as a factorization with respect to a DAG. We consider the identifiability of the target distribution within this class of models, and show that the most general identification strategies proposed so far retain a significant gap. To address this gap, we will describe a new algorithm that significantly generalizes the types of manipulations used in the ID algorithm, developed in the context of causal inference.

4 - Impact of Treatment Time on the Risk of Emergency Department Admission Decisions and Patient Outcomes

Gabriel Zayas-Caban, University of Wisconsin-Madison, Mechanical Engineering Building, Madison, WI, 53706-1691, United States, zayascaban@wisc.edu, Sebastian Alvarez Avendano, Amy Cochran, Keith Kocher, Brian Patterson

We address the question of how to optimize patient outcomes in a decision-making scenario using causal inference in a latent variable setting. We approach this question by controlling the patient treatment, which affects the decision to admit or discharge a patient over time. We examine which adjustments optimize a patient's outcome. We then analyze the impact of optimized adjustments on patient flow in the Emergency Department.

Emerging Topics in Healthcare Operations and Policy

Sponsored: Health Applications

Sponsored Session

Chair: Can Zhang, Duke University, Durham, NC, 27708, United States

1 - Personalized Models for Precision Heparin Dosing

Yonatan Mintz, Georgia Tech, Atlanta, GA, 30308, United States, ymintz@gatech.edu, Eva Lee

Finding optimal dose levels for time sensitive drugs such as heparin is crucial for avoiding adverse health effects. Computing these heparin doses for patients is particularly challenging since the concentration of heparin in the blood cannot be measured directly and the rates at which patients metabolize it vary greatly between individuals. In this talk we design a personalized framework for optimizing heparin doses. Using a pharmacokinetic model, we infer the current concentration of heparin and predict future therapeutic effects. We validate the predictive capabilities of our model against existing machine learning techniques and show how it can be used to optimize patient dosing.

2 - Pricing, Quality and Competition at On-demand Healthcare Service Platforms

Yixuan Liu, University of Texas, Austin, TX, 78705, United States, yixuan.liu@utexas.edu, Xiaofang Wang, Stephen M. Gilbert, Guoming Lai

We develop a strategic queueing model to study the strategic decisions of the parties at an on-demand healthcare platform. The platform decides the commission rate upon which potential doctors make their participation, service quality and pricing decisions and potential patients make their service acquisition decisions independently. We find that a higher commission rate always lowers doctor participation and service quality but may increase the service price. When the quality sensitivity of the patients increases, the service quality improves, accompanied with a higher price. Allowing the platform to control the service price may result in higher participation, higher quality and price.

3 - Incentive Mechanism Design for Patient Switching in Hospital Queuing Systems

Xinghao Yan, University of Toledo, 2801 W. Bancroft Street, Toledo, OH, 43606, United States, Xinghao.Yan@UToledo.edu, Hui Zhao, Guodong Pang

Effective use of doctor resources, especially specialized doctor resources, allows hospitals provide high-quality care to patients. However, hospitals in China experience high levels of inefficiency in the use of specialized doctors. While high levels of congestion are observed in the queues of specialized doctors, there are not enough patients in the general doctors' queues. However, not all patients in the queues of specialized doctors actually need to visit the specialized doctors. In this study, we design the incentive mechanism for the hospital to encourage patients to switch from the queue of specialized doctors to that of general doctor so as to achieve the optimized system utility.

4 - Risk-sharing Agreements for New Medical Treatments

Ozge Yapar, Indiana University, Wharton School of Business, Bloomington, IN, 19103, United States, oyapar@iu.edu, Stephen E. Chick, Noah Gans

Any estimate of a new treatment's value that relies only on clinical-trial data can have significant residual uncertainty. Post-marketing data, captured after the treatment has entered the market, can augment clinical-trial data to better validate the safety, efficacy, and economic value of the treatment. In fact, new risk-sharing contracts, in which a treatment's price is a function of post-marketing data, are under consideration around the world. We analyze several types of agreements that update the price according to a range of contract terms. Analytics for Healthcare Decision Making

Sponsored: Health Applications

Sponsored Session

Chair: Rema Padman, Carnegie Mellon University, Pittsburgh, PA, 15213, United States

1 - Can We Improve Timely Prediction of Stroke Diagnosis?

Min Chen, Florida International University, Miami, FL, United States, mchen2@fiu.edu, Rema Padman, Tan Xuan, Macickova Jana, Manjiri Kshirsagar, Ashita Vadlamudi

Timely and accurate prediction of prevalent acute diseases such as stroke can significantly reduce health care spending and improve patient outcomes. This study explores whether and how we can improve our ability to distinguish between stroke and stroke-like conditions ("stroke mimics") at hospital admission.

2 - Predicting the Risk of Surgery in Patients with Small Bowel Crohn's Disease

Mohammad Samie Tootooni, Mayo Clinic, Rochester, MN, 55906, United States, tootooni.mohammad@mayo.edu, Narges Shahraki, Benjamin Voss, Joel Fletcher, David Bruining, Mustafa Y. Sir, Kalyan Pasupathy

Crohn's Disease (CD) is one of the most prevalent inflammatory bowel diseases. We develop a logistic regression model to predict near-term surgical risk in patients with small bowel CD. The data is from 85 patients (42% female), who were treated at Mayo Clinic, Rochester, MN. Age, Harvey Bradshaw index, max mural thickness, presence of anastomosis, and multiple strictures are predictive of near-term surgical risk. The overall prediction accuracy on the validation se6t is 75% and AUROC is 0.73. This model can inform personalized treatment strategies in the management of small bowel CD.

3 - Readmission Risk Factors of CABG Surgery: Role of Surgeon and Hospital Workload

Indranil R. Bardhan, The University of Texas at Austin, Plano, TX, 75025, United States, indranil.bardhan@mccombs.utexas.edu, Jiongyun Li

We examine two critical drivers of outcome variation associated with CABG surgeries, namely hospital and surgeon cumulative workload. Drawing on data sets from Dallas Fort Worth Hospital Council and the Texas Quality Initiative, we study patient-level CABG surgeries among all patients in North Texas during a three-year period from 2011 to 2014. We find that hospital and surgeon volume are negatively associated with patient health outcomes. specifically 30-day readmission risk and frequency. Our research is one of the first studies to identify factors associated with readmission risk of CABG patients, based on data from patient visits across multiple hospitals in a large geographic region.

4 - Dynamic Classification of Rapid Progression of Glaucoma Using Supervised Machine Learning

Isaac A. Jones, University of Michigan, Ann Arbor, MI, 48141, United States, isaacaj@umich.edu, Mark P. Van Oyen, Christopher A. Andrews, Mariel Sofia Lavieri, Joshua D. Stein

To prevent vision loss, our method predicts if a patient with Glaucoma (OAG) at time t is about to experience an episode of rapid progression (RP) in the near future. RP classification is based on the predicted likelihood of progression from a current visit time t, through a follow-up window ending at year t+Y. RP was defined as a decrease of at least -1 dB/year loss in mean deviation (MD) indicated by linear regression. We developed a soft voting ensemble classifier with an ROC of 0.82 for classifying RP events over a window of the next 2 years with similar results for 3 years.

5 - Predicting Post-Surgical Complications

Rema Padman, Carnegie Mellon University, H. John Heinz III College, Mgmt Sci & Healthcare Informatics, Pittsburgh, PA, 15213, United States, rpadman@cmu.edu, Urmila Ravichandran, Jennifer Grant, Philip Prosapio, Nirav Shah

Early prediction of which patients are at increased risk of differing categories of postoperative complications can limit unnecessary testing and antibiotic prescribing and facilitate appropriate interventions. We apply multi-trajectory modeling and analysis to evaluate 589 elective colectomy patients from 2007-2013 who follow similar progression of inpatient stay to identify their distinct trajectories of physiological measurements and likelihood of serious complications.

Emerging Topics in Personalized Medicine II

Emerging Topic: Personalized Health

Emerging Topic Session

Chair: Dimitris Bertsimas, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States

1 - Stable Regression: on the Power of Optimization over Randomization

Ivan Paskov, Massachusetts Institute of Technology, Cambridge, NY, United States, ipaskov@mit.edu, Dimitris Bertsimas

In this paper, we investigate and ultimately suggest remediation to the widely held belief that the best way to train regression models is via random assignment of our data to training/validation sets. In particular, we show that taking a robust optimization approach, and optimally picking such training/validation sets, leads to models that yield lower prediction error, prediction standard deviation, coefficient standard deviation, superior support recovery, and is also equivalent to constructing models that are robust to all subpopulations in the data. All of this is accompanied by a very efficient algorithm that scales this optimization approach to training to essentially any desired size.

2 - Optimal Forests

Yuchen Wang, Massachusetts Institute of Technology, Cambridge, MA, United States, yuchenw@mit.edu, Dimitris Bertsimas

In our previous work, we present Optimal Classification and Regression Trees, a novel approach to solve the decision tree problem using mixed-integer optimization and local search techniques that yields a near-optimal decision tree for axis-paralleled splits (OCT, ORT) and with hyperplane splits and a linear regression function in the leaf nodes (ORT-LH). In this work, we show how to use ORT to form Optimal Forests, which has better performance than from Forests using randomness. We use an example in healthcare to illustrate that.

3 - A Unified Approach to Mixed-integer Optimization: Nonlinear Formulations and Scalable Algorithms

Ryan Cory-Wright, MIT, Cambridge, MA, United States, Dimitris Bertsimas, Jean A.N. Pauphilet

We propose a unified framework to address a family of mixed-integer optimization problems, including network design, sparse portfolio and sparse learning problems. These problems exhibit logical relationships which are usually reformulated linearly using a big-M formulation. In this work, we challenge this practice by expressing the logical constraints in a non-linear way. By imposing a regularization condition, we derive a convex binary reformulation, which is solvable via an outer-approximation procedure. Our approach solves network design problems with 100s of nodes; sparse portfolio problems with up to 3,200 securities; and sparse regression problems with 100,000s of covariates.

4 - Fast Exact Matrix Completion: A Unifying Optimization Framework

Michael Lingzhi Li, Massachusetts Institute of Technology, Cambridge, MA, United States, mlli@mit.edu

We consider the problem of matrix completion. We show that both the general case and the case with side information can be formulated as a combinatorical problem of selecting k vectors from p columns. We demonstrate that it is equivalent to a separable optimization problem that is amenable to stochastic gradient descent. We design fastImpute based on projected stochastic gradient descent to scale beyond n=105 . We report experiments to show fastImpute is competitive in both accuracy and time needed across all cases. Furthermore, when a high number of entries are missing, fastImpute is over 70% lower in MAPE and 10x faster than current state-of-the-art methods.

5 - Novel Mixed Integer Optimization Sparse Regression Approach in Spectroscopy

Driss Lahlou Kitane, Massachusetts Institute of Technology, Cambridge, MA, United States, driss@mit.edu, Dimitris Bertsimas

Laser Induced Breakdown Spectroscopy plays an increasingly role in chemometrics as a tool for real time chemical analysis. After irradiating the surface of a material to be analyzed, spectra are collected and used to determine the chemical composition of the material with high precision. While standards methods to analyse the spectra rely on Partial Least Square and LASSO methods, we present a novel method using Mixed Integer Optimization methods for sparse regression to interpret and estimate chemical composition using collected spectra. Presented method significantly improves accuracy and interpretability.

Simulation Analysis and Methods

Sponsored: Simulation

Sponsored Session

Chair: Qiong Zhang, Clemson University, Clemson, SC, 29634, United States

Co-Chair: Wei Xie, Northeastern University, Boston, MA, 02115, United States

1 - A Simulation-based Decision Framework for Stable, Flexible and Efficient Biomanufacturing Development

Wei Xie, Northeastern University, Boston, MA, United States, w.xie@northeastern.edu, Bo Wang, Tugce Martagan, Alp Akcay, Canan Corlu

We develop a stochastic simulation model for biomanufacturing risk analysis. By exploring bio-technology domain knowledge, we model how the properties or attributes of each batch dynamically evolves along the production process. We consider main sources of uncertainty leading to batch-to-batch variation. The proposed simulation framework can facilitate biomanufacturing risk management and guide operational decision making so that the stability of bio-drug quality can be improved while efficiently utilizing the resources and speeding up the time to market.

2 - Balancing Optimal Large Deviations in Sequential Selection

Ye Chen, Virginia Commonwealth University, Richmond, VA, United States, Ilya O. Ryzhov

In the ranking and selection problem, a sampling budget is allocated among a finite number of designs with the goal of efficiently identifying the best. A popular methodological strategy in the simulation literature is to first characterize optimal static allocations, by using large deviations theory to derive a set of optimality conditions, and then to use these conditions to guide the design of adaptive allocations. We propose a new methodology that can be guaranteed to adaptively learn the solution to these optimality conditions in a computationally efficient manner, without any tunable parameters, and under general assumptions on the sampling distribution.

3 - Dynamic Sampling Procedure for Selecting Important Nodes in Decomposable Random Network

Haidong Li, Peking University, Beijing, China, haidong.li@pku.edu.cn

In the world wide web and social networks, nodes are linked with each other randomly with certain transition probabilities, and their importance is ranked by the corresponding stationary probabilities in a Markov chain. We consider a Markov chain with several ergodic classes and unknown transition probabilities which can be estimated by sampling. In this study, we aim to select all of the best nodes in each ergodic class. Under a Bayesian framework, a dynamic sampling procedure is proposed to decompose the Markov chain and maximize a weighted probability of correct selection of the best nodes in each ergodic class. Numerical results demonstrate the superiority of the proposed sampling procedure.

Optimization in the Sharing Economy

Emerging Topic: Sharing Economy & Crowdsourcing

Emerging Topic Session

Chair: Konstantina Mellou, Massachusetts Institute of Technology, Cambridge, MA, 02141, United States

1 - Escrow Payments: A Smoother Driver Pay Mechanism

Daniel Freund, Lyft/MIT, 109 Lake St, Cambridge, MA, 14850, United States, df365@cornell.edu, Arash Asadpour, Garrett J. van Ryzin

Dynamic pricing is a frequently used tool to match supply and demand in the gig economy. The comparatively fast-paced dynamics of supply and demand have also led to dynamic pricing featuring prominently in the recent operations research literature.In practice, ridesharing platforms like Lyft and Uber no longer employ the strictly proportional commission. Further, beyond the driver's expected pay, the volatility in prices affects drivers' decision-making. We discuss a mechanism to smooth the driver's dynamic pay and analyze its properties in a stylized stochastic setting. We demonstrate both numerically and analytically the characteristics of the mechanism and discuss its potential benefits.

2 - Optimization in the Age of Connected and Automated Vehicles

Cathy Wu, Microsoft Research, Redmond, WA, United States

This talk describes techniques in machine learning and optimization critical for enabling mixed-autonomy mobility, the gradual and complex integration of automated vehicles into the existing transportation system. To address computational limitations of existing methods to large-scale control systems, generic reinforcement learning techniques for improved variance reduction are developed. Leveraging and advancing techniques in model-free deep reinforcement learning and control theory, the talk explores and quantifies the potential impact of a small fraction of automated vehicles on low-level traffic flow dynamics such as congestion on a variety of important traffic contexts.

3 - Dynamic Pricing and Matching in Ride-hailing Platforms

Chiwei Yan, Uber Technologies, San Francisco, CA, 94103, United States, University of Washington, Seattle, WA, United States, Nikita Korolko, Dawn Woodard, Helin Zhu

Advanced matching and dynamic pricing algorithms are the two key levers in ride-hailing platforms. We give a brief overview of state-of-the-art matching and pricing algorithms run by these platforms. We then demonstrate via a stylized model, calibrated with Uber data, that the synergy of these two levers can bring significantly more benefits. To be specific, we study a novel matching mechanism called dynamic waiting. We show that pricing and waiting could be jointly optimized in reducing rider and driving waiting times, lowering price volatility, and increasing trip volume and welfare.

4 - Car-sharing Service Design: A Simulation-based Optimization Approach for High Dimensional Problems

Tianli Zhou, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, Carolina Osorio

We present an algorithm for a class of high-dimensional discrete simulation-based optimization problems that arise in car-sharing service design. Through a Boston case study, we show how the use of analytical MIP information enables traditional simulation-based optimization algorithms to become scalable (i.e., suitable for high-dimensional problems) and computationally efficient. Specifically, we show how this MIP information improves the small sample size performance of both locally convergent and globally convergent general-purpose simulation-based optimization algorithms.

1 - A Competitive Analysis of Large Marathons

Thomas Robbins, East Carolina University, Greenville, NC, 27858, United States, robbinst@ecu.edu

A marathon is a 26.2 mile race. Every year tens of thousands of runners compete in marathons all over the world. The largest marathons attract more than tens of thousands of runners, with the largest marathon having more than 50,000 finishers. In this talk we review an analysis of more than 2.6 million times from 10 large marathons held over the last 10 years. We examine issues of competitiveness across races, age groups, and genders. We investigate how finish times as well as the effort to finish ahead of round number goals.

2 - The Impact of Rim Protectors in the NBA

Baback Vaziri, James Madison University, Harrisonburg, VA, 22807, United States, vaziribx@jmu.edu, Ryan Dailey, Scott Stevens

There are many factors that determine the makeup of an NBA roster. Thus, franchises are constantly evaluating these factors to help build a winning team. In this research study, the authors explore the impact of rim protectors on teams' regular season win total and championship outcomes from previous seasons. Traditional and binary logistic regression techniques are used to measure the statistical significance of the defensive rating (measure of defensive efficiency) of the rim protectors and their respective teams' projected 82 game win total and championship outcomes.

3 - Swing Shift: Placing Fielders to Minimize the Impact of a Batter

Kevin Hutson, Furman University, Dept of Mathematics, Greenville, SC, 29613, United States, kevin.hutson@furman.edu, Elizabeth Bouzarth, Andrew Hartley, Ella Morton, John Harris, Ben Grannan

Baseball is a sport that is tied to tradition. One of these traditions is the placement of fielders in the infield and outfield. Recently, some Major League Baseball teams have discarded tradition and moved fielders into seemingly strange configurations to try to increase the chances of getting a batter out or reduce the impact the batter has on the game. The rules of baseball only confine the positions of the pitcher and catcher, meaning that the other seven fielders are free to play anywhere. In this project we develop a MILP model that seeks the optimal field placement for each of the seven fielders so as to maximize a team's chance of getting a batter out based on the batter's specific hitting tendencies.

4 - Moneyball on Campus – As Experiential Learning

Scott Nestler, Academic Director, MSBA Program, University of Notre Dame, Notre Dame, IN, 46530, United States

In this presentation, we provide an overview of the process we followed to start a sports analytics club at the University of Notre Dame, beginning in 2016. Quick wins, showing value, buy-in from the athletics department, and organized student leaders are key. Specific examples from football, baseball, hockey, soccer, basketball, and volleyball will be shown. Additionally, we survey the landscape of what faculty and students are doing at other schools.

5 - Identifying Factors for Elbow Injuries of Major League Baseball Pitchers

Courtney J. Burris, University at Buffalo, Buffalo, NY, 14216, United States, cburris2@buffalo.edu, Demetrios Papazaharias, Carter Mann

Over the past decade, there has been an increase in analytics and data integration in sports. Accurate injury prediction for pitchers in MLB can have a significant economic effect throughout the league. We consider the problem of predicting which MLB pitchers are most at risk of tearing their UCL from a data science perspective. Also, we wish to understand which factors contribute most to a pitcher's injury risk. Factors are divided into three groups: cumulative metrics, performance metrics, and bio-metrics. Predictors from each of the three groups were considered when creating our models. We found that percentage of pitch types were the most important factors in predicting injury in MLB pitchers.

1 - How to Hire Secretaries with Stochastic Departures

Shai Vardi, Purdue University, West Lafayette, IN, 47906, United States, Thomas Kesselheim, Alexandros Psomas

We study a generalization of the secretary problem, where decisions do not have to be made immediately upon candidates' arrivals.After arriving, each candidate stays in the system for some (random) amount of time and then leaves, whereupon the algorithm has to decide irrevocably whether to select this candidate or not. The goal is to maximize the probability of selecting the best candidate overall. We assume that the arrival waiting times are drawn from known distributions. Our first main result is a characterization of the optimal policy for this setting. We show that when deciding whether to select a candidate it suffices to know only the time and the number of candidates that have arrived so far. Furthermore, the policy is monotone non-decreasing in the number of candidates seen so far, and, under certain natural conditions, monotone non-increasing in the time.Our second main result is proving that when the number of candidates is large, a single threshold policy is almost optimal.

2 - How Platform Businesses Create Value by Lubricating the Frictions in the Markets? An Information Theoretic Perspective

Anparasan Mahalingam, Krannert School of Management and School of Industrial Engineering, Purdue University, West Lafayette, IN, 47906, United States, anparasan@purdue.edu, Richard J. Makadok

Our contention in this paper is that platform-based business models supported by digital technologies are able to succeed and create value by lubricating long-standing frictions in the markets. Theoretical model in this paper looks into three classic information-economics frictions; search costs, coordination costs, and transaction costs, and discuss how synergies among the capabilities for solving these three problems can help platform businesses build and sustain competitive advantage over either rival platforms or non-platform substitutes.

3 - A Meta-analysis of P-hacking in E-commerce Experiments

Alex Miller, PhD Student, Wharton School, University of Pennsylvania, Wharton School, Philadelphia, PA, 19104, United States

We study the prevalence of p-hacking in a sample of nearly 2,500 experiments from more than 250 e-commerce firms conducted on a large A/B testing platform. Contrary to expectations, our empirical results across several specifications provide little evidence for p-hacking in our sample. We develop a set of simulated counterfactuals to demonstrate that, if a modest effect of p-hacking did exist, our statistical methodology would have the power to detect it at our current sample size. Despite finding a null result, this research makes a valuable contribution by providing empirical evidence that informs our understanding of how firms may use/abuse modern testing platforms.

4 - Firm-specific Network Formation on Lightning Networks

Vipul Aggarwal, University of Washington, Seattle, WA, 98105, United States, aggarv@uw.edu, Wanyi Chen, Yong Tan

In this paper, we investigate the network formation mechanism for Lightning Networks (LN). LN are widely believed to be the solution to Bitcoin's (and other similar cryptocurrencies) scalability problem. LN allows transacting parties to create bidirectional payment channels between themselves through which funds can be transferred immediately at very, very low transaction fees. However, capital constraints restrict the addition of new nodes. We look into the firm-centric transaction needs of users and analyze their impact on the resulting network topologies.

Procurement and Social Responsibility in Behavioral Operations

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Anyan Qi, The University of Texas at Dallas, Richardson, TX, 75080, United States

1 - The Behavioral Peril of Low Cost Sourcing

Jiayu Chen, The University of Texas at Dallas, Richardson, TX, 75080, United States, Anyan Qi, Elena Katok

We consider a stylized dyadic supply chain with one buyer and one supplier. The buyer decides the sourcing cost to pay the supplier, and the supplier decides the total surplus of the supply chain. We explore the behavioral peril of low-cost sourcing in such a supply chain and offer some novel and useful insights.

2 - Reliably Responsible: Structuring Supply Chains for Socially Responsible Behavior

Mahdi Mahmoudzadeh, Georgia Institute of Technology, Atlanta, GA, United States, Enno Siemsen

We revisit a classic model of responsible sourcing in supply chains by investigating behavioral influences on firms' decision to source from responsible and nonresponsible suppliers. The classic model predicts that only discouraging consumer reactions reliably incentivize firms to source responsibly. Our behavioral model predicts that an encouraging reaction, irrespective of its magnitude, always increases firms' responsible sourcing when the discouraging reaction from the market is weak, and further refines that a discouraging reaction always increases responsible sourcing irrespective of the type of product considered. We use a behavioral experiment to validate our behavioral model.

3 - Relational Strategies and Diversification in Nonprofit Organizations

Gloria Urrea, University of Colorado-Boulder, Boulder, CO, 47408, United States, gloria.urrea@colorado.edu, Sebastian Villa, Eric Quintane

Humanitarian organizations (HOs) face a tension to diversify operations. Diversification enables HOs to serve more social needs while increasing their chances to survive. However, diversification also reduces HOs' efficiency, which donors assess when deciding to provide funds. Literature typically assumes that HOs follow a broad relational strategy of approaching multiple donors to access funding. We argue that a broad relational strategy is inefficient and propose a second, more efficient, strategy: a focused relational strategy of developing long-term relationships with key donors. We empirically demonstrate the role of the focused relational strategy in fostering diversification.

4 - Shared Supplier Capacity as a Barrier to Socially Responsible Sourcing

Jacob Chestnut, Cornell College of Business, Ann Arbor, MI, 48108, United States, Ravi Anupindi

This experimental project considers the role of buyer behavior (e.g., time pressure, low margin, near delivery specificationchanges) in their supplier's performance along the dimension of social sustainability (forced OT, child labor, unauthorizedoutsourcing, etc.). We attempt to understand the relevant features (contractual and non-contractual) that suppliers use whencreating a preference ranking over buyers. Doing so allows us to assess the effectiveness of the operational and non-operationallevers that a "good buyer" might employ to improve their rank, thereby decreasing the likelihood that deviations occur on theirorder.

1 - When Worse is Better – Strategic Choice of Vendors with Differentiated Capabilities in a Complex Collaborative Environment

Shubham Gupta, Temple University, Philadelphia, PA, United States, tuj74944@temple.edu, Abhishek Roy, Subodha Kumar, Ram Mudambi

Existing literature on value co-creation has primarily focused on one (client) to one (vendor) relationship. We study the trade-offs and contract terms, in a complex yet practical value co-creation environment, featuring more than one vendor. We develop insights about the conditions under which the client prefers the more complex environment. We aim to find out scenarios under which a client would be better off working with two vendors instead of one. We show that the client could be better off adding a less efficient vendor. We also show the impact of adding new vendor on existing vendor.

2 - How to Make My Bug Bounty Cost-effective: A Game-theoretic Analysis

Leting Zhang, Temple Universisty, Philadelphia, PA, 19122, United States, Subodha Kumar

As a crowd-based cybersecurity solution, bug bounty programs have drawn extensive attention in recent years. By leveraging the wisdom of a group of security researchers, a firm could identify vulnerabilities in software systems earlier and patch them to prevent the potential losses caused by cyber incidents. However, because of information asymmetry and coordinated problem, a firm faces tradeoffs in deciding bounty and patching time in bug bounty programs. This paper uses a game-theoretical model to illustrate interactions between a firm and security researchers in a bug bounty program, then examining firms' decisions from the perspective of cost-effectiveness.

3 - Tackling Android Fragmentation: Strategies of Android Platform and Mobile Apps

Xi Wu, Fox School of Business, Temple University, Philadelphia, PA, United States, xi.wu@temple.edu, Subodha Kumar

Android has been criticized for its "Fragmentation Problem" in the past decade. How to address this issue becomes critical and imperative for the platform. In this work, we examine the Android's enforcement strategy on stimulating mobile apps updating their Android version and how mobile apps decide on the targeted Android version. We find some interesting results that mobile apps with low user base and high functionality size are unlikely to update. We also find that the optimal version requirement is not monotonic to the benefit and the developing cost that updating to a new Android version brings to the mobile apps. Our results provide practical insights to the mobile app developers and the platform.

4 - Dynamics of Competition in On-demand Economy: A Differential Games Approach

Samayita Guha, Temple University, Philadelphia, PA, 19121, United States, samayita.guha@temple.edu, Emre M. Demirezen, Subodha Kumar

The viability and success of ride-hailing platforms depend on how they manage their demand and pool of available drivers. In this paper, we examine how ride-hailing platforms can meet demand with supply in a competitive setting where the number of available drivers depends on policies of the platforms; and demand depends on current prices across multiple platforms for the current ride, perceptions of the platforms among their customers, and the expected wait times in different platforms. We develop our model in a differential game setup and consider a scenario of duopoly with two platforms. We discuss several managerial insights from our model and elaborate on the existing business practices.

Emerging Topic Session

1 - Using AI to Co-develop New Product Formulations

Robin Lougee, IBM Research, IBM TJ Watson Research Center, Yorktown Heights, NY, 10598, United States, Jing Fu, Richard Goodson, Christian Harris, Kimberly Lang, Joana Maria, Richard Segal, Tenzin Yeshi

Each year, more than 30,000 new consumer products are launched. An estimated 80% fail. In this presentation, we introduce computational creativity, present challenges in new product creation and share results from a novel AI system that helps product developers more efficiently and effectively create new product experiences.

2 - Democratization of Data Science to Combat AI and Machine Learning Bias

Brian Wright, Co-Director, Data Science Graduate Programs GW, George Washington University, Washington, DC, United States, bwright.wright6@gmail.com

The expansion of AI into commonplace everyday life brings with it the unanticipated challenge of confronting algorithmic decisions or recommendations that could be considered bias or even unethical. Technical approaches to combat bias have been advancing in recent years and show great promise, however, these solutions can only partly address the problem. Research shows that increases in general knowledge related to AI systems actually reduces trust. I'll discuss how this distrust could be healthy, that the nature of the field of data science works in our favor and ways that we can facilitate broader awareness to elicit increased discourse and allow for a "healthy distrust" of AI.

3 - Using AI/ML to Deliver a Smarter Supply Chain

Duncan Klett, Kinaxis, Ottawa, ON, Canada

A good demand forecast is better than no forecast at all, and AI/ML methods can certainly provide a better forecast, but, it's what you do with that forecast that counts. In this session, learn how to apply AI/ML models for:* Strategy and segmentation,* Managing change, and* Mitigating risks.To Each of these areas enable organizations to respond to supply chain variability more effectively to achieve business success.

4 - Analytics and OR for IBM's IT Service Deals

Aly Megahed, IBM Research-Almaden, 150 Palm Valley Blvd Apt 2066, San Jose, CA, 95123, United States

IBM Services competes to win highly-valued IT service contracts. To help IBM Services be more competitive and win more deals, the IBM Research team invented tools that leverage novel analytics and OR methods. The tools have been implemented and deployed in production, and have resulted in significant win rate increases, and a realized revenue increase of almost $350M.

Project Management

Contributed Session

Chair: Anshuman Tripathy, Indian Institute of Management-Bangalore, Bannerghatta Main Road, Bilekahalli, Bangalore, 560076, India

1 - An Improved Alternative to Heat Map Risk Matrices for Project Risk Prioritization

Jamie Monat, Professor of Practice, Worcester Polytechnic Institute, Worcester, MA, United States, jmonat@wpi.edu, Scott Doremus

Heat map risk matrices are widely used to prioritize project risks, but they suffer from several weaknesses, notably subjectivity, symmetry, category prioritization reversal, and a failure to account for Risk Aversion. Because of this, they can lead to serious mis-prioritization and mismanagement of risks. We propose an alternative project risk prioritization technique: the Risk-Adjusted Loss (RAL) method, and experimentally demonstrate its superiority over the heat map risk matrix approach.

2 - Resource-constrained Project Scheduling Problem in a Real-world Heavy Industry Company

Yoojin Na, Pohang University of Science and Technology (POSTECH), Pohang, Kyungbuk, Korea, Republic of, yoojin317@postech.ac.kr, Byung-In Kim, Minseok Song, JongWon Kim

This study presents a resource-constrained project scheduling problem. Multiple projects are considered and each project has about 7000 activities and 8000 activity-activity relations. There are four relation types, FS (finish to start), SF, SS, and FF, and each relation has an offset delay time. The offset can be negative. Every activity requires a specific type of resource and multiple resource types are considered. The objective of the problem is to minimize the total duration of all the projects. We propose a mixed integer programming formulation and an efficient algorithm for the problem.

3 - Lessons Learned in Building a Resilient and Adaptive Enterprise Project Management Office at U. S. Energy Information Administration

Tuncay Ugur Alparslan, U.S. Department of Energy, Washington, DC, United States, Tuncay.Alparslan@eia.gov

In 2016 the Energy Information Administration (EIA), a statistical agency within the Department of Energy, created an enterprise Project Management Office (PMO) to help improve its performance delivering on cross-cutting new products. The PMO developed measures and its own maturity model, based on a study of industry best practices, to help it stay focused on developing governance standards, tools and templates, a training program, a portfolio management approach, and quality stakeholder engagement. The presentation will cover lessons learned in piloting, sequencing, and maturing activities to build a resilient and adaptive PMO.

4 - Capabilities Erosion: An Architecture-viewed Approach to the Commons Challenge

Anshuman Tripathy, Indian Institute of Management-Bangalore, Bangalore, India, Shikha Safaya

The trend of successive offshoring by the US firms for arbitrage benefits has led to long-term erosion of manufacturing capabilities crucial to rebuilding its economy. We adopt a system architecture perspective to observe the capability loss for an OEM outsourcing manufacturing, and subsequently design to a CM. Studying the impact of modularity on system architecture, we find that higher modularity encourages offshoring and leads to a rapid decline in manufacturing knowledge of the OEM but a counter-intuitive increase in its system knowledge.

Estimation issues in Frontier Estimation

Emerging Topic: Productivity, Efficiency and Data Envelopment Analysis

Emerging Topic Session

Chair: John Ruggiero, University of Dayton, Dayton, OH, 45469-2251, United States

1 - Vine-copulas for Stochastic Frontier Analysis

Artem Prokhorov, University of Sydney, 6 Tantangara Place, Sydney, 2767, Australia, artem.b.prokhorov@gmail.com

The talk is about how to use copulas to measure firm efficiency and productivity. Copulas are mathematical concepts that model dependence between random variables. Traditional stochastic frontier analysis has ignored important aspects of production where dependence plays a key role. The dependence influences simultaneous decisions on how much to produce and what proportions of inputs to use. It influences how factors outside our control such as extreme weather or new legislation, affect how inefficient we are. Appropriate copulas capturing these dependencies allow for robust estimation and testing of production models and achieve remarkable improvements in productivity and efficiency.

2 - Examining the Determinants of Cost Efficiency of Primary Health Care Organizations: Latent Class Stochastic Frontier Analysis

Kwadwo Arhin, Lecturer, Ghana Institute of Management and Public Administration, Accra, Ghana, arhinkwadwo@gmail.com, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, arhinkwadwo@gmail.com, Eric Oteng-Abayie

The study was conducted using a panel data stochastic cost frontier with latent classes which allows the data to construct different frontiers for each group and evaluation of cost efficiency levels is carried out with respect to each group's own frontier. The Cobb-Douglas cost function model was employed. The latent class membership analysis is based on the hypothesis that unobservable technological heterogeneity exists among PHC facilities. The study results reveal that there are three statistically significant classes in the sample and that the effects of the major determinants of cost efficiency of a PHC facility are influenced by the class structure of that facility.

3 - Implicit Estimation for Stochastic Frontier Model

Mohamed Nejib Ouertani

The paper propose a novel approach (the Implicit approach), competitor to the Bayesian one, to estimate stochastic frontier models. As we reckon, to our limited knowledge, this approach steel has not been applied to the stochastic frontier approach. Hence, for the aim of highlighting the usefulness of this method we intend to establish a comparative analysis with the Bayesian one. For this purpose, the Markov Chain Monte Carlo (MCMC) techniques are used and implemented for both approaches subject of our study. Results shows that the Implicit approach is more appropriate than the Bayesian one, mainly with the presence of an improper prior case as well as a non-informative prior one. As matter of fact, our new approach has been applied in the case of a sample of Tunisian insurers.

4 - Measuring Efficiency Gains Using Distance Functions with Optimal Directions: Evidence from the U.S. Hospital Sector

Michael Vardanyan, Associate Professor, IESEG School of Management, Paris, 78100, France, Gary Ferrier, Herve Leleu, Vivian G. Valdmanis

Efficiency and productivity studies using directional distance functions have traditionally relied on ad hoc directions for projecting inefficient observations on the frontier of technology. Several recent studies have demonstrated how to select directions optimally, eliminating the need for placing restrictive assumptions on the components of the corresponding vector. We rely on Färe et al. (2017), who show how the goal programming algorithm of Aigner and Chu (1968) can be extended to endogenize the direction vector using nonlinear programming. We use the U.S. health sector data from 2004 to 2016 to estimate the output shortfalls and excess input use among various categories of hospitals.

5 - Estimating Efficiency with Quantile Functions

John Ruggiero, University of Dayton, Dayton, OH, 45469-2251, United States, jruggiero1@udayton.edu, Samah Jradi

In this paper we consider the estimation of efficiency of individual decision making units using quantile function estimation. Given the underlying distribution of measurement error and noise, we propose a quantile based measure of efficiency. We illustrate our approach using simulated and real world data and compare the results to alternative approaches.

Joint Session Agriculture/Practice Curated: Breaking Through: How Can We Deliver the Global Food Supply By Accelerating Innovation in Data Analytics?

Emerging Topic: Agriculture

Emerging Topic Session

Chair: Greg Doonan, Syngenta, Slater, IA, 50244, United States

Moderator

Greg Doonan, Syngenta, 2369 330 Street, Slater, IA, 50244, United States

The audience will have the opportunity to hear firsthand how data & digital analytics and operations research are driving innovation within agriculture. The panel features experts from industry, research centers and foundations that are focused on improving agricultural production across the globe. Listen to the exciting and innovative work that is being performed, the challenges they are addressing and the opportunities that remain to address global food security for an ever growing population.

Panelists

- Brian King, CIAT, Kilometro Palmira, 763537, Colombia
- Stewart Collis, Gates Foundation, Seattle, WA, United States
- Anirudh Badam, FarmBeats, Redmond, WA, United States
- Zaynab Saad, Syngenta, Dearborn Heights, MI, United States

Strategic Energy Systems Planning Models

Sponsored: Energy, Natural Res & the Environment/Natural Resources Petrochemicals

Sponsored Session

Chair: Dimitri Papageorgiou, ExxonMobil Research & Engineering, Annandale, NJ, 08886, United States

1 - Strategic Decision-making on Mature Offshore Oil and Gas Fields

Steffen Bakker, Norwegian University of Science and Technology, Trondheim, Norway, Asgeir Tomasgard

An increasing number of offshore oil and gas fields is reaching the end of their productive life-times. On these fields the main infrastructure is in place and the main decisions are typically when to shut down which wells. Nonetheless, strategic decisions can be made to enhance production and to increase the net present value of the asset. These decisions might include tying in new wells, performing slot recoveries or drilling injection wells to enhance oil recovery. In this work we present a first version of a multistage stochastic integer programming model that maximizes the net present value of an existing field and judge its performance for different instance sizes.

2 - Projecting North American Natural Gas Markets: The Natural Gas Market Module in The National Energy Modeling System

Michael Cole, U.S. Energy Information Administration, Washington DC, DC, United States, Kathryn Dyl, Yelena Dandurova, Peter Gross, Samantha Calkins

The National Energy Modeling System (NEMS) provides 25-30 year projections of a broad range of energy issues at both U.S. national and regional levels for the U.S. Energy Information Administration. The Natural Gas Market Module (NGMM) component of NEMS projects natural gas supply, end-use prices, and flow patterns of natural gas throughout the North American pipeline network. The NGMM employs a quadratic optimization model that solves for market equilibrium across the three main components of the natural gas market: the supply component, the demand component, and the transmission and distribution network that links them.

3 - Scenarios for Decarbonization of the Future Indian Electricity Sector

Dimitri Papageorgiou, ExxonMobil Research & Engineering, Annandale, NJ, 08886, United States, Ivan Rudnick, Audun Botterud, Carlos Batlle Lopez, Pablo Duenas Martinez, Bryan Mignone, Srinivasan Rajagopalan, Michael Harper, Karthik Ganesan

Using a high temporal resolution power system capacity expansion model, we investigate the impact of technology and policy assumptions on generation and energy storage capacity through a scenario-based study of India's 2037 grid. Results suggest that significant CO2 emissions reductions could be realized by developing viable decarbonization approaches and VRE growth may be constrained unless it is viably paired with natural gas and/or storage to enable reliable power generation.

4 - Simulation for Strategic and Operational Petrochemical and Logistics Planning

Mamdouh Mubarak, ExxonMobil Research & Engineering, Annandale, NJ, United States

We present examples of how simulation can be used to enhance decision support for strategic and operational petrochemical and logistics problems.

Issues in Energy Supply Chain

Sponsored: Energy, Natural Res & the Environment/Environment & Sustainability

Sponsored Session

Chair: Jason Nguyen, University of New South Wales, Sydney, Australia

1 - Supporting Supplier Competitiveness in High Energy Price Environments: The Role of Industry Targeted Interventions

Jason Quang Nguyen, University of New South Wales, Carlson School of Management, 321 19th Avenue South, Sydney, 55455, Australia, j.nguyen@unsw.edu.au, Karen L. Donohue, Mili Mehrotra

Energy consumption cause negative externalities to society which are not internalized into energy prices without policy interventions. This creates a disincentive for investing in Energy Efficiency (EE) improvements. However, internalizing these externalities into energy prices may affect the competitiveness of small-and-medium-sized enterprises (SMEs), as they could not pass these costs to larger customers. Most extant research has not examined the effectiveness of industry targeted interventions to mitigate the pressure of increased energy prices. In this study, we address these issues, focusing on the two most common interventions, energy price discount and EE investment subsidy.

2 - Utility-owned Combined Heat and Power: Improving Reliability and Lessening Environmental Impact

Eric M. Webb, Assistant Professor, University of Cincinnati, Cincinnati, OH, 45226, United States, eric.webb@uc.edu, Gilvan Souza, Owen Wu

Combined heat and power (CHP) plants generate electricity and useful heat at the same time. There are many benefits to utilities of having CHP plants in their portfolio, including reducing transmission losses, increasing power reliability, and meeting environmental regulations. Despite these benefits, only 3% of all CHP capacity in the U.S. is utility owned. We study the economics of utility ownership of CHP plants and examine the effect of regulatory policies on such investments. To encourage installation, we find a low to moderate emission tax to be most effective.

3 - Strategic Bidding of Wind Farms in a Competitive Electricity Market

Ali Shantia, Assistant Professor, Toulouse Business School, Toulouse, France, a.shantia@tbs-education.fr, Roman Kapuscinski, Owen Wu

We empirically study how strategic behavior of renewable generators translates to their higher profitability. Using the day-ahead and real-time market data, provided by Midcontinent Independent System Operator (MISO), we study what differentiates the bidding behavior of wind farms and analyze whether such strategic behaviors practically increase wind generation profitability and how this effect is moderated by market competition and wind intermittency.

4 - How Should Electricity Suppliers Trade to Optimally Hedge the Risk Associated with Power Demand Uncertainty?

Julien Vaes, University of Oxford, Oxford, United Kingdom, Julien.Vaes@maths.ox.ac.uk

As of now, electricity cannot be stored in large amounts. Because at all times supply must match demand, suppliers take long positions beforehand on the power future market in order to ensure the best price for customers. Subjected to power price and demand uncertainty, a risk-averse supplier most likely seeks the cheapest trading strategy. However, solving the required optimisation problem is cumbersome, as risk is estimated with Monte-Carlo simulations. To circumvent this issue, we suggest an estimation of the CVaR-risk measure based on a PCA making the problem more tractable while yielding to competitive solutions.

5 - Optimisation of Decarbonisation Pathways for Heat and Power Sectors in the UK

Vasileios Charitopoulos, Research Associate, University of Cambridge, Cambridge, United Kingdom, v.charitopoulos@jbs.cam.ac.uk, Chi Kong Chyong, David Reiner

In the present work, a spatially explicit optimisation-based approach to investigate the trade-offs among the different decarbonisation pathways on a national scale is proposed. The model simultaneously optimises investment and operational decisions for the power and heat sectors. By considering the whole multi-energy system, economic and policy insights are drawn based on the trade-offs between: (i) the electrification of off-gas grid areas, (ii) the role of hydrogen in substituting the incumbent natural gas-based system. Finally, results showcase how acknowledging resource endowments at sub-national level enables for synergistic decarbonisation of heat and power sectors.

Improving Power System Resilience and Flexibility Through Advanced Computation

Sponsored: Energy, Natural Res & the Environment/Electricity

Sponsored Session

Chair: Shmuel S. Oren, University of California-Berkeley, Berkeley, CA, 94720-1777, United States

Co-Chair: Georgios Patsakis, University of California Berkeley, Berkeley, CA, 94702, United States

1 - Optimization Methods to Enhance Resiliency of Distribution Systems

Chen-Ching Liu, AEP Professor and Director of PEC, Virginia Tech, Blacksburg, VA, United States, ccliu@vt.edu, Juan C. Bedoya, Jing Xie, Yubo W., Xi Zhang

Recovery of distribution systems from extreme operating conditions is vital, especially when the utility system is not available. The increasing penetration of distributed energy resources (DERs) in power networks opens a path for restoration of critical load using local non-utility resources. To do so, it is required to leverage available resources such that critical loads can be restored quickly. This presentation will provide a summary of recently developed distribution system restoration approaches where a resiliency function is maximized.

2 - Mixed Integer Programming Techniques for Efficient Black Start of the Power System

Georgios Patsakis, University of California Berkeley, Berkeley, CA, 94702, United States, gpatsakis@berkeley.edu, Ignacio Aravena, Deepak Rajan, Shmuel S. Oren

The power system operator relies on a few units (black start units) to restore the system after a large-scale outage. The problem that optimally allocates these units in the grid and restores the power system after an extended outage can be posed as a large-scale mixed integer program over the allocation and switching actions for a finite time horizon. We explore techniques to increase the computational efficiency of the problem: we describe how by using a stronger formulation of part of the constraints, a decomposition of the problem, and customized heuristics, we can obtain restoration plans with optimality guarantees within reasonable computational times.

3 - Distributed Restoration for Integrated Transmission and Distribution Systems with Distributed Energy Resources

Wei Sun, University of Central Florida, Orlando, FL, United States, sun@ucf.edu

This talk will introduce a distributed strategy for integrated transmission and distribution systems restoration. Based on ADMM, the distributed algorithm is able to provide the coordinated restoration for both transmission and distribution system operators by sharing limited information of boundary buses in an iterative procedure. The strategy coordinates the operation of distributed energy resources in terms of serving high priority loads across different networks. The effectiveness and advantage of developed models and algorithms are validated through testing of the integrated IEEE test cases.

4 - Algorithms for Optimal Design and Operation of Resilient Microgrids

Harsha Nagarajan, Los Alamos National Laboratory, Los Alamos, NM, 87544, United States

Microgrids have received increasing interest from utilities to support the resiliency posture of their systems. Various factors prevent remote communities from connecting to transmission systems and they rely on off-grid microgrids. Hence, we present methods that facilitate design and operation of off-grid microgrids over long periods of time. This includes modeling of component efficiencies and limits, batteries, unit commitment, capacity expansion, and power flow physics. We propose efficient model-predictive-control-based algorithms and corroborate the methods with extensive numerical studies.

Energy Modeling Platform for North America as Part of Worldwide Open Energy Modeling Efforts

Sponsored: Energy, Natural Res & the Environment/Energy Sponsored Session

Chair: Denis Lavigne, PhD, Royal Military College St-Jean, St-Jean-sur-Richelieu, QC, J2W 1E9, Canada

Co-Chair: Taco Niet, Simon Fraser University, BCIT, Burnaby, BC, V5G 3H2, Canada

1 - OSeMOSYS-PuLP

Mark Howells, KTH Division Energy Systems Analysis, Brinellvagen 68, Stockholm, 18368, Sweden, mark.howells@energy.kth.se

Recent open-data movements give access to large datasets derived from real-world observations. This data can be utilized to enhance energy systems modeling. Heterogeneity and randomness of the real-world can be captured that are usually found in large samples of real-world data. This paper presents a methodological framework for an empirical deterministic-stochastic modeling approach to utilize large real-world datasets in long-term energy systems modeling. A new software system—OSeMOSYS-PuLP—was developed and is available now.It adds the feature of Monte Carlo simulations to the existing open-source energy modeling system (the OSeMOSYS modeling framework).

2 - Impact of Prolonged Droughts on Colombia's Electric Infrastructure in a Low Carbon World: A Case Study using OSeMOSYS

Cristina Botero, Argonne National Laboratory, Lemont, IL, United States

Colombia's 50 million population relies on hydroelectric (dam) plants to satisfy 86% of its 70TWh yearly electricity demand. This makes the country's 16GW electric capacity extremely vulnerable to prolonged droughts, which are expected to become more frequent as a result of climate change. This study uses the open source tool OSeMOSYS to evaluate the impact of prolonged drought periods on Colombia's electricity mix in the next 30 years in a world with a high price on carbon. The influence of natural gas pricing is also considered, given Colombia's uncertain reserves and pricing forecasts.

3 - U.S. Electricity Infrastructure of the Future: Generation and Transmission Pathways Through 2050

Benjamin D. Leibowicz, Assistant Professor, University of Texas-Austin, Austin, TX, 78712-1591, United States, bleibowicz@utexas.edu, Gopika Jayadev, Erhan Kutanoglu

We develop an optimization model for the U.S. generation and transmission system and use it to explore electricity infrastructure pathways through 2050. By comparing results from numerous scenarios, we affirm five key insights and discuss their policy implications. For instance, we find that U.S. electricity can be substantially decarbonized at modest cost, but complete decarbonization is very costly. Investments in long-distance transmission are very limited, while investments in battery storage are much greater, under a wide range of assumptions. Optimal solutions include large investments in natural gas capacity, but gas capacity utilization rates decline steadily and significantly.

4 - The Regional Energy Deployment System (ReEDS): An Open-Access Model for the North American Electricity System

Kelly Eurek, National Renewable Energy Laboratory, Golden, CO, 80226, United States, Kelly.Eurek@nrel.gov, Maxwell Brown, Wesley Cole

The Regional Energy Deployment System (ReEDS) model is NREL's flagship capacity expansion planning tool for the electric power sector in North America. Originally developed in 2001, ReEDS has been used primarily by NREL researchers to conduct high-profile analysis of the potential evolution of the electricity system. In September 2019, the core model is being released for public use. In this presentation, we provide an overview of the model architecture, key model features, data sources, lessons learned, and sample model results for the North American electric power system.

5 - Building Better Models Through Collaboration

Taco Niet, Faculty, Simon Fraser University, Surrey, BC, V5G 3H2, Canada, taco_niet@sfu.ca

Many model analyses provide a path to low carbon energy but many of these studies use proprietary software and data, making their analysis opaque and impossible to validate. There is a significant movement in the modelling community towards open source and open data. In this presentation we will present a number of examples where collaboration and sharing of both source code and model data has resulted in errors being caught and better models being developed. The sharing of model source code and data makes for better models and better decision making.

Complex Infrastructure Systems

Sponsored: Energy, Natural Res & the Environment/Energy Sponsored Session

Chair: Valerie Thomas, Georgia Tech, Atlanta, GA, 30332, United States

1 - Integrated Process Optimization for Biochemical Conversion

Sandra D. Eksioglu, Clemson University, Department of Industrial Engineering, Clemson, SC, 29634, United States, seksiog@clemson.edu, Berkay Gulcan, Mohammad Sadekuzzaman Roni, Krystel Castillo

The objective of this study is to develop analytical tools to enable a biorefinery to identify optimal integrated process design to ensure a reliable, cost-effective, sustainable, robust and continuous feeding of biomass feedstocks to achieve the design throughput of the reactor. We propose a two-stage stochastic optimization. The first stage decides about long and medium term commitments of equipment capacities and settings. The second stage decides the flow of the biomass between equipment and the inventory kept under random discharge and failure rates of each equipment. A Discrete Element model develops functional relationships between product characteristics and equipment performance.

2 - Structure of Electricity Production Planning Models

Valerie Thomas, Georgia Tech, ISYE, Atlanta, GA, 30332, United States, vthomas@isye.gatech.edu

Electricity production planning models are widely used for analysis of future electricity system development in both developing and developed countries. Analysis of a typical electricity production planning model for developing countries shows structure that provides insight into the conditions under which substantially different electricity systems would be constructed for a given objective.

3 - Presenter

Hyejin Youn, Kellogg School of Management, Evanston, IL, United States

Urban scaling and its relation to the universality and self-similarity seem both trivial and non-trivial. On one hand, the dynamics of cities are so complex that it seems impossible to explain them in a simple way. Geographic factors and idiosyncratic historical paths are so entangled and complex that even a well-designed plan often results in unintended consequences. This contradicts the universality observed in almost every urban phenomenon due to its implication that the underlying dynamics are reducible to a simple form. On the other hand, universality is a natural, and even trivial, consequence derived from a common set of functionalities of cities, which are manifested as a single scaling law.

4 - Designing a Coal and Biomass Based Electricity Network Considering Different Emission Schemes

Vinay Gonela, Texas A. & M. University Central Texas, Killeen, TX, United States, vinay.gonela@tamuct.edu, Iddrisu Awudu, James Gosnell

This research focuses on designing a coal and biomass based electricity network considering different emissions schemes such as carbon cap, carbon tax, and carbon cap and trade. A stochastic optimization model is proposed that aims to determine the optimal location, production, and raw material procurement strategies under different emission schemes. A case study of North Dakota is used to illustrate the effectiveness of the proposed stochastic optimization model. The results provide optimal electricity network under different emissions schemes and at the same time help determine the best emission scheme. Sensitivity analysis is also conducted to provide managerial insights.

Trade-offs in Temporal, Geographic and Operational Granularity in Modeling Low-carbon Power Systems

Sponsored: Energy, Natural Res & the Environment/Energy

Sponsored Session

Chair: Michael Davidson, University of California, San Diego, CA Harvard Kennedy School, MA, United States

1 - Electricity Capacity Expansion Modeling with Distribution Networks and Distributed Energy Resources

Jesse D. Jenkins, Assistant Professor, Princeton University, Princeton, NJ, 02139, United States, Dharik Sanchan Mallapragada, Nestor Andres Sepulveda, Scott P. Burger

We present a new approach to model distributed energy resources (DERs), flexible and price-responsive demand, and distribution network losses and reinforcement costs alongside conventional generation and transmission network assets in an integrated electricity system planning framework. The methods capture important tradeoffs between locational value and economies of unit scale and help identify optimal deployment of DERs. We discuss results from a case study evaluating distributed solar photovoltaic and battery energy storage deployment to illustrate the value of the modeling framework.

2 - Scalable Integrated Infrastructure Planning with PowerSimulations.jl

Clayton Barrows, NREL, 15013 Denver West Parkway, Golden, CO, 80401, United States

We are witnessing a revolutionary transition of energy infrastructure around the world. Future infrastructure systems will be required to deliver critical services reliably, resiliently, securely, affordably, and in an environmentally responsible fashion. NREL is developing a suite of new scalable modeling and analysis capabilities to understand and inform this transition by enabling flexible representations of system planning and operational phenomena. This presentation will focus on the power system modeling capabilities enabled through PowerSystems.jl and PowerSimulations.jl.

3 - Value of Modelling Constraints in Generation Scheduling

Miguel Ortega-Vazquez, Sr. Technical Leader, Palo Alto, CA, 94304, United States

Power system tools based on unit commitment (UC) follow a top-down approach. These models concentrate on the top decision-making process and little detail is given to the UC process. As the penetrations of renewables deepen, the variability and uncertainty of the net-load increases requiring specific generation scheduling patterns. Also as energy storage is integrated, full temporal resolution becomes essential. These characteristics are ignored or indirectly accommodated in UC proxies and neither accuracy nor feasibility is guaranteed.The value of constraints is assessed for full temporal UC models to tradeoff among solution cost; solution reliability; and computational burden.

4 - Spatially Granular Renewable Resource Curves for Power System Planning

Michael R. Davidson, University of California, San Diego, La Jolla, CA, 02139, United States, mrdavidson@ucsd.edu, Da Zhang

Power system planning models of high renewable penetrations typically aggregate resource profiles over a large area—thus underestimating the variability of marginal capacity additions—or replicate a single resource profile—thus underestimating geographic smoothing. In this work, we derive spatially disaggregated supply curves for China's wind and solar resources based on a simplified power systems operation heuristic that maintains temporality and basic commitment constraints. The supply curves are further used to cluster contiguous areas of renewable resources as inputs to an expansion planning optimization.

Supply Chain, Closed Loop

Contributed Session

Chair: Kamil Ciftci, Lehigh University, Bethlehem, PA, 18015, United States

1 - Closed-loop Supply Chain Models with Buyback and Remanufacturing

Shuting Xu, Xiamen University, Xiamen, China, 17720150150164@stu.xmu.edu.cn, Zhaowei Miao

This paper develops two-period dynamic models to analyze the OEM's operation decisions while considering both buyback and remanufacturing strategies in its closed-loop supply chain. Two kinds of scenarios of buyback commitment are discussed in this paper, including with/without buyback commitment in Period 1 respectively. The results show that pre-announcing buyback rebate in Period 1 will promote OEM to adopt buyback and remanufacturing, and help OEM to attain more profit. This paper also provides some management insights for the policy maker.

2 - A Comparison of Collection Subsidy vs. Dismantling Subsidy: Government Policy in the New Energy Vehicle Battery Recycling Industry

Peiqi Ding, Northwestern Polytechnical University, Xi'an, China, dingpeiqi@mail.nwpu.edu.cn

As the number of waste batteries increases, firms involved in the new energy vehicle industry need to properly collect them, but what party is responsible remains unclear. Governments introduce two subsidies, i.e., collection subsidy and dismantling subsidy. We develop a stylized model to examine the collection strategies and compare the subsidies. We derive several insights from analysis. First, the collection strategies depend on the fixed collection cost. Second, the key factor determining the subsidy preference is the ratio of the dismantling cost to the raw material cost. Finally, governments decide the type of subsidies in terms of collection rate, environmental impact and social welfare.

3 - A Fuzzy Multi-objective Facility Location Model for Closed-loop Supply Chain Network Design under Uncertainties

Guiping Hu, Iowa State University, Ames, IA, 50011, United States, gphu@iastate.edu, Zhengyang Hu

The significance of considering both forward and backward flows in supply chain networks spurs an interest to develop closed-loop supply chain networks (CLSC). In this paper, a CLSC problem with two objective functions is investigated which includes minimizing overall cost and maximizing positive environmental impact. CLSC is one of the long-term decision making problems and hence a lot of parameters may have uncertain nature. A fuzzy programming model is proposed to cope with various uncertainties and an aggregation function is adopted to integrate different objective functions. A sensitivity analysis is provided to explore the impact of different input parameters.

4 - Two-period Closed-loop Supply Chain Model for Consumer Returns

Kamil Ciftci, California State University, Fresno, CA, United States, Yertai Tanai

We model two-period closed-loop supply chain for consumer returns in a retailer setting, in which products can be sold quickly after processing. Taking processing delays into account, we formulate stochastic price-dependent demand and develop a profit maximization model for the entire time horizon.

Joint Panel MIF/DEI: Diversity Statements and Beyond

Sponsored: Minority Issues

Sponsored Session

MIF/DEI: Diversity Statements and Beyond

Shengfan Zhang, University of Arkansas, Department of Industrial Engineering, Fayetteville, AR, 72701, United States

Karen T. Hicklin, University of North Carolina at Chapel Hill, Campus Box 7411, Chapel Hill, NC, 27599-7411, United States

Research shows that diverse environments enrich the educational experience, strengthen communities and workplaces, and promote a healthy society. In recent years many academic institutions have made it common practice to include a diversity statement in their application process for faculty candidates. The Minority Issues Forum and Diversity, Equity, and Inclusion committee present a panel discussion on the importance of diversity statements and the subsequent initiatives that follow to promote workplaces that are inclusive and enriched with varying perspectives, experiences, and capabilities.

Panelists

- Cole Smith, Clemson University, 206E Sikes Hall, Clemson, SC, 29634, United States
- Michael P. Johnson, University of Massachusetts Boston, Department of Public Policy & Public Affairs, Boston, MA, 02125-3393, United States

Location Analysis III

Sponsored: Location Analysis

Sponsored Session

Chair: Necati Aras, Bogazici University, Industrial Engineering Department, Bebek, Istanbul, 34342, Turkey

1 - Tabu Search for Mixed Strength Sensor Location Problems

Rex K. Kincaid, College of William and Mary, Dept of Mathematics, Williamsburg, VA, 23187-8795, United States, rrkinc@wm.edu, Robin M. Givens, Blair D. Sweigart

Location-detection problems in networks are pervasive, e.g. detection of faults in microprocessors or identifying contaminants in ventilation systems. Sensors are placed at node locations that uniquely detect and locate issues in the network. Sensor failures may be caused by extreme environmental conditions or by the act of a nefarious individual. Computational experience with a tabu search metaheuristic for the minimum Open Locating Dominating (OLD) set problem for sensors of varying strengths is reported. Extensions include OLD covering models and metric locating dominating sets.

2 - Locating Dominating Sets for Criminal Network Modeling

Daniel Blair Sweigart, United States Coast Guard, Maple Valley, WA, 98038, United States, Blair.sweigart@gmail.com

Locating dominating-sets (LDS) are network location constructs regarding the placement of sensors such that when an event occurs anywhere in the network it will be detected and its location immediately known by the unique set of sensors that detect it. This work presents ILP formulations to solve real world LDS problems, including a new model that combines Locating Dominating Sets and Identifying Codes, and explores the ILPs' use in monitoring criminal and terrorist networks

3 - Optimization Algorithms for Facility Layout: Applications of Ammunition Support Activities

Yihe Zhuo, Lehigh University, Bethlehem, PA, 18015, United States, yiz916@lehigh.edu, Lawrence V. Snyder, Robert H. Storer, Luis Zuluaga

We investigate optimization algorithms for automating the layout of facilities for Ammunition Support Activities. The optimization considers the amount and hazard class of material to be stored, land restrictions, risk, and stock retrieval times while meeting all separation distance safety requirements (inhabited buildings, public traffic routes, etc.) A mixed-integer model is developed with several objective functions representing different layout patterns. We also develop heuristics to match specific layout preferences and test both approaches on real case problems.

4 - A Network Interdiction Model to Disrupt Human Trafficking Supply Chain Networks

Xiaodan Xie, PhD Candidate, Ohio University, Athens, OH, 45701, United States, xx581716@ohio.edu

This presentation provides a thorough characterization of the human trafficking networks (HTNs) and maps it into a standard supply chain format. An integrated Network Interdiction Model (NIM) is developed to disrupt HTNs. The model's objective is to minimize the cumulative maximum flow of victims. The proposed NIM is tested on two real federally prosecuted human trafficking cases considering partial interdiction of the network. Computation results demonstrate NIM's capability and robustness in providing comprehensive and optimal interdiction results. The study's insights aim to inform and support the anti-trafficking community in developing effective interdiction strategies.

5 - Improving the Operational Resilience in Transportation Networks

Necati Aras, Bogazici University, Industrial Engineering Department, Bebek, Istanbul, 34342, Turkey, arasn@boun.edu.tr, Hande Küçükaydın

We consider a transportation network that is subject to disruptions by man-made attacks, i.e. when some stations and linkages in the network are attacked, then significant deterioration is observed in the service provision capability. We develop a trilevel Operator-Attacker-Operator model, where the first-level player is the system operator who wants to determine the components that must be protected to increase the operational resilience of the network, the second-level player is the virtual attacker who wants to cause the most disruption by interdicting the components, and finally the third-level player is the system operator who tries to reorganize the flow on the transportation network.

Economics

Contributed Session

Chair: Kathy Jung, University of Washington, Seattle, WA, 98101, United States

1 - Management and Innovation: Evidence from Randomized Experiments and Repeated Surveys in Vietnam

Yuki Higuchi, Associate Professor, Nagoya City University, Nagoya, Japan, yukihiguchi.wachi@gmail.com

We conducted randomized experiments to provide management training for 312 Vietnamese small manufacturers in 2010 and repeatedly collected follow-up data in the span of eight years. Analyzing panel data constructed from our original surveys with negligible incidence of attrition (less than 2 percent of the baseline sample), we find that our training sustainably improved management quality of the treated entrepreneurs. Such improved management spurred innovation by the quality improvement of an existing product. As a consequence, the treated entrepreneurs were 17 percentage points more likely to continue business and continued to have significantly higher business performance.

2 - Is the Seamless Connection the New Monopoly Leverage?

Esma Koca, Imperial College London, London, United Kingdom

We consider the release of a new product category when two asymmetric firms engage in price and quality competition. Ecosystem firm has the leverage of previous market coverage while the rival is new to the market. We investigate if ecosystem leverage keeps the rival at bay and decreases the innovation.

3 - Study on the Influence of the Development of Modern Service Industry on the Regional Economic Differences in China

Yan-Jun Hu, Beijing Union University, Beijing, China, gltyanjun@buu.edu.cn, Xin-Yue Zhang

Based on a classic economic growth model, this paper adopts the method of spatial econometrics, using the panel data of 2003-2016 to analyze the impact of the development of modern service industry on the economic differences among China's 31 provinces, autonomous regions and municipalities from the industrial scale and efficiency, industrial structure and system, industrial function and innovation, as well as industrial base and environment of modern service industry. The results show the indirect factors of the development of modern service industry, such as industrial innovation conditions, market potential and development environment, have a great impact on the growth of regional economy.

4 - Eco-efficiency and Industrial Agglomeration in China

Wenping Wang, Southeast University, Nanjing, China, wpwang@seu.edu.cn, Peiyi Yao, Lihua Wu

In this paper, we analysis how industrial agglomeration affects eco-efficiency by a panel data model from prefecture-level cities of China during the 2004-1017 period. We find industrial agglomeration has positive effect on improving eco-efficiency. Also, eco-efficiency of cities gradually increase during the study period. Cities in the optimizing development zone has higher eco-efficiency than those of the key development zone and the ecological development zone.

5 - Market Entry Strategies for City-based Platforms

Qing Wei, Clemson University, Fargo, ND, United States, qwei@clemson.edu

This paper studies the entry strategies of two competitive multi-sided platforms into segregate markets. We focus on two questions: 1) the conditions to be the market leader; 2) what factors are affecting the market structures. We simulate a two-player game and find that multi-sided platform by its nature is more likely to be concentrated. Also, high network effect and high switching cost may result in a natural monopoly, especially in small markets. And the largest market plays a crucial rule in the competition, if a player loses the opportunity to capture the largest market first, it may have to raise a huge amount of initial fund to overcome its disadvantages in the later competition.

6 - Spatial Search Friction and Allocative Efficiency in the Free-floating Car-sharing Industry

Kathy Jung, University of Washington, Seattle, WA, United States

Free-floating car-sharing services have revolutionized the car-sharing service by allowing users to pick up a car wherever and whenever they want and leave them anywhere. However, there are market allocation issues - there are unused cars in one place when people are looking for cars in other places. To better understand the market condition and estimate welfare, I build a dynamic spatial model using trip information data from ReachNow, a car-sharing company based in Seattle, from its launch in April 2016 to October 2018. I show the presence of search friction and inefficiency by incorporating two distinct market characteristics: consumption-as-supply and usage-based fixed-pricing scheme.

High-Dimensional Data Analytics: Methodology and Applications

Sponsored: Data Mining

Sponsored Session

Chair: Tianyi Lin

1 - Bidding and Allocation for Demand Side Platforms in Online Advertising

Alfonso Lobos, UC Berkeley, IEOR, Berkeley, CA, 94720, United States, alobos@berkeley.edu, Jose Blanchet, Aaron Flores, Neil Lien

In programmatic advertising, Demand Side Platforms (DSPs) acquire impression opportunities on behalf of advertisers by bidding on exchanges from Supply Side Platforms (SSPs). DSPs are facing important challenges as many SSPs have shifted their auction mechanisms from second to first price auctions. In this talk, we will give a practitioner perspective on the bidding an allocation that DSP faces putting special emphasis in that our allocation system can be seen as internal auction mechanisms. Some optimality results are discussed.

2 - Sparsemax and Relaxed Wasserstein for Topic Sparsity

Zhiyue Hu, University of California, Berkeley, Berkeley, CA, 94720, United States, zyhu95@berkeley.edu

Topic sparsity is the observation that individual documents usually focus on several salient topics, and a real topic also adopts a narrow range of terms. As topic sparsity in online social media increases, so does the difficulty of analyzing the online text sources using traditional methods. In this paper, we propose two novel neural models by providing sparse posterior distributions over topics based on the Gaussian sparsemax construction, and infer the variational distribution with the relaxed Wasserstein (RW) divergence. Experiments on different genres of large text corpora have demonstrated the effectiveness of our approaches as they outperform both probabilistic and neural methods.

3 - Leveraging Molecular Data in Drug Discovery Using Count Statistics

Zoe Vernon, PhD Student, University of California, Berkeley, Berkeley, CA, 94720, United States, zoe_vernon@berkeley.edu, Haiyan Huang, Yuting Ye, Bin Chen

Previous research has shown that drugs which reverse the expression across many disease associated genes have potential to be efficacious for treating the disease in question. Statistics that summarize this reversal require detection of local negative dependency at the extremes of the disease and drug expression profiles. We propose a rank based count statistic designed to detect these local dependencies that is robust to outliers and addresses issues that arise with other measures in this field.

4 - Dispatching Policies for Elevators in a High-Rise

Jiung Lee, University of California, Berkeley, Berkeley, CA, 94720, United States

We study a design and control problem for elevator systems in modern high-rises. We formulate a dynamic control problem for elevator dispatching, and propose a novel control policy based on simulation and queueing theory. We analyze its performance given traffic patterns, and compare the performance with that of the benchmark used in practice.

5 - Discrete-time Hawkes Model on Consumer Behavior: An Example of Yuebao-alibaba

Yuqian Xu, University of Illinois at Urbana-Champaign, Champaign, IL, 61820, United States, Lingjiong Zhu

In this paper, we propose a discrete-time hawkes process model to estimate a general class of data with two key properties. First, the underlying variable has either self-exciting or mutually-exciting property, i.e., the past events affect the future events. For instance, such a variable could be a measure of consumption, demand, default, etc. Second, only aggregated-level data are available.

Data Mining for Sustainable Transportation

Sponsored: Data Mining

Sponsored Session

Chair: Mustafa Lokhandwala

1 - Understanding the Impact of Heterogeneous Rider Preferences on a Shared Autonomous Vehicle System

Mustafa Lokhandwala, Purdue University, West Lafayette, IN, 47906, United States, mlokhand@purdue.edu

In a ride sharing system, riders may have varied behaviors in seeking shared or non-shared rides. This study segments the riders in a ride sharing system into five types (non-sharing only, non-sharing preferred, indifferent, sharing preferred, and sharing only) based on their sharing preferences. We use an agent-based model to simulate these preferences in a system of shared autonomous vehicles. The results show that higher service level is achieved when all riders in the system are open to sharing. The maximum service level is achieved when there is a 30\% proportion of sharing only riders with 70\% of sharing preferred or indifferent riders.

2 - Factors Influencing Electric Bike Share Ridership: Analysis of Park City, Utah

Yi He, Utah State University, LOGAN, UT, United States

In recent years, bike share programs have become increasingly popular. Electric bike sharing, however, remains in the early stages of development. In this paper, we analyzed the historical data of the electric bike share system (e-BSS) in Park City, UT, presented the system's performance experience and evaluated the user characteristics and travel behavior, and performed a Poisson regression analysis to investigate the factors that influence the e-bike share usage of this e-BSS. The findings of this paper can help the operators of Summit Bike Share to better understand their users and their e-BSS, while also providing a guide for other e-bike projects currently in the planning stages.

3 - Online Rebalancing Algorithms for Electric Car-sharing Systems

Theodoros Pantelidis, New York University, Brooklyn, NY, United States, tpp254@nyu.edu

Carsharing services have been shown to be effective in reducing numbers of cars on the road unsustainable in some cities. However, such services present a challenge both financially and operationally. The reason is that one-way carsharing systems require some degree of rebalancing to be effective in meeting demand, depending on the service area covered and demand patterns. This operational constraint is further exacerbated in EV systems that have an additional requirement to rebalance vehicles for charging. In this study we present an online heuristic algorithm to provide efficient rebalancing for large systems using data obtained from the BMW ReachNow car sharing system in Brooklyn, New York.

4 - Demand Prediction for Bike Share System Expansion and a Modeling Framework to Evaluate System Performance: A Case Study of Chicago

Zhaoyu Kou, Purdue University, West Lafayette, IN, 47906, United States, kouz@purdue.edu, Hua Cai

During the process of implementing and operating the bike share system (BSS), bike shortage causes unsatisfied demand, while bike oversupply also leads to wasted resources. This study builds a modeling framework to estimate the bike share demand and determine the required bike supply. A random forest model is trained for the demand prediction for expanded area, which helps evaluate the potential to further expand the system. We determine the bike supply through system simulations with the consideration of bike rebalance and parking behaviors. The framework proposed in this study will serve as a tool for the system operators to evaluate system performance, determine system type and bike supply.

1 - Generalized Additive Model with Neural Corrections - Learning Interpretable Main Effects in Healthcare Applications

Tong Wang, University of Iowa, Iowa City, IA, 52245, United States, tong-wang@uiowa.edu

Interpretability of a model is of critical importance in healthcare applications. This work addresses the collaboration of an interpretable model and a black-box model, where an interpretable model captures the main effects and the black-box model adds corrections that are orthogonal to the main effects. Here we choose generalized additive models as the interpretable component, that characterize individual contributions from each variable. The two models are jointly trained with the objective of minimizing error, model complexity, as well as the contribution from the neural network.

2 - Tracking Sepsis Progression: Development and Validation of a Dynamic Rule-based Phenotyping Using Longitudinal Electronic Health Records

Joseph Kapena Agor, Oregon State University, Corvallis, OR, 27606, United States, agorj@oregonstate.edu

Electronic Health Record (EHR) data analysis and modeling requires techniques for population selection and identification of health states during a patient visit. To overcome the challenge of limited information in an EHR, we propose a dynamic phenotyping algorithm to track the progression of sepsis. We apply the algorithm to two EHR datasets and the results show high sensitivity regarding identification of true sepsis visits. Moreover, we apply the Recent Temporal Pattern (RTP) mining model classification model and compare against prediction performance where ICD-9 codes are used as a ground truth showing that the proposed phenotyping is superior in performance.

3 - Predicting Length of Stay of Emergency Department Patients and its Implications for Operations Management

Yuan Zhou, University of Texas at Arlington, Arlington, TX, 76019, United States, yuan.zhou@uta.edu, Chen Kan, Wang Hao, Eniola Suley

Excessive length of stay (LOS) of emergency department (ED) patients has detrimental effects on ED operations (e.g., increased crowding level and resource consumption), patient outcomes (e.g., care delays), and hospital costs. To reduce the ED burden, proactive approaches that enable accurate LOS prediction during the early stage of ED encounters are urgently needed. This study utilizes ensemble learning classifiers coupled with majority voting selection to predict patients with excessive LOS at the triage stage. An intervention that allows re-locating those patients to a 'virtual' unit outside the ED is evaluated based on hourly ED crowding level changes and daily work hours saved.

4 - Aiding the Prescriber: a Machine Learning Approach to Personalized Risk Modeling for Chronic Opioid Therapy

Margret V. Bjarnadottir, University of Maryland, College Park, MD, margret@rhsmith.umd.edu, David Anderson, Ritu Agarwal, Kislaya Prasad, Al Nelson

The opioid crisis has assumed center stage in recent US health policy debates and discussions. While multiple factors may have contributed to the crisis, the widespread availability of opioids, fueled by physician prescribing patterns, diversion of prescribed medications, and the interaction of these factors with potential illicit opioid use, have been implicated as proximal causes for subsequent opioid dependence and mortality. In this talk we focus on how machine learning models can aid physicians in their prescription decisions with the goal of reducing high risk and/or unnecessary prescriptions.

5 - The Overdiagnosis Problem in Medicine: A Challenge for Medical and Computer Science Professionals Alike

Evangelos Triantaphyllou, Louisiana State University, Division of Computer Science & Engineering, Baton Rouge, LA, 70803, United States, etriantaphyllou@yahoo.com, Juri Yanase

Overdiagnosis in medicine is a complex and controversial issue. It is related to many serious medical conditions and diseases, such as various types of cancer. We demonstrate that even small amounts of overdiagnosis may inflate perceived benefits, such as improving survival rates. Many factors contribute to the emergence of this problem. More medical research is needed. However, data mining (DM) may offer a crucial way for helping to reduce overdiagnosis. We conjecture that overdiagnosed cases lie on or near the border of different diagnostic classes. Thus, new types of DM methods must be developed that are accurate on data that lie on or near the border between different diagnostic classes.

Combatting the Epidemic: Opioid Data Integration & Mining

Sponsored: Data Mining

Sponsored Session

Chair: Matthew Hudnall

1 - Prescriber and Pharmacy-Sharing Effect on Prescription Opioid Abuse: A Large-Scale Social Network Analysis

Yongcheng Zhan, Tucson, AZ, 85719, United States, Bin Zhang

Recent years have observed the spread of America's drug overdose epidemic. The implementation of the prescription drug monitoring program (PDMP) helps fight against the problem. However, it was reported that the impact of PDMPs remained nascent and inconsistent. We used innovative social network analysis techniques to study PDMP data in Arizona state. We found that there existed statistically significant network effect on patients' opioid high-dose status, which means sharing prescribers or pharmacies with other opioid high-dose patients was positively related to the high-dose status of the patients themselves.

2 - Aiding the Prescriber - Machine Learning for Decision Support

Margret Bjarnadottir, University of Maryland, College Park, MD, United States, margret@rhsmith.umd.edu

The opioid crisis has assumed center stage in recent US health policy debates and discussions. While multiple factors may have contributed to the crisis, the widespread availability of opioids, fueled by physician prescribing patterns, diversion of prescribed medications, and the interaction of these factors with potential illicit opioid use, have been implicated as proximal causes for subsequent opioid dependence and mortality. In our work we focus on how machine learning models can aid physicians in their prescription decisions with the goal of reducing high risk and/or unnecessary prescriptions.

3 - Prescribing Patterns and Adherence of Suboxone in Massachusetts

Md Noor-E-Alam, Northeastern University, Boston, MA, United States, mnalam@neu.edu

In recent years, the addiction and abuse of prescription opioids has reached an epidemic level in the US. This epidemic worsens health, drains productivity, and procreates crime; communities suffer significant direct and indirect losses. Given this public health emergency, immediate actions are required to make communities resilient against the opioid addiction epidemic. To that end, we aim to strengthen community resilience to combat the opioid crisis through developing a risk assessment tool to help physicians generate personalized opioid prescriptions for patients, which will help reduce the flow of opioids and minimize a patient's probability of addiction and overdose.

Chair: Nahid Majlesinasab

1 - A Fast Incremental Mirror Descent Method for Finite Sum Problems on Semidefinite Matrix Spaces

Nahid Majlesinasab, Oklahoma State University, Stillwater, OK, 74078, United States, nahid.majlesinasab@okstate.edu, Farzad Yousefian

We consider a finite sum problem where the goal is to minimize the summation of convex objectives on semidefinite matrix spaces. This type of minimization arises in problems such as sparse inverse covariance estimation. Despite the recent advancements in first-order methods addressing problems over vector spaces such as SAG and SAGA, there seems to be a major gap in the theory of the first-order methods for finite sum problems on semidefinite matrix spaces. Motivated by this gap, we develop a fast incremental mirror descent method. We show that the iterates generated by the algorithm converge to an optimal solution. Using a suitably defined error function, we derive a convergence rate statement.

2 - Randomized First-order Methods for Ill-posed Cartesian Variational Inequality Problems

Harshal Kaushik, Oklahoma State University, Ind, Stillwater, OK, 74078, United States, harshal.kaushik@okstate.edu, Farzad Yousefian

Motivated by multi-user optimization problems and non-cooperative Nash games, we consider Cartesian variational inequality problems (VI). To address ill-posedness in this regime, we consider the problem of minimizing a desired objective function over the solution set of the Cartesian VI. We develop a randomized block coordinate iterative regularized gradient method where at each iteration, a block is randomly selected and the iterate is updated at that block. We establish the almost sure convergence of the generated sequence by the scheme. In the case of merely monotone VIs, we derive a convergence rate in terms of a suitably defined gap function. Preliminary numerical results will be presented.

3 - Rate Analysis for Variance-reduced Stochastic Quasi-newton Schemes for Stochastic Convex Optimization

Afrooz Jalilzadeh, Pennsylvania State University, University Park, PA, 16801, United States, Azj5286@psu.edu, Angelia Nedich, Uday Shanbhag, Farzad Yousefian

This paper presents a quasi-Newton framework that can process merely convex and possibly nonsmooth (but smoothable) stochastic convex problems. (i) In strongly convex regimes with state-dependent noise, the proposed variable sample-size stochastic quasi-Newton (VS-SQN) scheme admits a non-asymptotic linear rate of convergence. In nonsmooth regimes, using Moreau smoothing the method retains the linear convergence rate. (ii) In merely convex but smooth settings, the regularized VS-SQN scheme displays a rate of O(1/k1-) while in nonsmooth regimes, the rate worsens to O(k-1/3). Such statements allow for a state-dependent noise under a quadratic growth property on the objective.

4 - Distributed Inference Over Networks: Geometrically Convergent Algorithms and Statistical Guarantees

Ying Sun, Purdue University, West Lafayette, IN, 47906, United States, Ye Tian, Gesualdo Scutari, Guang Cheng

In this talk, we present a decentralized projected gradient algorithm for solving high-dimensional convex ERM problems. We provide a sample-iteration complexity analysis and show that under the restricted strongly convex/smoothness conditions on the global loss function the algorithm converges at a linear rate to the statistical precision of the model, provided that the network is sufficiently connected. Our result also reveals an interesting tradeoff between the hardness of the problem and network connectivity on the impact of convergence rate: a problem with more scattered samples requires a more connected network to keep the rate invariant.

5 - First-order Augmented Lagrangian Method (iALM): Nonergodic Convergence and Iteration Complexity

Zichong Li, Rensselaer Polytechnic Institute, Troy, NY, United States, Yangyang Xu

Augmented Lagrangian method (ALM) is popular for solving constrained optimization problems. The global convergence rate of inexact ALM is open for problems with nonlinear inequality constraints. In this paper, we work on convex programs with both equality and inequality constraints. We first establish some important properties of the augmented dual function, Then we establish the nonergodic convergence rate of inexact proximal point method (iPPM). Later we establish the relation between iALM and iPPM, establish the global nonergodic convergence rate of iALM and estimate its iteration complexity. Finally we compare our results with existing works.

1 - Inferring Semantic Hierarchies from Taxonomic Curation at Pinterest

Emaad Manzoor, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, emaad@cmu.edu

Curated taxonomies enhance the performance of machine-learning systems via high-quality structured knowledge. However, manually curating a large and rapidly-evolving taxonomy is infeasible. In this work, we propose Arborist, an approach to automatically expand textual taxonomies by predicting the parents of new taxonomy nodes. Arborist handles the more challenging scenario of taxonomies with heterogenous edge semantics that are unobserved, and also provides example-based explanations. We evaluate Arborist on a large-scale taxonomy at Pinterest and demonstrate up to 60% in mean reciprocal rank and 80% in recall@15.

2 - Don't Classify, Translate: Multi-level E-commerce Product Categorization via Machine Translation

Stanley Kok, National University of SIngapore (NUS), Singapore, Singapore, stanley.kok@nus.edu.sg

E-commerce platforms categorize their products into a multi-level taxonomy tree with thousands of leaf categories. Conventional methods for product categorization are typically based on classification algorithms. These algorithms take product information as input to classify a product into a leaf category. We propose a new paradigm based on machine translation. In our approach, we translate a product's natural language description into a sequence of tokens representing a root-to-leaf path in a product taxonomy. In our experiments on two real-world datasets, we show that our approach achieves better predictive accuracy than a state-of-the-art classification system.

3 - Missing Not at Random in Matrix Completion: Debiasing Guarantees From Estimating Missingness Probabilities under Low Nuclear Norm Structure

George H. Chen, Assistant Professor, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, Wei Ma

Matrix completion is often applied to data where entries are missing not at random. For example, in a recommendation system, if users tend to only reveal ratings for items they like then the revealed entries can have a positive bias. In this case, matrix completion methods relying on revealed entries being uniformly sampled can yield overly optimistic predictions of unseen user ratings. In this paper, we propose a new approach for debiasing standard matrix completion losses via estimating probabilities of entries being revealed using low nuclear norm structure. We develop theory for this approach and show that it outperforms a number of baselines in practice.

4 - Predicting Cryptocurrency Movement: Analysis of Blockchain Transaction Graph

Yuxin Zhang, University of Texas at Austin, Austin, TX, United States, yuxin.zhang@utexas.edu, Rajiv Garg, Patrick L. Brockett, Linda Golden

In this paper, we propose an iterative learning model to predict the evolution of blockchain transactions based on its entire transaction history. We study patterns of transaction subgraphs and use those to predict volume and amounts of transaction graphs in future blocks. Furthermore, we develop the insights to predict the exchange rate for the cryptocurrency using the identified transaction subgraphs. We demonstrate this framework in the context of Bitcoin and discuss the generalizability for other cryptocurrencies. Additionally, we provide discussion on how framework is valuable in understanding anomalies in blockchain enabled supply chain.

1 - Applying Artificial Intelligence to Smart Built Environment

Young M. Lee, Johnson Controls, Milwaukee, WI, 53202, United States, young.m.lee@jci.com, Youngchoon Park, Sudhi Sinha

In smart built environment, equipment and systems such as chillers, boilers, air handling unit, rooftop unit, refrigeration units, energy storage system, security systems, assurance services systems and smart experience systems are equipped with sensors, are connected to each other, and generate real time data. AI analytics then use the data to make buildings safe and cost-effective, and make people more comfortable and productive. This talk describes AI analytics in built environment and how they are helping in reducing maintenance costs, reducing energy costs, improving the life of equipment, improving service level and improving security, comfort and productivity of building occupants.

2 - Automated Vibration Analysis with Convolutional Neural Networks

Kelsey Schuster, PhD, Johnson Controls, Milwaukee, WI, United States

Vibration analysis is an important diagnostic tool for identifying mechanical issues in rotating equipment. Typically, technicians collect vibration data on-site, and trained vibration analysts evaluate each dataset to identify potential issues so they can be corrected before serious damage occurs. We find that leveraging convolutional neural networks to identify abnormalities in vibration signals can automate a portion of this analysis, allowing vibration analysts to focus only on suspected faulty equipment and more efficiently evaluate data. Using historical chiller data, we find that we can identify all critical abnormalities while passing through 30% of acceptable machines.

3 - Statistical Modeling of Large-scale Repairable System Reliability Data in Big Data Environment

Xiao Liu, PhD, University of Arkansas, Fayetteville, AR, United States, xl027@uark.edu, Rong Pan

Leveraging the power of modern statistical learning, this paper investigates a statistical approach which integrates the additive-tree methods (Random Forests and Boosting) and the classical data analysis methodologies for repairable system reliability, such as the nonparametric estimator for the Mean Cumulative Function and the parametric models based on the Nonhomogeneous Poisson Process.

4 - Deep Learning to Predict Building and Sub-Meter Energy Consumption

Sugumar Murugesan, PhD, Johnson Controls, Santa Clara, CA, United States, sugumar.murugesan@jci.com, Young M. Lee

We present our experience developing energy prediction models for various JCI buildings. We focus on LSTM (Long Short-Term Memory) Sequence-to-Sequence (S2S) architectures, which are well-suited for capturing temporal dynamics in energy signals. Within LSTM S2S context, we report observations such as - impact of temporal memory, deterministic predictors, realized and forecasted weather, and mismatched holidays, followed by performance evaluation and comparison with ASHRAE guidelines. We conclude our presentation with discussion on ongoing efforts to build probabilistic predictions, domain adaptation to achieve 'deploy-and-then-learn' for new buildings.

5 - Economically Driven Adaptive Traffic Signal Control

Shan Jiang, PhD Student, Rutgers University, Piscataway, NJ, United States, sj576@rutgers.edu, Mohsen Jafari, Yufei Huang

This paper proposes an Economic Adaptive Traffic Signal Control model. The model uses a penalty function that grows with vehicle waiting time according to a continuous compounding economic model, with interest rate that varies with traffic flow. Each signal controller is assumed an intelligent agent seeking to minimize the total penalty it pays to vehicles that pass through. The agent control problem is formulated as a Markov Decision Process and Deep Q Network is utilized to solve it. The agent adopts an optimal control policy for signal timing and interest rate as functions of traffic state. A VISSIM simulation model with classic four-leg signalized intersections is used to demonstrate the model.

1 - A New Forecasting Model Selection in Supply Chain Management: Application to MonarchFx Inc.

Sajjad Taghiyeh, North Carolina State University, Raleigh, NC, United States

Selecting the most accurate forecasting model for a given time series has complex decision. The application of machine learning algorithms in model selection has emerged as a promising approach. We propose a new time series forecasting model selection procedure based on intermediate classification (MSIC). Our method trains the classification models using train and validation sets and predicts out-of-sample performance by the trained classifier. Proposed method has been adopted and applied to data provided by MonarchFx (a distributed logistics solutions provider). These findings suggest that our proposed selection approach results in more robust predictions with lower mean squared errors.

2 - Who Wants Green Jeans? A Dynamic Model of Publicity and Reputation

Susan A. Slotnick, Cleveland State University, Cleveland, OH, United States, s.slotnick@csuohio.edu, Monire Jalili

A firm produces two types of products (standard and green) and serves two types of customers (base and environmentally conscious). The production cost of the green product is higher than the production cost of the standard product, and the firm's expenditures on publicity serve to enhance its reputation for environmental responsibility over time, which broadens its market share and increases demand for both products. We investigate the trade-off between expenditures on sustainable products and publicity, and the potential for increased profit due to enhancement of the firm's reputation.

3 - Blockchain Technology and its Applications for The Supply Chain Management in the Food Industry

Jinwook Lee, Assistant Professor, LeBow College of Business, Drexel University, Philadelphia, PA, United States, jl3539@drexel.edu

Since the inception of blockchain and Bitcoin (Nakamoto (2008)), a decentralized-distributed network and its associated cryptocurrency, respectively, the world has witnessed a slew of newer adaptations and applications. Although the original distributed ledger technology (DLT) of blockchain is deemed secure and decentralized, the confirmation of transactions is inefficient by design. We introduce an efficient and secure DLT by reconstructing the chain of antichains given a DAG-pool of transactions. Further, we apply the conceptual "hybrid database" to DLT-augmented supply chain transparency in the food industry. Detailed real-life applications are presented.

4 - Analyzing the Sustainability Performance Indicators of Firms in the Indian Context Using Grey Theory

Rajesh Rajagopal, Assistant Professor, ABV-Indian Institute of Information Technology and Management, Gwalior, India, rajeshambzha@gmail.com

Sustainability enables the present supply chains to stabilize their gains. Here, we study the sustainability performances of 39 firms in the Indian context, listed in the Thomson Reuters ESG (Environmental, Social, and Governance) scores for a period of 5 years from 2014 to 2018. A grey incidence analysis is used to study the most important themes contributing to the sustainability performances. It is observed from the results that the Resource use score and the Environmental innovation score, emerges as the most important themes of ESG performances of Indian firms. And the research uncovers implications in the direction to improving the Governance performance of Indian firms.

5 - A Framework for Sustainable Supply Chain Management and Associated Construct Measurements

Xianghui (Richard) Peng, Assistant Professor, Penn State-Erie, The Behrend College, Erie, PA, United States, xzp17@psu.edu, Lu Xu, Ying Cao, Victor R. Prybutok

A thorough literature review on sustainable supply chain management (SSCM) shows that SSCM practices require additional investigation and refinement of the concepts. Construct measurements and framework development appear particularly needed in the SSCM literature. This research identifies and substantiates key SSCM practices. The key practices are then related to constructs that allow development of a SSCM framework. This research contributes to the theory development for SSCM.

1 - Using the INFORMS Analytics Capability Evaluation to Support Organizational Change and Analytics Capability Improvements

Walter Degrange, Cana Advisors, Chapel Hill, NC, United States, Norman Reitter

Are you wondering about how to determine the level of analytics capabilities that you need to meet your organization's needs? Do you have an approach that will help you and your organization set a path towards improvement? The INFORMS Analytics Capability Evaluation (ACE) initiative provides you the tools and coaches that you will need to get started. This presentation reviews the INFORMS ACE initiative - including the INFORMS standard for measuring analytics capability and a new Analytics Coaching program. We also talk about tips for performing your organizational level assessment and lessons that we have learned from facilitating analytics assessments to date.

Improving Patient Flow and Quality of Care

Sponsored: Applied Probability

Sponsored Session

Chair: Pengyi Shi, Purdue University, West Lafayette, IN, 47907, United States

Co-Chair: Nan Liu, Boston College, Chestnut Hill, MA, 02467, United States

1 - Improving Patient Flow in Emergency Departments via Hospital Bed Requests at Triage

Serhan Ziya, University of North Carolina, Department of Stat and OR, 356 Hanes Hall Cb#3260, Chapel Hill, NC, 27599, United States, ziya@unc.edu, Wanyi Chen, Sukriye Nilay Argon

In this paper, with the objective of reducing patients' length-of-stay in emergency departments, we consider the possibility of requesting hospital beds at the time of triage for patients who are predicted to have a high probability of being admitted to the hospital. We develop practical methods based on queueing theory and Markov decision processes and investigate the performances of the proposed methods with a simulation study.

2 - Optimal Allocation of Rehab Beds to Acute Care Patients

Berk Gorgulu, University of Toronto, Toronto, ON, M5J 1B7, Canada, bgorgulu@mie.utoronto.ca, Vahid Sarhangian

Due to limited rehab bed capacity, patients requiring rehab after their acute care often need to wait, occupying a bed and other resources in the acute part of their care. In this work, we propose a data-driven approach for optimal allocation of rehab beds to acute care patients with the goal of improving patient flow and reducing waiting times.

3 - An Equilibrium Framework for Assessing the Impact of Policy Changes under Endogenous Patient Choice

A. Cem Randa, University of Chicago, Booth School of Business, Chicago, IL, 60637, United States, randa@chicagobooth.edu, Baris Ata, John Friedewald

This paper develops an equilibrium framework for assessing the impact of the deceased-donor kidney allocation policy on the transplant candidates' organ acceptance behavior, the transplant waitlist, organ availability for different patient groups and organ wastage. We advance a fluid model of the transplant waitlist and a dynamic structural model of the transplant candidates' accept/reject decisions for organ offers. Taking the quality adjusting scores of deceased-donor kidney transplant candidates as an input to our model, we perform counterfactual studies using our equilibrium framework to assess the performance of so called borderless distribution of deceased donor kidneys.

4 - Analysis of Hospital Networks via Time-varying Fluid Models with Blocking

Noa Zychlinski, Columbia Business School, Israel, NYC, NY, 34354, United States, nz2307@columbia.edu, Avishai Mandelbaum, Petar Momcilovic, Izack Cohen

Bed-blocking has become a challenge to healthcare operators due to its economic implications and quality-of-life effect on patients. This motivated us to model and analyzes the flow of patients between hospitals and geriatric institutions in order to improve their joint operation. We develop a fluid model, which accounts for blocking, mortality and readmission — all significant features of the discussed environment. Then, for bed allocation decisions, we analyze the fluid model and its offered-load counterpart. Solving for the optimal number of geriatric beds in our system demonstrates that significant cost reductions are achievable, when compared to current operations.

1 - Finite-time Performance Bounds and Adaptive Learning Rate Selection for Temporal Difference Learning

R Srikant, University of Illinois at Urbana-Champaign, Coord Science Lab & Dept of ECE, Urbana, IL, 61801, United States, rsrikant27@gmail.com

We derive finite-time performance bounds for TD learning with linear function approximation and a constant learning rate. Then, we use these bounds to design an algorithm to adapt the learning rate to achieve fast convergence. Joint work with Harsh Gupta and Lei Ying.

2 - Fundamental Limits of Learning Adversarially Robust Classifiers

Daniel Cullina, Princeton University, Princeton, NJ, United States, dcullina@princeton.edu

How many training examples are required to learn a classifier that is not only accurate but robust to adversial examples? Does adding the robustness requirement increase this sample complexity? We extend the Vapnik-Chervonenkis framework to robust classification and obtain upper bounds on error rate that depend on a new quantity that is a property of a hypothesis class together with an adversarial constraint relation. We obtain bounds on error rate with unlimited training data via optimal transport. In a Bayesian setting, these translate into finite-sample lower bounds on error rate.

3 - Performance Analysis of Network Inference Algorithms for Bernoulli Autoregressive Processes

Carolyn L. Beck, Professor, University of Illinois Urbana-Champaign, Urbana, IL, 61801, United States, beck3@illinois.edu, Xiaotian Xie, Dimitrios Katselis, R. Srikant

We consider multivariate random processes that produce a vector of Bernoulli signals, and capture binary interactions over network structures; we refer to this paradigm as a Bernoulli Autoregressive (BAR) process. Our main goal is to identify or infer the causal interconnectivity structures of the underlying networks, which we assume are sparsely connected, using time-series data. We discuss sample complexity of MLE and greedy-like algorithms for solving the related inference problem, and note the relation of this complexity to mixing times of general BAR processes, which can be viewed as Markov chains with non-reversible dynamics.

4 - Distributionally Robust Losses Against Mixture Covariate Shifts

Hongseok Namkoong, Stanford University, Stanford, CA, 94305, United States, John Duchi, Tatsunori Hashimoto

Modern large-scale datasets are often collected over heterogeneous subpopulations, such as multiple demographic groups or multiple text corpora. Minimizing average loss over such datasets fails to guarantee uniformly low losses across all subpopulations. We propose a convex procedure that controls the worst-case performance over all subpopulations of a certain size. Our procedure comes with finite-sample optimality guarantees on the worst off subpopulation, and converges at the standard nonparametric rate. Empirically, we observe on lexical similarity and recidivism prediction tasks that our worst-case procedure learns models that do well against unseen subpopulations.

1 - Time-varying Asset Pricing Factors for Stock Returns

Markus Pelger, Stanford University, Stanford, CA, 94305, United States, mpelger@stanford.edu, Zihan Lin

We propose a new method to explain the time-series and cross-section of individual stock returns. Our approach allows for latent factors and time-varying loadings as general functions of time-varying firm characteristics. Our estimator enforces no-arbitrage and links the factor structure in the individual stock return space to a low dimensional structure in the space of non-linear firm characteristic basis functions. Empirically, we outperform models that ignore non-linear characteristic basis functions or neglect the no-arbitrage constraint in the factor extraction.

2 - A Computationally Efficient Significance Test for Machine Learning Models

Enguerrand Horel, Stanford University, Stanford, CA, 94305, United States, ehorel@stanford.edu, Kay Giesecke

We develop a simple and computationally efficient significance test for the feature variables of a machine learning model. Our forward-selection approach applies to any model specification, learning task and variable type. The test is non-asymptotic, straightforward to implement, and does not require model refitting. It identifies the statistically significant features as well as feature interactions of any order in a hierarchical manner, and permits rank-ordering the features according to their influence. Numerical results illustrate its performance.

3 - Estimating the Discount Curve

Ye Ye, Stanford University, Stanford, CA, United States, Damir Filipovic, Kay Giesecke, Markus Pelger

We propose two nonparametric methods for estimating the discount curve from large data sets of coupon bonds, with regularization penalties in terms of the smoothness of the approximating forward curve. We provide analytical solutions for a given regularization weight, and we propose a data-driven approach to determine the optimal regularization penalty that minimizes out-of-sample pricing errors. We apply our methods on a large data set of U.S. Treasury securities from 1961 to present to extract term structure estimates at daily frequency with daily-spaced maturities up to ten years. The resulting term structure estimates match standard benchmarks but have smaller pricing errors.

Emerging Topics in Retail Operations

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Mehmet Sekip Altug, George Mason University, Washington, DC, 20052, United States

1 - Impact of the Interplay Between Review Number and Rating in Digital Platforms: an Empirical Study

Samayita Guha, Temple University, Philadelphia, PA, United States, samayita.guha@temple.edu, Naveen Kumar, Subodha Kumar, Joydeep Srivastava

Consumers now increasingly depend on user-generated reviews. Based on the data collected from a digital-platform, we empirically examine the impact of interaction between the number of reviews and the average rating.

2 - Drivers of Direct Store Delivery Performance

Arzum E. Akkas, Boston University, Boston, MA, 02142, United States, aakkas@bu.edu, Yasin Alan, Tae-Youn Park

Direct store delivery (DSD) is a common method of sales and delivery in the grocery retail supply chains, in which a vendor delivers its goods directly to retail stores bypassing retailers' distribution centers. Our study empirically examines several factors that impact the performance of DSD operations such as employee characteristics and the vendor's delivery route structure. Our work has important implications for the efficiency of sales and delivery operations, bottom lines of DSD companies, and quality of service provided to retail stores.

3 - Opaque Selling and Last-minute Selling: Revenue Management in Vertically Differentiated Markets

Hang Ren, School of Business, George Mason University, Fairfax, VA, 22030, United States, hren5@gmu.edu, Tingliang Huang

We analyze the performance of opaque selling as a clearance strategy in vertically differentiated markets. Compared to last-minute selling, opaque selling may increase revenue because consumers who wait for the sales cannot choose the preferred product type. Its disadvantage, however, lies in the inflexibility in segmenting different types of consumers. Both the advantage and the disadvantage are radically different from their counterparts in horizontally differentiated markets. This contrast generates opposite policy recommendations across the two settings.

4 - The Impact of Online Product Reviews on Retailers Pricing and Return Policy Decisions

Mehmet Sekip Altug, Associate Professor, George Mason University, Fairfax, VA, 20052, United States, maltug@gmu.edu

Customers feel increasingly more comfortable with posting and using on-line product reviews. In a two-period setting, we explore the impact of product reviews on customer's valuation uncertainty for an experience-type product and how that in turn affects a monopolist retailer's pricing and refund decisions. Surprisingly, we find that the retailer makes its return policy even more lenient. In a duopolistic competition, the overall sentiment of the on-line reviews are influenced by the refund and pricing decisions of both retailers. Interestingly, we show that the retailers make their returns more lenient compared to the monopolist case when they collectively determine the review sentiment.

1 - Delay Information on a Ride-sharing Platform: a Large-scale Field Experiment

Qiuping Yu, Georgia Institute of Technology, University of Washington, Business School, Atlanta, GA, 98195-3226, United States, yqp2009@gmail.com, Yiming Zhang, Yong-Pin Zhou

In collaboration with a large ride-sharing platform in China, we study how delay estimates and their progress over time impact customers' abandonment behavior. To do so, we conducted a large-scale randomized field experiment in three Chinese cities in 2018, which covers 2.5 million rides. Not surprisingly, a higher delay estimate increases customers' likelihood to abandon. We find that such an impact increases as the congestion level increases, the progress of the estimates reduces customers' likelihood to abandon, and such impact is the largest in the middle of customers' waiting episodes.

2 - Does What Happens in the Ed Stay in the Ed? The Effects of Emergency Department Physician Workload on Post-ed Care Use

Mohamad Soltani, University of Wisconsin-Madison, Madison, WI, 53706, United States, mohamad.soltani@wisc.edu, Robert Batt, Hessam Bavafa, Brian Patterson

We study the effects of workload in Emergency Department (ED) on post-ED care. First, using an ED patient-level data, we show that attending physicians admit more patients to the hospital when their workload increases. Second, combining the ED data with an integrated health system billing data, we find different effects of physician workload on number of follow-up visits. As workload increases, even after controlling for the changes in the admission decision, the number of follow-up visits increases for the discharged patients but does not change significantly for the admitted patients. We also explore the changes in care provided during the ED visit as the possible drivers of these effects.

3 - Queues with Strategic Arrivals and Strategic Servers

Ragavendran Gopalakrishnan, Assistant Professor, Queen's University, Kingston, ON, Canada

We revisit Naor's seminal study of an observable M/M/1/FCFS queue where arrivals are strategic (with linear utilities) and introduce strategic server behavior. We find that a joint equilibrium between the arrivals and server may not exist, nor be unique when it does exist. Moreover, a socially optimal threshold for the arrivals (as defined by Naor) could exceed an equilibrium threshold, a phenomenon that does not occur in Naor's model (where the server is not strategic). We discuss the consequences of these results in designing optimal policies for service systems involving strategic behavior from both arrivals and servers.

4 - Signaling Quality and Speed Through Staffing Decisions

Park Sinchaisri, The Wharton School, Jon M. Huntsman Hall, Philadelphia, PA, 19104, United States, swich@wharton.upenn.edu, Serguei Netessine

From behavioral viewpoint, longer queue can signal high quality/low prices of the products. On the other hand, shorter queue can be attractive because of promise of a faster service. Using unique data on the people who pass by the small retail stores vs. enter and purchase, we evaluate these two behavioural effects of queuing and demonstrate their impact upon optimal staffing policies in the stores.

3 - Queues with Strategic Arrivals and Strategic Servers

Amy Ward

We revisit Naor's seminal study of an observable M/M/1/FCFS queue where arrivals are strategic (with linear utilities) and introduce strategic server behavior. We find that a joint equilibrium between the arrivals and server may not exist, nor be unique when it does exist. Moreover, a socially optimal threshold for the arrivals (as defined by Naor) could exceed an equilibrium threshold, a phenomenon that does not occur in Naor's model (where the server is not strategic). We discuss the consequences of these results in designing optimal policies for service systems involving strategic behavior from both arrivals and servers.

1 - Profit or Market Thickness? Dynamic Order Allocation Mechanisms with a Hybrid Workforce

Eryn Juan He, Institute of Operations Research and Analytics, NUS, Singapore, hej@u.nus.edu, Joel Goh

Several firms have launched their own on-demand platforms to engage freelancers. The emergence of such hybrid workforces raises new unexplored research questions: How should demand be shared between its regular employees of the firm and freelancers from the platform? Under what conditions will such system be sustainable in the long run? We design an optimal dynamic order allocation mechanism to maximize system's long run profit under a service-level constraint and stochastic network effects. We show that as the mean and variance of network effects vary, it can be optimal for the firm and platform to operate collaboratively or independently, the system may either be sustainable or not in the long run.

2 - Stands Assignment in Cargo Airport

Quanmeng Wang, National University of Singapore (NUS), Singapore, e0210515@u.nus.edu, Chung-Piaw Teo, Kim-Chuan Toh

Due to recent development in E commerce, there is a significant increase in cargo traffic at airports whose primary target is to serve passengers. To satisfy this demand, a new type of airpoint that only serves airplanes for cargo transportation has been built in China. In a typical business day of such airport, scheduled airplanes land at airport, stay and exchange cargo, finally leave at scheduled time. As a central planner of such airport, we study stands assignment problem in this setting, and our goal is to improve efficiency of cargo transportation during the stay of airplanes.

3 - Optimal Energy Trading with Capacitated Storage Asset in a Trading Hub

Qinghe Sun, National University of Singapore, Singapore, Singapore, qinghe_sun@u.nus.edu, Mabel Chou

The purpose of this paper is to develop a general merchant energy trading model for a hub accessible to multiple trading markets in which trading decisions can be analyzed and optimized. We introduce a multi-period warehouse problem under three types of constraints: storage space constraint, injection/withdrawal capacity constraints, and market-specific constraints. We formulate the problem a Markov decision process with uncertain spot prices, study the interplays among three types of constraints, and characterize the optimal trading policy under different scenarios. Finally, we present a computational example for a Liquified Natural Gas (LNG) hub and provide some managerial insights.

4 - Sparse and Efficient Rebalancing Operations: Concentrating the Flows in Dynamic Network

Jinjia Huang, Institute of Operations Research and Analytics, National University of Singapore, Singapore, Singapore, oraahj@nus.edu.sg, Mabel C. Chou, Chung-Piaw Teo, Linfeng Li

Motivated by the Bike Angels Program in New York's Citi Bike system, we study the use of volunteers as an alternative to rebalance bikes in a bike sharing system before peak hours. We discuss how a static network structure can be constructed to be used as the backbone to support the dynamic rebalancing operations, along with a simple algorithm to dispatch the volunteers in a real-time fashion. Depending on the operating conditions, our method produces a sparse structure that outperforms the long chains or recovers the fixed pick-up/drop-off structure used in the early days of the Bike Angels Program. We also verify the effectiveness of our method through a dataset from the Boston Hubway system .

1 - Managing Customer Churn via Service Mode Control

Jiaqi Lu, Columbia University, c/o Clara Magram, New York, NY, 10027, United States, Yash Kanoria, Ilan Lobel

We consider the problem faced by an investment manager who makes decisions overtime between a risky asset and a safe asset. Meanwhile, the customer is unsophisticated and his probability of churn depends on how satisfied he is with recent rewards. We show that either myopic or a sandwich policy maximizes CLV. The latter uses the inferior of the two arms for intermediate happiness levels. Specifically, the firm becomes risk averse when the customer is marginally satisfied and risk seeking when the customer is marginally unsatisfied. We show that our results are robust to several important idiosyncrasies for the investment manager setting.

2 - When is Society Susceptible to Manipulation?

Mohamed Mostagir, University of Michigan, Ann Arbor, MI, 48109, United States, Asuman Ozdaglar, James Siderius

We study the classic social learning problem where agents try to uncover a state of the world (for e.g. whether a particular vaccine is safe, or whether burning fossil fuels leads to accelerated global warming) through their own experiences as well as what they learn from their friends. A principal (like a firm or a lobbying group) tampers with the learning process of the agents in order to steer them towards a particular action that might benefit the principal but is sub-optimal for the agents (for e.g. not to vaccinate even though the vaccine is safe). We examine under what conditions such manipulation is possible and describe how networks that are susceptible to manipulation can become more resilient.

3 - Persuading Risk-conscious Agents: A Geometric Approach

Krishnamurthy Iyer, University of Minnesota, Minneapolis, MN, 14850, United States, kriyer@umn.edu, Jerry Anunrojwong, David Lingenbrink

Motivated by practical concerns, we consider a bayesian persuasion problem between a principal and an agent where the agent may not be an expected-utility maximizer. In particular, the agent's utility may be non-linear in her belief; we deem such agents as risk-conscious. In such settings, revelation-principle fails to characterize of the set of signals needed in the optimal signaling scheme. Using results from convex analysis, we bound the number of signals needed, and reduce the sender's problem to solving a convex optimization program. We illustrate our results in the setting of signaling in an unobservable queue with customers whose utilities depend on the variance of their waiting times.

4 - Persuading Customers to Buy Early: Value of Personalized Information Provisioning

Ramandeep Randhawa, USC, Los Angeles, CA, United States, ramandeep.randhawa@marshall.usc.edu, Shobhit Jain, Kimon Drakopoulos

We study a pricing and information provisioning game between a better informed seller (such as a retailer) and its customers. The seller is (ex-post) better informed about product availability and can choose how to communicate this information to the customers. Using a Bayesian persuasion framework, we find that public information provisioning in which the firm sends the same information to all customers has limited value. However, personalized information provisioning, in which the firm can share different information with different customers, has significant value and has attributes very similar to personalized pricing.

Demand Analytics in Retailing

Sponsored: Manufacturing & Service Oper. Mgmt/Supply Chain

Sponsored Session

Chair: Aditya Jain, Baruch College, Zicklin School of Business, New York, NY, 10010, United States

1 - Estimating Demand in the Absence of Sales and Inventory Information

Sripad K. Devalkar, Assistant Professor, Indian School of Business, Ac3 L1 Room 3114, Hyderabad, 500032, India, sripad_devalkar@isb.edu, Sarang Deo, Aditya Jain, Naireet Ghosh

The retail sector in emerging economies is dominated by unorganized retail stores. These stores are characterized by a lack of formal inventory management and data capturing systems, and suppliers often lack visibility into retailer sales and inventory information. The lack of reliable information on retail store level sales and inventory presents interesting challenges for the supplier to estimate demand and plan replenishment decisions. We develop a demand estimation methodology built on the Expectation-Maximization algorithm using data on replenishments to the stores, often the only information available to the supplier.

2 - Robust Demand Estimation with Customer Choice Based Models for Sales Transaction Data

Sanghoon Cho, University of South Carolina, 413 Hawkeye Ct, Columbia, SC, 29206, United States, Mark Ferguson, Jongho Im, Pelin Pekgun

We propose a statistical procedure that can estimate the effect of product attributes and unobservable lost sales under a choice-based demand model using only historical sales transactions, product availability data, and market share information. Our proposed approach does not require time-homogeneous arrival rates, and allows for varying product attributes and choice sets over time. A set of simulation studies and an application to a real hotel dataset are conducted in comparison to several existing methods.

3 - Intertemporal Pricing under Customer Heterogeneity via Nonparametric Estimation

Hansheng Jiang, University of California Berkeley, Berkeley, CA, 94706, United States, hansheng_jiang@berkeley.edu, Junyu Cao, Zuo-Jun Max Shen

We study an intertemporal pricing problem for a group of products under unknown customer heterogeneity. Customers make choices according to a random coefficient multinomial logit (RCMNL) model that contains product features including price. We provide a highly scalable algorithm for estimating the distribution of customer's preference from observed sales data. We then study an intertemporal pricing optimization problem for heterogenoeous customers. Our data-driven approach integrates the customer segmentation and the pricing strategy. We illustrate the effectiveness of our method through both the synthetic and real data.

4 - Demand Estimation Error Caused by Latent Backorder

Sheng Zhao, National University of Singapore, Singapore, Singapore, zhaosheng@u.nus.edu

In a market where products face frequent stock out, demand estimation is extremely difficult due to censored data. A common practice is to take account the time when stock out occurs to estimate the demand. However, such estimation could be inflated due to consumer's backorder behavior. We propose a queuing model to address this issue, and characterize several properties that can explain the counter-intuitive phenomena in the market, using fluid approximation. We also conduct numerical experiments to test our findings, and conclude that our model provides considerable improvement to the performance.

1 - Choosing a Dual-channel Strategy: An Analytical Model with Pricing and Return Policy Decisions

Armagan Ozbilge, McMaster University, Hamilton, ON, Canada, ozbilgea@mcmaster.ca, Elkafi Hassini, Mahmut Parlar

Due to the proliferation of e-commerce, many traditional "bricks-and-mortar" retailers established an online channel and have become "bricks-and-clicks." This has presented retailers with the opportunity of operating different channel structures and at the same time the challenge of selecting and operating the right channel strategy. In this study we develop a stylized model where a dual-channel retailer selling a single product through an online channel as well as a physical store wants to determine the best pricing and return policy mix strategy.

2 - Supply Chain Design and Operations under Omni-channel Environment

Jia Guo, the University of Alabama, Tuscaloosa, AL, 35401, United States, jguo23@crimson.ua.edu, Burcu B. Keskin

We focus on supply chain design and omnichannel strategies with demand segmentation, cost structure, and more importantly, the company's operation ability. We formulate our problem as a two-stage stochastic programming model and use first-order optimality conditions to study the optimal inventory replenishment decisions. The omnichannel strategy decisions are made by analyzing the expected profit. We show that omnichannel strategies are not necessarily profitable for all retailers. Poor execution ability may result in losing the inventory pooling benefits when running omnichannel strategies.

3 - Crowdsourced Delivery: State-of-the-art, with Applications to Omnichannel Supply Chains

James Bookbinder, University of Waterloo, Toronto, ON, Canada, Aliaa Alnaggar, Fatma Gzara, Aliaa Alnaggar

Crowdsourced delivery is a new last-mile transportation solution adopted by many supply chains. We analyze its current industry status and provide a taxonomy of available platforms based on their matching mechanisms, target markets and compensation schemes. We review the OR literature addressing this topic and assess the realism of its assumptions in real-world problems. We highlight the application of crowdsourced delivery in omnichannel supply chains and identify key elements that distinguish it from classical transportation systems, to ultimately shed light on promising research directions.

Fun Ways of Introducing Business Analytics

Sponsored: Education

Sponsored Session

Chair: Jimmy Chen, Bucknell University

1 - Introduction to Probability: Bison Hold'em Poker Game

Jimmy Chen, Assistant Professor, Bucknell University, 95 Sunnyside Dr., Lewisburg, PA, 17837, United States, cmc052@bucknell.edu

Probability literacy is the foundation of business analytics. This study presents an interactive pedagogical game that aims to help students' learning of probability. Primarily designed for undergraduate students in business analytics courses, our game follows classic Texas Hold'em poker and is developed with Visual Basic Applications to function in most commonly available Microsoft Excel. Regardless of their prior exposure to Texas Hold'em poker, students can easily play along as every game rule is code-enforced. Through answering quiz questions embedded in the gameplay, our goal is to introduce the basics of probability to the students in a fun and immersive way.

2 - Lessons Learned Teaching a Case-Based Business Analytics Class

Eric Logan Huggins, Fort Lewis College, Durango, CO, 81301, United States, huggins_e@fortlewis.edu

One of the key lessons I have learned from teaching multiple sections of a case-based introductory business analytics course is that the more students are engaged - i.e., the class is "fun" - the more they tend to learn. So what are the best practices to engage students in this class? I will discuss the trade-off between open-ended versus well-defined assignments, how real data makes a difference, the triumphs and perils of group work and how I try to indoctrinate analytics as an ethos.

3 - Teaching Analytics Through Non-traditional Sports

Keith A. Willoughby, University of Saskatchewan, Department of Finance and Mangement Science, Saskatoon, SK, S7N 5A7, Canada, willoughby@edwards.usask.ca

Regrettably, many of our students approach quantitative courses with emotions ranging from fear to loathing. The deployment of sports examples may help students gain an enhanced appreciation for the value of analytical methods in understanding, exploring and helping to solve actual problems. We present a series of opportunities to illustrate important analytical concepts through the investigation of key problems in non-traditional sports. Our experience asserts the positive impact afforded by sports examples in the classroom, even if such sports may not be particularly well-known.

4 - Using Games in the Classroom to Shorten the Analytics Learning Curve

Kathryn Wilson Ernstberger, Professor of Decision Sciences, Indiana University Southeast, New Albany, IN, 47150, United States, kernst@ius.edu, Munirpallam A. Venkataramanan

Numerous methods for using games to introduce students to predictive and prescriptive analytics techniques are discussed and some are demonstrated. Engaging students first in a familiar and fun manner provides a natural and less intimidating transition to more complex business scenarios. The authors will discuss their experiences with these approaches in their analytics classes.

CC- Room 309

Innovations in Financing

Sponsored: Manufacturing & Service Oper. Mgmt/iFORM

Sponsored Session

Chair: Jiri Chod, Boston College, Chestnut Hill, MA, 02467, United States

1 - Consumer Privacy and Platform Design via Personalized Pricing and Ranking

Xiaoyu Wang, Washington University in St. Louis, St. Louis, MO, 63144, United States, xiaoyuwang@wustl.edu, Fuqiang Zhang

We propose a model of platform operations design via personalized pricing and ranking, and examine the impact of consumer privacy and information externality on the platform's profit and reputation.

2 - Platform Tokenomics

Nikolaos Trichakis, MIT, Cambridge, MA, 02143, United States, Jiri Chod, S. Alex Yang

We study two alternative business models of financing, building, and operating a platform that matches buyer and sellers in a multi-period setting and in the presence of moral hazard. In the traditional model, an entrepreneur raises capital by issuing equity, and makes money only by charging fees to platform users. In the blockchain-based business model, the entrepreneur raises capital and makes money by issuing cryptocurrency to be used on the platform, over which she relinquishes authority. We show that the latter model is preferable if (i) building the platform requires significant entrepreneurial effort and (ii) joining the platform by a user requires a significant irreversible investment.

3 - Contingent Stimulus in Crowdfunding

Longyuan Du, University of San Francisco, San Francisco, CA, United States, ldu5@usfca.edu, Ming Hu, Jiahua Wu

We study a model where backers arrive sequentially at a crowdfunding project. We characterize the dynamics of the pledging process. To boost success, we propose and characterize contingent stimulus policies including feature upgrade and limited-time offer. We show that the benefit of contingent policies is greatest in the middle of crowdfunding campaigns. Testing with the Kickstarter data, we demonstrate the benefit of the stimulus policies and highlight the importance of the timings to use those policies.

4 - Values of Traceability in Supply Chains

Yao Cui, Cornell University, Ithaca, NY, 14853, United States, yao.cui@cornell.edu, Ming Hu, Jingchen Liu

Recent technology development (e.g., Blockchain) has enabled end-to-end traceability of supply chains. When product failure occurs, such traceability information can be used to identify which supplier is at fault. This could revolutionize supply chain operations for industries where traceability is difficult to achieve under traditional technologies (e.g., agri-food and pharmaceutical). In this paper, we investigate the value of traceability under two different supply chain structures: 1) parallel supply chains, where all suppliers belong to the same tier of the supply chain, and 2) serial supply chains, where each supplier belongs to a different tier of the supply chain.

Research on Electric Vehicles and Energy Systems

Sponsored: Manufacturing & Service Oper. Mgmt/Sustainable Operations

Sponsored Session

Chair: Owen Wu, Indiana University, Bloomington, IN, 47405, United States

Co-Chair: Safak Yucel, Georgetown University, Washington, DC, 20057, United States

1 - Shared Autonomous Electric Vehicles for Strengthening Future Urban Microgrids

Wei Qi, Assistant Professor, McGill University, Montreal, QC, H3A 1G5, Canada, wei.qi@mcgill.ca, Mengyi Sha, Shanling Li

We envision the prospect where shared autonomous electric vehicles (SAEVs) will reinforce future urban electricity infrastructure in the form of solar-powered micrograms. We integrate cross-disciplinary modelling of transport and power systems with optimization to investigate the potential of SAEVs for improving the self-sufficiency and resilience of urban microgrids. Our model prescribes optimal citywide SAEV fleet operations of ride-sharing, repositioning, charging and discharging amidst various urban heterogeneities. Our findings highlight the value of centralized dispachability of SAEVs.

2 - Joint Planning of Refueling Stations and Grid Reinforcement for Hydrogen Fuel-cell Vehicles

Long He, National University of Singapore, Singapore, 119245, Singapore, longhe@nus.edu.sg, Wei Qi, Hongcai Zhang

In this paper, we propose an approach to jointly planning hydrogen refueling stations and power grid reinforcement. Our model explicitly handles the interconnectedness between transportation and power distribution networks. Furthermore, it captures the complexities of drivers' vehicle choice behavior and renewable energy integration.

3 - On the Range Anxiety for Electric Vehicles: An Empirical Investigation

Sang Won Kim, Assistant Professor, The Chinese University of Hong Kong, Hong Kong, skim@cuhk.edu.hk, Ho-Yin Mak, Marcelo Olivares, Ying Rong

Electric vehicles are an important technology for curbing the carbon footprint of road transportation. Despite substantial government incentives, mass adoption has yet to happen in major auto markets. Among the major shortcomings of EVs on the market are limited driving range and long recharging time, creating psychological concerns to drivers called range anxiety and making them reluctant to adopt EVs. Although the range anxiety is quite well-recognized, it has not been adequately quantified, quite possibly due to the lack of quality data. In this work, we propose a novel way to quantify the drivers' range anxiety on EVs by use of a dataset from a car sharing platform.

4 - Smart Charging of Electric Vehicles

Owen Wu, Indiana University, Kelley School of Business, Bloomington, IN, 47405, United States, owenwu@indiana.edu, Safak Yucel, Helen Zhou

Electrical vehicles increasingly penetrate the electrical grid, while the common practice at most charging stations is to charge EVs at the maximum possible speed. In this talk, we aim to look for the optimal pricing policy of a charging station that incentivizes customers to choose the 'right' parking time period to allow time-varying speed charging. By properly designing the pricing policy, we can incentivize customers with different time-sensitivity to pick up their vehicles at different times, reducing the charging cost and associated emissions.

5 - Pricing and Charging Time Policies for Electric Vehicles under Congestion

Chen-An Lin, Duke University, 100 Fuqua Drive, Durham City, NC, 27708, United States, chen.an.lin@duke.edu, Kevin Shang, Peng Sun

This paper studies a joint pricing and charging time control problem for a fast charging station, where customers (electronic vehicle drivers) are price and wait time sensitive. The station owner announces a menu that indicates the total payment and charging time. Each arriving driver decides whether to join the queue, which affects the congestion level. We characterize the optimal policy, compare it with benchmark policies, and reveal insights on managing fast charging stations.

CC- Room 3A

Joint Session DAS/Practice Curated: Applications of Decision Analysis for Federal, State, Provincial, and Tribal Natural Resource Management II

Sponsored: Decision Analysis

Sponsored Session

Chair: Sarah Converse

1 - Using Decision Science to Develop Conservation Management Strategies for an Imperiled Amphibian

Katherine M. O'Donnell, US Geological Survey, Gainesville, FL, United States, kmodonnell@usgs.gov

In recovery planning for federally-threatened Frosted Flatwoods Salamanders (Ambystoma cingulatum), we used structured decision making to address uncertainty about the effectiveness of possible habitat restoration actions at one of two remaining strongholds for the species (St. Marks National Wildlife Refuge, FL). We used stochastic dynamic programming to identify optimal strategies that balance species persistence and management costs. We have implemented several conservation actions, and we continue to monitor the species and its habitat to improve our model. This approach has enabled us to carry out important management actions despite uncertainty inherent in these decisions.

2 - Using Structured Decision Making and Machine Learning to Adaptively Manage Invasive Annual Bromes in Grassland Habitats in the National Parks

Max Post van der Burg, USGS, Jamestown, ND, United States, maxpostvanderburg@usgs.gov, Heather Q. Baldwin, Amy Symstad

National Parks preserve and protect historical and ecological landscapes which are under threat from invasion of exotic annual brome grasses. Managing these species is difficult because of uncertainty about the effectiveness of control strategies. We present a management framework to guide park control decisions, while improving understanding of the effects of management actions. Our framework was built using a structured decision-making process for defining management objectives and a Bayesian network model for predicting optimal actions. We describe how parks are using the framework and how new data generated following management actions are used to update the model over time.

3 - Decision Analysis to Identify a Restoration Strategy for Chinook Salmon in California's Central Valley

Adam Duarte, Oregon State University, Corvallis, OR, United States, James T. Peterson

Chinook salmon are in severe decline in many of their native habitats, including tributaries in California's Central Valley. We used a decision theoretic approach to identify Chinook salmon conservation objectives and develop a decision model to identify optimal state-dependent policies while considering various possible restoration actions. Forward simulation suggested this strategy greatly improved future fish populations, but sensitivity analyses indicated that these predictions were strongly influenced by model uncertainties. Thus, we also discuss how monitoring data can be used to reduce uncertainties and improve future management decisions.

4 - Prioritizing Threat Management for Species Recovery

Tara Martin, University of British Columbia, Vancouver, BC, Canada

One million species are at risk of extinction. The identification of actions needed to recover and conserve species, and ensure effective governance to oversee action implementation, presents enormous challenges. Priority Threat Management (PTM) is a decision tool that prioritizes solutions to this global crisis by estimating the cost-effectiveness and complementarity of alternative management actions. It draws on expert judgement through a structured expert elicitation process to estimate the cost, benefit and feasibility of actions and governance. Application of PTM to date spans 4 continents and in each case produces a blueprint for cost-effective species recovery under global change.

Joint Session MCDM/Practice Curated: Combining AI, Spatial and Decision Analysis in a Decision Support System to Change the World

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Philip J Murphy, InfoHarvest Incorporated, Seattle, WA, 98125-2055, United States

1 - Overview of EMDS Workflows and How They Support Strategic and Tactical Decision Making

Keith M. Reynolds, Research forester, USDA Forest Service, Corvallis, OR, United States, kreynolds@fs.fed.us

EMDS is a general spatial decision support framework for environmental analysis and planning, built on the open source Microsoft Workflow Foundation. The system includes four core analytical engines that collectively support both strategic and tactical planning as well as scripting tools for data summarization, transformation, and statistical analysis. The talk will address both standard workflows that users can manually invoke through the main EMDS interface as well as customized workflows that users can design with a built-in workflow editor to automate complex workflow task sequences.

2 - What Regional Land Managers and Planners Needs from an SDS in the Face of Climate Change and Population Growth

Phillip North, The Tulalip Tribes, WA, United States

Protecting functioning habitats and restoring degraded habitats are critical actions for salmon and Puget Sound recovery. Restoration alone cannot keep up with habitat loss and water quality degradation from development and the pressures of anticipated population growth and climate changes. We need a framework for prioritizing diverse projects and programs that takes into account the complexity of the science, competing stakeholder goals, treaty obligations, and the need for regulatory harmonization. Such a framework is at the heart of the Tulalip Tribes Harmonization project.

3 - Changing the World Requires Funded Action – Creating Programs of Funded Projects

Bill Levings, WHLevings, Seattle, WA, 98125, United States

Improving infrastructure or ecosystems requires generating sets of projects that deliver benefit and can be funded within budgetary constraints. Such programs of projects need to be understood and supported both by the communities where the projects will be sited and the larger community that will be funding them. We demonstrate an integrated process to prioritize proposed projects based on their spatial attributes and how well they support social, ecological and economic objectives. Based on multiple funding sources, a program of projects is generated. We describe how the map interface can communicate important information about these programs to decision makers and effected communities.

4 - Combining Rules-based Expert System to Support Permit Regulations for Ecosystem Management

Philip J. Murphy, InfoHarvest Incorporated, Seattle, WA, 98125-2055, United States, Philip.Murphy@InfoHarvest.Com

Federal agencies, states, and counties develop regulations that require permit approval for new projects that will significantly affect the landscape. For land owners, this presents the challenge of how to find which permits are likely required for a specific type of projects in a specific place on the land scape. Based on the governing regulations, they will need to understand the proximity of the project site to wetland, navigable waters, etc. We will show how the VisiRule rules-based experts system combined with a spatial information system can provide a sustainable solution for both the general public and permit reviewers to use to identify all permits per project or for all projects in an area.

Addressing Human Trafficking and Societal Issues through OR and Analytics

Emerging Topic: Humanitarian and NotforProfit Operations

Emerging Topic Session

Chair: Renata Alexandra Konrad, Worcester Polytechnic Institute, Worcester, MA, 01609, United States

1 - Human Trafficking Transit Monitoring in Nepal: A Data Analytics Case Study

Geri Dimas, Worcester Polytechnic Institute, Worcester, MA, United States, gldimas@wpi.edu, Renata Alexandra Konrad, Kayse Lee Maass, Andrew C. Trapp

Like many data involving vulnerable people, human trafficking (HT) data are fragmented and disparate. Understanding individuals vulnerable to HT is an important step in elucidating the underlying structure of these illicit networks. We explore six years of transit monitoring survey data from an anti-HT operation in Nepal, discuss insights gleaned, and introduce a data envelopment analysis model to increase the effectiveness of identifying HT in a resource constrained environment. We conclude by discussing lessons learned and the importance of data structure and domain expertise.

2 - A Review of Questions Driving Analytic Approaches to Ending Sex Trafficking of Children in the United States

Kendra Taylor, KEYFFICIENCIES, Atlanta, GA, 30308, United States, kendra@keyfficiencies.com

We look at the pressing questions to which analytics has provided answers or insight regarding sex trafficking and exploitation of children in the United States. We also look at the unanswered questions to which analytics can provide answers or insight. This approach begins with policy and economic motivators to maximize the utility of the analytics results.

3 - Disrupting Exploitation and Trafficking Labor Supply Networks in Post-Harvey Rebuild

Matt Kammer-Kerwick, The University of Texas at Austin, Austin, TX, 78723, United States, mattkk@ic2.utexas.edu, Yanling Chang

Construction is one of the largest industrial sectors in the global economy as it accounts for about 11 percent of global GDP. The sector is characterized by low barriers of entry, low-wages, hazardous work (the International Labor Office defines construction as one of the most hazardous sectors for workers), and a disproportionate share of migrant workers. The project aims to provide an improved understanding of the states of exploitation and trafficking that can occur among day laborers working in the chaotic environment that accompanies recovery and rebuild efforts after a natural disaster. Specifically, the project involves three major activities: 1) Conducting qualitative case studies to explore quantitative parameterization of the problem space. 2) Exploring multi-agent, game theoretic decision support frameworks as an initial attempt to rigorously model human trafficking. 3) Providing managerial insights to policy makers, regulators, and companies on how to monitor, combat, and disrupt exploitation and labor trafficking with limited resources. The modeling frameworks being developed address the partial observability of laborers as well as the intelligent and adaptive behavior of both laborers and those who exploit them. This presentation reviews findings from fieldwork and preliminary modeling approaches as part of the first year of a two year project.

4 - Improving Community Paramedicine via Data Driven Optimization: Selective, Proactive Treatment of Patients

Shima Azizi, Worcester Polytechnic Institute, Worcester, MA, 01609, United States, Andrew C. Trapp, Sharon Johnson, Renata Konrad, Brenton Faber

Community paramedicine is a recent healthcare innovation that enables proactive visitation of patients at home, often shortly after Emergency Department and hospital discharge. We propose to reduce both hospital costs and readmissions, and increase patient welfare. We develop an integer program that selects patients and routes healthcare providers to maximize overall patient welfare, while prioritizing shorter tours. We discuss our computational experiments on a variety of test instances inspired by real, deidentified data from a rural hospital system, which solve in reasonable runtimes.

Joint Session Serv Sci/Practice Curated: AI in Service Science

Joint Session

1 - Early Detection of the Replicability of Scientific Findings Using Human and Machine Intelligence

Yang Yang, Kellogg School of Management, Evanston, IL, United States, yang.yang@kellogg.northwestern.edu, Youyou Wu, Uzzi Brian

Using 413 studies from 80 journals that underwent rigorous manual replication, we test the ability of artificial intelligence to address the replication problem in science. We calibrate our model using 96 studies and tested it on 317 diverse studies that span disciplines, methods, and topics. We find that our model predicts replicability better than statistics (i.e., p-value) and individual reviewers and as accurately as prediction markets. Further, tests indicate that our model does not show biases common to human. Finally, we discuss how AI can address replication problems at scale in ways that current methods cannot and can advance research by combining human and machine intelligence.

2 - Closing the Gap Between AI Methods and Better Decisions

James Williams, Sr. Principal Consultant, FICO Xpress, Roseville, MN, United States, JWilliams@fico.com

With no shortage of capable predictive methods available to analytics professionals, why do so many organizations struggle converting all of that power to actually enable better business decisions? The answer may depend on the lens taken by project teams. This talk will center on putting the end game of better decisions in primary focus, aligning all efforts (data, methods and yes, even user adoption psychology) with that goal.

3 - Predicting the Most Useful Online Reviews Using Advanced Latent Topic Features

Eunjung Lee, University of Wisconsin-Milwaukee, Brookfield, WI, United States, lee482@uwm.edu

With the enormous growing amount of online reviews in websites, diverse methods to identify the most helpful reviews have been studied actively by many researchers. However, most previous studies tried to find helpful reviews without considering entities of business or products. “A” review can be considered as the most helpful review for “B” product, but not for “C” product. In this research, we aim to predict the best five reviews for each business entity. Furthermore, to improve the precision of the prediction, we developed advanced features by analyzing latent topics of online reviews. This research successfully shows that our suggested model predicts the best reviews better than existing approach.

4 - Emotional Response of the Public to the Development of Artificial Intelligence—Sentiment Analysis Based on Microblog Text

Ma Liyi, Beijing Union University, Beijing, China, maryliyi@126.com, He Qin

The existing studies on the impact of technological progress on employment effect mainly focus on phenomenal description, detail analysis and trend prediction, and there is no research that can accurately quantify the impact of the development of artificial intelligence (AI) on the public sentiment. Based on social media, this study builds a sentiment analysis model based on support vector machine using machine learning, sentiment analysis and other related methods, and carries out a quantitative evaluation on the psychological impact of artificial intelligence on the public, and finally verifies the effectiveness of this model.

Decision Making and Data Driven Decision Models in Service Industry

Sponsored: Service Science

Sponsored Session

Chair: Y. Ilker Topcu, ITU, Turkey

Co-Chair: Sezi Cevik Onar

1 - Revisiting the Decision Support Model for Prioritizing Critical Road Structures of Istanbul

Ozay Ozaydin, Dogus University, Istanbul, 34722, Turkey, oozaydin@dogus.edu.tr

A decade has passed since the last study on evaluating the critical road structures of Istanbul. Since then, the road network has significantly changed. To determine the important network elements, a model with four main criteria was developed with decision makers from the Istanbul Metropolitan Municipality. The same decision support model has been revisited, and the data is updated. The total number of road network elements have increased, but the number of critical structures has decreased. A comparative analysis is also conducted to visualize the effects of urbanization on emergency management.

2 - Analyzing Relationship Between Human Development and Competitiveness Using DEA and Cluster Analysis

Ozgur Kabak, Associate Professor, Istanbul Technical University, Istanbul, 34367, Turkey, kabak@itu.edu.tr, Hakan Kılıc

This study analyses the bilateral relations between human development (HD) and competitiveness (COM). Data Envelopment Analysis (DEA) with windows is used to calculate efficiencies of countries on converting their HD to COM and COM to HD. Stepwise cluster analysis for time periods is used to analyze the results of the DEA models. 56 countries are evaluated for the years 2010-2017 based on the data of the Global Competitiveness Index and Human Development Index. We find that the competitiveness of a country has a positive impact on its human development with a three-year time lag. Furthermore, we ranked the countries based on their human development and competitiveness levels.

3 - Stochastic Location Allocation Model for Mobile Blood Facilities

Ilker Topcu, Istanbul Technical University, Isletme Fakulte, Istanbul, 34367, Turkey, Gul Imamoglu

Blood supply can only be provided by voluntary donors. To provide this supply, it is necessary to create the opportunity of blood donation at points where there are plenty of people. For this reason, besides local blood centers, mobile blood facilities, which are easy to access by donors and cost effective facilities, are established. Since these mobile facilities only capable of blood collection and not capable of processes such as centrifugation, collected blood should be taken to the local blood centers within a limited time. The aim of this study is to construct a two stage multi period stochastic location-allocation model for blood collection to minimize overall cost while demand is met.

4 - Stochastic Location Allocation Model for Mobile Blood Facilities

Gul Imamoglu, Istanbul Technical University, Turkey, Ilker Topcu

Blood supply can only be provided by voluntary donors. To provide this supply, it is necessary to create the opportunity of blood donation at points where there are plenty of people. For this reason, besides local blood centers, mobile blood facilities, which are easy to access by donors and cost effective facilities, are established. Since these mobile facilities only capable of blood collection and not capable of processes such as centrifugation, collected blood should be taken to the local blood centers within a limited time. The aim of this study is to construct a two stage multi period stochastic location-allocation model for blood collection to minimize overall cost while demand is met.

Co-Chair: Haluk Demirkan, University of Washington, Tacoma, University of Washington, Tacoma, Tacoma, WA, United States

1 - An Empirical Analysis of the Effect of Mismatched App and OS Versions on Consumer Purchase

Luna Zhang, Assistant Professor, University of Washington Tacoma, Tacoma, WA, United States, xyzhang5@uw.edu, Ruomeng Cui, Yuliang Yao

The proliferation of mobile devices and mobile networks makes the mobile commerce an increasingly important yet understudied research topic. Using a large dataset from an online retailer, we empirically examine the adoption of mobile operation system (OS) and mobile application (app) on consumer purchase. We find that consumers with a newer app version are more likely to make a purchase than those with an older app version. A further investigation reveals that a mismatch between mobile OS version and app version can increase consumer probability of purchase. We attribute this result to the reduced consumer shopping pace.

2 - The Role of Emotion in Human Decision Making: Impacts on Agents and AI

Margo Bergman, University of Washington Tacoma, Tacoma, WA, United States, mwb4@uw.edu

Agent-based modeling, by necessity, involves modeling real-world human decisions that contain factors such as emotion, thought, and habit are difficult or impossible to observe, however, should be included in models to improve our understanding of people and systems. Research in agent-based modeling has questioned whether computational agents, if they are to mimic human decisions, must be able to include the emotional component of decision making in their algorithms. This paper will present a brief survey of theories of emotion in human decision making; analyze the literature of, and make recommendations for, integrating models of emotion into the decision making of agents.

3 - Value Co-creation and Out-tasking with Smart Analytics and Artificial Intelligence

Haluk Demirkan, Professor, University of Washington Tacoma, Tacoma, WA, United States, haluk@uw.edu

There is no doubt that computers are increasingly capable of doing things that humans could once do exclusively. Smart machines are gaining human capabilities, such as recognizing voices, processing natural language, and interacting and learning with the physical world through vision, smell, touch, mobility and motor control. In some cases, these machines do a much faster and better job than people at recognizing patterns, performing rule-based analysis from very large amounts of data, and solving structured and unstructured problems. We will discuss how we can utilize these smart machines as tools, assistants, collaborators and coach to work effectively with smart machines.

4 - Principles of Emergence of Co-creation from Service Ecostructures

Ralph D. Badinelli, Virginia Polytechnic Institute, Dept of Business Information Tech (0235), Blacksburg, VA, 24061, United States, ralphb@vt.edu

Motivated by the proliferation of new service ecostructures enabled by Internet of Things (IoT), Big Data Analytics (BDA) and Artificial Intelligence (AI), this paper derives principles for the design of viable, smart service systems and predictions of their performance. Engagement decisions of service participants are mediated by these technologies in ways that can be beneficial and detrimental. Principles of system design are derived from theoretical constructs of transformation functions, decision analysis, service ecostructure, Normalized Systems Theory (NST) and Viable Systems Approach (VSA). The paper presents simulations of service trajectories to illustrate these principles.

Joint Session AMD/Practice Curated: Economics of Auctions and Market Design

Sponsored: Auction and Market Design

Sponsored Session

Chair: Robert Day, University of Connecticut, Storrs, CT, 06269-1041, United States

1 - Procuring Lemons

Giuseppe Lopomo, Duke University, FSB, Durham, NC, 27708, United States

When the quality of a good or service is non-contractible, a procurement agency faces a ``lemons” problem. In a model where each supplier is privately informed about both the quality of its product and its production cost, we show that the buyer’s expected surplus is maximized by a ``low-bid-lottery” auction (LoBLA). In this auction, if some bidders bid below a ``target price”, each of these bidders sells the good at the target price with the same probability; and if all bidders bid above the target price, the lowest bidder supplies the good and is paid the second lowest bid.Expected gains from trade are also maximized, subject to incentive constraints, by a LoBLA with a higher target price.

2 - Optimization and Analytics at the Federal Communication Commission

Karla L. Hoffman, Professor, George Mason University, System Eng and Operations Research Dept, Fairfax, VA, 22030, United States, khoffman@gmu.edu, Brian B. Smith, Tony Coudert, Rudy Sultana, Yasser Nadeem

We present the current work of the optimization team at the FCC. We detail the current state of the television transition following the Broadcast Incentive Auction and describe the constant coordination that is allowing more than 1000 television stations to move to their new channels assignments. In addition, we will present the optimization models developed for the upcoming combined auction of 37, 39, and 47 GHz spectrum for 5G (known as Auction 103). Optimization is used to reconfigure existing licenses in a manner that allows the auctioning-off of 3400 MHz of high-frequency spectrum nationwide.

3 - Robust Bidding in First-price Auctions: How to Bid Without Knowing What Others Are Doing

Bernhard Kasberger, University of Oxford, High Street, Oxford, OX14AW, United Kingdom, Karl Schlag

We show how to bid in first-price auctions when a bidder knows her own value but not precisely how others will bid. To do this we introduce a novel and general method for how to make choices in strategic settings without assuming common knowledge or equilibrium behavior. Accordingly, we first eliminate environments that are believed not to occur and then find a robust rule that performs well in the remaining environments. We test our bid recommendations using data from laboratory experiments and from the field. We find that our bids outperform those actually made by the real bidders.

4 - The Menu-Size of Approximately Optimal Auctions

Yannai A. Gonczarowski, Postdoctoral Fellow, Microsoft Research, Cambridge, MA, United States, yannai@gonch.name

We consider a monopolist who wishes to sell n goods to a single additive buyer whose valuations for the goods are drawn from independent distributions. The question of the possibility of extracting an arbitrarily high fraction of the optimal revenue via a finite menu size remained open since the seminal paper of Hart and Nisan (2013), and so has the question of any lower bound on the menu size that suffices for extracting an arbitrarily high fraction of the optimal revenue when selling a fixed number of goods, even for two goods and even for i.i.d. bounded distributions. In this talk, we resolve both of these questions. Based upon Babaioff, Gonczarowski and Nisan (STOC 2017); and Gonczarowski (STOC 2018).

1 - Capacity Planning with a Blended Workforce

Jing Dong, Columbia University, Uris Hall 413, 3022 Broadway, New York, NY, 60208, United States, Rouba Ibrahim

We study cost-minimizing staffing decisions in service systems where the manager must decide on how many flexible (contractors) and/or fixed (full-time) agents to staff in order to effectively balance operating costs, varying customer demand patterns, and supply-side uncertainty, while not compromising on the quality of service offered to customers. We derive the optimal staffing policy and glean insights into the appropriateness of alternative workforce models. We also shed light on the distinction between demand- side and supply-side uncertainties in queueing systems.

2 - Operational Transparency: Showing When Work Gets Done

Robert Louis Bray, Kellogg School of Management, Northwestern University, Evanston, IL, 60202, United States, r-bray@kellogg.northwestern.edu

I study how customers respond to operational transparency with Alibaba logistics data. The sample describes 4.68 million deliveries. Each delivery has between four and ten track-package activities, which customers can check in real time, and a delivery service score, which customers leave after receiving the package. I regress the delivery scores on the track-package-activity times. I show that customers punish early idleness less than late idleness, leaving higher delivery service scores when track-package activities cluster toward the end of the shipping horizon.

3 - Optimal Delay Information Design to Manage the Customer Waiting Experience

Sina Ansari, Tuck School of Business Dartmouth College, Hanover, NH, 03755, United States, sina.ansari@tuck.dartmouth.edu, Robert Shumsky, Laurens G. Debo

We study the optimal delay information design to a customer who has to wait for an uncertain amount of time for a service to start. We characteristic the optimal predictor taking into account (a) customers' aversion for delays in expected start time, as well as (b) their preference for more precise information while waiting. We show that the former informs customers about extreme events (either a very short or very long wait time, or, wait time around average), while the latter informs the customers about the expected wait (either a short or a long wait). We discuss implications for practice.

4 - Quoting Lead-times When Quotes Affect Customer Satisfaction

Riccardo Mogre, Durham University, Millhill Ln, Durham, DH1 3LB, United Kingdom, Tava Olsen, Valery Pavlov

We study a lead-time quotation problem for a manufacturing or service provider. We represent its processing system as a single-server queue. Based on recent empirical evidence, we explicitly model the effects of quotes and delays on customer satisfaction, which the provider takes into account when quoting lead-times.

Tutorial: Data-driven Methods for Markov Decision Problems with Parameter Uncertainty

Emerging Topic: Tutorials

Emerging Topic Session

1 - Data-driven Methods for Markov Decision Problems with Parameter Uncertainty

Shie Mannor, Technion, Haifa, Israel, Huan Xu

In nearly every real sequential decision problem there is some uncertainty concerning the actual parameters of the decision problem. In this tutorial we survey different approaches to tackle the problem of finding an optimal, or at least a reasonable, policy when the parameters are not known in advance. Not knowing the parameters leads to two problems: first, the policy is not optimal and second the estimated return of the policy the decision maker chooses is typically overly optimistic. We advocate for using robust optimization to circumvent these effects and survey different approaches for different settings where the model is data-driven and hence some uncertainty in the parameters must be taken into account.

Military and Civil Works Applications

Sponsored: Military and Security

Sponsored Session

Chair: Christina Rinaudo

Co-Chair: Randy K. Buchanan, USACE - ERDC, Vicksburg, MS, 39180, United States

1 - A Systems Engineering Approach for Sensor Integration and Placement

Randy K. Buchanan, USACE - ERDC, Vicksburg, MS, 39180, United States, Christina Rinaudo, James Richards, Mohammad Marufuzzaman

Agencies are challenged with developing measures to optimize emerging security sensing technology options to ensure area protection. A systems engineering integrated approach could provide insight into optimization resulting in increased effectiveness and lower costs. This presentation provides an overview of research efforts related to conducting a system of systems sensor simulation and placement assessment. The proposed final model could help in identifying courses of action for deployment of sensor suites for increasing the likelihood of recognizing and interdicting elements breaching a given area.

2 - Using Dredge Portfolio Optimization Methods to Improve Waterway Network Maintenance

Kayla A. Cotterman, Research Scientist, Engineer Research and Development Center, Vicksburg, MS, United States, kayla.a.cotterman@erdc.dren.mil, Drew A. Loney, Dustin T. Brown, K. Ned Mitchell

The U.S. Army Corps of Engineers (USACE) has developed two optimization tools to fulfill its mission to maintain safe and reliable transportation across ports and inland waterways. Dredge Project Selection allocates funding to projects given the disruption caused by channel shoaling and the interconnectivity of the waterway trade network. Dredge Scheduling organizes the public and private dredge fleets to maximize production and uptime given project environmental and dredge operating constraints. Within the two-year rolling budget cycle, these tools have a multi-year planning window creating a comprehensive strategy for the USACE dredging program.

3 - Assessing Computer-aided Models of Civil Structures Using an Immersive Virtual Collaboratory Experience

Michael Andre Hamilton, Mississippi State University, Vicksburg, MS, United States, michaelh@iser.msstate.edu, Parker Jones

The CAD-BIM Technology Center & MSU have been evaluating the use of VR to better evaluate CAD models during the verification and validation process. The goal is to minimize the number of unidentified issues during the modeling phase by providing a realistic virtual walkthrough to investigate problem areas. A test product was developed using VR to perform a walkthrough of the Wilkinson Pump Station CAD model. The system was built to accommodate multiple users from different physical locations collaborating to evaluate the models. The users are provided with virtual tape measures and the ability to write notes in the environment about items that require modifications, removals, or additions.

4 - Value Model and Metric Development to Support USACE Civil Works Portfolio Investment Decision Making

Christina Rinaudo, USACE Engineer Research and Development Center, Vicksburg, MS, 39180-6199, United States, christina.h.rinaudo@usace.army.mil, Kayla Cotterman

The US Army Corps of Engineers (USACE) Civil Works (CW) portfolio includes $250 billion worth of capital assets. As infrastructure ages and budgets decrease, new asset management strategies are required that support maintenance, repair, replacement (MR&R), and acquisition activities while also providing the greatest value to the USACE and to the Nation. This presentation provides an overview of research efforts related to analyzing value models and investigating relevant metrics in order to support the USACE-CW efforts towards generating defensible budgets that could bring high value to the USACE and to the Nation.

Optimizing Supply Chains under Uncertainty

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Eojin Han, Northwestern University, Evanston, IL, 60208, United States

Co-Chair: Omid Nohadani, Northwestern University, Evanston, IL, 60208-3119, United States

1 - Designing Interpretable Policies in Pharmacy Supply Chain

Eojin Han, Northwestern University, Evanston, IL, 60208, United States, eojinhan2020@u.northwestern.edu, Chaithanya Bandi, Omid Nohadani

We consider a two-stage inventory network problem where the demands at multiple locations are fulfilled from several warehouses. The decision maker needs to replenish inventories of the warehouses before observing demands, and the deliveries are made upon their realization. To address uncertainty in demand distribution, we model the problem as a two-stage distributionally robust optimization problem. We develop easy-to-interpret policies via dividing future uncertainties into finite subsets with contingency plans assigned for each piece. We show that an optimal partitioning structure can be constructed by "translated orthants", and discuss its tractable implementation.

2 - Statistical Bias in the Newsvendor Model

Michael R. Wagner, University of Washington, Foster School of Business, University of Washington, Seattle, WA, 98195, United States, mrwagner@uw.edu, Andrew Siegel

We consider the Newsvendor model where uncertain demand is assumed to follow a probabilistic distribution with known functional form, but unknown parameters. These parameters are estimated, unbiasedly and consistently, from data. We show that the classic maximized expected profit expression exhibits a positive systematic bias, where realized profits are overestimated. We provide an asymptotic adjustment so that the estimate of maximized expected profit is unbiased. Extensive numerical experiments confirm our theoretical results.

3 - Multisourcing under Dependent Supplies

Qi Feng, Professor, Purdue University, West Lafayette, IN, 47907, United States, annabellefeng@purdue.edu, Justin Jia, J. George Shanthikumar

Firms inevitably source from suppliers with dependent material flows, and such supply dependence, created by common second-tier suppliers or common economic environment, is often positive. By expanding the space of ordering decision to a class of contingency policies, we identify conditions under which the dynamic planning model has a concave transformation. Our analysis suggests that the firm may order more from a less reliable supplier than from a more reliable one who charges the same procurement cost.

CC- Room 602

Pyomo I

Sponsored: Optimization/Computational Optimization and Software

Sponsored Session

Chair: David Bernal Neira, Carnegie Mellon University, Pittsburgh, PA, 15232, United States

1 - Recent Developments in Pyomo

Bethany Nicholson, Sandia National Laboratories, Albuquerque, NM, United States, John Siirola

In this presentation we highlight some of the recent developments in the Pyomo project, including improved performance, improved expression management, new solver interfaces, and new optimization algorithms implemented natively in Pyomo.

2 - A Generalized Cutting Set Approach for Robust Process Design

Natalie M. Isenberg, Carnegie Mellon University, Dept of Chemical Engineering, Pittsburgh, PA, 15213, United States, nisenberg@cmu.edu, Paul Akula, Debangsu Bhattacharya, David C. Miller, Chrysanthos E. Gounaris

There is a breadth of literature studying robust optimization in the context of linear and convex models. However, chemical processes often possess complex nonlinearities and non-convexity due to physical and chemical state equations. In this work, we extend the robust cutting-set method, which sequentially hedges against realizations of parametric uncertainties, to identify risk-averse solutions to chemical process models. Our proposed method handles the case where a model consists of mostly state equations that cannot be readily simplified out of the formulation, and is also valid for models with nonlinearities and non-convexities in both the decision variables and uncertain parameters.

3 - Mixed Integer Nonlinear Decomposition Toolbox in Pyomo MindtPy

David Bernal Neira, Carnegie Mellon University, Pittsburgh, PA, 15232, United States, debernal@andrew.cmu.edu, Romeo Valentin, Qi Chen, Ignacio E. Grossmann

This work describes a software toolbox developed in Pyomo, a modeling and optimization application in Python, where decomposition methods for solving mixed-integer nonlinear programs (MINLP) are implemented. Decomposition methods for MINLP rely on the iterative solution of mixed-integer linear programs and nonlinear programming; which have had a steady and considerable improvement in the last years. Several decomposition methods, together with recent algorithmic improvements such as primal heuristics and level based methods, are available in MindtPy. We illustrate the application of this toolbox on a set of convex MINLP problems of varying sizes and degrees of difficulty.

4 - Shot – A Polyhedral Outer Approximation Based Solver for Convex MINLP

Jan Kronqvist, Dr, Imperial College London, London, 20500, United Kingdom, j.kronqvist@imperial.ac.uk, Andreas Lundell

The Supporting Hyperplane Optimization Toolkit (SHOT) is an open-source solver that has proven to be very efficient for solving convex mixed-integer nonlinear programming (MINLP) problems. SHOT combines lower bounding algorithms based on linear outer approximations of the feasible region together with several primal heuristics. The latest developments include improved non-convex capabilities and we are working on making SHOT available in Pyomo, and thus, expanding the options for solving MINLP in Pyomo.

Approaches to Business Applications of Data Mining and Risk Analysis Techniques

Sponsored: Data Mining

Sponsored Session

Chair: Paolo Catasti

1 - A From-Scratch, Data-Driven Approach to Teaching Simulation Modeling of Business Decisions.

Jeffrey W. Ohlmann, University of Iowa, Henry B. Tippie Coll of Bus Mgmt Sci, Iowa City, IA, 52242-1000, United States, jeffrey-ohlmann@uiowa.edu

We step through a pedagogical approach to integrating data analysis and mathematical modeling in a case-style problem starting "from scratch." A general problem context is proposed and then we progress in a Socratic method, guiding students through a formal problem statement, identification of the data required or desired to analyze the problem. Encouraging trial-and-error, the analysis then proceeds to data wrangling, using data to model uncertainty in a simulation model, construction of model logic, and assessment of model output.

2 - Teaching Factorization Machines to Deep Learning Architectures: Business Use Cases with Code Examples

Matthew A. Lanham, Purdue University, 112 Eastland Drive, Lafayette, IN, 47905, United States, lanhamm@purdue.edu

This talk explains and demonstrates with software some state-of-the-art predictive modeling approaches and how they are being used within business. The motivation for this talk is that advances in machine learning and AI continue to happen rapidly. Fortunately, many of these recent developments are available in either open-source libraries or commercial software, but you may not be sure where to start. The talk will be useful for those interested in data mining or business analytics that would like some business use cases and code examples that might one might use for teaching, adaptation and exploration to your own business problems, or scholars looking for a place to start experimenting.

3 - Predicting Bone Marrow Transplant Clinic Staffing Requirements from Historical Patient Data

R. Jerome Dixon, PhD Student, Integrative Life Sciences, Virginia Commonwealth University, Richmond, VA, 23284, United States, dixonrj@vcu.edu

Virginia Commonwealth University's Massey Cancer Center Bone Marrow Transplant Center requested an analysis of their historical patient data to forecast future staffing requirements. This analysis uses a myriad of machine learning and data visualization tools (SAS Enterprise Miner, Tableau, R/RStudio, and Excel) with System Dynamics to formulate a clinical staffing forecast model.

4 - An Approach to the Evaluation of Teaching Effectiveness at the School of Business Using a Combination of Data Mining Techniques.

Paolo Catasti, Virginia Commonwealth University, Richmond, VA, 23284, United States, pcatasti@vcu.edu, Evandro Moreno

We used a combination of multiple regression analysis and hierarchical clustering to develop a model that evaluates teaching effectiveness at the Virginia Commonwealth University School of Business by accounting for variables such as class size, evaluation completion rate, class mean GPA, class grade distribution, and course difficulty level. The model is first trained on 2,636 records of 3-credit hour classes across five academic years consisting of information received from anonymized course evaluations and confidential students' records; and then validated on two additional academic semesters. Finally, a metric that may help department chairs to evaluate instructors is proposed.

Integrated Methods in Optimization

Sponsored: Optimization/Integer and Discrete Optimization

Sponsored Session

Chair: Joris Kinable, Eindhoven University of Technology, Eindhoven, 5612 AR, Netherlands

1 - Exploiting Counterfactuals for Scalable Stochastic Optimization

Meinolf Sellmann, Lab Director, General Electric, Niskayuna, NY, United States, Kevin Tierney, Stefan Kuhlemann

We propose a new framework for decision making under uncertainty to overcome the main drawbacks of current technology: modeling complexity, scenario generation, and scaling limitations. We consider three optimization problems, Stochastic Knapsack, Stochastic Shortest Path, and Resource Scheduling with uncertain job durations, all with recourse. We illustrate how an integration of constraint optimization and machine learning technology can overcome the main practical shortcomings of the current stateof the art.

2 - On the Consistent Path Problem

David Bergman, University of Connecticut, Storrs, CT, United States, david.bergman@uconn.edu

In this talk we will discuss a new and promising decomposition approach to combinatorial optimization problem that are modeled through recursion. We will discuss several applications and present some ideas on how to efficiently optimize over such a decomposition.

3 - Computing Wasserstein Distances via GPU-accelerated Column Generation

Louis-Martin Rousseau, Professor, Ecole Polythechnique de Montreal, Montreal, QC, H3C 3A7, Canada, louis-martin.rousseau@polymtl.ca, Stefano Gualandi

This paper presents a GPU-accelerated Column Generation algorithm for the exact computation of Wasserstein distance between a pair of discrete measures. Currently,exact solvers can only solve instances of moderate size, because the fully dense cost matrix becomes too large to be stored in computer memory. We solve the master problem with a new implementation of the Network Simplex algorithm that support reoptimization, and and a efficient parallel algorithm that solves the pricing subproblems on a GPU. Numerical results on standard benchmarks show that our exact solver is competitive with current state-of-the-art exact approaches in terms of running time, while it can solve much larger problems.

4 - Learning Scheduling Models from Event Data

Arik Senderovich, University of Toronto, Toronto, ON, Canada, sariks@mie.utoronto.ca, Kyle Booth, Chris Beck

A significant challenge in scheduling is the creation of a parameterized model: the set of resources and their capacities and the types of activities and their temporal and resource requirements. In practice, such models are developed manually by skilled consultants and used repeatedly to solve new problem instances. In this work, we automate the creation of such models by learning them from data. We introduce a novel methodology that combines process mining, timed Petri nets (TPNs), and constraint programming (CP). To demonstrate the value of the approach we conduct experiments in which we learn and solve models using real-world data from an outpatient hospital.

Robust Optimization and Learning under Uncertainty

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Phebe Vayanos, University of Southern California, Los Angeles, CA, 90089, United States

1 - Robust Optimization with Decision-dependent Information Discovery

Han Yu, University of Southern California, Center for Artificial Intelligence in Society,, Los Angeles, CA, United States, Phebe Vayanos, Angelos Georghiou

We consider two- and multi-stage robust optimization problems in which the decision variables control the time of information discovery. The time of information discovery is decision-dependent and the uncertain parameters only become observable after an often costly investment. We prove and leverage our new model to provide a solution method inspired from the K-adaptability approximation approach, whereby K candidate strategies for each decision stage. We reformulate the problem as an MBLP solvable with off-the-shelf solvers and demonstrate its effectiveness on stylized problems.

2 - Thomson Sampling with Adversarial Data

Chaithanya Bandi, 1987, Evanston, IL, 60208, United States, c-bandi@kellogg.northwestern.edu

Thompson Sampling is one of the oldest and most popular heuristics for multi-armed bandit problems. It is a randomized algorithm based on Bayesian ideas, and has recently generated significant interest after several studies demonstrated it to have better empirical performance compared to the state-of-the-art methods. In this paper, we consider its application in the presence of adversarial corruptions in observed rewards. We show that, ignoring such adversarial corruptions, can lead to linear regret. To remedy this, we present a distributionally robust version of Thomson Sampling that alleviates these problems.

3 - Robust Active Preference Learning

Phebe Vayanos, University of Southern California, Viterbi School of Engineering, Los Angeles, CA, 90089, United States, phebe.vayanos@usc.edu, Duncan McElfresh, John P. Dickerson, Eric Rice

We consider the problem faced by a recommender system that seeks to offer a user their favorite item. Before making a recommendation, the system has the opportunity to elicit the user's preferences by making a moderate number of queries. We propose an exact robust optimization formulation of the problem which integrates the learning (preference elicitation) and recommendation phases and an equivalent reformulation as a mixed-binary linear program. We evaluate the performance of our approach on synthetic and real data from the US homeless youth where we learn the preferences of policy-makers.

Learning and Stochastic Optimization

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Ruiwei Jiang, University of Michigan, Ann Arbor, MI, 48109, United States

1 - Nonconvex Parameter Search for Stochastic Optimization

Andy (Di Jia) Su, Princeton University, Princeton, NJ, United States, dsu@princeton.edu, Warren Powell

Hyperparameter tuning is very critical in many learning problems. For instance, in stochastic gradient update algorithm, we have $x_n = x_{n-1} + \alpha_n * \nabla F$, we are tuning $\alpha_n $. In can be viewed as a sequential decision problem in which are we assigning α_n at each time step(we called this as the stepsize policy). We understood that there are four classes of policies: CFA, PFA, PFA, and DLA. In the traditional setting, most stepsize policy is handcrafted (for instance, the harmonic stepsize, i.e. PFA). In this talk, we will be tackling this problem from the VFA approach (specifically, Bellman's equation) in the derivative based and the derivative free setting.

2 - A Linear Piecewise Value Function Approximation Policy for Lagged Energy Commitment Problems

Brian H. Cheung, Princeton University, Princeton, NJ, 08540, United States, bcheung@princeton.edu, Warren B. Powell

We present a model of a stochastic lagged resource commitment problem with rolling dynamic forecasts, which we develop in the context of energy portfolio management. Portfolios of energy generators can include steam generators, gas turbines, renewable sources such as wind and solar, as well as storage devices such as batteries; they are characterized by different notification times and efficiencies and together form a rich lagged decision process. We tackle this problem via approximate dynamic programming with piecewise linear approximations to the value functions.

3 - Optimal Online Knowledge Gradient Policy

Donghun Lee, Princeton University, NJ, United States

Please check the mobile app for this abstract.

4 - Online Estimation in Stochastic Optimization Using Variable-Dimensional Learning

Ga Yeong Lee, Princeton University, Princeton, NJ, 08540, United States, gylee@princeton.edu, Warren B. Powell

We consider the sequential decision problem where attribute data arrives randomly over time, and we recommend an offer from a set of discrete offers. We assume that there is a delay in the arrival of feedback, which makes the information collection for one data point expensive. We cluster similar data together and leverage the aggregate information. We propose a variable-dimensional method using ensemble layers of clusters, where we dynamically calculate the weights on each layer at each timestep, according to the inverse mean-squared error rule. We then apply this to a real-life dataset of hotel offer recommendation problem.

5 - Using Radial Basis Functions to Optimize Expensive Functions with Heterogeneous Noise

Yichi Shen, Research Fellow, National University of Singapore, Singapore, 689865, Singapore, isesy@nus.edu.sg, Christine A. Shoemaker

We introduce an algorithm that extends the Metric Stochastic Response Surface (MSRS) approach to optimize functions with heterogeneous noise. The proposed algorithm utilizes Radial Basis Functions (RBFs) as the surrogate and sequentially determines the next expensive evaluation point. In each iteration a new evaluation point is selected in two stages based on the defined metric distances, which capture the trade-off between observation accuracy, exploitation and exploration. Performance of the algorithm is compared with alternative kriging-based algorithms through standard test functions. The numerical results show that the proposed method is more efficient than the prior algorithms.

Stochastic Mixed Integer Applications in Energy Systems

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Haoxiang Yang, Northwestern University, Evanston, IL, 60208, United States

1 - Optimizing Concentrating Solar Plant Operations and Maintenance under Pricing and Weather Uncertainty

Alexander Zolan, National Renewable Energy Laboratory, Golden, CO, United States, Alexander.Zolan@nrel.gov, Jesse Wales, Alexandra M. Newman, Michael J. Wagner

Concentrating solar power (CSP) technologies utilize the heat from sunlight that is redirected by a field of sun-tracking mirrors to a central location. The heat produced by this process may be (i) converted to electricity using conventional power cycle technology, and/or (ii) paired with thermal energy storage (TES) in the form of molten salts, to be stored for later use. The use of TES makes the electricity produced by CSP highly dispatchable and, therefore, unique among non-hydropower renewable energy resources. We present a collection of models which find operations decisions that minimize operations and maintenance costs in real time, in which weather, pricing, and repair times are uncertain.

2 - A Bundle Method for Bilevel Stochastic Programming with Applications in Risk-averse Decision Making

Deniz Eskandani, Rutgers University, Piscataway, NJ, United States, deniz.eskandani@rutgers.edu, Jonathan Eckstein

We present a proximal bundle method to efficiently find an upper bound for maximizing bilevel stochastic programs. To provide a lower bound, we further propose an approach to find a feasible solution. We implement our algorithm in the gurobipy module of Python and apply it to various classes of problems, including risk-averse supply chain planning, and compare our computational results with the existing mixed integer programming approaches. We find that our approach can provide a better approximation for the optimal solution and can scale to larger problems.

3 - Stochastic Dispatch Optimization for Concentrated Solar Power Systems

Gokce Kahvecioglu, PhD Student, Northwestern University, Evanston, IL, 60208, United States, gokcekahvecioglu2014@u.northwestern.edu, David Morton

Concentrated solar power (CSP) technology with thermal energy storage is dispatchable, i.e., it has the flexibility to adapt power output to the demand. While there are several key advantages of CSP, so-called direct normal irradiance (DNI), the source of power for CSP, is challenging to accurately forecast. We focus on producing scenario-based DNI estimates rather than just a point estimate of DNI via a new sampling method that allows temporal dependence and non-identical errors. We then input the scenarios into the stochastic dispatch optimization model that states how the system should operate over the next few hours, and positions the system to be well-hedged against the set of DNI scenarios.

4 - Microgrid Operations under Stochastic Disruptions

Haoxiang Yang, Northwestern University, Evanston, IL, 60208, United States, haoxiangyang2019@u.northwestern.edu

We propose a robust optimization model for the alternating current optimal power flow (ACOPF) problem and its extensions considering stochastic disruptions. We consider uncertain demand and availability of renewable energy resource, develop a new type of uncertain events named stochastic disruptions, and use an uncertainty set to model it under the context of robust optimization. Based on the convex relaxation schemes for ACOPF problem, we construct a robust convex optimization problem with recourse. We propose a decomposition method with enhancements to solve this problem. Experimental results indicate a tight lower bound and an acceptable solution for the non-convex robust ACOPF problem.

Joint Session RAS/Practice Curated: OR/OM Impact on Freight Railway Services

Sponsored: Railway Applications

Sponsored Session

Chair: Steven Harrod, PhD, Technical University of Denmark, Kgs. Lyngby, 2800, Denmark

1 - Efficiency and Effectiveness Analysis of the EU Ten-t Freight Railway Network

Steven Harrod, Technical University of Denmark, Denmark, stehar@dtu.dk, Shengdong Li

The TEN-T network is a designated international set of railway corridors within the European Union for freight transport. Each corridor has its own managing authority, but each corridor also depends on the infrastructure and services of the individual countries through which it passes. This analysis applies data envelopment analysis (DEA) to value both the relative efficiency and effectiveness of each corridor. Efficiency quantifies how well the corridor uses material inputs to produce transportation, and effectiveness quantifies how that raw transportation is actually put to practical use (utilization).

2 - A Collection of Aspects Why Optimization Projects for Railway Companies Could Risk Not to Succeed – A Multi-perspective Approach

Christian Liebchen, Professor for Transportation Operations, TH Wildau, Am Waldberg 22c, Berlin Area, D-12683, Germany, liebchen@th-wildau.de, Hanno Schülldorf

There are more publications on promising projects on how mathematical optimization could improve the performance of railway companies, than success stories in the sense that OR methods really entered the practice of railways. We investigate projects, which finally did NOT enter the practice of railways. We conduct a survey in which we ask railway practitioners (ordering party) and optimization experts (R&D solution provider). We discuss the most frequent replies to our question about the key factors why in the past mathematical optimization methods did not enter the practice of railways. Hereby, we offer a knowledge base to future project managers.(originally presented at ICROMA 2019)

3 - Retrospective Impact of Operations Research & Operations Management on Freight Railway Operations

Marc Meketon, Vice President, Oliver Wyman, Princeton, NJ, 08540, United States, marc.meketon@oliverwyman.com, David T. Hunt

We will review the use of analytical techniques used in the railway industry over the past 100+ years, including time-table development, dispatch optimization, meet-pass planning, local operation optimization, equipment optimization and more.

4 - Service Network Design for China Railway Express under the Belt and Road Initiative Considering Market Competition

Yingzi Peng, Tsinghua University, Beijing, China, pengyingzi288@163.com, Lefei Li

This paper aims to reconstruct the railway service network between China and Europe by considering customers' choice among several transportation modes. In particular, to reflect the decision making process in reality, a bi-level programming model is established to maximize the total profit of the China Railway company in the upper level and to minimize the total disutilites of the customers in the lower level. Diseconomies of sclale is adopted to reflect freight cost structure between hub links. We propose beners decomposition to solve the linearized MIP and use a method to accelerate convergence. Our method offers significant computational benefits compared to commercial solver Cplex.

Scalable Algorithms for Nonsmooth and Nonconvex Optimization

Sponsored: Optimization/Nonlinear Programming

Sponsored Session

Chair: Shiqian Ma

1 - Scalable Optimization Algorithms for Subspace Clustering

Daniel Robinson, Associate Professor, Lehigh University, Bethlehem, PA, 21218, United States, Chong You, Rene Vidal

This talk will discuss recent work on developing scalable optimization algorithms for performing the unsupervised task of clustering data drawn from a union of subspaces. Data with such union-of-subspace structure arises in various applications such as face and image clustering, motion segmentation, hybrid system identification, and multiple view geometry.

2 - Stochastic Methods for Nonsmooth Nonconvex Optimization

Dmitriy Drusvyatskiy, Associate professor, University of Washington, University of Washington, Mathematics Department, Seattle, WA, 98195, United States, ddrusv@uw.edu

Stochastic iterative methods lie at the core of large-scale optimization and its modern applications to data science. Though such algorithms are routinely and successfully used in practice on highly irregular problems, few performance guarantees are available outside of smooth or convex settings. In this talk, I will describe a framework for designing and analyzing stochastic methods on a large class of nonsmooth and nonconvex problems, with provable efficiency guarantees. The main thread of the proposed framework is appealingly intuitive. I will show that a wide variety of stochastic methods can be interpreted as inexact gradient descent on an implicit smoothing of the problem.

3 - Stochastic Subgradient Method Converges on Tame Functions

Damek Davis, Cornell University, Ithaca, NY, 14850, United States

This work considers the question: what convergence guarantees does the stochastic subgradient method have in the absence of smoothness and convexity? We prove that the stochastic subgradient method, on any semialgebraic locally Lipschitz function, produces limit points that are all first-order stationary. More generally, our result applies to any function with a Whitney stratifiable graph. In particular, this work endows the stochastic subgradient method, and its proximal extension, with rigorous convergence guarantees for a wide class of problems arising in data science—including all popular deep learning architectures.

4 - An Average Curvature Accelerated Composite Gradient Method for Nonconvex Smooth Composite Optimization Problems

Jiaming Liang, Georgia Institute of Technology, Atlanta, GA, United States, Renato D. C. Monteiro

This talk discusses an accelerated composite gradient (ACG) variant for solving nonconvex smooth composite minimization problems. As opposed to well-known ACG variants which are based on either a known Lipschitz gradient constant or the sequence of maximum observed curvatures, the current one is based on the average of all past observed curvatures. Another feature of it is that it never backtracks.

Conic Optimization in Operations Management

Contributed Session

Chair: Joseph Atwood, Montana State University, Ag Econ & Economics, Bozeman, MT, 59717-2920, United States

1 - Coordinating Inventory, Fulfillment and Transshipment Decisions in Omni-channel Stores

Ebrahim Arian, University of Illinois at Urbana-Champaign, Urbana, IL, United States, arian2@illinois.edu, Xin Chen

We analyze a joint inventory, fulfillment, and transshipment control problem for multiple omni-channel stores selling single product over a finite horizon. In each period before demands realization, each store replenishes its inventory and puts a threshold to accept or reject online demands. After fulfilling all possible offline demands, the accepted online demands will be fulfilled with different resources. We develop a dynamic two-stage stochastic programming model which is not convex. We convert the non-convex model to an equivalent convex one and establish the integrality of the optimal solutions of the model. Based on a retailer data, we evaluate the performance of our fulfillment policy.

2 - Optimal Workforce Planning in a Federal Revenue Collection Agency

Rima Gooden, Deloitte Consulting LLP, Arlington, VA, United States, rimagooden@deloitte.com

A large-scale workforce planning and allocation model for a large tax-collecting government agency is considered. The approach maximizes non-linear objective functions subject to geographic and temporal constraints. Two approximation paradigms are considered and compared: i) a linear approximation of the objective function with integer decision variables, and ii) a non-linear objective function with removal of the integrality constraint. The former is solved with standard MIP methodologies, while the latter is solved using disciplined convex programming.

3 - Continuous LP Approximations to NP-hard Portfolio Optimization Problems Subject to VAR or Related Risk Constraints

Joseph Atwood, Montana State University, Bozeman, MT, United States, jatwood@montana.edu

A common class of NP-hard problems involve applications of binary mixed-integer optimization MILP models in which the MILP model endogenously identifies a proportion of constraints that are allowed to violated or "relaxed". This paper presents a continuous LP procedure that quickly obtains approximate solutions to the NP-hard relaxed constraint (RC) problem. The procedure nests the original problem in an LP model allowed to endogenously contort the polytope while also optimizing within a stochastic inequality that guarantees that no more than a given proportion of the original constraints are violated. An application in portfolio optimization is presented.

Connected and Interdependent Critical Infrastructure Systems

Sponsored: Optimization/Network Optimization

Sponsored Session

Chair: Zhaomiao (Walter) Guo

1 - Modeling Airline Frequency Decisions in Large Networks with Connections

Vikrant Vaze, Dartmouth College, Murdough Center, Hanover, NH, 03755, United States, vikrant.s.vaze@dartmouth.edu, Reed Harder

We develop a two stage game theoretic model of airline competition, where airlines choose service frequencies during the first stage and set fares during the second stage. First, we show that a simplified version of this game has a credible and tractable subgame perfect Nash equilibrium solution. We then develop a new approximation scheme to show that these properties extend to more realistic models, and enable fast solution of the games. Leveraging these properties, we develop and implement an approach to solve our game for a real-world network, and empirically validate the frequency predictions of our model.

2 - Multi-dimensional Analysis of Critical Network Components

Jeffrey Lineberry, Graduate Student, University of Oklahoma, Norman, OK, United States, Nafiseh Ghorbani Renani, Kash Barker

Critical Infrastructure is an interdependent system of networks that are subject to disruption, and decisions are often necessary to allocate resources to protect before a disruptive event and restore afterward. This work explores a means to identify a critical set of network components along multiple dimensions to which resources will be allocated. A tri-level protection-interdiction-restoration problem will be solved using different sets of these critical components, chosen from different determinants, and a comparison made.

3 - Interdependent Restoration Routing Problem

Nazanin Morshedlou, Mississippi State University, Starkville, MS, United States, nazanin.morshedlou@ou.edu, Kash Barker, Andres David Gonzalez

After disruptions, crews are dispatched from depots to a transportation network to restore disrupted infrastructure networks. The road network itself may be affected by the disruptive event. To restore other networks, we require to restore the connectivity of the transportation network is such a way that the critical components become geographically accessible. This perspective connects the transportation network components to moderate traffic congestion and decrease the evacuation process and expected commuting time. We consider restoration routing optimization to strike a balance between these perspectives and find the optimal synchronized paths for restoration crews.

4 - Power and Transportation System Interdependence: A Stochastic Multi-agent Optimization Approach

Zhaomiao Guo, University of Central Florida, Orlando, FL, 32816, United States

We present a mathematical model that supports renewable energy infrastructure planning under uncertainty. The interdependence between different stakeholders in the system is captured in an energy supply chain network, where new entrants of renewable investors compete with existing generators for natural resources, transmission capacities, and demand markets. Through reformulation, the equilibrium solution of the stochastic energy supply chain planning problem can be obtained through solving traffic network equilibrium problems. Establishing such a connection has a potential for improving the computational efficiency in large scale power system problem.

5 - Designing Corridor Systems with Modular Vehicles Enabling En-route Docking: Continuous and Discrete Modeling Methods

Xiaopeng Li, University of South Florida, Tampa, FL, 33620, United States, Zhiwei (Nicklaus) Chen

This study proposes two modeling methods, i.e. continuous and discrete models, to jointly design the dispatch headway and capacity for corridor systems. The continuous model presents a macroscopic view of the system and yields a sub-linear time complexity solution method that can achieve near-optimal solutions to the investigated problem very efficiently. The discrete modeling method, however, takes a microscopic point of view and yields exact optimal solutions with a tailored branch-and-bound algorithm.

Boosting Combinatorial Optimization using Machine Learning

Sponsored: Computing

Sponsored Session

Chair: Quentin Cappart, QC, Canada

1 - Learning a Cutting Plane Selection Policy

Antoine Prouvost, Polytechnique Montréal, Montréal, QC, Canada, Aleksandr M. Kazachkov, Andrea Lodi

Cutting planes are one of the main drive in mixed-integer linear programming. We propose to learn a policy to filter rounds of cuts through self supervised deep reinforcement learning. Our approach models mixed-integer linear programs as a bipartite graph and leverage graph neural networks to learn the selection policy though policy gradient ascent. We apply our methodology to a distribution of 2-matching instances and aim to solve them with a minimal number of cuts.

2 - Graph Convolutional Neural Networks for the Travelling Salesman Problem

Chaitanya Joshi, Nanyang Technological University, Singapore, Singapore

The most famous NP-hard combinatorial problem today, the Travelling Salesman Problem, is intractable to solve optimally at large scale. In practice, existing techniques such as Concorde can efficiently solve TSP up to thousands of nodes. This talk introduces a recent line of work from the deep learning community to directly 'learn' good heuristics for TSP using neural networks. Our approach uses Graph ConvNets to operate on the graph structure of problem instances and is highly parallelizable, making it a promising direction for learning combinatorial optimization at large scale.

3 - Learning for Cutting Planes

Elias B. Khalil, Postdoctoral Scholar, Polytechnique Montréal, Montreal, QC, 30309, Canada, lyes@gatech.edu

Cutting Planes (or cuts) are a fundamental tool in solving Mixed Integer Programming (MIP) problems. Despite their mathematical underpinnings, cuts in MIP solvers are generated and selected using heuristic procedures. I will explore the potential for using Machine Learning to help in the process of cut generation.

4 - Janos: Integrated Predictive and Prescriptive Modeling Framework

Teng Huang, University of Connecticut, Storrs, CT, United States, teng.huang@uconn.edu, David Bergman, Philip Brooks, Andrea Lodi, Arvind Raghunathan

Business research practice is witnessing a surge in the integration of predictive modeling and prescriptive analysis. We describe a modeling framework JANOS seamlessly integrates the two streams enabling practitioners to make optimal data-driven decisions. JANOS allows for specifying a prescriptive model using the standard optimization modeling elements such as constraints and variables. The key novelty lies in modeling constructs allow for the specification of commonly used predictive models and their features as constraints and variables in the optimization model. We demonstrate the flexibility of the framework through two examples in workforce allocation and student enrollment.

Joint Session ICS/Practice Curated: Rigorous Foundations for Cybersecurity Science Based in Operations Research

Sponsored: Computing

Sponsored Session

Chair: Jean-Paul Watson, Sandia National Laboratories, Albuquerque, NM, 87113-2065, United States

1 - Solving Energy System Models with GAMS on HPC Platforms

Michael Bussieck, GAMS, Braunschweig, Germany

GAMS is a widely used platform to implement Energy System Models (ESM) like unit commitment, optimal power flow, and economic dispatch. Such models developed and maintained by (academic) research institutes, multi-national organizations, and commercial companies often evolved over time and represent sophisticated and intricate software systems. The modeled time horizon of ESMs spans decades and due to open markets for electricity these models cover bigger and bigger regions. Hence ESMs tend to push the boundaries of available computational resources. In the last three years a multidisciplinary team of researchers from ZIB/TU Berlin/JSC/HLRS/GAMS/DLR investigated ways to handle linear programming based ESMs of exceptional size in a project named BEAM-ME (http://www.beam-me-projekt.de/beam-me/EN/Home/home_node.html). We will give an overview of the various activities in this project and emphasize on challenges related to migrating GAMS based ESMs to a high-performance computing environment.

2 - Cyber Threat Modeling and Validation

Eric Vugrin, Sandia National Labs, Albuquerque, NM, United States, Gerardo Cruz, Christian Reedy, Alexander Outkin, Vincent Urias, Thomas Tarman

The Science and Engineering of Cybersecurity by Uncertainty quantification and Rigorous Experimentation (SECURE) project aims to develop new cybersecurity modeling and analysis tools that implement rigorous, scientific experimental methods. One of SECURE's key research challenges is credible representation of cyber threats and attacker strategies in cybersecurity models. This presentation describes the SECURE project's approach to integrating mathematical models and network emulations for developing and validating cyber threat models. This approach is demonstrated in a scenario involving network scanning by an attacker and intrusion detection by a system operator.

3 - Uncertainty Quantification in Cyber Emulation

Laura Painton Swiler, Sandia National Labs, Albuquerque, NJ, United States

As cyber researchers increasingly rely on virtualized testbeds, there is a need to use uncertainty quantification to generate ensembles of cyber experimental runs or emulations. Principled statistical approaches can provide rigor in analyzing results and support inferences made from such results. In this paper, we outline sampling approaches that can be used to design experiments for emulation testbeds, including orthogonal arrays, Monte Carlo sampling, and multifidelity uncertainty quantification. We present results and lessons learned.

4 - Bilevel Optimization of Cyber Physical Models for Power Grid Resilience

Bryan Arguello, Sandia National Labs, Albuquerque, NM, 87111, United States

We discuss state-of-the-art for bilevel optimization applied to defender-attacker and attacker-defender Stackelberg games on cyber-physical infrastructures. In particular, we extend seminal work in this area on power grid resilience to incorporate ICS/SCADA topologies, threat models, and cybersecurity-based mitigation strategies. We discuss some of the difficulties in model fidelity due to formulation abstraction, and potential solution techniques to solve these problems at scale. We conclude with some preliminary results and future directions for our work.

1 - Distributed Zero-order Algorithms Nonconvex Optimization

Yujie Tang, Harvard University, Cambridge, MA, 91125, United States, yujietang@seas.harvard.edu, Na Li

Most existing distributed algorithms assume knowledge of first-order information of the objective, which may not be available when one can only evaluate the function values at finitely many points. In this talk we develop derivative-free distributed algorithms for nonconvex consensus-based convex optimization, based on recent progress in zero-order optimization. We establish convergence of the proposed algorithms, and provide some applications in distributed learning where one can employ the proposed algorithms to develop model-free methods.

2 - Lazy Aggregation for Communication-efficient Distributed Learning

Tianyi Chen, Rensselaer Polytechnic Institute, Troy, NY, United States, Georgios Giannakis, Tao Sun, Wotao Yin

Considering the massive amount of devices, centralized machine learning via cloud computing incurs considerable overhead, and raises serious privacy concerns. Today, the consensus is that future machine learning tasks have to be performed starting from mobile devices. In this context, we will highlight key challenges, including communication overhead and heterogeneity. We will introduce a new class of (stochastic) gradient methods for distributed machine learning that adaptively skip the gradient calculations to learn with reduced communication and computation. Our methods enabled by the key idea of lazy aggregation are simple to implement, and come with rigorous performance guarantees.

3 - Decentralized Second-order Methods for Consensus Optimization

Aryan Mokhtari, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States

In this talk, we study decentralized consensus optimization problems where different summands of a global objective function are available at nodes of a network that can communicate with neighbors only. In particular, we focus on developing algorithms for consensus optimization when we have access to high-order information of local functions. We first talk about a decentralized quadratically approximated ADMM algorithm (DQM), which minimizes a quadratic approximation of the objective function that ADMM minimizes at each iteration. Then we talk about extending the use of second-order methods to the framework of augmented Lagrangian methods.

4 - Randomized Primal-dual Block-coordinate Algorithms for Asynchronous Distributed Optimization

Lin Xiao, Microsoft, Redmond, WA, United States, Adams Wei Yu, Qihang Lin, Weizhu Chen

Machine learning with big data often involves large models, and frequent communication and synchronization of all model parameters can be very costly. A promising solution is to use parameter servers to store different subsets of the model parameters, and update them asynchronously at different machines using local datasets. We focus on distributed optimization of large linear models with convex loss functions, and exploit their structure by doubly stochastic coordinate optimization with variance reduction (DSCOVR). Compared with other first-order distributed algorithms, we show that DSCOVR may require less amount of overall computation and communication, and less or no synchronization.

Design and Control of Shared Mobility Services

Sponsored: Transportation Science & Logistics/Intelligent Transportation Systems (ITS)

Sponsored Session

Chair: Michael Hyland, University of California, Irvine, CA, 92697-3600, United States

1 - Dynamic Pricing for Ride Pooling Systems

Kai Yang, Wayne State University, Detroit, MI, 48201, United States, Mohammad Abdollahi

We propose a queuing theoretic framework for optimal dynamic pricing of ride pooling systems. Specifically, we focus our attention on dynamic element of pricing meaning that the price can react to online changes of supply-demand balance and will make the system more robust and controllable by pricing dynamically. The dynamic pricing will not basically achieve better performance compared to static pricing, however, it lets the system to realize the benefits of optimal static pricing even with imperfect information in the system.

2 - Hierarchical Control Framework for Autonomous Mobility-on-demand

Kaidi Yang, Stanford University, Stanford, CA, United States, ykd07@stanford.edu, Marco Pavone

We propose a hierarchical control framework for Autonomous Mobility-on-demand where self-driving vehicles serve on-demand travel requests. The road network is divided into several subnetworks based on network topology, demand, traffic conditions, etc. The control framework builds on a network flow model and consists of two levels: 1) an upper level that optimizes the traffic flow (passenger and rebalancing flow) between subnetworks, and 2) a lower level that optimizes the traffic flow within each subnetwork, considering the upper-level control decisions. Results show that the proposed hierarchical control framework can reduce the computation time while yielding satisfactory solutions.

3 - Travel Pattern and Emission Implications in a Fleet of Conventional, Autonomous and Shared Autonomous Vehicles

Harprinderjot Singh, Michigan State University, East Lansing, MI, United States, singhh24@msu.edu, Mehrnaz Ghamami, Hadis Nouri, Timothy Gates

Autonomous and Shared Autonomous Vehicles (AV/SAVs) can improve roadway capacity, driver productivity and mobility in a transportation system. However, the adoption of these vehicles will increase vehicle miles traveled (VMT) which can increase travel time and emission production in the system. The higher purchase price of AVs may also hinder the adoption of these vehicles. This study first models and calibrates the above functions, and then captures the trade-off between the above factors to estimate the optimum fleet configuration resulting in maximum system benefits.

4 - Optimal Design of Mobility Service Networks Based O\ON Travel Dispersion

Navjyoth Sarma, University of California, Irvine, Irvine, CA, United States, nsarma.js@uci.edu, Michael Hyland

Emerging mobility modes such as flexible transit and ride-sharing have the potential to substitute or complement segments in a fixed transit network. This study aims to find the optimal integrated mobility service network with fixed and flexible components. As a critical first step in the mobility service network design problem, this study presents a method to quantify travel dispersion in a region considering the spatial distribution of trips and the underlying transportation network. Then, using parsimonious analytical models, we aim to determine a generalizable relationship between travel dispersion and the optimal combination of mobility service modes to serve the region.

5 - How Can Taxis Up Their Games in the Age of Uber

Shih-Fen Cheng, Associate Professor, Singapore Management University, Singapore, Singapore, sfcheng@smu.edu.sg, Shashi Shekhar Jha, Rajendram Rishikeshan

Taxis are facing stiff competitions from new technology platforms such as Uber globally. In this talk, I will discuss how big data analytics and data-driven decision support can help us improve taxi industry's competitiveness. In particular, I will discuss how to derive insights on demand and supply from raw taxi traces, and how we can estimate demand and supply imbalances. To address these imbalances, we have developed the Driver Guidance System (DGS), which aims to provide driver-specific recommendations to maximize driver's revenue. The DGS has been tested for more than 3 years; with over 500 drivers, we show that driver's vacant roaming time can be reduced by 27% if drivers follow our guidance.

Chair: Tingting Zhao, University of South Florida, Tampa, FL, 33612, United States

1 - Exploring Insignificant OD Pairs: A Compressed Sensing Model for OD Demand Estimation

Xuegang Ban, University of Washington, Seattle, WA, United States, banx@uw.edu, Jingxing Wang

Origin-Destination demand is critical for many transportation applications. Given the fact that in the real-world OD matrix, the majority of OD pairs own small demands while only a small portion have high demands, this study proposes a compressed sensing-based OD estimation model that tries to retain the insignificance feature of OD matrices. The compressed sensing technique is employed in this model to guarantee the sparsity of the deviations between estimates and its prior information or newly-acquired field data. We propose a sufficient condition that can guarantee the insignificance feature of OD matrices. The uniqueness condition for model solution is also investigated for this model.

2 - List-wise Ranking Method for Transportation System Restoration Resource Allocation

Tingting Zhao, University of South Florida, Tampa, FL, 33612, United States, tingtingzhao@mail.usf.edu, Yu Zhang

The performance evaluation for transportation network with several links disrupted is inevitable for the restoration resource allocation. Conventional optimization-based problem formulations are challenging to be solved efficiently as they are combinatorial problems. We proposed a machine-learning framework to address this problem. Both topological and network-flow features are considered for network feature matrix generation. A supervised list-wise ranking model is proposed to rank the performance of a given list of transportation networks with different disrupted links. Our results show that this approach can efficiently assist in transportation restoration resource allocation.

3 - Synthetic Data Generation for Interdependent Food-Energy Systems

Charalampos Avraam, Johns Hopkins University, Baltimore, MD, United States, cavraam1@jhu.edu, Sauleh Ahmad Siddiqui, Emma Cogan, Roni Neff

The regional nature of critical interdependent infrastructures, such as the food and energy systems, requires modelers to extend their analysis to a level of detail that is often more granular than the available data. To generate these synthetic data, we pose the problem of generating candidate values and uncertainty bounds on the required data as a Mathematical Program with Equilibrium Constraints and propose a two-stage decomposition to significantly reduce computational time. In the first stage, the sub-modules are individually calibrated and in the second stage the data at the inter-dependencies are generated. We test our method by linking a US food model with an energy module.

4 - Optimal Network System Restoration Regarding Cascading Failures using Reinforcement Learning

Jian Zhou, Rutgers University, Somerset, NJ, 08873, United States, Dali Wang, David W. Coit

A new approach is proposed to help rapidly identify important system components to mitigate cascading failures impact within large scale networks. It provides distinct advantages to stop failure propagation by efficiently identifying critical system components denoted by minimum vertex cover. Our method adopts graph embedding techniques to represent the characteristics of network systems, and then uses deep reinforcement learning to quickly detect minimum vertex cover from the real-time system topology changed by cascading failures. A case study on western U.S. power transmission grid is presented to illustrate the problem formulation procedures and demonstrate the practical usefulness.

Models for Logistics Capacity Planning and Flexible Urban Delivery

Sponsored: Transportation Science & Logistics/Freight Transportation & Logistics

Sponsored Session

Chair: Teodor Gabriel Crainic, Université du Quebec a Montreal, School of Management, Department of Management & Technology, Montréal, QC, H3C 3P8, Canada

1 - Flexible Urban Delivery and On-demand economy: The Case of a Medium-Sized City

Guido Perboli, Politecnico di Torinbo, Turin, Italy, guido.perboli@polito.it, Luce Brotcorne, Maria Elena Bruni, Mahamud Hasan

We focus on the decision maker adopting a satellite and distributing from there through contracted vehicles. In particular, he can adopt mixed-fleet composed by traditional vehicles, low-environmental vehicles or traditional vehicles owned by unprofessional users. We model this problem by proposing a new variant of the bin packing problem Variable Size Cost Bin Packing Problem (VCSBPP) with time-dependent cost, in which we consider a generalized objective function, represented by a generalized cost given by the cost of the warehouse and the delivery cost represented by the routing costs of electric vehicles at a specific time slot. Results from a case study on the city of Turin are presented.

2 - Capacity Planning with Uncertainty on Contract Fulfillment

Walter Rei, University of Quebec-Montreal, 10673 Larose, Montreal, QC, H2B 3C4, Canada, rei.walter@uqam.ca, Teodor Gabriel Crainic, Guido Perboli, Mariangela Rosano

We focus on the problem faced by a shipper seeking to secure different transportation and warehousing capacity units provided by a carrier while facing various sources of uncertainty in the planning context. In particular, we consider that the contracted capacity may not be entirely available at the shipping day following different unfavorable situations. We thus introduce an extended Stochastic Variable Cost and Size Bin Packing model to formulate the problem and apply solution methods to solve it. Numerical experiments were conducted on both long-haul transportation and urban distribution problems, providing some relevant managerial insights regarding this type of capacity planning.

3 - Multi-period Bin Packing Models for Logistics Capacity Planning

Franklin Djeumou Fomeni, Postdoctoral Researcher, University of Quebec in Montreal, Pavillon Andre-Aisenstadt, 2920 Chemin de la Tour, Montreal, QC, H3T 1J4, Canada, franklin@aims.ac.za, Teodor Gabriel Crainic, Walter Rei

We present a multi-period bin packing model which has practical applications in logistics planning. This model is aimed at minimizing, simultaneously, the cost of selecting the bins and the costs of assigning items to bins, which may depend on other criteria than the volumes of the items as assumed in most existing bin packing models. We show that in some practical applications, such as multi-modal logistics systems, the cost of assigning an item to a bin needs to account for both the physical characteristics of the bins and other economical attributes of the system. A constructive heuristic framework for solving the model will be presented. Some computational results will also be discussed.

4 - An Integrated Location-routing Model for a Hybrid Uav-based Delivery System

Lavinia Amorosi, PhD, Universita di Roma - La Sapienza, Roma, Italy, lavinia.amorosi@uniroma1.it, Teodor Gabriel Crainic, Paolo Dell'Olmo, Nicoletta Ricciardi

Unmanned aerial vehicles (UAVs) have been adopted in a number of cases [1] and applications to delivery systems have recently received considerable attention. In this talk, we present a multiperiod location-routing problem of one truck and a set of UAVs for package delivery in an urban area. Following work [2] we present solution method and preliminary computational results. [1] Otto A. et al., Optimization approaches for civil applications of unmanned aerial vehicles (UAVs) or aerial drones: A survey, Networks 72 (2018) 411-458.[2] Amorosi L. et al., Energy-Efficient Mission Planning of UAVs for 5G Coverage in Rural Zones, IEEE International Conference on Environmental Engineering, EE 2018, 1-9.

Sponsored: Transportation Science & Logistics/Urban Transportation

Sponsored Session

Chair: Neda Masoud, University of Michigan, Ann, MI, 48109, United States

1 - A Data-driven Optimization Approach for Dynamic Shuttle Dispatching Problem

Amirmahdi Tafreshian, University of Michigan, Ann Arbor, MI, 48109, United States, atafresh@umich.edu, Mojtaba Abdolmaleki, Neda Masoud

The problem of dispatching shuttles to serve trip requests can be mathematically formulated as a dial-a-ride problem (DARP). With on-demand mobility services gaining more popularity in recent years, the real-time application of DARP is attracting ever more interest. However, the fact that size of DARP grows exponentially with number of requests renders the current solution methodologies inadequate for online applications. In order to tackle this issue, we propose a general framework that shifts much of the computational burden of the optimization problems that need to be solved into an offline setting, thereby addressing on-demand requests with fast and high-quality solutions in real time.

2 - Analysis of the Impact of Regulation in the Ride-sourcing Market

Daniel Vignon, University of Michigan, Ann Arbor, MI, 48105, United States, dvignon@umich.edu, Zhengtian Xu, Yafeng Yin

Despite their increasing popularity, ride-sourcing platforms like Uber and Didi face mounting pressure from political and regulatory agents. Especially, given the mounting evidence that these services contribute to congestion, there is increasing support for regulations that addresses the aforementioned externality. However, there is also a need to understand the potential impact of proposed measures—such as congestion pricing or fleet size caps—on service quality and accessibility. Thus, in this work, we propose a model of the ride-sourcing market and explore the potential impact of popular measures aimed at reducing ride-sourcing generated congestion.

3 - Data-driven Matching for Ride Sharing System Using Trajectory Data and Dynamic Time Warping

Alexander Sundt, University of Michigan, Ann Arbor, MI, United States, asundt@umich.edu, Mehrdad Shahabi, Yafeng Yin

Recent research in ride-sharing has focused heavily on real-time systems and the implementation of their matching algorithms, but has overlooked user history in facilitating these matches. In order to bridge this gap, we present a robust optimization formulation to match users for ride-sharing based on their historical trajectory data. Using modifications to the dynamic time-warping algorithm, we obtain approximate distances between trajectories and we present centralized and decentralized formulations for matching users based on these distances. The procedure is tested on a small toy dataset as well as the large Microsoft GeoLife dataset.

4 - Modelling Impact of Demand Shocks in Pricing of Ride-hailing Services

Sohil Shah, MIT, Cambridge, MA, United States, sshah95@mit.edu, Saurabh Amin, Patrick Jaillet

Demand fluctuations for ride-hailing services have been classically dealt with by setting market clearing prices. However, little is known about strategic pricing after demand shocks such as those following sporting events and disruptions in public transit. We present a network queuing model that captures the interaction between the dynamics of rider requests and pricing strategies employed by employed by ride-hailing services in areas adjacent to a demand shock. We validate the model using data collected after the conclusion of baseball games in the Boston Area.

Sponsored: Transportation Science & Logistics/Facility Logistics

Sponsored Session

Chair: Xin Wang, University of Wisconsin-Madison, Middleton, WI, 53562-4278, United States

1 - Longitudinal Trajectory Control of Connected Autonomous Vehicle with Deep Reinforcement Learning

Xiaopeng Li, University of South Florida, Tampa, FL, 33620, United States, xiaopengli@usf.edu, Yu (Crystal) Wang

We develop a dynamic data-driven control architecture to optimize the trajectory of Connected Autonomous Vehicle. We adapt controller parameters by training an artificial neural network and minimize the fuel consumption without sacrificing safety or efficiency with the reinforcement learning method. The proposed controller over-performs human and Cooperative Adaptive Cruise Control method.

2 - Optimal Charging Plan for Electric Vehicles: Dynamic Scheduling under User Decisions

Leila Hajibabai, North Carolina State University, Department of Civil Engineering, Raleigh, NC, 11794, United States, lhajiba@ncsu.edu, Amir Mirheli

This study develops a dynamic scheduling scheme for electric vehicle (EV) charging facilities that aims to determine the demand-based assignment of EV users to the facilities considering their waiting time and time-window constraints. The problem is formulated into a dynamic programming model that minimizes the (i) total costs including travel and charging expenses and (ii) number of un-served users, under uncertain demand and charger availability. A stochastic look-ahead technique is proposed that integrates Monte Carlo tree search algorithm and shooting heuristic. Numerical experiments confirm the quality and efficiency of solutions obtained from the proposed methodology.

3 - An Exchange Market Platform for Parking

Xin Wang, University of Wisconsin-Madison, Middleton, WI, 53562-4278, United States, Xiaotian Wang

Parking difficulties in urban areas cause cruising traffic, which leads to a series of social and economic problems. A few reservation-based parking management strategies have been proposed to eliminate cruising, while they have a high level of requirements on the infrastructure, which is unrealistic in most cases. To solve parking problems without restrictions on the infrastructure, we build a parking spot exchange market where parking availability information is treated as a merchandise to trade. To be specific, an arriving driver pays to get a specific parking spot from another driver who is about to depart. Social objective is considered, and pricing is centralized to avoid discrimination.

4 - A Deep Model-based Deep Q-learning Algorithm for Traffic Signal Timing at Urban Intersections

Yun Yuan, Postdoctoral Research Associate, The University of Utah, Salt Lake City, UT, United States, yun.yuan@utah.edu, Hao Wang, Tian Zhao, Yang Liu, Xianfeng (Terry) Yang

This study employs a Deep Q-learning Learning method and Deep Q neural network for traffic signal split optimization problem at an urban intersection. To accelerate the training computation, a deep model is investigated to extract features and predict states from flawed data. The deep model outperforms simulators regarding the running time. The proposed method is tested on a real-world testbed with Automatic Number-Plate Recognition data. The case study shows the deep model can predict the traffic state in limited computational time and the deep Q-learning algorithm is 3.9% better than the field data of the adaptive control system SCOOT and 22% better than the time-of-day plan by SYNCHRO.

5 - Operational Models for Smart Unmanned Aerial Mobility Networks

Qiao-Chu He, Southern University of Science and Technology (SUSTech), Shenzhen, China, heqc@sustech.edu.cn, Lan Lu, Lishuai Li, Zheng Zhu

Smart logistics enabled by the sophistication of unmanned aerial vehicles (UAVs), is in multiple dimensions: (1) from hardware design to service platform driven by data and algorithms; (2) from uncoordinated fleet of vehicles towards logistics-as-a-service paradigm. We investigate this emerging service operations by proposing an integrated systems models: At a strategic level, we design the infrastructures, including airport location/capacity and types of UAVs; At a tactic level, we optimize the logistics network; At an operational level, we develop scheduling algorithms. We work with a leading industry partner whose UAVs logistics service network is already operational.

6 - Optimizing Water Pollution Monitoring Systems: Regulation Policy Guideline for Curbing Nutrient Pollution

Xin Wang, University of Wisconsin-Madison, Madison, WI, United States, Michael Lim, Jeffrey Linderoth

We consider regulatory policy guidelines for improving the surface water quality. Specifically, we establish a practical water pollution regulation system by determining the optimal location of monitor stations along with proper regulatory schemes to curb the nutrient pollution resulting from various farming activities. We develop a central planner's monitoring system optimization model along with analysis methodologies. We construct an innovative computational solution method for optimizing and analyzing the above model for a large-scale water network, and implement the model to Mississippi River Watershed. The proposed modeling framework and solution method is applicable to any general water network, and thus can be further implemented to other water networks in any other region.

Joint Session AAS/TSL Air/Practice Curated: Airline Delay and Recovery

Sponsored: Aviation Applications

Sponsored Session

Chair: Yifei Sun, Dartmouth College, Lebanon, NH, 03766, China

1 - Preemptive Rerouting of Airline Passengers under Uncertain Delays

Lindsey McCarty, Cedarville University, Cedarville, OH, 48105, United States, lasel@umich.edu, Amy Cohn

An airline's operational disruptions can lead to flight delays that in turn impact passengers, not only through the delays themselves but also through possible missed connections. We consider preemptive rerouting of airline passengers before the length of the delay is realized. We consider the simplified version in which only a single flight is delayed, and model this problem as a two-stage stochastic programming problem. We present a Benders Decomposition approach and give computational results to demonstrate the reasonable run time in solving our model. This research lays the groundwork for the more-realistic case in which multiple flights in the network may experience concurrent delays.

2 - A Column Generation-based Heuristic for Aircraft Recovery Problem under Typhoon Disruption

Lei Zhou, Tongji University, Shanghai, China, zjzhoulei@tongji.edu.cn, Zhe Liang

Airline aircraft recovery problem (ARP) is the essential part of the schedule recovery process, which is to re-schedule flights and re-assign aircraft. We consider the ARP under typhoon disruption, and propose a mixed integer programming model with considerations in actual business scenarios. We solve the model with a column-generation based heuristic consisting of a master problem for selecting routes and sub-problems for generating better routes for each aircraft. A real-world problem with complicated constraints can be solved to near optimal within 20mins. Our recovery model and solution method has been applied in the decision support system of a Chinese airline.

3 - Integrated Recovery of Aircraft and Passengers Considering Passengers' Irrational Choice

Yuzhen Hu, Harbin Engineering University, Zhongguancun East Road, Harbin, China, hyzshd@126.com, Pu Zhang, Song Zhang, Yizheng Yang, Bo Fan

The consideration of passengers' irrational choice in the optimization research of airline disruption management will reverse the undesirable situation of concerning interests of company but passengers' demands, and emphasizing explicit cost but recessive cost during airlines' flight rescheduling, and thereby reduce dual losses of airlines and passengers. This research focuses on the multiple objective optimization problem of integrated recovery of aircraft and passengers with choice preference between endorsing and ticket refunding. Additionally, passengers' irrational psychology, based on prospect theory, is reflected in the second objective.

4 - Introducing New Flights under Departure Time Dependent Passenger Demand Uncertainty

Ozlem Cavus, Bilkent University, Department of Industrial Engineering, Ankara, 06800, Turkey, ozlem.cavus@bilkent.edu.tr, Ozge Safak, Selim Akturk

We accommodate new flights into an existing airline flight schedule by considering passenger demand uncertainty. To open up space for new flights, we not only make operational changes like shifting the departure times of current flights and adjusting the aircraft cruise speed, but also introduce a more strategic decision of leasing an aircraft. We also consider the effect of departure times of new flights on the distribution of passenger demand. We introduce a unified two-stage stochastic mixed-integer nonlinear programming formulation for the problem and suggest an exact solution algorithm.

Joint Session RMP/Practice Curated: Data Driven Models for Revenue Management and Pricing in Industry

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Ravi Kumar

1 - A New Approach to Price Optimization

Richard Liu, SAS Institute, Inc., Cary, NC, 27513, United States, Richard.Liu@sas.com, Matthew Maxwell

We develop a new approach to estimate the price to maximize expected revenue. Unlike in an estimate-then-optimize approach, we do not use any parametric model for the random demand. This allows us to work with limited historical data, where only prices, final sold, and final revenue are observed at the end of a selling horizon. We find via simulation that our approach is accurate and robust.

2 - Cancellation Predictors in Airlines and Hospitality

Ger M. Koole, Vrije Universiteit Amsterdam, Department of Mathematics, De Boelelaan 1081A, Amsterdam, 1081 HV, Netherlands, ger.koole@vu.nl, Daniel Hopman, Jeroen de Korte

We use machine learning techniques to predict which customer will cancel their reservations in an airline and in a hotel case.The results are surprisingly accurate, and we show how to use these results to determine the optimal overbooking limit.

3 - Dynamic Pricing for Ancillaries in Travel Industry

Ravi Kumar, Senior Scientist, PROS Inc, Houston, TX, 77098, United States, Guangrui Xie, Ang Li

In recent times, ancillaries have become a key driver for revenue growth for travel industries. Traditionally, pricing and offer generation for ancillary items have been managed using static business rules. In such scenarios, where historical prices show very little or no variation, typical methods of estimating purchase probabilities and then finding the optimal price are not applicable. In this study, we develop practical approaches for dynamic pricing of ancillaries based on reinforcement learning ideas and demonstrate using simulations that these methods can efficiently discover the optimal price.

4 - Medium Term Revenue Management in Air Cargo

Dirk Sierag, PROS Inc, Houston, TX, United States

There are two revenue management problems in Air Cargo: medium term and short term. Short term deals with adhoc sales, which is similar to the passenger airline problem. Medium term deals with seasonal contracts, where clients reserve space on recurring flights or origin-destinations over several months. We solve the medium term problem using a data-driven approach in two steps: (1) determine how much space to allocate for the contracts and how much for adhoc sales; (2) solve the medium term problem using flexible products.

Recent Advances in Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Jue Wang, Smith School of Business, Queen's University, Kingston, ON, K7L 3N6, Canada

1 - Optimal Inventory Decisions When Offering Layaway

Stanko Dimitrov, University of Waterloo, Waterloo, ON, Canada, sdimitrov@uwaterloo.ca, Oben Ceryan

Layaways allow budget constrained consumers, with sufficiently high valuations to acquire products without using high-cost financing, by reserving the right to purchase a product over time. However, a retailer, offering layaway, may lose opportunities to sell a product to a non-layaway consumer only to have the layaway canceled. In our work, we derive optimal order quantities of a retailer offering layaway, and the market conditions in which a retailer is better off offering layaways. We conclude by considering some timing issues in layaways.

2 - Which Customers Are More Valuable in Dynamic Pricing Situations?

Anton Ovchinnikov, Queen's University, Kingston, ON, K7L 3N6, Canada, ao37@queensu.ca, Jue Wang

Firms commonly rely on cash-flows attributed to a customer relationship to measure customer value. We show that this approach could be potentially flawed when firms operate in dynamic pricing situations with limited capacity: a customer who pays less can have a higher value than one who pays more, and the expected value of a customer could be, independent of, or even decrease in, the price paid by (cash-flow received from) the customer. That said, we also show that certain non-stationary customer arrival patterns could restore the "intuitive" directional relationship that higher-paying customers are more valuable.

3 - Finite-Horizon Decomposition for an Infinite-Horizon Dynamic Capacity Allocation Problem

Rui Zhang, University of Colorado Boulder, Boulder, CO, United States, Thomas Vossen

A rolling-horizon dynamic capacity allocation problem can be formulated as an infinite-horizon discounted cost Markov decision process. We show that the problem can be decomposed by the resources over the booking horizon. The solutions provide upper bounds and can be used to construct heuristic control policies. Computational results are discussed.

4 - Quantifying Mileage Runs: Strategic Consumer Behavior in Premium-Status Loyalty Program

Yang Chen, Queen's University, Kingston, ON, K7L 4A9, Canada, Anton Ovchinnikov

We report on the results of a large-scale field quasi-experiment done in partnership with a major loyalty program to understand strategic consumer behavior with respect to the premium status tier reward. We find that strategic behavior is quite pronounced and adds to nearly 4% increase in the target group's spending. However, we also observe on substantial heterogeneity in consumer behavior, which aligns with the existing theory and enriches the existing empirical evidence of strategic consumer behavior.

New Directions in Pricing and Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Georgia Perakis

1 - Promotions with Rewards Programs: Improving Fast-food Chain Operations

Rim Hariss, McGill University, Operations Research Center, 1 Amherst Street, Montreal, QC, 02142, Canada, rhariss@mit.edu, Georgia Perakis, Yanchong Zheng

In this work, we study the problem of deciding price discounts while accounting for the effect of the rewards program on demand. Using a partially linear model, we embed the impact of different classes of customers points balance on price sensitivity in demand estimation. We consider the store's problem of maximizing total expected revenue over time by deciding discounts for every period and accounting for the customers redemption behavior. We show conditions under which a unique optimal threshold discounting policy exists. Using data from a fast food chain, we then perform counterfactual analysis to evaluate the revenue improvement of the proposed optimal strategy relative to current practice.

2 - Managing in-class-fulfillment at a Large Fashion E-retailer

Yiannis Spantidakis, MIT, Cambridge, MA, United States, yspant@mit.edu, Georgia Perakis, Divya Singhvi

We consider the problem of optimizing initial inventory distribution for one of the largest fashion retailers in India in order to maximize in-class fulfillment. We formulate this problem as a multi-product, multi-warehouse newsvendor problem with capacity and depth constraints, and propose an efficient iterative algorithm to optimize the inventory distribution. With our industry partner, we run a nation-wide pilot and observe considerable gains in the in-class-fulfillment.

3 - Increasing Healthy Food Consumption Among Low-income Populations

Elisabeth Paulson, MIT, Cambridge, MA, 16801, United States, epaulson@mit.edu, Retsef Levi, Georgia Perakis

A growing number of strategies are being proposed to increase consumption of healthy food in low income food deserts. While there is agreement that food environments are linked to diet and health outcomes, there is surprisingly little agreement about the impact of certain interventions, due to a lack of understanding of the underlying mechanisms that influence household food choice. In this work we empirically evaluate the impact of access- and education-based interventions. We then use these findings to build a novel behavioral model of household grocery shopping, nested into a bi-level model to optimize government funding across price-, access-, and education-based interventions.

4 - Bike Sharing Systems - The Economic and Environmental Impact of Operational Strategies

Sanjith Gopalakrishnan, University of British Columbia, Vancouver, BC, V6T 1Z2, Canada, sanjith.gopalakrishnan@sauder.ubc.ca, Daniel Granot, Frieda Granot

Despite their growing popularity as a sustainable urban transport option, bike share programs in several cities such as Seattle and Montreal have run into financial difficulties due to low ridership and high operational costs. Further, their environmental benefits are ambiguous since a majority of users are substituting from public transport or walking. In this work, we adopt a consumer transport mode choice model and analyze the economic and environmental implications of three key operational levers: the pricing structure, station coverage and density, and frequency of rebalancing operations.

5 - Analytics-driven Inspection Operations for Failure Localization

Mathieu Dahan, Georgia Institute of Technology, Atlanta, GA, United States, mdahan@mit.edu, Steven B. Link, Saurabh Amin, Georgia Perakis

In this talk, we present a prescriptive analytics framework for localizing failures in the aftermath of a natural disaster. Given the diagnostic information provided by a failure prediction model, we consider a generic team orienteering problem with stochastic rewards and service times. We derive a compact mixed-integer programming formulation of the problem that computes an optimal a-priori routing of the inspection teams. Using the data collected by a major gas utility after an earthquake, we demonstrate the value of predictive analytics for improving their response operations.

Revenue Management and Marketplace Analytics II

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Kalyan Talluri, Imperial College Business School, London, SW7 2AZ, United Kingdom

1 - Dynamic Double Auctions: Toward First Best

Santiago Balseiro, Columbia University, New York, NY, 10027, United States, srb2155@columbia.edu, Vahab Mirrokni, Renato Paes Leme, Song Zuo

We study the problem of designing dynamic double auctions for two-sided markets in which a platform intermediates the trade between one seller and multiple buyers, repeatedly over a finite horizon, when agents have private values. Motivated by online platforms for advertising, ride-sharing, and freelancing markets, we seek to design mechanisms in which the platform never asks the seller to make payments nor are buyers ever paid and every agent derives a non-negative utility from every trade opportunity. We provide mechanisms satisfying these requirements that are asymptotically efficient and budget-balanced with high probability as the number of trading opportunities grows.

2 - Estimating Large-scale Tree Logit Models via a Difference of Strictly Convex Functions

Srikanth Jagabathula, NYU Stern School of Business, New York, NY, 10012, United States, sjagabat@stern.nyu.edu, Paat Rusmevichientong

We describe an efficient estimation method for large-scale tree logit models, using a novel change-of-variables transformation that allows us to express the negative log-likelihood as a difference of strictly convex functions. Exploiting this representation, we design a fast iterative method that computes a sequence of parameter estimates. No step size or second-order derivative is required. The sequence of parameter estimates yields increasing likelihood values, and we show that every limit point is a stationary point. Numerical results show that our algorithm outperforms state-of-the-art optimization methods, especially for large-scale tree logit models with thousands of nodes.

3 - Sourcing Strategies for Online Retail Marketplaces

Nikolay Osadchiy, Emory University, Atlanta, GA, 30322, United States, Sridhar Seshadri, Vishal Gaur, Marti Subrahmanyam

Motivated by empirics of price trajectories in online marketplaces, we study the inventory ordering problem under selling price and demand uncertainty. We show how price uncertainty changes the ordering pattern and how suppliers can benefit from offering time-flexible ordering policies to firms selling through online marketplaces.

4 - Revenue Management of a Professional Services Firm

Kalyan Talluri, Imperial College Business School, E, C/Ramon Trias Fargas 25-27, London, SW7 2AZ, United Kingdom, kalyan.talluri@imperial.ac.uk, Angelos Tsoukalas

The operations management of large professional service firms (law, accounting, medicine, investment banking, architecture, advertising, and consulting) has not been well studied despite their prominence in the service sector. The goal of this paper is to get insight into their revenue management operations and also develop optimization models to aid the partners in their bidding and matching process.

Business Applications

Contributed Session

Chair: Songrui Liu, S F Technology Co Ltd, Shenzhen Software Industry Base 1B, Shenzhen, 518061, China

1 - Game Review

Zheng Zhang, University of Tennessee, Knoxville, Knoxville, TN, United States, zzhan100@vols.utk.edu

Econometric and machine learning methods have been applied to financial performances predictions. However, asynchronous time series make analysis from classical theories cannot be applied directly. In this paper, we apply the traditional vector auto-regressive (VAR) model and weighted generalized elastic-net Granger (WEGEG) to forecast the financial indices based on predictors from social media and third-party platforms. We offer the financial institutions managerial suggestions when facing the negative evaluations from the Internet. Moreover, we find that WEGEG performs better the state-of-art method especially when the distribution of the data is hard to be identified.

2 - The Impact of Embedding Self Descriptive Information in Product Reviews

Arda Zuber, University of Connecticut-Storrs, Mansfield, CT, United States

In this study, we investigate the product category specific impact of reviewer credibility by examining the self-descriptive information disclosure present in the review text. Our results show that disclosure of different types of personal information does not have homogeneous effects across product categories, and revealing a certain type of self-descriptive information has varying effects on review helpfulness posted for products in different product categories.

3 - Exploring Hybrid Innovation Capabilities in Manufacturing

Yu-Yu Lu, National Cheng Kung University, Tainan City, Taiwan, Hsin-Hsin Chang

Providing service is a crucial issue for capital goods manufacturers. This study aims to explore firms with the capability of processing customer information through knowledge integration mechanism and absorptive capacity are able to improve their hybrid (product and service) innovation capability. Through case studies of Taiwanese equipment manufacturers, the preliminary result of this study indicates that firms who collect and identify the suitable customer information and transform them to useful firm knowledge are able to improve their incremental hybrid innovation capability, however, the radical hybrid innovation capability is hardly seen in the case companies.

4 - Cluster Analysis of the Relationship Between Logistics Performance Index and Economic Growth

Youqin Pan, Salem State University, Salem, MA, United States, ypan@salemstate.edu

This study applied cluster analysis to investigate the relationship between logistics performance index and economic growth. The findings demonstrate that variables such as logistics quality , infrastructure, tracking and tracing are drivers of cluster membership. Countries in different clusters may have different priorities in improving their logistics performance, which in turn may boost its national economy and help expand trade among trading partners.

5 - Automated Timetabling Framework

Songrui Liu, S.F. Technology Co., Ltd., Shenzhen, China, liusr228@outlook.com, Jing Wang

The time and computing complexity of timetabling rises exponentially as the size of realistic problems goes up. Thus an effective framework—ATF is proposed for convenience, consisting of six modules: shift design, staffing, duty scheduling, assignment, parameters tuning, and results adjustment. Each module of this framework is configurable based on personalized decomposition of problems. Objectives are also customized to maximize personnel utilization and enhance employee satisfaction. For solving, both Mixed Integer Programming model and heuristics algorithms are developed throughout the framework. In terms of applications, several modules of ATF have already been adopted in SF.

Joint Session PSOR/Practice Curated: Rapid-onset Disaster Operations Management

Sponsored: Public Sector OR

Sponsored Session

Chair: Mahyar Eftekhar

1 - Pre-positioning Disaster Relief Assets for Improved Rapid Response

Christopher Zobel, Virginia Tech, Blacksburg, VA, 24061-0235, United States, czobel@vt.edu, Andrew N. Arnette, Duygu Pamukcu

In this work, we build on our previous research with the Red Cross on developing a disaster relief asset pre-positioning model. The original model developed a risk function based on hazard likelihood, exposure, and vulnerability in order to pre-position assets for opening shelters in response to rapid onset disasters. Potential extensions being explored include the incorporation of weather information and advisories to improve shelter opening decisions, and the development of a two-stage stochastic programming model to extend the pre-positioning model into early stages of relief replenishment.

2 - Fleet Composition in Response to Natural Disasters and Armed Conflicts

Alfonso J. Pedraza-Martinez, Associate Professor, Indiana University Bloomington, Bloomington, IN, United States, alpedraz@indiana.edu

This study examines empirically the fleet composition of a large international humanitarian organization (HO) that responds to natural disasters and armed conflicts. We focus on understanding how the HO configures its fleet and specifically decides on renting or subcontracting transportation to deliver services to its beneficiaries. Transportation expenses are one of the largest expenses for the organization. We use thirteen-year panel data on transportation and personnel (local and expatriate) expenses of twenty-four country offices of this organization to build a fixed-effect model. We combine our proprietary data with publicly available data on natural disasters and armed conflicts.

3 - Preparing for Hurricane Preparation

Eva D. Regnier, Professor, Naval Postgraduate School, Monterey, CA, 93943, United States, eregnier@nps.edu, Cameron MacKenzie

The Hurricane Decision Simulator is an online training environment for US Marine Forces Reserve personnel to gain realistic experience making high-stakes dynamic decisions regarding costly preparation to protect safety, assets, and mission from a threatening hurricane. Working with US Marines at a headquarters facility in New Orleans and a small Reserve Training Center outside Miami, we have mapped their decision timelines, with costs and consequences, in preparation for an oncoming hurricane. We report on its use in practice, experimental results for a simplified scenario, and future directions.

4 - Supply Management for the Immediate Relief Period of Rapid-onset Disasters

Mahyar Eftekhar, Arizona State University, BA 433, Tempe, AZ, 85287, United States, eftekhar@asu.edu, Jing-Sheng Jeannette Song, Scott Webster

Focusing on the immediate relief period, we consider two common alternatives for both single and multiple items, in the presence of budget and local supply uncertainties. In this setting, due to many unknowns such as time, place, and magnitude of a disaster, supply management is a significant challenge. We define a model to determine the optimal prepo stock level assuming local purchasing is prioritized. We derive properties of the optimal solution, identify exact solution methods, and identify approximate methods that are easy to implement. We characterize the interplay of supply, demand, and budget uncertainties, as well as the impact of product characteristics on optimal prepo stock levels.

Data Driven Insights for Decision Making

Sponsored: Public Sector OR

Sponsored Session

Chair: Gabriela Gongora Svartzman, PhD Candidate, Stevens Institute of Technology, Hoboken, NJ, United States

1 - Urban Data Analytics to Analyze Quality of Experience in City Services

Gabriela Gongora Svartzman, PhD Candidate, Stevens Institute of Technology, Hoboken, NJ, United States, ggongora@stevens.edu, Jose Emmanuel Ramirez-Marquez

Research is rich in analyzing the quality of city services, while the quality of experience lacks exploration. Data mining of social media, natural language processing and urban analysis techniques are employed to measure the quality of experience in city services, by measuring the perception of customers towards a service. This work provides a framework to analyze how services react to different types of disruptions (e.g., weather) through time and their effect on customers. Two of these effects being social cohesion and resilience during disruptions The results are presented through visualizations and data analytics for decision makers.

2 - Extracting Decision-making Metrics from Text and Placing the Human Feedback in the Quantitative Loop

Carlo Lipizzi, PhD, Stevens Institute of Technology, Hoboken, NJ, 07030, United States, clipizzi@stevens.edu

Having tools to support decision taking has been a necessity since a while. When most of the available input is text, the challenge is to extract valuable metrics from the text, merging it with available numeric data, collect quantitative humans' input - for the ethic-centric components and for expert scoring - and provide proper visualizations.We present a method leveraging on a computational version of Marvin Minsky's framework theory and an application in a case study.

3 - Data Driven Insights for Cancer Diagnosis.

Shikha Soneji, Stevens Institute of Technology, Hoboken, NJ, 07030, United States, ssoneji@stevens.edu

Researchers have found that AI is able to detect cancer and other diseases earlier than possible through standard diagnostic methods, which could be lifesaving for future patients. The aim of this study is to measure the survival data of the 10 most common types of cancer cases in the world. This is achieved by using different journal and conference papers regarding cancer and its detection methods and the results obtained will help in analyzing them. These visualizations are different graphs developed using languages like Python and JavaScript for making it a dynamic interactive visualization, which would help the healthcare community to further diagnose these diseases in a faster way.

4 - Approximate Dynamic Programming for Bayesian Optimization with Multi-information Sources

Xubo Yue, University of Michigan, Ann Arbor, Ann Arbor, MI, 48105, United States, maxyxb@umich.edu

In this work, we consider a dynamic programming (DP) formulation for multiple information sources Bayesian optimization (BO). DP algorithm employs non-myopic (non-greedy) strategies to actively select sampling points and account for future information, allowing a balance between exploration and exploitation in BO and thus a better performance. Due to the large state space and the action space, we approximate DP using rollout, a sequential approach to optimization problem. Experiments on synthetic and real world data show that the proposed framework outperforms state-of-the art approaches.

5 - Exploratory Data Analysis to Recognize Vulnerable Groups for Human Trafficking

Nafisa Mahbub, University at Buffalo, Amherst, NY, United States, nmahbub@buffalo.edu, Jun Zhuang

Human Trafficking can be spotted as the most violated human rights among all the crimes. Examining the relational and functional properties of different types of crimes and illicit trade networks is essential to identify vulnerability (segments of the population targeted in terms of socio-economic factors, crime profile of a geographic location) of the group of people to either being involved or being victimized by the illicit trade networks. Novel data visualization, supervised and unsupervised machine learning techniques have been exploited here to identify different clusters based on similarities in crime profile.

6 - Mining the Topics for Budget Allocation in Group Decisions

Chen Wang, Tsinghua University, Tsinghua University, Beijing, 100084, China, chenwang@mail.tsinghua.edu.cn, Tanpisit Chen, Shenming Song

In group decision making, people express their preferences and try to influence the collective decision. This research proposes a text mining method to identify key topics of the conversation and the decisiveness of each topic in determining how much each player in a group obtains in a budget allocation scenario. We then characterize heterogeneity of players' capabilities and interactions based on a large number of simulation exercises completing the same allocation task.

Vendor Tutorial

1 - Increasing Operational Efficiency with Automation Anywhere's Digital Workforce Platform

Amitai Jacobsen, Automation Anywhere, San Jose, CA, United States

The Automation Anywhere bot building tutorial is designed to showcase Robotic Process Automation (RPA), Cognitive Automation and Analytics tools that make up Automation Anywhere's Digital Workforce Platform. We will demonstrate the process of building digital workers, or bots, on our platform and within minutes. These bots can collect and analyze data and perform tasks that otherwise would be performed by humans, making processes more efficient, reducing errors and improving operational efficiency. The tutorial will feature Automation Anywhere Enterprise, IQ Bot, and Bot Insight and will show that these tools are not meant exclusively for engineers or IT experts but indeed also for business users. Participants will learn the process of creating bots, automating common processes and will have a chance to familiarize themselves with Automation Anywhere's software solutions.

2 - 16 Tips for Teaching a Marketing Analytics Course

Scott Yost, Stukent, Idaho Falls, ID, United States

Are you struggling to teach your marketing analytics course? In this session, Scott will share the top tips to teaching a more complete course including what platforms you should use, available resources, and the ways you can keep your course up-to-date.

Joint Session QSR/Energy: Statistical Learning for Energy Analytics

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Ahmed Aziz Ezzat, Rutgers University

Co-Chair: Hoon Hwangbo, University of Tennessee, Knoxville, TN, 37996-2315, United States

1 - Renewable Energy: The Forgotten Solutions

Andrew Kusiak, Professor, University of Iowa, Dept of Industrial and Systems Engineering, Iowa City, IA, 52242-1527, United States, andrew-kusiak@uiowa.edu

Generation of renewable energy has been steadily increasing, however, decades are needed to reach the clean footprint of energy. The developments in renewable energy over the last two decades have focused on increasing power of energy generators and construction of large-scale wind and solar farms. To accelerate deployment of renewable energy, innovation across the life-cycle of renewable energy is needed. Problems and solutions in the renewable energy chain awaiting research and development attention are addressed.

2 - The Calibrated Regime-switching Model for Wind Speed and Power Forecasting

Ahmed Aziz Ezzat, Rutgers University, New Brunswick, NJ, 77840, United States

We propose an advanced spatio-temporal statistical model, called the calibrated regime-switching model. The proposed model is designed to capture salient properties of wind fields: regime-switching dynamics, spatio-temporal dependencies, transport effect of wind, and nonstationarity. Tested on 11 months of hourly data from 200 wind turbines, double-digit improvements in the accuracy of wind speed and power forecasts are achieved relative to six widely used approaches in the literature.

3 - Wind Resource Assessment and Characterization at Non-observational Locations

Youngchan Jang, University of Michigan, Ann Arbor, MI, United States, mapsossa@umich.edu, Eunshin Byon

Selecting an appropriate wind farm site is one of the most important keys for ensuring the profitability of a wind farm. To this end, a thorough analysis of characterizing non-stationary and volatile features of wind conditions is critical. This study proposes a probabilistic spatio-temporal model for estimating wind speeds at potential sites where wind measurements are not unavailable. The proposed models are constructed using measurements collected from nearby meteorological stations, and day-to-day and station-to-station variations of wind speeds are quantified. The performance of the proposed approaches is evaluated using actual data collected in multiple meteorological stations.

4 - Data-driven Approach to Dynamic-var Compensator Placement for Voltage Stabilization on Feeders with High PV Penetration

Nader Samaan, Pacific Northwest National Laboratory PNNL, Richland, WA, United States, nader.samaan@pnnl.gov

Distribution feeders with a high penetration of distributed photovoltaic (PV) systems can experience voltage variability caused by the changing power flow injections corresponding to the availability of the solar resource. Dynamic Var Compensators (DVCs) can be used for local voltage stabilization. This presentation introduces a statistical framework to characterize voltage variability and stabilization, proposes a data-driven approach to DVC placement, and presents the results of a planning study on a real feeder using real data.

Advanced Data Analytics in Cyber Manufacturing Systems

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Xiaoyu Chen, Virginia Tech, Blacksburg, VA, 24060, United States

Co-Chair: Ran Jin, Virginia Tech, Blacksburg, VA, 24061, United States

1 - Model Selection Consistency of Penalized Likelihood Methods in Statistical Transfer Learning

Zhenli Song, HKUST, Hong Kong, Hong Kong, Fugee Tsung

Nowadays, automatic data acquisition is now frequently deployed in manufacturing and service applications. Consequently, many data generating processes have been activated, which require effective and efficient modeling procedures to analyze the data and estimate the unknown parameters. However, the data collected from lately activated processes are usually of high variability and low volume. Meanwhile, abundant data is usually available in the processes that have operated for a long time, some of which share similar statistical structure with the process of interest. In this paper, we investigate the model selection consistency property in the context of statistical transfer learning.

2 - Multi-response Adaptive Computation Pipelines via Clustered Low-rank Regularization in Cyber-manufacturing Computation Services

Xiaoyu Chen, PhD Candidate, Virginia Tech, Blacksburg, VA, 24060, United States, xiaoyuch@vt.edu, Lening Wang, Ran Jin

Existing adaptive computation pipeline method AdaPipe formulates a recommender system with single performance metric (i.e., accuracy) to match pipelines with contexts in a cyber-manufacturing system (CMS). However, recommendation based on single metric cannot satisfy multi-dimensional metrics (e.g., latency, redundancy), which are critical in a complex CMS. Simply adding dimensions will easily violate the low-rank assumption of AdaPipe and matrix completion models. Thus, we propose a multi-response adaptive pipelines by using clustered low-rank regularization to accurately match pipelines with contexts. An evaluation in a fiber CMS validates the proposed method.

3 - Matching Computation Pipelines with Contexts in Cyber-manufacturing Computation Services

Ran Jin, Virginia Tech, Blacksburg, VA, 24061, United States, jran5@vt.edu, Xiaoyu Chen

Cyber-manufacturing systems (CMS) will accelerate the transformation from offline modeling to online computation services, e.g., modeling and prediction. Various data analytical methods can be organized in sequences as computation pipelines. However, it is computationally challenging to identify the best one given different needs and contexts from many pipelines in a CMS. Thus, we formulate the selection of pipelines as a recommendation problem to rank and suggest the superior pipelines. A new extended matrix completion method is proposed to match computation pipelines and CMS contexts. An evaluation in 60 datasets and 27 pipelines validates the effectiveness of AdaPipe.

4 - Copula-based Multi-event Modeling and Prediction Using Fleet Service Records

Akash Deep, University of Wisconsin Madison, Madison, WI, 53703, United States, Shiyu Zhou, Dharmaraj Veeramani

Recent advances in information and communication technology are enabling availability to event sequence data from fleets comprising potentially a large number of similar units. We present a novel method for modeling and prediction of such event sequences using fleet service records. The proposed method uses Copula to create the joint distribution of time-to-event variables, where the marginals distributions needed for Copula are obtained through Cox PH regression models. Our method is flexible and efficient in modeling the relationships among multiple events compared to traditional methods.

5 - Decision Support System for Hybrid Additive Manufacturing Implementation

Michael G. Kay, North Carolina State University, Raleigh, NC, 27695, United States, Brandon McConnell, Guha Manogharan

Decision tradeoffs between performance and cost are not unique to the military, but consequences for failure differ. This work presents a decision support system for hybrid additive manufacturing (AM) logistics to address two key decisions: (1) whether to employ AM in a logistics network & (2) how to allocate AM capability within the network. The research establishes a methodology to address these decision points and identify the key tradeoffs between performance (e.g. readiness, lead time, production time, etc.) and costs (e.g. fixed/operating/logistics cost, etc.). Real production data of selected parts from a specific military portfolio is employed to evaluate the benefits of hybrid metal AM.

Co-Chair: Sait Tunc, University of Chicago, Booth School of Business, Chicago, IL, 60615, United States

1 - Treating to the Priority in Heart Transplantation

Sait Tunc, University of Chicago, Chicago, IL, 60615, United States, Burhaneddin Sandikci, Philipp Afeche, William F. Parker

US heart allocation system assigns priorities to waiting candidates based on the therapies they receive, where the severity of therapies used is assumed to measure the urgency of a candidate to receive a heart transplant. It is, however, constantly debated that therapy-based prioritization opens up room for gaming the system. Manipulation of the waitlist priority is even acknowledged by the medical community and there is an active debate on the issue. We propose a novel framework to analytically study the gaming decisions of heart transplant centers, understand when strategic gaming emerges under different competition types, and how it can be prevented within the confines of the current system.

2 - Karda: A Simulator for Kidney Acceptance Rejection Decisions

Masoud Barah, Northwestern University, University of Tennessee, Evanston, IL, United States, mbarah@northwestern.edu, Sanjay Mehrotra

Candidates for the deceased-donor kidneys are in a long waitlist before they are offered an organ. Once offered, a recipient and the physician have a short window to accept or reject the offer. We present a stochastic tree based kidney acceptance/rejection decision simulator to help facilitate the provisional offer acceptance decision making. The simulator incorporates future provisional offers of random quality, arriving at random times. It provides insights into the survival benefit of the current offer against simulated future provisional offers. Moreover, our engine computes a set of metrics that are useful for the patient and the physicians to make an informed decision.

3 - An Empirical Framework for Sequential Assignment: The Allocation of Deceased Donor Kidneys

Nikhil Agarwal, MIT Department of Economics, Cambridge, MA, 02142, United States, Itai Ashlagi, Michael A. Rees, Paulo Somaini, Daniel Waldinger

The theoretical trade-offs in designing waitlist offer systems depend on agent preferences. We propose an empirical framework for analyzing the waiting list for deceased donor kidneys. The model views the decision to accept an organ offer as an optimal stopping problem. Our estimates show that there is substantial match-specific heterogeneity in values. Past reforms to the kidney waitlist primarily resulted in redistribution, with similar welfare and organ discard rates as the benchmark first come first served mechanism. Other theoretical benchmarks also remain far from optimal: we design a mechanism that increases patient welfare by 14.2 percent.

4 - A Queueing Approach to Evaluate the Impact of Conditions of Participation on Organ Discards and Transplant Waiting List Mortality

Mohammad Delasay, Assistant Professor of Operations Management, Stony Brook University, NY, 11733, United States, mohammad.delasay@stonybrook.edu, Sridhar R. Tayur

We investigate waiting list management from the viewpoint of a transplant center in the presence of the conditions of participation (COP). COP penalizes centers with lower-than-expected post-transplant survivals. We model the waiting list as a multi-dimensional queue, which we analyze by proposing accurate truncation bounds of its state space. We show how an inappropriately assigned COP threshold for a transplant center without consideration of its specifications could induce cherry-picking of the candidates and offered organs. We discuss that COP lacks a net benefit approach by focusing only on post-transplant outcomes.

Queues in Emergency Departments

Sponsored: Health Applications

Sponsored Session

Chair: Daniel Ding, UBC, Vancouver, BC, Canada

1 - Priority, Capacity Rationing, and Ambulance Diversion in Emergency Departments

Tianshu Lu, University of Toronto, Toronto, ON, M5S 3E6, Canada, Tianshu.Lu15@Rotman.Utoronto.Ca, Opher Baron, Jianfu Wang

Capacity rationing and ambulance diversion are two important practices in emergency department (ED) management. We model these practices as a two classes non-preemptive priority M/M/c+M queue where high- and low-priority customers correspond to acute and non-acute patients, respectively. We model capacity rationing by reserving k servers to high priority customers, and ambulance diversion by blocking high priority customers from entering the system when the total number of patients is high. We give the first exact results for a multi-server queue with non-preemptive priorities. Numerical results provide insights on the control of capacity rationing and ambulance diversion in EDs.

2 - Dynamic Server Assignment in Multiclass Queues with Shifts, with Application to Nurse Staffing in Emergency Departments

Vahid Sarhangian, University of Toronto, Mechanical and Industrial Engineering (MIE), Toronto, ON, M5S 3G8, Canada, sarhangian@mie.utoronto.ca, Carri Chan

Nurse staffing decisions in emergency departments (EDs) are typically assigned weeks in advance, which can create staffing imbalances as patient demand fluctuates. In this work, we consider the potential benefits of assigning nurses to different areas within an ED at the beginning of each shift. We study the problem of optimal reassignment of nurses to areas by considering a multiclass queueing model of the system. We analyze an associated fluid control problem and use the solution to develop policies that achieve asymptotically optimal performance under fluid-scaling for the original stochastic system. We find this additional flexibility can substantially reduce waiting times for patients.

3 - Wait Time Announcements at Emergency Departments

Marco Bijvank, University of Calgary, Calgary, AB, T2N 1N4, Canada, marco.bijvank@haskayne.ucalgary.ca, Zhankun Sun

Numerous hospitals have started publishing live emergency department (ED) wait times online in an effort to provide patients with expectations on how long they will have to wait to be seen for non-urgent care. The goal of this study is to accurately predict real-time ED wait times. We propose a decomposition approach of continuous-time Markov chains to calculate busy periods as predictor. The applicability and performance of each prediction technique is analyzed based on a case study of an ED in Calgary. Survey results show how announced wait times are used in practice, whereas the potential impact of the different prediction techniques on patient flow care are studied with a simulation model.

4 - Head-of-Line Delay Based Scheduling in Multiclass Queues with Applications to CTAS

Xu Sun, Assistant Professor, University of Florida, Gainsville, FL, United States, xs2235@columbia.edu, Yunan Liu

Motivated by the Canadian triage acuity scale (CTAS), we consider a delay-based prioritization policy for a multi-class queueing system having time-varying arrivals, with the objective of achieving differentiated service levels for all customer class. Specifically, CTAS classifies patients in Canadian EDs into 5 acuity levels, ranging from “resuscitation” (level 1) to “non-urgent” (level 5), with delay targets ranging from 0 to 120 mins and probability of excessive delay ranging from 2% to 20%. Motivated by CTAS, our policy guarantees that each customer class is served with a quality-of-service target based on the tail probability of delay with class-dependent delay and probability targets.

1 - Nursing Home Staffing Decision Support Platform under Heterogeneous and Temporally Evolving Service Demands of Residents

Xuxue Sun, University of South Florida, Tampa, FL, United States, Nan Kong, Hongdao Meng, Kathryn Hyer, Chris Masterson, Mingyang Li

Nursing homes (NHs) are critical healthcare infrastructures for caring frail older adults with 24/7 formal care and personal assistance. Adequate staffing is of great importance to ensure quality of care and desired resident outcomes. Existing healthcare staffing literatures mainly assume homogenous and/or static service demands of patients. This work proposes a NH staffing decision support platform by characterizing heterogeneous, temporally evolving service demands of NH residents via novel integration of statistical modeling, computer simulation and optimization techniques. A case study is also provided to demonstrate the superior performance of the proposed work.

2 - Explainable Learning for Disease Risk Prediction Based on Comorbidity Networks

Qingpeng Zhang, City University of Hong Kong, Kowloon, 12180, Hong Kong, qingpeng.zhang@cityu.edu.hk, Zhongzhi Xu

In this paper, we propose a comorbidity network involved end-to-end trained disease risk prediction model. The adoption of side information and the end-to-end framework together assign both high accuracy and transparency to the model. To demonstrate the prediction performances of the proposed model, a real case study based on three years’ medical histories from the Hong Kong Hospital Authority is considered. Results show that the proposed model exhibits superior prediction performance while learns explainable rules.

3 - Diagnosis of Cardiac Diseases via Higher Order Hidden Markov Model: Application to Personalized Biomedical Radar Data

Ying Liao, Texas Tech University, Lubbock, TX, United States, Yisha Xiang, Changzhi Li

Analysis of heartbeat signals is critical to provide information for the diagnosis of cardiac diseases, e.g., beat detection, segmentation and classification based on electrocardiogram (ECG) signals. Since the ECG data collection requires medical assistance, recently, a new personalized biomedical radar has been devised, which can monitor long-term continuous heartbeat signals. This research applies a higher order hidden Markov model (HOHMM) to identify heartbeat patterns utilizing the collected data, which extends the basic hidden Markov model (HMM) by allowing the hidden health state to depend on its more distant past.

4 - Discharge Control in Congested Nursing Homes Using Markov Decision Process

Zhouyang Lou, Purdue University, West Lafayette, IN, 47904, United States, zlou@purdue.edu, Nan Kong

With the aging population, we are facing a spike in demand for nursing home care. However, nursing homes will experience the insufficient capacity issue due to workforce shortage and resource to community care. Imbalanced supply and demand will lead to congestion in nursing homes and hospitals. To improve patient flow into nursing homes, we consider the problem of finding an optimal discharge policy using Markov decision processes to minimize the wait time taken to be admitted and the rehospitalization risk. We will analyze the benefits as opposed to the situation with no discharge control for different supply and demand scenarios.

5 - Opioid Prescription Optimization Model for Total Joint Replacement Surgery Patients

Sujee Lee, University of Wisconsin-Madison, Madison, WI, 53705, United States, slee776@wisc.edu, Philip A. Bain, Jingshan Li

Opioid overdose has become a public health hazard in the United States. One of the reasons for overdose is over-prescription in hospitals to treat chronic and acute pain. The current guidance in opioid prescription often takes one-size-fits-all prescription approach and rarely considers differences between patients. In this talk, we propose an optimization model that simultaneously classifies patients based on their profiles and opioid use patterns and minimizes remaining opioids to reduce the opioid over-prescription and overdose for total joint replacement surgery patients.

Matrix Estimation, Multi-armed Bandits, and Healthcare Applications

Sponsored: Health Applications

Sponsored Session

Chair: Mohsen Bayati, Stanford University, Stanford, CA, 94305, United States

1 - Matrix Completion Methods for Causal Panel Data Models

Khashayar Khosravi, Stanford University, Stanford, CA, 94305, United States, khosravi@stanford.edu, Susan Athey, Mohsen Bayati, Nikolay Doudchenko, Guido Imbens

A central tool in empirical operations management is the average treatment effect (ATE) estimation from observational data. In this setting, the presence of potential confounders leads to biased estimates of ATE. One way to reduce this bias is to use panel data models where a subset of units is exposed to a binary treatment during some time-periods and the goal is estimating the counterfactual outcomes for all treated units/time-period pairs. We study a class of estimators that minimize the distance between the estimated matrix and the original matrix while favoring less complex models. We prove the consistency of our estimators by extending the existing results in the matrix completion literature.

2 - Matrix Completion Bandit with Healthcare Applications

Carolyn Kim, Stanford University, Stanford, CA, 94305, United States, Mohsen Bayati

We introduce a matrix completion formulation of the multi-armed bandit problem, where we observe some subset of entries of columns that arrive over time and we wish to impute the rest of the entries. This can be used to model the decision-making process of a physician whose chooses lab tests to maximize the information gained from the results while satisfying a budget constraint. We adapt the proof of classical matrix completion results to our bandit setting to show a sublinear regret bound. Experimentally, we demonstrate our strategy performs well against a number of baseline strategies.

3 - Active Synthetic Control

Ruoxuan Xiong, Stanford University, Huang Building Stanford, CA, 94305, United States, rxiong@stanford.edu, Mohsen Bayati, Susan Athey, Guido Imbens

In clustered randomized trials (CRT), experiments are randomized at the group level instead of the individual level to avoid contamination. For example, in a trial comparing different weight-loss programs, patients may meet each other in the waiting room and communicate about their respective strategies. But randomization at the provider level, would reduce the risk of contamination. However, CRTs suffer from low statistical power. In this talk, we combine ideas from synthetic control and active learning to design CRTs that can significantly increase statistical power.

4 - Phase Transitions and Cyclic Phenomena in Bandits with Switching Constraints

Yunzong Xu, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, David Simchi-Levi

We consider the classical stochastic multi-armed bandit problem with a constraint on the total cost incurred by switching between actions. We prove matching upper and lower bounds on regret and provide near-optimal algorithms for this problem. Surprisingly, we discover phase transitions and cyclic phenomena of the optimal regret. That is, we show that associated with the multi-armed bandit problem, there are phases defined by the number of arms and switching costs, where the regret upper and lower bounds in each phase remain the same and drop significantly between phases. The results contribute new insights to this fundamental problem.

5 - Personalizing Many Decisions with High-dimensional Covariates

Nima Hamidi, Stanford University, Stanford, CA, United States

We consider the k-armed stochastic contextual bandit problem with d dimensional features, when both k and d can be large. To the best of our knowledge, all existing algorithm for this problem have a regret bound that scale as polynomials of degree at least two in k and d. The main contribution of this paper is to introduce and theoretically analyse a new algorithm (REAL-bandit) with a regret that scales by $r^2(k+d)$ when r is rank of the $k\times d$ matrix of unknown parameters. REAL-bandit relies on ideas from low-rank matrix estimation literature and a new row-enhancement subroutine that yields sharper bounds for estimating each row of the parameter matrix that may be of independent interest.

Personalized Medicine III

Emerging Topic: Personalized Health

Emerging Topic Session

Chair: Dimitris Bertsimas, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States

1 - Machine Learning Approaches for Stroke

Agni Orfanoudaki, Massachusetts Institute of Technology, Cambridge, MA, 02142, United States, agniorf@mit.edu, Dimitris Bertsimas, Charlene Ong, Amre Nouh, Rebecca Zhang

Modern machine learning methods can leverage data from both observational studies and Electronic Health Records to create personalized risk prediction models. In this talk we will present our work on the development of interpretable non-linear tools for primary stroke prediction as well as natural language processing techniques for the detection of presence, location and acuity of ischemic stroke. We provide a comprehensive framework for structured and unstructured data in the medical setting that can be leveraged in wide range of medical applications.

2 - A Network-based Approach to Drug-target Interactions in Cancer

Holly Mika Wiberg, Massachusetts Institute of Technology, Cambridge, MA, 02144, United States, hwiberg@mit.edu, Dimitris Bertsimas, Agni Orfanoudaki

We propose a novel graph-based optimization approach to modeling gene regulatory networks for the purpose of understanding gene interactions and pathway function in the presence of mutations. We use a maximum flow formulation to evaluate pathway disruption which provides biological insight into the optimal drug targets for a given mutation profile. Empirical results suggest that this approach recovers biologically valid relationships between genes. We extend the work by Bertsimas and Zhuo to incorporate this structured pathway model and demonstrate recovery of new drug-target interactions.

3 - Tensor Completion with Noisy Side Information

Colin Pawlowski, Massachusetts Institute of Technology, Cambridge, MA, United States, Dimitris Bertsimas

We develop a new method for tensor completion which incorporates noisy side information available on the rows and columns of a 3-dimensional tensor. This method learns a low rank representation of the data along with regression coefficients for the observed noisy features. We apply this method to the task of predicting anti-cancer drug response at particular dosages, and we demonstrate significant gains in out-of-sample accuracy filling in missing values on two large-scale anti-cancer drug screening data sets with genomic side information.

4 - Optimal Trees for Estimating Risk of Mortality and Morbidity in Elective Surgery Patients

Katerina Giannoutsou, Massachusetts Institute of Technology, Boston, MA, United States, giannoutsou.kat@gmail.com, Dimitris Bertsimas

Most risk assessment tools assume that the impact of risk factors is linear and cumulative. Using data from The American College of Surgeons National Surgical Quality Improvement Program's database and utilising Optimal Classification Trees (OCT), a novel machine learning technique that combines high accuracy with interpretability, we designed an interactive, non-linear risk calculator to predict postoperative mortality as well as 18 specific complications for patients undergoing four different types of Elective Surgery

5 - Will They Stay or Will They Go? Anticipating Patient Discharges with Machine Learning

Jean Pauphilet, Massachusetts Institute of Technology, Cambridge, MA, United States, jpauph@mit.edu, Dimitris Bertsimas

We investigate how machine learning can provide precise information about patient discharges at a major hospital using data from EHRs. Combining expertise-driven modeling and data analysis tools, we predict with high accuracy (a) daily discharge volume, (b) long-stay patients, (c) discharge destination, (d) administrative delays to discharge. The predictions are made at a patient level, updated daily and currently used to improve daily operations. In this effort, tree-based methods were instrumental because of their interpretability and ability to deal with missing data.

1 - Rapid Search with Gaussian Markov Improvement Algorithm

Eunhye Song, Penn State University, University Park, PA, 16802, United States, eus358@psu.edu, Mark Semelhago, Barry L. Nelson, Andreas Waechter

We introduce rapid-Gaussian Markov Improvement Algorithm (r-GMIA) that models the objective function over a large discrete solution space as a realization of a Gaussian Markov random field. r-GMIA alternates between rapid search and global search phases to balance computational efficiency and search effectiveness using complete expected improvement (CEI) as the sampling guide. At a global search iteration, a set of promising solutions is constructed. During the rapid search iterations, we restrict CEI computations and sampling decisions within the set. Per-iteration computational cost of rapid search phase is negligible compared to that of a global phase resulting a faster search progress.

2 - On the Stability of Kernelized Control Functionals on Partial and Biased Stochastic Inputs

Haofeng Zhang, Columbia University, New York, NY, United States, hz2553@columbia.edu, Henry Lam

We investigate some theoretical properties of kernelized control functionals (CFs), a recent technique for variance reduction, regarding its stability when applied to subsets of input distributions or biased generating distributions. This technique can be viewed as a highly efficient control variate obtained by carefully choosing a function of the input variates inside a reproducing kernel Hilbert space. We show that CFs retain good theoretical properties and lead to variance reduction in some contexts relevant to large-scale stochastic simulation analysis. We also compare these properties with importance sampling, particularly a related type using a similar kernelized approach.

3 - Rare-event Simulation for Gibbs Measures: Properties and Applications of the Infinite Swapping Algorithm

Pierre Nyquist, KTH Royal Institute of Technology, Stockholm, Sweden, pierren@kth.se

Rare-event sampling is a hindrance to efficiently sampling from Gibbs measures, especially in the settings of high dimension or ``low temperature”, where the prevalence of local minima causes slow convergence. Infinite swapping is a Monte Carlo method designed to overcome the problem of rare-event sampling in the setting of computing integrals with respect to Gibbs measures. This talk will focus on properties of infinite swapping and (non-standard) applications - quantum dynamics, machine learning - and the use of empirical measure large deviations and ergodic control problems to study convergence rates for MCMC methods. The talk is based on joint work with Dupuis, Doll, Hult and Ringqvist.

4 - Importance Sampling for General Levy Processes with Heavy-tailed Increments

Chang-Han Rhee, Northwestern University, Chicago, IL, 60613, United States, chang-han.rhee@northwestern.edu, Xingyu Wang

Chen et al. (2019) proposed a strongly efficient rare-event simulation algorithm for a broad class of rare events associated with heavy-tailed random walks and compound Poisson processes. In this talk, we discuss how one can extend the rare-event simulation algorithms in Chen et al. (2019) to deal with general Levy processes.

Chair: Huan Xu, ISyE Ga Tech, Atlanta, GA, 30332, United States

1 - Distributionally Robust Omnichannel Stocking Decisions in Quick-Fulfillment Systems

Hanzhang Qin, Massachusetts Institute of Technology, Cambridge, MA, 02142, United States, hqin@mit.edu, Louis L. Chen, David Simchi-Levi, Huan Xu, Zirun Zhang

This work is inspired by the daily operations of Alibaba’s HEMA supermarket, which manages multiple demand channels (offline, online, etc.). We study how to make a stocking decision for a SKU in advance of uncertain demand arising in several consecutive time frames that is robust to an adversarial coupling of available (marginal) demand distributions by channel and by time frame. We provide both an efficient procedure and analytical characterization of the adversary’s coupling. While the full problem is non-convex, we identify sufficient conditions for convexity, along with a tractable algorithm. Finally, we conduct experiments with HEMA data to evaluate the performance of our approach.

2 - Contextual Linear Bandit under High-dimensional Data via Lasso and Random Projection

Tao Yao, Alibaba, 349 Leonhard Building, Seattle, PA, 16803, United States, taoyao2005@gmail.com

In the era of big data, products’ contextual information is widely available and has accumulated with extraordinary speed. The resulting high- dimensional feature data, however, leads to two major challenges in implementing contextual bandit algorithms in online settings: The poor estimation of high-dimensional feature coefficients with access to limited samples and the high computational time complexity. We propose a contextual linear bandit algorithm under high-dimensional data, the Lasso-RP-Bandit algorithm, by combining the Lasso and random projection to alleviate the computational complexity and ensure its regret performance.

3 - Traffic Shaping – Online Learning and Optimization in E-commerce

Nan Li, Alibaba Group, Hangzhou, China, nanli.ln@alibaba-inc.com

In traffic shaping, a collection of sessions arrive in an online manner, and within each session, we need to make optimal decisions such that immediate reward is maximized while certain constraints over the entire sessions are satisfied. In practice, the constraints can be business operation strategies, this problem has found applications in online businesses. In this talk, we will talk about our recent developments in traffic shaping, including the framework, algorithms, systems. Also, we will share some applications of traffic shaping in e-commerce.

4 - Large-scale Time Series Anomaly Detection via Robust Decomposition

Liang Sun, Alibaba Group, Bellevue, WA, United States, liang.sun@alibaba-inc.com

The exponential increase of streaming data calls for more efficient and low-latency analytics. Anomaly detection, which identifies unusual patterns from data, is crucial in many applications. In this talk, we introduce an anomaly detection framework based on decomposition for time series data. Compared with the widely used forecasting-based anomaly detection algorithms, our method is robust to noisy data and outliers. Our framework can detect different types of anomalies, including spikes and dips, change of mean, change of variance, and long-term monotonic trend. Our experiments on real-world benchmark datasets demonstrate the effectiveness and efficiency of our method. applications.

5 - Optimal Sequencing of Heterogeneous, Non-instantaneous Interventions

Kai He, Alibaba Inc, Bellevue, WA, United States, kai.he@alibaba-inc.com, Oleg A. Prokopyev, Lisa M. Maillart

Consider a stochastically deteriorating system that generates reward at a rate that depends on its condition. There are three heterogeneous interventions/actions that can be performed. Two of these are one-time interventions, each of which is either ineffective or effective with some known probability after a specific delay period. The third intervention is palliative in nature, and has no effectiveness delay. To maximize the total expected reward, we examine the problem of optimally sequencing these interventions to simultaneously balance three inherent trade-offs: the time until (potential) effectiveness is revealed, probability of effectiveness, and cost.

6 - Secondary Market Mitigates Demand Uncertainty

Jian Lou, Kirkland, WA, 98033, United States

In this paper, we study how a free-trading secondary market could mitigate players’ demand uncertainty in the primary market. We consider the following setting: a resource manager is allocating resources to some autonomous players with uncertain demands. These players report their orders to the manager, pay, and receive requested resources before the demands have been realized. These players also have stipenalties for failing to subsequently fulfill the demand, which creates incentives for players to over-request the resources. However, the resulting behavior by individuals imposes unnecessary costs on the system. As a means to mitigate this issue, we introduce a secondary market that allows players to trade resources after demand uncertainty has been resolved. To analyze the impact of the secondary market on the player resources requesting behavior, we model the setting as a two-stage game, with the first stage identical to the newsvendor model, and the secondary market taking place in the second stage. We mainly consider a large market, which we analyze asymptotically as the number of players n tends to infinity. We find that an individual’s inuence on the price in the secondary market is O(1/sqrt(n)) and the expected price in equilibrium in the secondary market is equal to the price in the primary market as the number of players approaches innity. Signicantly, we find that the social welfare is within O(sqrt(n) of optimal, in contrast to a game with no secondary market, which exhibits Theta(n) difference to the optimum.

1 - Consistent Probability Assignments in Two Player Contests with Maximum Entropy

Christopher Gaffney, Drexel University, Philadelphia, PA, United States, ctg39@drexel.edu

We consider the problem of determining probabilities in contests involving two players. We assume that each player's overall winning percentage is known and that the players have had at least some common opponents. A nonlinear programming model is used to determine, for each pair of players, the probability that one defeats the other. The constraints correspond to various consistency needs of the ensuing probability assignments, while the objective is to maximize the entropy of the probability distributions resulting from the problem.

2 - Predicting Injuries Through the Use of Force Plate and Strength and Conditioning History

Kiatikun Louis Luangkesorn, Assistant Professor, University of Pittsburgh, Pittsburgh, PA, United States, lluangkesorn@pitt.edu, Yiqi Verna Tian, Yuezhe Wendy Wang, Tharunkumar Amirthalingam

The goal of a university strength and conditioning program is to minimize the risk of injury for student-athletes while improving athletic performance for the athlete's sport. The is accomplished through individually programming exercises using multiple modalities and variety. We use both the force plate assessments over time as well as the athlete's strength and conditioning programming history as inputs to a predictive model to predict injury risk for student-athletes, with the goal of using the model to motivate assessments by coaches to prevent the injury from occurring.

3 - Normalization Strategies and Development for Improved NCAA Basketball Tournament Predictions

Jessica M. Rudd, PhD Candidate, Kennesaw State University, Kennesaw, GA, United States, jess@irudd.com

The study utilizes various normalization techniques for NCAA basketball tournament prediction. Baseline models using tournament seeds, several popular sports ranking methods, regular season game statistics, and tournament results, dating back to 1985 where available, are compared with results using several normalization strategies, including approaches not known to be tested on this problem as well as a novel season rank-based approach. Baseline models predicted previous tournament wins with accuracy as high as 76%. Normalized model brackets performed as high as 97% accuracy in the 2019 tournament.

4 - Probabilistic Models Focusing on the Scoring Order in a Sports Match

Kengo Hamada, Keio University, Yokohama, Japan, kengo.hamada@keio.jp, Ken-ichi Tanaka

Sports matches have been subjected to extensive mathematical analyses, and most previous studies have focused mainly on match outcomes (e.g., the final score or win-loss records). On the other hand, as a new attempt, we focus on the process up to that: scoring order in which two competing teams score as the match progresses. For example, we formulate the probability of the favorite team falling behind the opposing team but then making a comeback, which is introduced based on lattice path enumeration. We also present some variants and extensions of the proposed model.

5 - Planning for a New Soccer Stadium: A Real Options Approach

Carlos Abreu, Federal University of Rio Grande do Norte State (UFRN), Natal, Brazil, calexandreabreu@ect.ufrn.br

Real Options valuation models are used in financial analysis in scenarios with high uncertainty. This decade has been important in the development of new soccer stadiums for Brazilian clubs. The decision-making on the construction of sports arenas have an elevated uncertainty due to the uncertain impacts on game day future revenues. Using Real Options with the proper forecasting data on expected revenues and prices permits the estimation of an optimal investment return considering the expectation created on fans regarding the new arena and its effects on the clubs revenues.

1 - Wisdom of Crowds and IPO Hype Cycle

Alvin Leung, Assistant Professor, City University of Hong Kong, Hong Kong, acmleung@cityu.edu.hk

This paper investigates when wisdom of the crowds fails on social media. When information becomes one-sided and online users tend to follow the crowds, investors are likely to be herded and stock price is likely to experience abrupt change. By observing online chatters, we may observe whether such phenomenon occurs. Analyzing over 10-year data of 1000 IPO stocks from StockTwits, we find that we can foreshadow the occurrence of failure of wisdom of crowds from social networks and online chatters. We can make use of the data to predict the IPO hype cycles. Our study has important implications to existing literature on social media and stock returns predictions.

2 - An Empirical Examination of Cryptocurrency and Online Peer-to-peer Lending Markets

Keong Tae Kim, Chinese University of Hong Kong, Shatin, Hong Kong, keongkim@cuhk.edu.hk, Sunghun Chung, Chulho Lee

We study the effect of cryptocurrency markets on borrowers in peer-to-peer (P2P) lending markets. By using the combined data from both markets during the period January 2017 to February 2019, we provide several novel findings. Our results indicate that the growth in cryptocurrency markets is associated with a large amount of loan requests in the P2P market. This complementarity is strong for borrowers who have good credit grades and are likely to have further knowledge of and might use the borrowed money for investing in the cryptocurrency market. Furthermore, the growth in cryptocurrency markets is not associated with a decrease in the loan quality.

3 - Social Comparison and Social Fitness Network Evolution

Ben Choi, Nanyang Technological University, Singapore, Singapore

Social fitness apps have become a cost-effective way to promote regular physical activity. This research proposal intends to draw on the social comparison theory to investigate the longitudinal usage of social fitness apps. We posit that similarity and dissimilarity in exercise performance between a user and others will influence the likelihood of forming new social connections, maintaining existing social ties, and user's subsequent exercise performance. To operationalize the study, we constructed a panel data using a popular social fitness app. Exponential random graph model and latent growth model were constructed to analyze the data.

4 - Software Development Kit Network and Mobile App Success

Yu Xia, The University of Hong Kong, Hong Kong, yuxia0230@gmail.com, Chen Hailiang

The adoption of third-party Software Development Kits (SDKs) in mobile app development is becoming increasingly popular. While the impact of SDKs on app success has not been well examined. This study aims to quantify the effect of SDK adoption on mobile app performance and in particular focuses on the role of SDK network. Our dataset covers all mobile apps released on both Apple App Store and Google Play from 2008 to 2018. Mobile app performance is measured by the number of app downloads and revenues. We use the number of apps that install two SDKs at the same time to denote the strength of the SDKs' connection. Our findings would help app developers better understand the role of SDKs in mobile app development.

5 - Ladies First, Gentlemen Third! The Effect of Narrative Perspective on Medical Crowdfunding

Xitong Li, Associate Professor, HEC Paris, 1 rue de la Liberation, 78351, France, lix@hec.fr

In practice, a majority of medical fundraising campaigns are narrated from the third-person perspective without knowing whether it is the most effective approach or not. We propose that the relative effectiveness of the first- vs. third-person perspective depends on patient gender. To test the hypotheses, we conduct a randomized field experiment on a leading medical crowdfunding platform, involving more than 1.2 million potential donors. The results show that the third-person perspective is more effective in motivating donation-related behaviors for male-patient fundraising campaigns, whereas the first-person perspective is more effective for female-patient fundraising campaigns.

Chair: Pelin Pekgun, University of South Carolina, Columbia, SC, 29205, United States

1 - Modeling Human Decisions in a Dynamically Coupled Natural and Human Systems Framework to Develop Freshwater Sustainability Policies

Jessica L. Heier Stamm, Kansas State University, Manhattan, KS, 66503, United States, jlhs@k-state.edu, Gabriel Granco, Jason S. Bergtold, Matthew R. Sanderson, Marcellus M. Caldas, Steven M. Ramsey

Culture is an important factor influencing human decisions about freshwater conservation policies. Despite this, most human decision models embedded in coupled natural and human system frameworks adopt a purely economic approach. We describe an agent-based simulation model that employs the values-beliefs-norms socio-psychological theory to represent stakeholders' decisions to support sustainability policies based on explicit feedbacks between humans and their environment. The model is applied to the Smoky Hill River Watershed in the U.S. Great Plains, where it enables insights about freshwater sustainability policies and their impacts on the coupled systems.

2 - Mechanism of Donation in Humanitarian Sector

Mahyar Eftekhar, Arizona State University, Tempe, AZ, 85287, United States, eftekhar@asu.edu, Iman Parsa, Charles J. Corbett

Humanitarian organizations (HOs) rely heavily on donations. Using a panel data from over 100 US-based HOs between 2000 and 2014, we examine the impact of fundraising investment, program spending ratio, transparency, media exposure, and program diversity on humanitarians' donation income. Based on the existing theories, we illustrate what mechanism of donation is dominant in this sector, and whether or not humanitarian organizations can adopt policies to increase their income.

3 - The Impact of Service Level on Inventory Decisions

Sebastian Villa, University of Los Andes, Cra. Bogota, Colombia, s.villab@uniandes.edu.co, Jaime Andres Castaneda, Gloria Urrea

We study the fundamental tradeoff in inventory management between inventory costs and service level to satisfy customers. This tradeoff is critical in settings like humanitarian operations, in which failing to provide a high service level could mean the loss of lives. We derive the optimal policy using a newsvendor framework, imposing a service level and the cost associated with filling this target if running out of stock. We next design an experiment to study how subjects place orders in a high-profit inventory task, varying understock costs and service levels. Compared with low service levels, results show that high service levels lead to improved orders when understock costs do not exceed revenues.

4 - Analyzing Drivers Behind Food Waste in Food Banks

Fan Zou, University of South Carolina, Columbia, SC, United States, Fan.Zou@grad.moore.sc.edu, Luv Sharma, Pelin Pekgun, Sanjay L. Ahire

This study identified factors contributing to food waste in food banks and operational decisions that can reduce waste.

Business Transformation in the Age of Analytics

Sponsored: Information Systems

Sponsored Session

Chair: Ling Xue, Georgia State University, Atlanta, GA, 30302, United States

1 - Regulating Professional Player in Peer-to-peer Markets: Evidence from AirBnB

Wei Chen, University of Arizona, Tucson, AZ, 85718, United States, weichen@email.arizona.edu, Zaiyan Wei, Karen Xie

The influx of "professional players"—large companies or powerful individuals—in peer-to-peer (P2P) platforms has been widely documented. Yet the impacts of these professional players and whether platforms should regulate their participation are largely unanswered. Utilizing a unique policy change on Airbnb, we evaluate the role of professional players on market structure and transaction efficiency in peer-to-peer markets. We find that restricting institutionalized players leads to mitigation in market concentration. Consequently, it increases consumer welfare by lowering the equilibrium price and improving service quality.

2 - An Empirical Analysis of User Satisfaction with Chatbots

Ling Xue, Georgia State University, Department of Computer Information Systems, J. Mack Robinson College of Business, Atlanta, GA, 30302, United States, Cheng Zhang, Xia Zhao

The use of AI-enabled customer service systems is often associated with risks and uncertain customer satisfaction. In this study, we use operational level data of customer service chatbots to develop insights about how chatbots may affect both the productivity of human customer support representatives and the satisfaction of individual customer. Our findings suggest that while the use of chatbots may not necessarily increase the overall efficiency of the customer service process, it can effectively reduce the burden for human representatives. Also, we find that while more experienced customers are more likely to report declined satisfaction possibly because of their higher expectations.

3 - Disentangling the Effect of Longitudinal Consumer Reviews on Professional Service

Hongfei Li, School of Business, University of Connecticut, Storrs, CT, United States, hongfei.Li@uconn.edu, Jing Peng, Gang Wang, Xue Bai

Online diaries are series of posts generated by consumers in chronological order to record their post-consumption experience over time. This paper empirically investigates whether providing follow-ups in online diaries affects the sales of professional services, and how this impact is moderated by the perceived risk and the quality of service. We find that providing follow-ups has a positive effect on the sales. The effect is weaker for high-quality service. Interestingly, this effect is asymmetric for service with high and low perceived risks. Our findings provide important implications for both platform owners and service providers.

Optimization Applications in Engineering and Industry

Sponsored: INFORMS Section on Practice

Sponsored Session

Chair: Aristotelis E. Thanos, GE Global Research Center, Glenville, NY, 12302, United States

1 - Activity Assignment and Routing of Field Personnel in Zillow Offers Business

Suleyman Karabuk, Zillow, Seattle, WA, 98109, United States

Zillow Offers business buys and sells homes as a service. An acquired home is renovated before it is put on the market under the Zillow brand name. Each renovation is managed by an assigned Superintendent (SI), who visits a home several times during the process. On a daily basis Zillow routes a team of SIs to visit homes subject to time window constraints. These decisions are constrained by the prior assignment of homes to SIs. We solve a combined multi-day assignment and one-day routing problem, which compared to manual decision making saves thousands of miles per month.

2 - Workforce Deployment Planning in GE Healthcare

Nitish Umang, GE Global e deployment in a GE healthcare application.

Please check the mobile app for this abstract.

3 - Prescriptive Decision Support for GE Fleet, Maintenance, Repair and Overhaul

Aristotelis E. Thanos, GE Global Research Center, 408 Reserve Cr, Glenville, NY, 12302, United States

We present a prescriptive analytic platform for decision support in the GE aviation industry targeting to reduce jet engine lease cost and aircrafts on ground for our customers. Our platform targets both optimal decision for managing aircraft fleet and capacity optimization in our overhaul shops.

Location Analysis II

Sponsored: Location Analysis

Sponsored Session

Chair: Pawel J. Kalczynski, California State University-Fullerton, Fullerton, CA, 92834-6848, United States

Co-Chair: Zvi Drezner, California State University-Fullerton, Fullerton, CA, 92834, United States

1 - Self Organized Carpools with Hubs

Malgorzata Miklas-Kalczynska, California State University-Fullerton, Fullerton, CA, 92834-6848, United States, mmiklas-kalczynska@fullerton.edu, Pawel J. Kalczynski

We incorporate optional hubs into two types of carpooling problems. We provide a theoretical analysis of neighborhoods for problems with and without hubs and use the findings to formulate enumeration models. We test the new models on simulated problem instances using a decentralized self-organization heuristic and a centralized optimization algorithm. Our findings show that introducing hubs increases carpool participation and produces savings. We demonstrate that self-organized carpools, which maximize individual savings, are comparable with centralized solutions, optimized for system-wide savings. Additional savings from hubs depend on the type of the carpooling problem.

2 - Multiple Obnoxious Facilities Location: A Cooperative Model

Pawel J. Kalczynski, California State University-Fullerton, Fullerton, CA, 92834-6848, United States, PKalczynski@fullerton.edu, Zvi Drezner, Tammy Drezner

A given number of communities exist in an area. Several obnoxious facilities, such as polluting factories need to be located in the area. The nuisance emitted by the facilities is cumulative. The objective is to minimize the nuisance inflicted on the most affected community. This problem is useful for planners who frequently face this problem of locating obnoxious facilities and have no good way to determine a good set of locations for these facilities. A multi-start approach by the SNOPT and IPOPT solvers in Matlab gave poor results. However, an innovative, specially designed Voronoi based heuristic produced much better results in a small fraction of the run time.

3 - Computational Results for Solving the Euclidean Distance Min-max Location Problem with Fixed Distances in N-dimensions Using a Dual Algorithm

Mark Cawood, Senior Lecturer, Clemson University, Clemson, SC, 29634-0975, United States, cawood@clemson.edu, Lin Dearing

Computational results for the dual algorithm are presented for the problem, also called the minimum covering Euclidean ball of a set of Euclidean balls in n-dimensions. The algorithm searches along a directed path that is a ray, a hyperbola, or an ellipse. The step size is computed explicitly at each iteration.

4 - Maximal Covering Location with Ellipses

Sergio Garcia Quiles, University of Edinburgh, School of Mathematics, James Clerk Maxwell Bldg, King's Building, Edinburgh, EH9 3FD, United Kingdom, sergio.garcia-quiles@ed.ac.uk, Victor Blanco

In a covering location problem there is a set of demand points and a set of potential sites for locating facilities. A point is covered by a facility only if it is within a certain distance from the facility. These problems have applications in areas like the location of emergency services or nature reserve selection. In the Maximal Covering Location Problem introduced in the 1970s, a fixed number of facilities must be located so that the amount of covered demand is maximized. The geometric shapes used to cover the demand points are circles. Motivated by applications to Wireless telecommunications networks, in this talk we will present a variant of this problem where the covering shapes are ellipses.

Flash Session I

Flash Session

Chair: Iris Moryossef, Hadassah Academic College, Harel 99740, Jerusalem, 99740, Israel

1 - Religious and Consumer Behavior of the First Time Mother

Iris Moryossef, Senior Lecture, Hadassah Academic College, Jerusalem, Israel, rsgernter@gmail.com

Among the features including in the culture of the consumer effecting its consumer behavior, religious is one of the most powerful factors (Shukor, & Jamal 2013). Religious as a part of culture is a dramatic feature that takes place during transition in the life cycle of the person including motherhood Motherhood is a major transition in the women's life were the changes are physical, emotional and behavioral. The mother to come is changing her consumption decision process, information collection and brand evaluation (Gertner 2014) In this article we will examine the culture of new mothers in the religious Orthodoxy culture in Israel and its implication.

2 - A Branch-and-price Algorithm for the Integrated Production Scheduling and Delivery Routing Problem with a Product

Peiyang He, Huazhong University of Science & Technology, WuHan, China

In this paper we study the integrated production scheduling and delivery routing problem, which is NP-hard in the strong sense. In the production stage, the manufacturer has to produce a set of products on a single machine with constant production rate. In the distribution stage, there are a given number of homogeneous vehicles with limited capacity. The objective is to minimize the sum of waiting time of all customers. We propose a new set-covering formulation and present a branch-and-price algorithm for solving this problem. The computation results show that, the proposed formulation and algorithm are efficient.

3 - A Classification Algorithm Based on Consumer Segmentation for Online Purchase Forecast

Xinxin Ren, Huazhong University of Science and Technology, Wuhan, China, renxinxin@hust.edu.cn, Xianhao Xu

In the era of big data, lots of historical consumption data can be used to predict consumers' purchase behavior and target marketing. However, low active consumers are prevalent in the online market, each of them generates several action records and rarely purchase. So, there is larger amount of negative data (no purchase) that may cause imbalance data and have adverse effect for prediction. Therefore, we propose a hybrid algorithm where we segment consumers into low active and high active segments, then establish predictive models for each segment. Finally, we compared the performance of proposed model with the benchmarks, and the result indicates that the performance is improved.

4 - A Conceptual Framework for Calculating the Return on Investment for Continuous Improvement

Mahmoud Al-Odeh, Bemidji State University, Bemidji, MN, United States, malodeh@bemidjistate.edu

The methodology of calculating the return on investment (ROI) of continuous improvement (CI) activities will be explained. The framework consists of three segments, which will be connected to financial factors. The presenter will show the use of the cost and benefits factors and convert them into factors to measure the effectiveness of CI activities. Different strategies for calculating ROI for CI will be discussed. The audience will be provided with specific factors and excel templets to conduct the ROI analysis. This framework is used to track the financial aspects of process improvements and organizations use it to improve their returns on investment. Cases will be shared with the audience.

5 - A Framework for Analyzing the U.S. Coin Supply Chain

Yiwei Huang, Pennsylvania State University, Sharon, PA, United States, yuh201@psu.edu, Yunxia Zhu, Subodha Kumar, Bala Shetty, Chelliah Sriskandarajah

We study a coin supply chain problem to provide a near-optimal or an optimal operating policy that minimizes the total cost of producing, supplying, and managing coin inventory in the U.S. Coin Supply Chain. The extensive tools and insights developed in this study may prove to be beneficial to the Federal Reserve's Cash Product Office (CPO) that manages the distribution of the nation's coin inventory. The robust optimization framework and the resulting insights presented in this paper could potentially help the CPO to manage demand uncertainty and achieve its cost reduction goals. The paper demonstrates a modeling approach that can also be used for managing similar coin supply chains around the world.

6 - Reducing Preventable Hospital Readmissions for Long Term Care

Emily Garcia, University of California-Berkeley, Berkeley, CA, United States, emilygarcia1216@berkeley.edu

We present an approach to determine risk factors and utilization costs associated with hospital admissions and readmissions originating from long-term care (LTC) facilities for post-acute care. Indiana Medicaid and Minimum Data Set data were used in the analysis. The risk model was used in the development of a discharge support tool in order to reduce unnecessary LTC readmissions.

7 - A Flow-Based Network Robustness Metric

Mohammad Najarian, University of Houston, Houston, TX, United States, mohammad.najarian@gmail.com, Gino J. Lim

Resilience of a single commodity network flow can be improved by increasing the capacity of components and improving the topology of the network. Several studies characterized the key elements in a robust network using the centrality measures. In this study we introduce a new flow- based centrality measure that and a novel functional connectivity matrix that can be used to design a more resilient network against cascading failure.

8 - A New Cluster Validity Index in Feature Space

Changwan Ko, Chonnam National University, Gwangju, Korea, Republic of, kcw7536@naver.com, Youngseon Jeong

This paper proposes a new cluster validity index(CVI) in which the compactness and separation of a cluster is measured in the kernel space by using kernel functions to overcome the noise sensitivity for arbitrary shapes, sub-clusters, and noise in data. The proposed CVI is evaluated through a series of experiments and shows that the proposed method can successfully determine the correct cluster number for most cases.

Operations Management III

Contributed Session

Chair: Gulsah Hancerliogullari Koksalmis, Istanbul Technical University, Macka Campus Faculty of Management, Department of Industrial Engineering, Istanbul, 34367, Turkey

1 - Hotel Room Assignment Optimization

Andrew Vakhutinsky, Oracle Labs, Burlington, MA, United States, andrew.vakhutinsky@oracle.com, Setareh Borjian Boroujeni

We describe our work on hotel room assignment for the given set of room reservations made for different room categories. In order to alleviate the overbooking in the basic categories, the hotel operator may upgrade the rooms for more valuable guests. In addition, each room may have its own features that should match the guest preferences as close as possible. We formulate the hotel room assignment problem as multicommodity flow problem with integer variables and compare various solution approaches including Lagrangian relaxation and Dantzig-Wolfe decomposition using the real hotel booking data. We also share the lessons learned from implementing the optimization methods in the production system.

2 - Set Asides for Small Businesses in Public Procurement: Evidence from Federal Government Research & Development Contracts

Dwaipayan Roy, University of Minnesota, Minneapolis, MN, United States, Anant Mishra, Kingshuk K. Sinha

Preference programs in public procurement encourage the participation of specific types of contractors in the government contracting process. However, such programs may not always lead to the selection of the most qualified contractor to execute a contract. We examine the performance outcomes of R&D contracts that have been awarded preferentially to small businesses by the U.S. federal government. We also investigate how contractor experience and contract type influence the relationship between a contract’s set aside status and its performance outcomes. Study findings offer insights on how the federal government can simultaneously accomplish its welfare and efficiency maximization goals.

3 - An Effective Matheuristic for the New Large-scale Task Assignment Problem

Haichao Liu, Northwestern Polytechnical University, Xi’an, China, z929880965@126.com, Yang Wang, Haibo Wang, Abraham P. Punnen

We propose a three-stage matheuristic to solve a new task assignment model with the significantly increased number of variables and constraints. The initial phase decomposes the problem into a sequence of sub-problems, each of which is solved by GUROBI to quickly obtain a feasible solution. The intensification stage repeats performing variable fixation and MIP model solving until a local optimum is reached. The diversification phase solves such a modified model that adds a distance component into the objective. Experimental comparisons with GUROBI indicate that the proposed matheuristic is able to obtain better solutions, where the computational time is reduced by an order of magnitude.

4 - Should We Wait Before Outsourcing? Analysis of a Revenue-generating Blended Contact Center

Benjamin Legros, EM Normandie, Paris, France, benjamin.legros@centraliens.net, Oualid Jouini, Ger Koole

We consider a revenue-generating call center with inbound and outbound calls, where service and sales activities are blended. Two levels of control are exercised; agent reservation for inbound calls and call outsourcing. We consider an optimal control problem for maximizing the call center’s revenue. We investigate the strategy of outsourcing customers who have waited already, as opposed to outsourcing at arrival. We prove that the optimal policy for reservation and outsourcing is of threshold type. Our main conclusion is that outsourcing customers after letting them wait in-house generates higher revenue than outsourcing calls at arrival. However, it is also detrimental to service quality.

5 - Factors Influencing the Adoption of Bitcoin: An Empirical Study in the United States

Gulsah Hancerliogullari Koksalmis, Istanbul Technical University, Istanbul, Turkey, ghancerliogullari@itu.edu.tr

The aim of this research is to investigate and incorporate variety of factors affecting people’ behavioral intention to use Bitcoin. The technology acceptance model (TAM) and the perceived risk theory (PRT) were integrated to propose a theoretical model. The data was collected from the participants at the North American Bitcoin Conference, a part of “World Blockchain Forum: Investments & ICOs” which took place in the United States, in January 2018. The implications of the outcomes are discussed, and suggestions for future research are made.

Scheduling I

Contributed Session

Chair: Thomas Lavastida, Carnegie Mellon University, Pittsburgh, PA, 15232, United States

1 - A Two-Stage Fast Heuristic for Food Delivery Route Planning Problem

Huanyu Zheng, Meituan-Dianping Group, Beijing, China, zhenghuanyu@meituan.com, Shengyao Wang, Ying Cha, Feng Guo, Jinghua Hao, Renqing He, Zhizhao Sun

Online food-delivery platforms are expanding choice, allowing customers to order from a wide variety of restaurants. As an industrial level technology, route planning algorithm is required to be fast enough. This paper proposes a two-stage fast heuristic for route planning, which solves the problem at millisecond level. To speed up the algorithm, we further utilize geographic information so that invalid search attempts are prevented. Finally, we compare our algorithm with brute-force algorithm and several state-of-the-art algorithms to show its effectiveness and efficiency.

2 - Scheduling Trucks at a Cross-docking Facility Using Parallel Evolutionary Algorithms: A Delayed Start Concept

Maxim A. Dulebenets, Florida A&M University-Florida State University, Tallahassee, FL, United States, mdlbnets@gmail.com

Cross-docking facilities have been widely used in supply chains. This study aims to enhance scheduling of the arriving trucks at a cross-docking facility and proposes a Delayed Start Parallel Evolutionary Algorithm. The algorithm launches separate Evolutionary Algorithms on its islands sequentially and exchanges the good-quality solutions among the active islands based on certain adaptive migration criterion. The numerical experiments demonstrate superiority of the proposed algorithm in terms of the major algorithmic performance indicators against the alternative metaheuristic algorithms.

3 - Supply Chain Scheduling with Fixed Time Interval Supplies

Guohua Wan, Shanghai Jiao Tong University, Shanghai, China, ghwan@sjtu.edu.cn, Xueqi Wu

We consider a supply chain scheduling problem with fixed time interval supplies, where the materials/components for production are only supplied at fixed delivery dates. The objective is to minimize the sum of job flowtime (representing work-in inventory) so as to minimize the inventory holding costs. We develop a branch and pricing algorithm to solve the problem, employing various techniques to speed up the solution process and conduct comprehensive computational experiments to test the performance of the algorithm. The computational results show that our algorithm can solve the problem with reasonable size to optimality in short times.

4 - Development of Scheduling Algorithms for a Crowdsourced Delivery Persons

Juntaek Hong, POSTECH, Pohang, Korea, Republic of, Myungho Lee, Kyungduk Moon, Kangbok Lee

In last decades, e-commerce has changed the logistics environment into much more competitive and time critical. Furthermore, as people want to have grocery or food to their doors in daily bases, demands for local delivery service has also increased. A service provider of crowdsourced delivery system wants to find an incentive mechanism or an operational policy to manage revenue and expand their business. Prior to the decision, they should understand how delivery persons would actually behave when demand and incentive are disclosed. This study suggests a mathematical model for the delivery person’s scheduling problem that optimizes their own profit under crowdsourcing environment.

5 - Online Load Balancing via Learned Weights

Thomas Lavastida, Carnegie Mellon University, Pittsburgh, PA, United States, tlavasti@andrew.cmu.edu, Silvio Lattanzi, Benjamin Moseley, Sergei Vassilvitskii

The use of machine learning and predictive models have produced a revolution in science and engineering. Online optimization problems are a natural source of uncertainty that predictions can be used to manage and improve performance. This paper studies how predictive techniques can be used to break through worst case barriers in online scheduling. The make-span minimization problem on unrelated machines and its special case, restricted assignment, are classic problems in online scheduling theory. In this paper we construct non-trivial predictions for these problems and design algorithms that utilize these predictions to compute solutions online.

Applications in DEA

Emerging Topic: Productivity, Efficiency and Data Envelopment Analysis

Emerging Topic Session

Chair: Ole Bent Olesen, University of Southern Denmark, Odense, 5230, Denmark

1 - Benchmarking and Regulation of Electricity Network Companies - Scale Assumptions and Potential for Strategic Mergers

Endre Bjorndal, NHH Norwegian School of Economics, Bergen, Norway, endre.bjorndal@nhh.no, Guanqing Wang, Terje Vassdal, Mette Bjorndal

Electricity network operators are natural monopolies and therefore often regulated. An example is the yardstick regulation model used by the Norwegian regulator, based on DEA-CRS benchmarking. Agrell & Teusch (2016) show that mergers between peers can change the comparison set for inefficient companies to their advantage, and companies may therefore pursue cost-increasing mergers that decrease social welfare. We discuss how alternative scale assumptions in the benchmarking model will influence the potential for such "peer" effects. We use data for Norwegian electricity distribution companies to illustrate our discussion.

2 - Incentives for Optimal Scale in the Regulation of Electricity Distribution Companies

Guanqing Wang, UiT The Arctic University of Norway, Tromsø, Norway, Endre Bjørnda

Electricity network companies are natural monopolies and are therefore often under regulation. An example is Norway, where yardstick regulation combined with data envelopment analysis (DEA) has been applied since 2007. The regulator's choice of scale assumption in the benchmarking model, e.g., constant returns to scale, will affect the network companies' incentives for structural reform. We discuss how alternative scale assumptions would affect the companies and their customers. We study how the relative profitability of companies in different size classes, as well as network charges for their customers, would be affected. Our discussion is based on data of Norwegian distribution companies.

3 - A Review of the Use of DEA in Accounting

Julie Harrison, University of Auckland, Department of Accounting & Finance, Auckland, 1142, New Zealand, j.harrison@auckland.ac.nz, Lily Chen, Fred Ng, Paul Rouse

DEA has become increasingly popular with accounting researchers and has been used to examine a range of issues, including audit firm productivity and the benchmarking of company performance using DEA. This paper critically reviews the accounting DEA literature to identify how and why DEA is used to answer accounting, as distinct from economic, research questions. The paper evaluates the constructs used and variables chosen and identifies potential application issues.

4 - Developing a Conceptual Foundation for 'Financial DEA'

Claire Cui, University of Aukland, Aukland, New Zealand, J ulie Harrison, Fred Ng

Recent years have seen the emergence of research measuring aspects of firm performance using 'Financial DEA', that is, models that only incorporate financial data. However, DEA conventionally uses physical data to measure productivity, underpinned by economics productivity theory. This study uses a summarised structured literature review and simulated data to examine (1) conceptual aspects of firm performance measured by 'Financial DEA'; and (2) methodological issues in 'Financial DEA' application.

Joint Session Agriculture/Practice Curated: Uncovering Opportunities: How the Syngenta Crop Challenge Sparked Innovation in Agriculture

Emerging Topic: Agriculture

Emerging Topic Session

Chair: Greg Doonan, Syngenta, Slater, IA, 50244, United States

1 - Syngenta Crop Challenge and its Impact

Greg Doonan, Syngenta, Slater, IA, 50244, United States

Syngenta and the Analytics Society of INFORMS partnered in 2015 to launch the Syngenta Crop Challenge. Now in its fifth year, the Syngenta Crop Challenge in Analytics has brought awareness and excitement to the challenges and needs within agriculture. The agriculture industry delivers the world's food supply and by collaborating with INFORMS we have been able to engage the analytics community to identify new inter-disciplinary ways to tackle the challenges of feeding a growing population sustainably. Listen to past finalists discuss their work, what the competition has meant to them and their organizations and how their work has driven innovation in agriculture.

2 - Hierarchical Modeling of Seed Variety Yields and Decision Making for Future Planting Plans

Huaiyang Zhong, Stanford University, Stanford, CA, 94305, United States, hzhong34@stanford.edu

Eradicating hunger and malnutrition is a key development goal of the twenty first century. This paper addresses the problem of optimally identifying seed varieties to reliably increase crop yield within a risk-sensitive decision-making framework. Specifically, a novel hierarchical machine learning mechanism for predicting crop yield (the yield of different seed varieties of the same crop) is introduced.

3 - Novel Research Directions at Biosense Institute Sparked by Syngenta Crop Challenge

Oskar Marko, BioSense Institute, Novi Sad, Serbia, oskar.marko@biosense.rs, Sanja Brdar, Gordan Mimic, Marko Pani, Milica Brkic, Vladimir Crnojevic

BioSense Institute has a continuity of participation in Syngenta Crop Challenge, where we won the 1st prize in 2017 with an innovative solution for the optimal distribution of seeds across the American Midwest and came 4th and 3rd in 2016 and 2019. Based on the datasets provided by Syngenta we developed advanced machine learning algorithms for yield prediction, seed selection, characterisation of maize hybrids and model explanation. The challenge allowed us to better understand the practical problems that farmers, breeders and retailers are facing and to see how state-of-the-art technology can be employed for their solution.

4 - Combining Expert Knowledge and Neural Networks to Model Environmental Stresses in Agriculture

Jannis Schuecker, Fraunhofer Gesellschaft, IAIS, Sankt Augustin, Germany

Despite the great successes of machine learning, it can have its limits when dealing with insufficient training data. A potential solution is to incorporate additional knowledge into the training process which leads to the idea of informed machine learning. Based on an extensive research survey we establish a taxonomy that considers the kind of additional knowledge, its representation, and its integration into the machine learning pipeline. We use this methodology to combine agricultural expert-knowledge with representation learning capabilities of neural networks to model environmental heat and drought stress. This approach allows us to identify resistant corn hybrids.

Collaboration in Innovation and New Ventures

Sponsored: Technology, Innovation Management & Entrepreneurship

Sponsored Session

Chair: Joel Wooten, University of South Carolina, Columbia, SC, 29208, United States

Co-Chair: Necati Tereyagoglu, University of South Carolina, Columbia, SC, 30308, United States

1 - Incentivizing Knowledge Creation in Innovation Contests

Sanjiv Erat, University of California-San Diego, Rady Sch Mgmt Otterson Hall, La Jolla, CA, 92093-0553, United States, Lakshminarayana Nittala

Knowledge created in the process of conducting their current innovation activities is often cumulative, and enables firms to gain greater value in their future endeavors. Still, the difficulty in measuring knowledge makes it much more common to solely incentivize the output. The current talk shall offer a formal model where individual employees engage in knowledge creation ("learning") and/or knowledge utilization ("doing"), and shall examine how the firm's relative value from employee learning and doing is affected by the incentives.

2 - Entrepreneurial Market Research: Theory and Experiments

Evgeny Kagan, Johns Hopkins University, Carey Business School, Baltimore, MD, United States, Stephen Leider, William S. Lovejoy

This work studies the effectiveness of different search policies for a variant of the bandit model, revised to account for features of the entrepreneurial market research process.

3 - How Do Entrepreneurs Who Fail Find Success

Pek-Hooi Soh, Professor, Simon Fraser University, Beedie School of Business, Vancouver, BC, V6C 1W6, Canada, psa28@sfu.ca, Wenwei Zhang, Wenhong Zhao

We study how entrepreneurs who recover from failures draw on past venturing experience and better prepare a new venture for success. Our SEM results show that an entrepreneur's setback experience from past ventures directly affects a venture's commitment to learning and indirectly via a positive attitude towards failure. Moreover, the impact of setback experience on attitude is reduced for entrepreneurs who gain more information access via industry ties. An entrepreneur's attitude towards failure is a good predictor of venture learning so long as it is not interfered by extraneous information.

4 - Overview of Collaboration in Innovation and New Ventures

Joel Wooten, University of South Carolina, Columbia, SC, 29208, United States, joel.wooten@moore.sc.edu

We set the stage for this session by giving an overview of collaboration, how it has been studied, and how the papers presented in the session fit into this topic.

Chemical and Petrochemical Applications

Sponsored: Energy, Natural Res & the Environment/Natural Resources Petrochemicals

Sponsored Session

Chair: Dimitri Papageorgiou, ExxonMobil Research & Engineering, Annandale, NJ, 08886, United States

Chair: Lois Kamga-Ngameni, University of Colorado, CO, United States

1 - Experimental Study of Non-Darcy Flow in a Proppant Pack Using Nitrogen Gas under High Pressure

Lois Kamga-Ngameni, CO, United States

Historically, Darcy's equation has been used to predict hydrocarbon production over a year-long time horizon. Unfortunately, this equation is not able to accurately predict the production of hydrocarbon in unconventional reservoirs. We present the Barree-Conway model (2004), which is valid for high gas rate and unconventional reservoirs while considering parameters that pertain to fluid flow at high Reynolds numbers.

2 - Incorporating Process Variables and Categorical Responses in Mixture Experiments

Mona Khoddam, Arizona State University, Tempe, AZ, United States, mkhoddam@asu.edu

Chemical and Pharmaceutical industries utilize mixture experiments widely where the levels of the experimental factors are varying proportions of several chemical components that sum to a 100%. Sometimes the response in hand is measured as a categorical variable, instead of a numeric, continuous one so we need and special type of modeling. Besides, some process variables, factors which are not mixture components but affect the blending properties of the mixture ingredients, are playing role in our experiment as well and this makes modeling and analysis more complicated.In this work, we discuss such an application.

3 - Process Control Optimization of Multistage and Multiresponse Production

Kihyuk Yoon, Ulsan National Institute of Science and Technology (UNIST), Ulsan, Korea, Republic of, Hojin Cho, Chiehyeon Lim, Junghye Lee

Companies attempt optimization of their production process control with newly available data. We optimized the control of a chemical product production process with real data by developing and combining different prediction and optimization models. The process involves multi stages and responses (quality characteristics) that affect the yield. Our models contribute to the factory to increase the yield and make more profit (approximately 1 million USD per year). In this presentation, we focus on the unique characteristics of our models that relfect the theoretical characteristics of multistage-and-multiresponse production problem and the empirical characteristics of available data.

4 - Dynamic Location and Relocation of Modular Manufacturing Facilities

Qi Zhang, University of Minnesota, Minneapolis, MN, United States, Andrew Allman

In the chemical industry, there is an emerging trend toward building manufacturing facilities consisting of modules that can be constructed off-site and then shipped to the site locations where they are assembled into whole functional production plants. These plants can significantly increase the ability of a supply chain to react to changes in demand. This work addresses the dynamic location and relocation of such facilities. We introduce a new MIP model for the problem and develop a tailored branch-and-price algorithm to solve large instances. Through various case studies, we provide insights into the value of module mobility and demonstrate the effectiveness of the proposed solution algorithm.

Smart City Sustainability Aspects

Sponsored: Energy, Natural Res & the Environment/Environment & Sustainability

Sponsored Session

Chair: Victoria C. P. Chen, The University of Texas at Arlington, Arlington, TX, 76019-0017, United States

1 - Bounds for Optimal Control of a Real-time Multi-agent Demand Response System

Alireza Fallahi, PhD Candidate, University of Texas at Arlington, Arlington, TX, 76013, United States, Jay Michael Rosenberger, Victoria C. P. Chen

In stochastic programming (SP), a wait-and-see solution is at least as good as an optimal policy. On the other hand, a policy that uses the expected value problem is never as good as an optimal policy. This is well established in SP when there is a single agent. A question arises whether bounds exist when we have two agents. The present study develops a research methodology to answer this question. Our experiments show that if we have two separate agents, and both agents get perfect information, this can be worse compared to both agents doing the mean value problem. Nevertheless, we have found that there are bounds when the first stage follows the same set of actions. A two-agent demand response problem has been used as a case study to show this claim.

2 - Optimizing Water Supply Through Reservoir Conversion and Storage of Return Flow- A Case Study at Joe Pool Lake

Srividya Sekar, The University of Texas at Arlington, Arlington, TX, United States, srividya.sekar@mavs.uta.edu, Victoria C.P. Chen, Jay Michael Rosenberger, Glenn Clingenpeel, Yu Zhang, Amin Daghighi

Maintaining adequate water supply is one of the key challenges faced by the Dallas-Fort Worth Metroplex. In this study, UTA collaborated with Trinity River Authority (TRA), in conducting an exploratory study of the possibility of converting flood storage in Joe Pool Lake (JPL) to improve reliability of water supply and cost efficiency. It employs a linear programming (LP) approach that factors in the costs, revenues, demand/supply scenarios over the Trinity River Basin and the waste water treatment facilities of TRA. Given the inputs, the LP yields an optimal expansion of JPL and associated storage-diversion strategy on an annual basis.

3 - Crowd Logistics for Regional Food Systems

Narjes Sadeghiamirshahidi, University of Texas at Arlington, Arlington, TX, 76019, United States, narjes.sadeghiamirshah@mavs.uta.edu

Regional food systems have the potential to improve food supply chain sustainability. However, small-scale farmers struggle with cost-effective transportation and distribution. Direct sales via farmers' markets are inefficient and do not scale well, and distributors are too expensive and inflexible. One potential alternative is the use of crowd logistics, in which a decentralized network of potential transportation providers (the "crowd") is connected to customers seeking logistics services via a software platform. This research describes an agent-based model that was designed to study the potential of crowd logistics to improve transportation in regional food systems.

4 - Two Stage Stochastic Model for Enhancing Seismic Resilience of Water Pipe Networks

Azam Boskabadi, PhD Candidate, University of Texas at Arlington, Arlington, TX, United States, azam.boskabadi@mavs.uta.edu, Jay Michael Rosenberger, Mohsen Shahandashti, Binaya Pudasaini

Earthquakes may cause substantial damage to regional water pipe systems. Consequently, utility managers may rehabilitate pipes to limit damage in future disasters. In this research, we develop a nonlinear two-stage stochastic program to maximize post-disaster serviceability after an earthquake. We develop an approximate piecewise linear formulation and a reformulation-linearization technique. We discuss scenario generation and provide computational experiments.

Market Design for Sustainable Energy Systems

Sponsored: Energy, Natural Res & the Environment/Electricity Sponsored Session

Chair: Yue Zhao, NY, United States

1 - On the Market Equilibria of Renewable Power Producers in Congestion-constrained Power Networks

Yue Zhao, Stony Brook University, Stony Brook, NY, 11794, United States, yue.zhao.2@stonybrook.edu, Hossein Khazaei, Andy Sun

A two-settlement power market mechanism in which both conventional generators and renewable power producers (RPPs) participate is studied. A key advantage of the mechanism is that the independent system operator (ISO) does not need to consider the renewable's uncertainty when solving the economic dispatch problems in congestion-constrained power networks. The locational marginal prices at both stages are used for paying the RPPs. Under this market mechanism, an efficient method for computing the Nash Equilibrium among the strategic price-making RPPs is developed. Conditions under which the market equilibrium approaches the social optimum are developed and demonstrated in simulations.

2 - Electricity Pricing under Uncertainty via Chance Constraints

Yury Dvorkin, New York University, Metrotech Center, Fay Street, Brooklyn, NY, 11201, United States, dvorkin@nyu.edu

This presentation describes a stochastic electricity market design based on the use of chance constraints for modeling uncertain injections of renewable generation resources. The proposed design makes it possible internalize the effect of uncertainty within the price formation process, while considering technical limits on transmission network operations (e.g. ac power flow and voltage limits). We prove that the proposed market design yields a robust competitive equilibrium and can accommodate a variety of probabilistic assumptions on the underlying uncertainty. Our numerical simulations demonstrate the usefulness of the proposed market design on large-scale test systems.

3 - Mobile Storage for Demand Charge Reduction

Junjie Qin, UC Berkeley, Berkeley, CA, 94306, United States, qinj@berkeley.edu, Kameshwar Poolla, Pravin Varaiya

EV batteries, an increasingly prominent type of energy resources, are largely underutilized. This paper proposes a new business model that monetizes underutilized EV batteries to significantly reduce the demand charge portion of many commercial and industrial electricity users' electricity bills. This business requires minimal hardware to enable discharging batteries of electric vehicles and a sharing platform that matches EVs to commercial electricity users in real time. Using real meter data, we establish the financial viability of the business by studying the temporal distribution of user requests. We then discuss user-side and platform-side challenges for implementing this business.

4 - Demystifying Transactive Energy System: Glossary, Principle & Application

Jianming Lian, Pacific Northwest National Laboratory, 902 Battelle Blvd, Richland, WA, 99352, United States, jianming.lian@pnnl.gov

Transactive Energy System (TES) has gained great interests in the Power and Energy community. TES optimizes the operation of distributed energy resources through market-based transactions between participants. The underlying transactive control incorporates the economic concepts and principles into the decision making and controller design of individual market participants. It shares the advantages of both direct load control and price responsive control. However, as a newly emerging concept, it is still kind of mysterious to the research community. In this presentation, TES will be introduced from there aspects of technical glossary, theoretical principle and practical application.

5 - Dimensioning Operating Reserves in Multi-Cycle Processes

Miguel Ortega-Vazquez, Electric Power Research Institute, Palo Alto, CA, 94304, United States, Erik Ela

As the penetration of renewable generation deepens in power systems, there is an increased need for flexibility to accommodate vagaries and deviations from forecasts. System operators allocate flexibility via headroom and ramping requirements in the form of reserves. Reserves are typically held in day-ahead cycles and released in real-time cycles. Excessive amounts of reserve result in unnecessarily expensive schedules, and insufficient reserve results in poor system reliability. A practical method to determine exact reserve needs that do not require scheduling re-formulation (e.g., stochastic or robust) is proposed, and its advantages in terms of cost and system reliability are studied.

Equilibrium Models in Energy II

Sponsored: Energy, Natural Res & the Environment/Energy Sponsored Session

Chair: Steven A Gabriel, University of Maryland, College Park, MD, 20742-3021, United States

Co-Chair: Simon Risanger, Norwegian University of Science and Technology (NTNU), Alfred Getz vei 3, Trondheim, 7034, Norway

1 - An Equilibrium Approach Assessing Tariff Designs for Local Energy Markets in the Context of Active Consumers

Magnus Askeland, SINTEF Energy Research, Trondheim, Norway, Magnus.Askeland@sintef.no, Norwegian University of Science and Technology, Trondheim, Norway, Thorsten Burandt, Steven A. Gabriel

As consumers go from passive to active, it is necessary to consider if the price signals from the grid are enough to promote optimal utilization of the decentralized resources in the context of the larger power system. The research considers tariff design options in the context of active consumers that can participate in both local and centralized electricity markets. The interaction between a neighborhood with the possibility of a local market and the grid is modeled as a complementarity problem. The results provide insight into the appropriateness of different tariff design structures and an assessment of the impact of a local market on the deployment and operation of decentralized resources.

2 - Redispatch in Zonal Pricing Electricity Markets

Mario Blazquez de Paz, NTNU, Trondheim, Netherlands, mario.blazquezdepaz@ntnu.no

Zonal markets operate sequentially. First, the suppliers compete in a spot market. Second, to alleviate the congestion in the transmission line, in a redisptach market, the suppliers in the importing node are called into operation to increase their production, and the suppliers in the exporting node are compensanted to reduce their production. I characterize the equilibrium in a zonal market when the competition is imperfect and the spot and redispatch markets operate sequentially. I find that the consumers' welfare and suppliers' profits depend crucially on the type of redispatch design implemented by the auctioneer, and that could introduce long term investment distortions.

3 - Equilibrium Models for Modelling an Oligopoly with a Competitive Fringe

Mel Devine, University College-Dublin, Dublin, Ireland, meldevine07@gmail.com

Mixed Complementarity Problems (MCPs) are typically used to model strategic in energy market models. However, when market power is characterised by an oligopoly with a competitive fringe, myopic and unrealistic behaviour is observed. To overcome this issue, we also present an Equilibrium Problem with Equilibrium Constraints (EPEC) model and detail how market power influences investment decisions. However, EPECs are much a more complex model and thus cannot model the same level of operational detail as an MCP. Consequently, we also discuss the modelling trade-offs between using an MCP and an EPEC when modelling electricity markets characterised by an oligopoly with a competitive fringe.

4 - From Linking to Integration of Energy System Models and Computational General Equilibrium Models

Asgeir Tomasgard, Norwegian University of Science and Technology, Dept. of industrial economics, Alfred getz vei 3, Trondheim, 7491, Norway, asgeir.tomasgard@iot.ntnu.no, Per Ivar Helgesen

This paper compares hard-linked and integrated approaches of hybrid top-down and bottom-up models in terms of equilibria and convergence. The integrated model provides the same solutions as the hard-linked models. Also, an alternative integrated model is provided, where the bottom-up model objective is optimized while the top-down model is included as additional constraints. This nonlinear program corresponds to a multi-follower bilevel formulation, with the energy system model as the leader and the general equilibrium players (firms and household) as followers.

5 - New Formulation of Unit Commitment Model with Near Integer Solution of Continuous Relaxation and Associated Algorithms

J. David Fuller, Professor Emeritus, University of Waterloo, Waterloo, ON, Canada, dfuller@uwaterloo.ca

The optimal solution of the continuous relaxation of a reformulated single-hour unit commitment (UC) model has a simple structure: ranking generators by their minimum prices to be profitable, the cheapest have on/off binary variables equal to 1; at most one has a binary variable between 0 and 1; the remainder have 0 binaries; and the market price is either the minimum price of the most expensive generator with a nonzero binary, or greater than this but less than the next most expensive. A simple algorithm finds the optimal solution quickly, and rounding (if necessary) finds a good integer solution. The multi-hour UC model has similar properties each hour, suggesting possible algorithms for it.

Co-Chair: Hadi Charkhgard, University of South Florida, Tampa, FL, 33620-5350, United States

1 - Integrated Electrical-Thermal Operation of Residential Building Equipped with Hydro-pneumatic Energy Storage

Yang Chen, Ph. D., Oak Ridge National Laboratory, Oak Ridge, TN, 37830, United States, Fadwa Dababneh, Saiid Kassaee, Ayyoub Momen, Brennan Smith

The building sector is responsible for a large portion of total global energy consumption and carbon emissions. Using a novel hydro-pneumatic energy storage (GLIDES) invented in Oak Ridge National Laboratory, opportunities for leveraging this low grade heat in residential building can be amplified. In thisresearch, the potential of utilizing thermal energy from different energy sources to augment electricity generation of GLIDES is investigated. Due to nonlinear thermal dynamics, a mixed integer nonlinear model is formulated for day-ahead domestic energy system operation planning at 5-minutes time step. Resultsshow that more cost savings and higher energy efficiency could be achieved.

2 - Multi-user Energy Storage Sharing Based on the Nash Bargaining Solution

Rui Dai, University of South Florida, Tampa, FL, 33613, United States, ruidai@mail.usf.edu, Hadi Charkhgard, Mohammad Javad Feizollahi

Efficient energy storage sharing should coordinate the conflict of efficiency and fairness. The efficiency requires the strategy to create higher energy arbitrage. The fairness ensures the stored energy is fairly exchanged among multiple users and the arbitrage is properly allocated. To address this challenge, we propose a Nash Bargaining Solution based sharing strategy for energy storage sharing to balance the conflict of efficiency and fairness. This strategy creates a compensation mechanism to realize the fair exchange of the stored energy. The computational study shows that the proposed sharing strategy outperforms the reference strategies in terms of efficiency and fairness.

3 - A Robust bi-objective Optimization Approach for Energy Storage Sharing under-price Uncertainty

Hadi Charkhgard, University of South Florida, Tampa, FL, 33620-5350, United States, Rui Dai

Energy storage sharing can boost energy arbitrage by allowing the users to exchange their stored energy in contrast to using the energy storage independently. However, it is hard to assure this arbitrage under prices uncertainty. We present a robust bi-objective optimization approach to fairly and efficiently operate an energy storage shared by two users under price uncertainty. To facilitate solution efficiency, we propose a tractable binary formulation for piecewise McCormick relaxations. The computational study demonstrates the effectiveness of our robust sharing strategy and the efficiency of the binary formulation for piecewise McCormick relaxations.

4 - A Bilevel Conic Optimization Model for Routing and Charging of Electric Vehicles.

Vignesh Subramanian, University of South Florida, Tampa, FL, 33617, United States, vigneshs@mail.usf.edu, Kevin A. Melendez, Felipe A. Feijoo, Sriram Sankaranarayanan, Tapas K. Das

A bilevel electric-transportation model that uses a conic AC power flow formulation is presented in this paper. The upper level determines both the optimal route for the electric vehicles (EVs) by minimizing the cost (given the location marginal price, LMP) of charging, and the EV charging facility locations. The lower level represents electric system operator and solves for market clearing decision to determine the LMPs for the charging stations (a large increase of EVs demand will affect LMPs). Since, charging of EVs require reactive power support from the electricity grid. To model for this, an AC power flow formulation is used to account for the reactive power balance in the network.

Smart Manufacturing

Emerging Topic: Advanced Manufacturing

Emerging Topic Session

Chair: Hui Yang, Pennsylvania State University, University Park, PA

1 - Online Optimal Parameter Settings for Additive Manufacturing Processes by Reinforcement Learning with Knowledge Transfer

Zhenyu Kong, Virginia Tech, Dept of Industrial and Systems Engineering, Blacksburg, VA, 24061, United States, zkong@vt.edu, Jihoon Chung

Since additive manufacturing (AM) can produce complex 3-D geometries with various types of materials, the machine parameter settings may need to be adjusted adaptively. Traditionally design of experiment (DOE) has been utilized to identify the optimal machine parameter setting. However, DOE method cannot handle the complexity of AM processes. To overcome this challenge, we proposed a method that integrates offline (DOE) and online reinforcement learning, and can also accelerate learning rate by knowledge transfer during the printing process.

2 - Data Driven Modeling of Thermal History for Additive Manufacturing

Linkan Bian, Mississippi State University, Industrial and Systems Engineering Department, PO Box 9542, Mississippi State University, MS, 39762, United States, bian@ise.msstate.edu

Our objective in this study is to develop an efficient thermal history prediction of AM processes in a layer-track manner using thermal image streams. Most of the existing physics-based models are not able to provide comprehensive understanding of AM processes. We propose a network-tensor structure for freeform shapes based on thermal image streams obtained in metal-based AM process. The proposed approach is validated using numerical models and experimental data.

3 - The Internet of Things for Smart Manufacturing

Hui Yang, Pennsylvania State University, Industrial and Manufacturing Engineering, University Park, PA, 16801, United States, Soundar Kumara, Satish T. Bukkapatnam, Fugee Tsung

Modern manufacturing industry is investing in new technologies such as the Internet of Things (IoT), big data analytics, cloud computing and cybersecurity to cope with system complexity, increase information visibility, improve production performance, and gain competitive advantages in the global market. These advances are rapidly enabling a new generation of smart manufacturing, i.e., a cyber-physical system tightly integrating manufacturing enterprises in the physical world with virtual enterprises in cyberspace. To a great extent, realizing the full potential of cyber-physical systems depends on the development of new methodologies on the Internet of Manufacturing Things (IoMT) for data-enabled engineering innovations. This talk presents a review of the IoT technologies and systems that are the drivers and foundations of data-driven innovations in smart manufacturing.

Health Care, Modeling and Optimization IX

Contributed Session

Chair: Ashkan Hassani, Texas A&M University, College Station, TX, 77840, United States

1 - Operational Impact of mHealth Adoption in Clinical Practice

Balaraman Rajan, Assistant Professor, California State University East Bay, Hayward, CA, United States, Saligrama Agnihothri, Arvind Sainathan

Chronic conditions place a high cost burden on a healthcare system and deplete the quality of life for millions of patients. There is significant medical literature showing that continuous monitoring of patient health at home with the addition of provider support, improves patient health. Digital innovations such as mHealth technology can help provide efficient, effective, and patient centered healthcare. However, implementing mHealth technology can also significantly change the composition of clinical staff and patient flow. We use patient health progression models and queuing analyses to evaluate the trade-offs from implementing mHealth technology in a clinical practice.

2 - Predictive Decision Analytics for Interpretable Elderly Readmission Healthcaring

Jiandong Zhou, City University of Hong Kong, Kowloon, Hong Kong, jiandzhou3-c@my.cityu.edu.hk, Qingpeng Zhang, Frank Y. Chen, Eman Leung

Predictive decision analytics act as core module of healthcare systems for preventable readmissions mitigation to deliver high-quality healthcare services with lower cost and higher efficiency. We develop an easy-for-use and provable predictive analytics model, termed as field-aware interpretable factorization machine (FIFM), to predict elderly patient readmissions with full interpretability via histograms and heatmaps. We test our model using a unique large-scale clinical dataset in Hong Kong, showing its superiority over extant regression and black-box-like machine learning models. Resource allocation decisions are optimized with the results of readmission predictive analytics.

3 - Dynamic Tuberculosis Test Scheduling for Healthcare Employees

Mahsa Kiani, Clemson University, Clemson, SC, United States, Burak Eksioglu, Tugce Isik

Tuberculosis (TB) is a contagious disease. There are two TB tests on the market: skin test and blood test. The cost of the blood test is much higher than the skin test. But, the possibility of getting a false positive result in skin test is higher especially for persons with specific characteristics. This causes an extra cost of X-Ray test. TB screening is required annually for healthcare employees. In our study, we create a Markov decision process model to decide which TB test should be done by each group of employee based on the characteristics of the group to decrease the total cost and infection rate. Due to the curse of dimensionality, we use approximate dynamic programming to approximate the solution.

4 - Surgery and Resource Scheduling in Operating Theater

Thierry Garaix, Mines Saint-Etienne, Saint-Etienne, France, garaix@emse.fr, Roberto Bargetto, Xiaolan Xie

The scientific contribution of this work is a Column Generation algorithm and the overlying Branch-and-Price-and-Cut algorithm to solve the Integrated Operating Theater Planning Problem. In addition to previous researches, the surgeon can operate in different operating rooms the same day, nurse capacity is accurately taken into account by specialty and their over working time IS minimized. The proposed approach is applied to instances from the hospital CHU Saint-Etienne, and to published benchmarks for a comparison against state-of-the-art algorithms.

5 - A Multi-attribute Optimization Approach for Post-acute Provider Selection

Ashkan Hassani, Texas A&M University, College Station, TX, United States, ashkanhassani@tamu.edu, Hossein Badri, Maryam Khatami, Kai Yang, Mark Alan Lawley

In this study a decision making approach is developed for Post-Acute Care Provider (PACP) selection problem. This approach includes two stages. In the first stage, some quality metrics are used in a TOPSIS method to calculate the closeness coefficients of each candidate PACP to shortstay patient's and long-stay patients. In the second stage, these coefficients are used in a mathematical programming model, along with some other cost and service level metrics to select the best PACP's for both short-stay and long-stay patients. The proposed approach is implemented for PACP selection problem in the city of Houston, TX, and the results are presented and analyzed.

Systemic Risk and Financial Contagion

Sponsored: Finance

Sponsored Session

Chair: Zach Feinstein

1 - Pricing in an Eisenberg-Noe Framework under Comonotonic Endowments

Zachary Feinstein, Stevens Institute of Technology, Hoboken, NJ, 63130, United States, Tathagata Banerjee

In this talk we present formulas for the valuation of debt and equity of firms in a financial network under comonotonic endowments. We demonstrate that the comonotonic setting provides a lower bound to the price of debt under Eisenberg-Noe financial networks with consistent marginal endowments. Such financial networks encode the interconnection of firms through debt claims. The proposed pricing formulas consider the realized, endogenous, recovery rate on debt claims. Special consideration will be given to the setting in which firms only invest in a risk-free bond and a common risky asset following a geometric Brownian motion.

2 - Price Mediated Contagion Through Capital Ratio Requirements

Tathagata Banerjee, Washington University in St. Louis, St Louis, MO, 63108, United States, tbanerjee@wustl.edu, Zachary Feinstein

We develop a framework for price-mediated contagion in financial systems where banks are forced to liquidate assets to satisfy a risk-weight based capital ratio requirement after an exogenous shock to the system. We consider the case of multiple illiquid assets and develop conditions for existence and uniqueness of equilibrium prices. We show that sensitivity analysis of these prices with respect to the system parameters can be written as a fixed point problem and we prove the existence and uniqueness of this fixed point problem. We also develop a methodology to quantify and compare the risk posed by the different banks. Numerical case studies are provided to study the application of this model to data.

3 - Value and Size Effects

Andrey Sarantsev, University of Nevada, Reno, Davidson Math & Science Center 314, Mathematics & Statistics, Reno, NV, 89557, United States, asarantsev@unr.edu

We compare exchange-traded funds issued by leading financial companies, such as Vanguard, to verify the famous statement by Fama and French (1993) that value stocks outperform growth stocks, and small-cap stocks outperform large-cap stocks.

4 - An Adaptive Learning Agent Approach to Interbank Market Liquidity Hoarding Risk

Steve Yang, Stevens Institute of Technology, Babbio Center #536, Castle Point on Hudson, Hoboken, NJ, 07030, United States, steve.yang@stevens.edu, Xingjia Zhang

This paper investigates how the counterparty risk can lead to dry-up of liquidity in the interbank market with learning agents. Using policy gradient reinforcement learning agents, we demonstrate the adaptive learning banks can endogenously form liquidity hoarding phenomenon under an exogenous shock to the system. We incorporate RE sales and study how RE sales would affect interbank lending market dynamics, and the results show that RE sales exert negative effect on liquidity hoarding, and they tend to drive banks to increase the interbank lending in order to balance their market risk under a distressed market.

Sponsored Session

Chair: Ismail Capar, Texas A&M University, College Station, TX, 77843-3367, United States

Co-Chair: Ibrahim Capar, Bowling Green State University, Bowling Green, OH, 43403, United States

Co-Chair: Yudai Honma, The University of Tokyo, Tokyo, 153-8505, Japan

1 - Relationships between AFV Demand Assumptions and AFS Optimal Locations: A Case Study of Tokyo

Yudai Honma, The University of Tokyo, Ce405, Tokyo, 153-8505, Japan, yudai@iis.u-tokyo.ac.jp

In this study, based on the real GIS data in the Tokyo region, relationships between AFV demand assumptions and AFS optimal locations are discussed in detail. For the comparison, two station location models are introduced that extend the Flow Capturing Location Model (FCLM) and p-Median Problem (PMP) by consistently defining upper limits on vehicle driving range and maximum inconvenience on refueling trips. Both models are also extended to the multi-objective models between the node-based and path-based objectives.

2 - Analysis of Streetscape Impression Based on Deep Learning for Autonomous Vehicles

Tomoaki Fukuzumi, The University of Tokyo, Tokyo, 1538505, Japan, fukuzumi@iis.u-tokyo.ac.jp, Yudai Honma

In this study, we quantify the "impression" of streetscapes using the image processing methods. Since image processing methods have been researched actively in the field of computer vision, we can extend the study by using such latest progress. We are now considering to detect each segment based on deep learning library for the autonomous vehicle. It will enable us to collect visual information as more mathematics-friendly data.

3 - The Impact of Load on the Energy Consumption and Route Planning of Electric Freight Vehicles

Bülent Çatay, Sabanci University, Faculty of Engineering and Natural Sciences, Tuzla, Istanbul, 34956, Turkey, catay@sabanciuniv.edu, Sina Rastani, Tugce Yuksel

Despite the advancements in battery technology, range anxiety still constitutes a major barrier to the adoption of EVs in freight transport operations. Since cargo weight can significantly affect the energy consumption, it should be taken into account for effective route planning. In this study, we revisit the Electric VRP with Time Windows by considering load factor. We present a mixed integer linear programming formulation of the problem and perform an extensive experimental study using benchmark data from the literature to investigate how cargo weight influences energy consumption and routing decisions. Our aim is to present managerial insights to both researchers and practitioners.

4 - Assessment of EV Charging Network Design under Various Service Metrics

Ibrahim Capar, Bowling Green State University, Department of ASOR, 355 Business Administration Building, Bowling Green, OH, 43403, United States, icapar@bgsu.edu, Ismail Capar, Ozgur M. Araz

In this research, we present a service network design framework to improve the electric vehicle infrastructure with quality of service constraints taken into consideration. Specifically, we consider a flow-refueling location model with capacitated charging stations and budget constraints. We capture the average waiting time on the network in addition to the total flow captured. We propose several new objective functions to capture the tradeoff between the total waiting time and the total flow captured.

5 - A Novel Location-allocation-routing Model for Siting Multiple Recharging Points on the Continuous Network Space

Pitu B. Mirchandani, Arizona State University, School of Computing, Informatics and, Decision System, Tempe, AZ, 85287, United States, Yazhu Song

While automobile companies and governments are trying to incentivize greater use of electric vehicles, they are still not widely used due to a sparse charging infrastructure. This talk introduces a new location-allocation model for siting battery recharging points (RPs) on the continuous points on a network to minimize total detouring of trips from origins (O) to destinations (D). Since the cost of a RP is generally high, the talk first addresses the problem of finding the minimum number of RPs to "cover" all the OD trips. The talk then addresses the problem of locating these RPs as well as how to route EVs to result in the least total detouring. Problem complexity and solution algorithms are presented.

Emerging Topics in Coordinated Care and Organization Performance

Sponsored: Manufacturing & Service Oper. Mgmt/Healthcare Operations

Sponsored Session

Chair: Pengyi Shi, Purdue University, West Lafayette, IN, 47907, United States

Co-Chair: Nan Liu, Boston College, Chestnut Hill, MA, 02467, United States

1 - Coordinated Care for Mental and Physical Health

Sandeep Rath, Assistant Professor, University of North Carolina at Chapel Hill - Kenan Flagler, CB #3490, McColl Building, McColl 4705, Chapel Hill, NC, 27599, United States, sandeep@unc.edu, Jayashankar M. Swaminathan

Multiple clinical trials have demonstrated the benefits of coordinating treatment of mental health conditions like depression and chronic physical conditions like diabetes. However, sustainability of coordinated care outside trial settings has not been fully demonstrated. A sustainable coordinated care will be revenue neutral for the providers and improve patient outcomes. Towards this, we propose a mathematical optimization model which would optimize care management plans to improve patient outcome while balancing revenue and resource usage costs.

2 - Length-of-stay Prediction and its Application to Optimal Staffing for Long-term Rehabilitation Facilities

Eugene Furman, PhD Candidate, Schulich School of Business, Toronto, ON, M3J 1P3, Canada, enfurman@mathstat.yorku.ca, Adam Diamant, Andre Augusto Cire

Using extensive data from a rehabilitation company in the U.S., we use a Bayesian inference framework to predict treatment duration for patients who require long-term care due to brain and spinal-cord injuries. Specifically, we implement a mixture hidden Markov model and show that patients can be clustered into different latent categories. Then, using referral data to predict cluster membership, we leverage this prediction tool to forecast the workload of medical practitioners and support personnel in order to design practical and effective staffing policies.

3 - Rich Dad Poor Dad: A Perspective of Operational Fit on the Acquisition Performance of Multiunit Service Organizations

Kejia Hu, Vanderbilt University, Nashville, TN, 37215, United States, Lauren Xiaoyuan Lu, Susan F. Lu

We study how merge and acquisition affect nursing homes performance and the chains acquired it.

4 - Empirical Analysis of the Impact of Operational Factors on Clinical Decision Making in a Chronic Care Clinic

Zehra Onen, Koc University, Istanbul, Turkey, zeonen@ku.edu.tr, Evrim D. Gunes, Tolga Tezcan, Raj Sengupta

The rising prevalence of chronic conditions (for which there is currently no cure, and which are managed with drugs and other treatment) is one of the main challenges facing health-care systems globally. We investigate how non-clinical operational factors affect clinical decisions of health professionals using 75,702 patient visit data from a rheumatology outpatient clinic in Bath, UK. We focus particularly on the decision to follow-up or discharge a patient and re-attendance of discharged patients. We show that increasing workload and patient waitlist size decrease discharges and increase re-attendances. By contrast, continuity of care increases discharges and decreases re-attendances.

1 - Agglomeration or Competition: How Online Reviews Change the Effect of Firm Geographical Clustering on Revenue

Kezhen Wei, Xi'an Jiaotong University, Xi'an, China, kezhenw001@126.com, Shan Liu, Baojun Gao

This paper develops a model of how online consumer reviews change the influence of firm geographical clustering on its revenue. Based on 32,087 observations of 1,170 Texas hotels consisting of tax data and online reviews, we analyze the dynamic panel data using a Generalized Method of Moments approach. Our results reveal that firm geographical clustering positively affects revenue, indicating an agglomeration rather than a competition effect. However, such effect decreases with the increase of consumer online reviews, regardless of whether the reviews are positive or negative. Our findings provide important implications on the offline competition with online channels.

2 - The Effects of Prior Experiences on Current Weight Loss Outcome in Online Weight Loss Communities

Lun Li, Beijing Institute of Technology, Beijing, China, 2120171541@bit.edu.cn, Zhijun Yan, Qiuju Yin, Junwei Kuang, Chenxi Guo

This study explores the effects of prior weight loss experiences on the current weight loss outcome using a dataset from an online weight loss community. We find that successful prior experiences have a positive effect on the result of current weight loss session while failure experiences create negative effects. Moreover, online social support enhances the positive impact of successful experiences and decrease the negative effects of failure experiences. In addition, there are significant gender differences.

3 - Designing Social Products: An Analysis of the Effects of Social Influence

Xiaoxi Liu, Korea University, Seoul, Korea, Republic of, polar1018@korea.ac.kr, Byung Cho Kim

It is well acknowledged that consumers looking to signal their uniqueness by consuming scarcity goods. The consumer psychology of pursuing uniqueness is also manifested in social products, in a way that users who have the desire for uniqueness will choose the social products which distinguish themselves from others in terms of interests, hobbies or purposes. In this paper, we propose an analytical model of conspicuous consumption on social products using the rational expectation framework and examine how social effects and market structure can influence the design of social products. We examine both the monopoly and duopoly cases to investigate the optimal design of social products.

4 - The Mediating Role of Empathy in Effort Allocation in Question & Answer Online Communities

Tao Wang, Simon Fraser University, Vancouver, ON, Canada, wangtaow@sfu.ca

The answers created in Question & Answer online communities can range from very brief to very detailed. How do people determine the amount of cognitive efforts when replying questions? Adopting the 'empathy-altruism hypothesis,' I suggest that the displayed emotions can lead to affective empathy and affect the level of cognitive effort. The similarity of the question and the replier's expertise can have positive impact on the cognitive empathy, which will affect the level of cognitive effort as well. I draw support from the empirical study using the log data of an entrepreneurship forum of Reddit.com from 2012 to 2018.

5 - Crying Baby Gets the Milk? Displayed Emotions and Knowledge Acquisition in Online Communities of Entrepreneurs

Tao Wang, Simon Fraser University, Vancouver, BC, Canada, wangtaow@sfu.ca

How does displayed emotions in Question & Answer online communities affect the knowledge acquisition? Using the log data of an entrepreneurship forum of Reddit.com from 2012 to 2018, I examine the dynamics of dyad formation and the usefulness of knowledge under the variation of displayed emotions in question. I argue that the negative emotions (sadness and anxiety) displayed in the questions affect the occurrence of knowledge acquisition as well as have positive impact on the usefulness of the knowledge acquired. In addition, knowledge specificity drives different paths for the negative emotions affecting the usefulness of knowledge.

6 - Mechanism Design for Online Marketplace Lending with Institutional Investors

Anparasan Mahalingam, Purdue University, Krannert Building, West Lafayette, IN, 47906, United States, Mohammed Alyakoob, Mohammad Saifur Rahman

A relatively new strand of management scholarship studies the strategic concerns of mechanism design in online platform markets. In this paper, we examine the ex-post performance implications arising from ex-ante mechanism design choices for a peer-to-peer lending platform with heterogeneous participants. We demonstrate how seemingly innocuous platform mechanism design choices related to lender side expansion, through incorporating institutional lenders, can have negative spillover effects on the market and far reaching implications for all market players—focal platform, lenders and borrowers.

Modeling and Optimization of Biomanufacturing Operations

Sponsored: Manufacturing & Service Oper. Mgmt/Healthcare Operations

Sponsored Session

Chair: Tugce Martagan, Eindhoven University of Technology, Eindhoven, 5611AZ, Netherlands

1 - Achieving Coordination via Effort-based Contracts for Biopharmaceutical Projects

Yasemin Limon, University of Wisconsin-Madison, Madison, WI, 53705, United States, ylimon@wisc.edu, Tugce Martagan, Ananth Krishnamurthy

In biopharmaceutical drug development, achieving the desired yield and quality involves high uncertainty and costs. Large biopharmaceutical companies and niche biotech companies often collaborate to leverage individual capabilities, reduce risks and lower costs. We investigate the performance of various contract designs for this supply chain. We show that fixed-price and revenue sharing contracts may not coordinate, but effort-based contracts can achieve supply chain coordination.

2 - Optimal Subsidies for Early Access to Rare Disease Therapeutics

Tugce Martagan, Eindhoven University of Technology, Eindhoven, Netherlands, t.g.martagan@tue.nl, Wendy Olsder, Christopher S. Tang

We consider subsidies to encourage faster access to rare disease treatments. We present a three-stage Stackelberg game to determine an optimal allocation of a limited subsidy budget (i.e., subsidize patients only, manufacturers only or both). We consider different pricing schemes, and characterize the optimal R&D effort and the unit selling price for rare disease treatments.

3 - A Systematic Risk Analysis and Sensitivity Analysis Framework to Facilitate Biopharmaceutical Production Learning and Stability Improvement

Wei Xie, Northeastern University, Boston, MA, 02115, United States, w.xie@northeastern.edu, Bo Wang, Cheng Li, Jared Auclair

Since there are many process parameters and quality attributes impacting on the bio-drug product quality, we propose a risk and sensitivity analysis framework to quantify their criticality and further identify dominate factors to monitor and control. We first develop Bayesian Network-based risk analysis for integrated production process to assess the criticality of process parameters and quality attributes. Then, we propose uncertainty quantification and sensitivity analysis to facilitate the science-based monitoring and learning for the production process stability control.

4 - Optimal Harvesting and Replenishment Decisions to Reduce Changeovers in Biomanufacturing

Yesim Koca, Eindhoven University of Technology, Eindhoven, 5600MB, Netherlands, Tugce Martagan, Lisa M. Maillart, Ivo Adan

We develop an MDP model to reduce the number of changeovers in biomanufacturing fermentation processes. We determine optimal harvesting and replenishment policies that maximize the expected total discounted profit in the long run. We analyze structural characteristics of the optimal policies and illustrate the industry use of the model through a case study.

Joint Session MIF/HAS: Cancer Care and Health Disparities

Sponsored: Minority Issues

Sponsored Session

Chair: Karen T. Hicklin, University of North Carolina at Chapel Hill, Chapel Hill, NC, 27599-7411, United States

1 - Incorporating Patient Preferences and Risk of Overdiagnosis in Breast Cancer Treatment Decisions

Juan David Bolivar, Universidad de los Andes, Bogotá, Colombia, Shengfan Zhang, Raha Akhavan-Tabatabaei, Ahla Ko

The importance of shared decision making in cancer care has been increasingly recognized in the medical community. Cancer patients are working more closely with care providers to choose the best treatment plan. In particular for breast cancer, a number of treatment alternatives are available, each with different side effects that could significantly impact patients both physically and psychologically. We develop a dynamic decision model to determine the optimal breast cancer treatment selection that incorporates not only medical considerations but also a quantitative measure of personal preferences.

2 - Optimization of Telemedicine Clinic Locations for Increasing Access to Bladder Cancer Screening

Ayca Erdogan, Assistant Professor, San Jose State University, Davidson College of Engineering, Industrial and Systems Engineering, San Jose, CA, 95192, United States, ayca.erdogan@sjsu.edu, Van Khanh Phan, Tracey Krupski, Jennifer Mason-Lobo

Telemedicine aims to increase patients' access from rural or remote areas to specialty care that is not locally available. We present a model to determine the locations of telemedicine clinics to open with the aim of maximizing patient access/adherence. The model is developed and tested for the purpose of opening telemedicine clinics to reduce disparities in rural Virginia by increasing bladder cancer screening, diagnosis and treatment. We assume that patients can choose either the central hospital or a telemedicine clinic and their adherence is affected by the distance they need to travel.

3 - The Making of Practice Guidelines-Dynamics of Selection and Detection Criteria in Population Screening

Ozge Karanfil, Harvard University School of Public Health, Cambridge, MA, 02140, United States, okaranfil@ku.edu.tr

Clinical practice guidelines (CPGs) for routine screening are contentious and often fluctuate over time. We develop the first broad boundary feedback theory and formal model to explain dynamics of screening policy formation. Our behaviourally realistic model of detection and selection for screening explains oscillations in CPGs as decision makers weigh harms and benefits. The model endogenously generates fluctuations in policy thresholds leading suboptimal guidelines. We use cancer screening as a motivating example, but the model is generic and applicable to other diseases such as Alzheimers or to nonmedical contexts such as airport screening, background checks or automotive emission tests

4 - Assessing the Impact of Multicomponent Interventions on Colorectal Cancer Screening: What Would it Take to Reach the 80% Target?

Karen T. Hicklin, University of North Carolina at Chapel Hill, Campus Box 7411, Chapel Hill, NC, 27599-7411, United States, khicklin@email.unc.edu, Meghan C. O'Leary, Siddhartha Nambiar, Maria E. Mayorga, Kristen Hassmiller, Melinda M. Davis, Stephanie B. Wheeler

Healthy People 2020 and the National Colorectal Cancer Roundtable have set national colorectal cancer (CRC) screening targets at 70.5% and 80%, respectively. While CRC screening has increased in recent years, with approximately two-thirds of age-eligible individuals screened, the feasibility of these targets at the population level remains uncertain. We use microsimulation to identify which combinations of multicomponent interventions and health policy changes may be capable of achieving current targets in North Carolina in addition to the long-term effects on CRC incidence and mortality.

5 - Pancreatic Cancer Screening Impact: Effort to Screen and Five-year Survival Rates

Julie Simmons Ivy, North Carolina State University, Raleigh, NC, Lena Abu-El-Haija

Pancreatic cancer is a deadly disease with a five-year survival of 8.5%. Resection, surgical removal of the tumor, is the only cure. There have been calls for screening to detect the disease at a resectable stage to improve the chances of survival. A discrete-event simulation model for pancreatic cancer screening was developed with a resectability prediction tool upon detection. A wide range of screening policies were tested on heterogeneous and homogeneous populations. The resulting tradeoff between five-year survival and the effort to screen under each policy was assessed. Effort versus five-year survival efficiency frontiers were used to identify policies by race, gender, and relative risk.

1 - Flexboost: A Flexible Boosting Algorithm with Adaptive Loss Functions

Dong-Hyuk Yang, Sungkyunkwan University, Gyeonggi-do, Korea, Republic of, wayne0831@skku.edu, Yong-Seok Jeon, Dong-Joon Lim

AdaBoost is an algorithm that can build a strong classifier by optimally combining weak classifiers in such a way that subsequent weak classifiers are tweaked in favor of instances misclassified by previous classifiers. However, It is known to be susceptible to overfitting problems due to the static nature of its weight-updating process. In this paper, we propose a new boosting algorithm, named FlexBoost (Flexible AdaBoost), that can enhance classification performance by employing adaptive loss functions for each weak classifier. The performance benchmarks on 30 binary classification problems taken from the UCI and Kaggle datasets are presented to empirically validate the proposed algorithm.

2 - Application of Multivariate Analysis in Prediction of Absenteeism at Work

Motahareh Tavakolikashi, Student, Binghamton University, Binghamton, NY, United States, Naseem Khan, Yuqiao Cen, Shuxia Susan Lu

In the highly competitive market, the urge to produce more with utilizing fewer resources puts lots of pressure on employees and causes absenteeism at work. In this paper, first different feature selection methods are implemented to identify the most important attributes. Then, different machine learning algorithms (Decision Tree, Naïve Bayes, Logistic Regression and Linear Discriminant Analysis) have been implemented to achieve an accurate predictive model for absenteeism. The performance of these algorithms is evaluated by several metrics including accuracy, sensitivity, specificity, and AUC of the ROC curve. The results show that the DT algorithm outperforms other algorithms.

3 - Image Decomposition-based Sparse Extreme Pixel-level Feature Detection with Application to Medical Treatment Planning

Jialei Chen, Georgia Institute of Technology, Atlanta, GA, United States, Geet Lahoti, Zhen Qian, Chuck Zhang

While planning medical treatment, it is important to identify, (a) calcification as positive extreme features and (b) soft tissues as negative extreme features, from a computed tomography image of the human heart. We propose a novel, automatic image decomposition-based sparse extreme pixel-level feature detection model to decompose an image into mean and extreme features. To estimate model parameters, a high-dimensional least squares regression is utilized. An algorithm based on the alternating direction method of multipliers and the proximal gradient method is developed to solve the optimization problem.

4 - Hierarchical Structured Sparse Learning in Biomedical Data Analytics

Fangyun Bai, Tongji University, Shanghai, China, baifyr@163.com, Shouyi Wang, Wenyong Zhou

Investigation of massive biomedical data to advance knowledge and medical breakthroughs has taken a center stage in modern data analysis. Although complex, the underlying representations of most biomedical data are often sparse. In this talk, we will present a hierarchical structured sparse learning method as a powerful tool to model high-dimensional biomedical data, and provide with high degree of model interpretability for knowledge discovery.

5 - A Dual Model Agnostic Strategy to Explore Representativeness and Informativeness in Active Learning

Ghazal Shams, Arizona State University, Tempe, AZ, United States, gshams@asu.edu, Enrique Del Castillo, George Runger

Active learning techniques have shown promising results in accelerating learning procedures while reducing the cost of data annotation. Although density based strategies have been widely adopted to improve uncertainty based techniques in active learning, they do not take the uncertainty associated with our understanding of perplex high-dimensional feature space into account. In this work, we propose a stochastic label query strategy for pool-based active learning based on a coherent and consistent measure that unifies classification and input data structure uncertainties.

Supply Chain Management, Green

Contributed Session

Chair: Olga Battaïa, ISAE-SUPAERO, Toulouse, 31055, France

1 - Sustainability as a Vehicle for Value Innovation: Recent Case Studies

Suri Gurumurthi, Hong Kong University of Science and Technology, Culver City, CA, United States

In recent successful cases of value innovation driven by sustainability initiatives, a gradual, continuous, and optimized investment in waste reduction and efficiency gains across the supply chain results in a competitive cost structure for the firm. Leveraging this stable platform, breakthrough investment in sustainable processes and technologies then creates a powerful differentiator for the firm in its industry. Together, we propose that a hybrid strategy of continuous improvement across the supply chain, coupled with breakthrough investment in sustainability can potentially deliver value innovation in the industry at relatively lower risk of failure.

2 - Analytical Approaches to Study the Impact of Environmental Regulations and Customer Environmental Awareness on the Sourcing Strategy

Olga Battaïa, ISAE-SUPAERO, Toulouse, France, olga.battaia@isae-supaero.fr, Narjes Kandil, Ramzi Hammami

We consider an outsourcing problem under economic, environmental and social considerations for a profit-maximizing firm having the possibility of producing in-house or outsourcing a part of its production process to a foreign country. The firm faces a carbon tax and demand and cost uncertainties. We develop analytical approaches to study the impact of environmental regulations and customer environmental awareness on the sourcing strategy and the green investment of the firm.

3 - The Competition and Cooperation for Green Product Producing in Supply Chains

Xifei Liu, Peking University, Beijing, China, Shuxiao Sun

The sustainable supply chain has attracted a lot of attention not only in the industry but also in the academic society. This study focuses on the pricing and determination of the degree of greenness (eco-friendliness) of two substitute products. The two kinds of products are produced by two competing manufacturers while they can cooperate with each other to improve the degree of greenness.

Plenary: Planning Transportation Capacity at Amazon

Plenary Session

1 - Planning Transportation Capacity at Amazon

Russell Allgor, Amazon

Amazon has continued to speed up delivery while the number of shipped packages continues to grow, shortening the time it takes between when an item is ordered and the moment that item arrives on a customer's doorstep. Prime customers experience faster delivery speeds, whether that comes from the broad selection for free two-day and one-day delivery from coast to coast, free same day delivery in select locations, or free two-hour delivery with Prime Now on tens of thousands of items. At the same time, Amazon's fulfillment business - along with that of other online retailers - has increased the pressure on parcel delivery transportation capacity both in the US and overseas. Continuing to satisfy customers' needs and increase delivery speed will require more efficient use of existing networks and the creation of additional capacity for package sortation, line haul trucking, air freight, and last mile delivery. The challenge of designing a network that can meet these dynamic needs requires us to develop technical solutions implemented through design tools that incorporate the latest process innovations. We must overcome both technical and organizational challenges to design and operate the logistics network, involving facility locations, inventory placement, facility operations, network connections, and scheduling. While the technical challenges are at least partially met through solving large-scale combinatorial optimization problems, the organizational challenges require innovative mechanisms that motivate network-wide cooperation while also allowing decentralized, scalable operation.

The presentation will cover the challenges that we face, the way we have formulated some of the problems, and some the challenges and opportunities that remain.

Tuesday, 10:30AM - 12:00PM

Novice Applications in Data Mining

Sponsored: Data Mining

Sponsored Session

Chair: Sara Masoud

1 - Online Assessment of Surgical Proficiency Using VR-based Hybrid Reality Simulation under Time and Situational Uncertainty

Saurabh Jain, The University of Arizona, Tucson, AZ, 85719, United States, saurabhjain@email.arizona.edu, Seunghan Lee, Barber Samuel, Eugene Chang, Young-Jun Son

Data mining has been a prominent method for evaluations of the user's proficiency within the surgical training simulation. Online feedback and appropriate assessment of the surgical skills are essential to study the underlying surgical decision-making processes under different situations based on time-crunch, risk and sleeplessness. Thus, we propose a generalized evaluation framework using the real-time data (e.g., time and motions) to provide feedback and their aggregated scores for steepening their learning curve. It will immensely reduce the cost and enhance the fidelity of surgical training.

2 - A Dynamic HMM-based Tracking Framework Utilizing UHF Passive RFID

Bijoy Dripta Barua Chowdhury, Graduate Research Assistant, University of Arizona, Tucson, AZ, 85716, United States, Sara Masoud, Young-Jun Son, Chieri Kubota, Russell Tronstad

An indoor tracking system is designed using ultra-high frequency (UHF) passive Radio Frequency Identification technology, where a K nearest-neighborhood Hidden Markov Model (HMM) is developed to track motions of moving objects by combining static localization with dynamic tracking. Statistically validated regression models are developed based on the tags' Received Signal Strength Indicator (RSSI) to estimate locations of the targeted static tagged objects, which are then augmented given the probabilistic likelihood of tags potential locations to construct the HMM. Finally, the performance of the proposed framework is evaluated by a set of experiments given different metrics.

3 - Finding a Scapegoat of the Exchange Rate Anomaly with Machine Learning Methods

Levent Bulut, Lecturer, Valdosta State University, Valdosta, GA, United States, Zeliha Gormez

When currencies are driven by unobservables shocks and fundamentals fail to explain the disconnect, the scapegoat theory of exchange rates justifies this with market participants' changing expectations about the structural parameters as they might put excessive weights to a specific fundamental, as a scapegoat, that was off-the-track at the time. In this paper, we use machine learning techniques to pinpoint the fundamentals that can serve as scapegoat factors. Our approach detected the majority of the scapegoat factors of exchange rates that were reported in the literature. We showed that while interest rates and trade gaps act as scapegoat factors, inflation rate and growth rate gaps did not.

4 - A Real-time Framework for Hand Gesture Detection

Sara Masoud, University of Arizona, Tucson, AZ, 85716, United States

Although gesture detection has been playing an important role in human-computer advanced interaction systems in a variety of applications such as gaming and virtual reality, the never-ending improvement of technology has provided new opportunities for gesture detection with more affordable, faster and more accurate sensory readings. Training and performance evaluation are emerging applications for gesture detection in many practices. Here, a semi-supervised real-time hand gesture detection framework is developed for performance evaluation based on readings provided by VMG-30 data gloves. The proposed framework is evaluated by matrices such as accuracy, precision, and f-1 score.

Sponsored Session

Chair: Victor Zitian Chen, PhD, UNC Charlotte; GoPeaks.org, Charlotte, NC, United States

1 - Detecting Causal Explanations in Natural Discourse Using Recurrent Neural Networks

Youngseo Son, Stony Brook University, Stony Brook, NY, United States, yson@cs.stonybrook.edu

Causal explanations — reasons given for happenings in one's life — are important psychologically, linked to physical and mental health, and generally give insight into one's understanding of mechanisms in the world. Automatic identification of causal explanations in social media, while challenging in many aspects, offers a larger-scale alternative to expensive manual ratings and opens the door for new applications (e.g. studying beliefs about climate change). Here, we present a deep recurrent neural network method for automatic causal explanation analysis. Also, we apply our complete pipeline for analyzing demographics in Facebook and causal explanations in Yelp reviews.

2 - Systematic Literature Review Tools: Examples in Software Engineering

Jeffrey Carver, University of Alabama, Tuscaloosa, AL, United States, carver@cs.ua.edu

Even with the increasing use of Systematic Literature Reviews (SLRs), authors still face number of barriers. These barriers increase the cost of conducting SLRs). This talk will discuss recent work on tool support for SLRs in Software Engineering (SE). The talk will first overview some of the challenges with conducting SLRs that could benefit from tool support. Then, the talk will discuss existing solutions. Finally, the talk will conclude with new work on automated analysis approaches, including machine learning and AI, to support the extraction and analysis of information during SLRs. While these experiences originate from SE, the lessons learned are relevant to other domains.

3 - Incorporating Context in Literature Based Discovery

Neil R. Smalheiser, Professor, University of Illinois at Chicago, Chicago, IL, United States, neils@uic.edu

In the Swanson ABC model of discovery, a single entity or concept that is discussed in two separate contexts can be used to link assertions to form new hypotheses. Other models of discovery also rely crucially on context: For example, a breakthrough in one field may appear to have specific or restrictive features which cause it to be neglected in other contexts. I will outline an approach to literature based discovery that employs semantic predications and analogies to infer new hypotheses. This approach employs NLP techniques to measure and handle not only the entities, concepts and relations, but their varying contexts.

4 - Bridging Non-interacting Research Communities Through Machine-guided Discovery Synthesis

Gus Hahn-Powell, Lum AI, Tucson, AZ, United States, ghp@lum.ai, Dane Bell

We align a large-scale venue-level citation network (journal A cites journal B) with a graph of millions of causal relations (X decreases Y) mined from text. The aligned graph allows us to map the dispersion of scientific findings, estimate the degree of communication taking place between research communities, and generate novel hypotheses through Swanson linking. From the citation network, we derive venue-level representations (embeddings) and use their similarity to surface chains of causal relations which bridge isolated communities engaged in complementary research.

5 - Construct Identification and Causal Mapping of the Business/Management Literature

Dikshya N. Mohanty, University of North Carolina, Charlotte, NC, United States

Discordant naming of constructs —construct identity fallacy (CIF) -is a persistent problem in synthesizing knowledge from social sciences. We propose to design a machine learning algorithm for Constructs and building a causality map to access their relationship with one another. Through the employment of REACH (Reading and Assembling Contextual and Holistic Mechanisms from Text) which is information extraction system for the biomedical domain, which aims to read scientific literature and extract causal pathways, we test detecting construct identity and building a dynamic network model using business/management scientific papers.

6 - Transfer Learning for Large Text Corpus Using Deep Machine Reading at Scale

Anusua Trivedi, Senior Data Scientist, Microsoft, Redmond, WA, United States, antriv@microsoft.com

Deep learning (DL) based Machine Reading Comprehension (MRC) algorithms assume a relevant text is already identified and given to the model, which is not realistic in building an enterprise QA system. This leads us to DL based Machine Reading at Scale (MRS). It is focused on maintaining the challenge of DL-MRC, while searching over a large resource. Building machines that can perform DL-MRS would be of great interest to enterprises. But it seems like a lot of cost to enterprises to create a custom data set as large as SQUAD to train the DL models. In this talk, we attempt to capture an existing MRS algorithm and show how transfer learning can achieve good results on a custom large target text corpus.

1 - Multimodal Data Fusion in 3d Printing Quality Prediction

Weihong (Grace) Guo, Rutgers, The State University of New Jersey, Piscataway, NJ, 08854, United States, wg152@rutgers.edu

Additive manufacturing, or three-dimensional (3D) printing, is an emerging technology that enables the direct fabrication of complex shapes. The material solidification in 3D printing, however, may yield geometric shape deviation in the printed parts, which adversely affects product quality and performance. The advancement in sensing technology enables us to collect measurement data to facilitate efficient and automated quality inspection for 3D printing. The objective of this study is to develop a data fusion method that can effectively fuse the different sources of sensor data and process data to evaluate the quality of 3D-printed parts. Results show that the proposed method is effective.

2 - Functional Principal Component Analysis for Extrapolating Multi-stream Longitudinal Data

Seokhyun Chung, University of Michigan, Ann Arbor, MI, United States, seokhc@umich.edu, Raed Al Kontar

We propose a functional principal component (FPC) analysis based approach to predict the evolution of multi-stream longitudinal data for an in-service unit based on other historical units. Our approach first decomposes each stream into eigenfunctions and corresponding FPC scores. A Gaussian process prior for the FPC scores is then established based on a semi-metric measuring similarities between streams of historical units and the in-service unit. Finally, an empirical Bayesian updating strategy is derived to update the prior using real-time data obtained from the in-service unit. Strengths of the model are illustrated through numerical studies using synthetic and real-world data.

3 - ResNet-based Learning for Dimensionality Reduction in Complex System

Jiaxin Zhang

A ResNet-based isosurface learning approach is proposed for dimensionality reduction in high-dimensional complex system approximation. Conventional methods, including active subspace methods and sliced inverse regression, reduce the dimensionality through an affine/linear transformation. This work aims to extend such transformation to the nonlinear regime using reversible ResNets, which is exploited to learn the target functions' isosurfaces and approximately parameterize the isosurfaces in low-dimensional spaces. High dimensional functions and complex system model are employed for illustrating the improved approximation accuracy with the use of the nonlinear transformation.

4 - A Degradation-Based Detection Framework Against Covert Cyberattacks in SCADA Systems

Dan Li, Georgia Institute of Technology, Atlanta, GA, United States, dli352@gatech.edu, Nagi Gebraeel, Kamran Paynabar

Supervisory control and data acquisition (SCADA) systems are commonly used in critical infrastructures. However, these systems are typically vulnerable to cyberattacks. Among the different types of cyberattacks, the covert attack is one of the hardest to detect — it is undetectable when the system is operating under normal conditions. In this paper, we develop a data-driven detection framework that utilizes the degradation process of the system to detect covert attacks. We derive mathematical characteristics of the degradation signals under covert attacks for different scenarios. We verify our methodology through an extensive numerical study as well as a case study.

5 - A Prognostic Framework for Complex Engineering Systems with Multi-failure Modes

Liexiao Ding, Georgia Institute of Technology, Atlanta, GA, United States

Many systems and subsystems usually have more than one cause of failure. Therefore, in real world applications, it is important to distinguish between these different causes of failures also known as Multi-failure Modes. To address the challenges, we develop a prognostic method-ology, utilizing multi-sensor stream, to identify failure mode and then predict remaining useful life(RUL) of partially degraded systems. We propose a finite mixture of (log)-location-scale regression to model inhomogeneous sensor streams and use a grouped-penalized maximum likelihood estimator to perform sensor selection.

1 - Combining Causal Inference and Queueing Theory to Study Waiting in Emergency Department

Danqi Luo, Stanford Graduate School of Business, Stanford, CA, United States, Mohsen Bayati, Sara Kwasnick, Erica Plambeck

This work provides theoretical and empirical evidence that in an ED, the arrival of an additional low-acuity patient substantially delays high-acuity patients. To estimate the effect, we propose a temporal causal structure motivated by queueing theory to estimate the cumulative extra wait times caused by one low-acuity patient on high-acuity patients. A stylized queueing model mimicking ED operations is built to provide robustness checks for our estimation framework, moreover, under which, we provide theoretical lower bounds for the extra wait times to understand better the delaying process. Evidence from a quasi-randomization in a wait-time forecast field experiment provides insights on how to mitigate such delay.

2 - MMR Vaccination Rates and the Effect of New Information

Lida Anna Apergi, University of Maryland, College Park, MD, 20742, United States, Margret V. Bjarnadottir, John Baras, Bruce L. Golden

The MMR vaccine against measles, mumps, and rubella is administered to young children. An increasing number of parents choose not to vaccinate their children in part due to a misconception that links the MMR to autism spectrum disorders. Those concerns are not supported by scientific evidence. Nevertheless, the MMR vaccination rates have dropped in recent years, which has led to a number of measles outbreaks in the US including the extensively covered outbreak in Disneyland in early 2015. In this study, we investigate policy, economic and demographic factors that influence MMR rates in addition to the effect of the Disneyland outbreak.

3 - Continuity of Care and Primary Care Workload

Harshita Kajaria, University of Cambridge, St Edmunds College, Mount Pleasant, Cambridge, CB3 0BN, United Kingdom, Michael Freeman, Stefan Scholtes

We present a comprehensive dataset of longitudinal patient-level data from the NHS, comprising primary and secondary care usage of 5M patients registered with 300 primary care practices across the UK over the course of 10 years. We will present preliminary results on the effect of continuity of care, i.e. seeing your preferred primary care physician, on the duration and frequency of primary care appointments.

4 - Sequence Mining for the Patient Journey: Process Clustering in Claims Data

Katherine Bobroske, Cambridge Judge Business School, Trumpington Street, Cambridge, CB2 1AG, United Kingdom, kab80@jbs.cam.ac.uk, Lawrence Huan, Christine Larish

Medical and pharmaceutical claims provide a rich basis for research in healthcare operations; however, the structure and level of detail in medical claims makes it difficult to draw generalizable insights. Some work in data and process mining has clustered patients into analyzable subsets based on patient characteristics and similarities in their healthcare encounters. In this research, we investigate whether there is added value to clustering patients using the sequence of their healthcare interactions. We develop a data-driven algorithm (inspired by gene sequencing) and compare the predictive power of the resulting clusters to those obtained with more traditional approaches.

1 - Computational Process Research: A Sequence Analytics Approach

Zhewei Zhang, Assistant Professor, University of Warwick, Coventry, United Kingdom, Zhewei.Zhang@warwick.ac.uk, Habin Lee, Youngjin Yoo, Youngseok Choi

Existing process studies generally rely on researchers' own observations and interpretations to embrace the contextual richness. Our paper introduces the computational sequence analytics as a methodological tool for process study. We argue that computational tools and theoretical ideas need to be tightly integrated, and discuss how the critical realism thinking can play important roles in such study. Based on these ideas, we propose an integrated framework, and show particularly how sequential pattern mining can be used to detect latent patterns of social changes and help to understand the underlying mechanisms.

2 - A Network Perspective on the Shaping of Routines in Open Source Software Project

Xinyu Li, Case Western Reserve University, Cleveland, OH, United States

This study seeks to extend existing knowledge on routines in open source software (OSS) projects. We propose a framework to theorize how routines in OSS contexts are shaped by a network of OSS projects. We argue that more similar routines tend to emerge between OSS projects when the projects are more related to each other in the network due to their overlapping developers. Empirically, we investigated a set of OSS projects utilizing 90,975 digital trace data. We found that the routine similarity is negatively associated with the network distance between the projects. Our findings suggest that network relations among OSS projects may be an overlooked factor that shapes routines in the projects.

3 - Customer Engagement at Fingertips: A Large-scale Field Experiment Using Tap Stream Data

Wei Chen, University of Arizona, Tucson, AZ, 85718, United States, weichen@email.arizona.edu, Karen Xie, Jiaheng Xie, Dong Jing

In this research, we aim to increase the acceptance rate of push-notification request by incorporating the engagement state of users generated from users' tap data on smartphones and machine learning algorithms. We achieve this goal in two steps: First, we use machine learning to learn the engagement state of a user with the user's click and tapping data on a mobile phone device. Second, we use the machine learning model trained in the first step to evaluate the engagement state of a user in real time, and based on that to conduct a field experiment to evaluate the effectiveness of incorporating the engagement state of the user.

4 - Use of the Word Embedding Space to Identify Pragmatic Categories, i.e., Categories Defined by Sharing Pragmatic Contexts

Aakash Saxena, University of Colorado-Boulder, Boulder, CO, 80309, United States, aakash.saxena@colorado.edu, Jintae Lee

Recently developed methods of creating a vector space of word embeddings have produced evidence that they capture similarities among words. They capture semantic similarity because semantically similar words share many contexts. They also capture pragmatic similarity for the same reason. For example, vectors of the leader and visionary words have high cosine similarity because they appear together in the same contexts, as they are related pragmatically. We propose a method that uses word vector space to identify pragmatic categories, members of each of which are closer in the space as they co-occur in many instances of a given pragmatic context, such as in evaluating leaders, services, or products.

Innovative Methods in Text Mining

Sponsored: Data Mining

Sponsored Session

Chair: Jiao Wu

1 - The Hierarchical Text Mining Approaches for Multilevel Online Reviews

Ying Wang, Ph.D, Northern Illinois University, Dekalb, IL, 60115, United States, ywang15@niu.edu, Jaeki Song

Although considerable studies been conducted to analyze online reviews, little research addresses the hierarchical structure of this complex unstructured data in consumer's decision-making process, which consists of an original post followed by reply posts ordered by time. This paper is to investigate online reviews with multiple levels of nesting structure - reply posts nested within original posts within products. We aim to reveal the linguistic pattern embedded in online reviews, focusing on investigating how linguistic alignment and information congruence among reviews influence prospective consumer's information processing as well as their attitudes towards reviews and products.

2 - Adapting Neural Language Models for Classifying Microblog Sentiment

Jiao Wu, Northern Illinois University, 990 Parkhill Cir, Aurora, IL, 48858, United States, Shuyuan Deng, Dong-Heon Kwak, Atish P. Sinha, Huimin Zhao

In recent years, neural language models have been widely used for sentiment classification. However, general word embeddings are not designed to capture sentiment information. This study proposes a deep learning architecture that incorporates both general word embeddings and sentiment-specific word embeddings. It has achieved state-of-the-art results in classifying sentiment of investment-related microblog messages.

3 - Friend Recommendations Based on User-generated Contents

Jiaxi Luo, Ph.D, Midwestern State University, Wichita Fall, TX, 76308, United States, jiaxi.luo@msutexas.edu

Web 2.0 technologies have made modern SNSs increasingly popular, and SNS has expanded explosively across the web. Too many new users may cause the cold start problem. Users sign up on a SNS and discover they do not have any contacts. Normally, SNSs solve it by recommending potential friends. The huge amount of UGC could provide rich data for building an accurate, extensible user model that reflects their interests, sentiments, and personalities. From the computer-supported social matching process, these attributes could influence friend matches. In this study, we develop a text analytic framework. The results show that text features could further improve recommendation performance.

4 - Clustering Clinical Trials with Text Mining

Euisung Jung, PhD, the University of Toledo, Toledo, OH, 43606, United States, Euisung.jung@utoledo.edu

The focus of the study is to cluster and summarize clinical trial information at cluster level to enhance trial search efficiency. We propose a novel method to narrow the clinical trial search space using a custom dictionary and the UMLS Semantic Network. In this study, we cluster similar clinical trials using the domain-specific lexicon and a semantic-based feature expansion technique using Unified Medical Language System (UMLS) to resolve semantic ambiguity. A hierarchical agglomerative clustering algorithm is used. We generate word n-gram features for each clusters and modify the features with the domain-specific dictionary matching process which can be used to map a patient to a cluster.

5 - How Consumers Evaluate a New Fashion Product Through Online Review Platform

Peng Li, Ph.D, Rutgers Business School Newark and New Brunswick, Piscataway, NJ, 08854, United States, peng.li.scm@rutgers.edu, Shaoqiong Zhao, Ke Liu

With the rise of social media, online review has become more and more important as an influential source of information both for the managers and consumers. Now we can utilize this new source of information to understand how consumers evaluate new fashion products. In this paper we not only examine the contents of attributes of clothing consumers value when they stay but also attempted to categorize a number of key areas by the level of importance as measured from consumers' online reviews. In addition, the text mining methodology and inverse classification help us identify the key features that are related to positive/negative overall attitudes of online consumers.

6 - How MicroFinance Empowers the Economies of Developing Countries, a Social Media Analytics Approach

Ahmed Elnoshokaty, PhD, Northern Michigan University, Marquette, MI, 49855, United States, aelnosho@nmu.edu, Mohamed Elsaied

Microfinance is a category of financial services targeted at poor individuals and small businesses who lack access to conventional banking and related services. Although microfinance empowers the economies of developing countries, microfinance challenges remain for reaching wide-scale adoption and use. This work aims to achieve a wider spread of the microfinance services through a particular emphasis on enlightening microfinance service providers with insights on factors that influence microfinance adoption derived from mining borrowers and potential borrowers concerns on Twitter.

Joint Session DM/Practice Curated: Data Mining Applications in Electronic Health Records

Sponsored: Data Mining

Sponsored Session

Chair: Ozgur Ozmen

Co-Chair: Olufemi Omitaomu

1 - De-identifying Clinical Notes at Scale

Ioana Danciu, Oak Ridge National Laboratory, Oak Ridge, TN, United States, Everett Rush, Edmon Begoli

Clinical notes offer invaluable insights into patients' health trajectories, but transforming the text into a research-ready form is no easy task. We present our approach to scrubbing billions of notes of protected health information (PHI) as defined by HIPAA. We used Apache Spark and worked with the National Library of Medicine (NLM) to adapt their PHI scrubber to our big data framework. The framework is generalizable to other natural language processing tasks. The results are supporting the Million Veterans Program (MVP) and are available to Veterans Affairs (VA) and Department of Energy (DOE) researchers.

2 - Aggregation and Reporting Frequencies of Healthcare Transactions to Identify Anomaly

Ozgur Ozmen, Oak Ridge National Laboratory, Oak Ridge, TN, United States, ozmeno@ornl.gov, Hilda Klasky, Karthik Rajasekar, Olufemi Omitaomu, Mohammed Olama, Laura Pullum, Teja Kuruganti

The implementation of the health IT systems has resulted in unintended consequences, often escalating to hazards in patient care. Monitoring the anomalous number of healthcare transactions is an effective way of detecting hazards. In this talk, we describe a method of aggregating clinical order transaction counts (i.e., rejections) that extracts the data from Veterans Affairs EHR system and preprocess the data by leveraging high performance slice-and-dice analytics. We present a Statistical Process Control based detector that works on the meta-data and describe a use-case that guides root cause analysis of hazards via fast data aggregations.

3 - Hazard Detection in Electronic Health Records Using Real-time Forecasting Approach

Jordan Pellett, Oak Ridge National Laboratory, Oak Ridge, TN, United States, pellett.jordan@uwlax.edu, University of Tennessee, Knoxville, TN, United States, Olufemi Omitaomu

Detecting hazardous events in Electronic Health Records (EHR) is a challenge due to the diverse and noisy contents of EHR. In this paper, we present a real-time forecasting approach to detect hazardous events in EHR streaming data. This approach uses temporal frequency of activities to characterize events. Once a hazardous event is detected, our approach suppresses its effect in subsequent time intervals; this enables the detection of new and emerging events. Experiments are performed using EHR data from the Corporate Data Warehouse of the Veterans' Affairs. Results show considerable improvement over existing hazard detection methods in most cases.

4 - Reverse-engineering Event Sequence Data from Clinical Order Transactions for Machine Learning Techniques

Hilda Klasky, Oak Ridge National Laboratory, TN, United States, Ozgur Ozmen

A common way of analyzing electronic health records is to represent them as event sequences and investigate temporal patterns. In the absence of well-defined event logs in corporate data warehouses (CDW), we needed to extract relevant information scattered among numerous tables. In this talk, we will describe the procedure applied to clinical order transactions in Veterans Affairs CDW. We extracted recorded dates columns related to status updates and represented them as time-sorted event sequences. These event sequences were leveraged for process mining techniques. We will conclude the talk with an example of how machine learning can be applied to this data to identify irregular order patterns.

5 - Online Detection of Abrupt Transitions in Electronic Health Records

Yunhe Feng, University of Tennessee, Knoxville, TN, United States, yfeng14@vols.utk.edu, Olufemi Omitaomu, Qing Cao

Abrupt transitions in data from Electronic Health Records (EHR) could suggest anomalous behavior of Health IT systems. In this paper, we present new approaches for detecting abrupt transitions in EHR data with special focus on machine-generated errors. We used the results obtained to quantify the spatio-temporal patterns of machine errors in large-scale EHR data.

Emerging Themes at the Intersection of Artificial Intelligence and Optimization

Emerging Topic: Artificial Intelligence & Machine Learning

Emerging Topic Session

Chair: Rahul Mazumder, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States

1 - understanding Accelerated Optimization Methods via Differential Equations

Weijie Su, The Wharton School, University of Pennsylvania, Philadelphia, PA, United States, suw@wharton.upenn.edu

This talk introduces a framework that uses ordinary differential equations to model, analyze, and interpret gradient-based optimization methods. We derive a second-order ODE that is the limit of Nesterov's accelerated gradient method for non-strongly objectives (NAG-C). The continuous-time ODE is shown to allow for a better understanding of NAG-C and, as a byproduct, we obtain a family of accelerated methods with similar convergence rates. Next, we derive high-resolution ODEs as more accurate surrogates for three first-order methods. This is based on joint work with Stephen Boyd, Emmanuel Candes, Simon Du, Michael Jordan, and Bin Shi.

2 - Robustness and Generalization Guarantees for Overparameterized Neural Network Training

Mahdi Soltanolkotabi, University of Southern California, Los Angeles, CA, United States

Modern neural nets are trained in an over-parameterized regime of where the parameters exceed the size of the training dataset. These models in principle have the capacity to (over)fit any set labels including pure noise. However, somewhat paradoxically, models trained via first-order methods predict well on yet unseen test data. I will discuss some results aimed at demystifying such phenomena by demonstrating that gradient iterates: (1) converge at a geometric rate to a generalizable global optima and (2) are provably robust to noise/corruption/shuffling on a fraction of the labels with these algorithms only fitting to the correct labels and ignoring the corrupted labels.

3 - Learning Hierarchical Interactions at Scale

Hussein Hazimeh, MIT, Cambridge, MA, United States, hazimeh@mit.edu, Rahul Mazumder

In many learning settings, it is beneficial to augment the main features with pairwise interactions. Such interaction models can be often enhanced by performing variable selection under "strong hierarchy": an interaction is nonzero only if its associated main features are nonzero. We model the problem as a MIP and develop a scalable algorithm for solving it, by integrating a specialized first order method into a non-linear branch-and-bound (BnB) framework. While modern MIP solvers cannot go beyond 20,000 interactions, our open-source BnB handles 50 million interactions in minutes. Comparisons with state-of-the-art relaxations indicate considerable statistical gains from solving the MIP.

4 - Constrained Optimization in Machine Learning

Juan Pablo Vielma, Massachusetts Institute of Technology Cambridge, MA, 02142, United States, Ross M. Anderson, Chris Coey, Joseph Huchette, Lea Kapelevich, Will Ma, Christian Tjandraatmadja

While the machine learning world is dominated by unconstrained optimization models and methods, the operation research world often (or even mostly) considers constrained optimization models and methods. In this talk we consider the potential impact of constrained optimization in machine learning through two specific applications. The first application considers the use of mixed integer programming to verify robustness of trained deep neural network. The second application considers the use of advanced interior point solvers for shape constrained regression.

5 - Randomized Gradient Boosting

Rahul Mazumder, MIT, Cambridge, MA, 02142, United States, Haihao Lu

Gradient Boosting Machine (GBM) introduced by Friedman is an extremely powerful supervised learning algorithm that is widely used in practice —- it routinely features as a leading algorithm in machine learning competitions such as Kaggle and the KDDCup. In spite of the usefulness of GBM in practice, our current theoretical understanding of this method is rather limited. In this work, we propose Randomized Gradient Boosting Machine (RGBM) which leads to significant computational gains compared to GBM, by using a randomization scheme to reduce the search in the space of weak-learners.

Sponsored Session

Chair: Feng Qiu, Argonne National Laboratory, Lemont, IL, 60439, United States

Co-Chair: Alinson Xavier, Argonne National Laboratory, Argonne, IL, 60439, United States

1 - Real-time Faulted Line Localization and PMU Placement in Power Systems

Deepjyoti Deka, Los Alamos National Lab, 3200 Canyon Road, Los Alamos, NM, 87544, United States

Diverse fault types, fast re-closures, and complicated transient states after a fault event make real-time fault location in power grids challenging. We present a localization method based on a Convolutional Neural Network (CNN) classifier using bus voltages. Unlike prior data-driven methods, the proposed classifier is based on features with physical interpretations that improve the robustness of its performance. Further a phasor measurement units (PMU) placement strategy is proposed to maximize the performance. A significant aspect of our methodology is that under very low observability, the algorithm is still able to localize the faulted line to a small neighborhood with high probability.

2 - Learning for Constrained Optimization by Identifying Active Constraints

Sidhant Misra, Los Alamos National Lab, Los Alamos, NM, United States

Decision making process in many energy systems involve solving similar optimization problems routinely with small variations in parameters. By using the information available in this repeated solution process, we propose to learn a model of the optimal solution as a function of the parameters. The method is based on identifying the optimal active constraints, and provides a natural way to enforce constraints while being interpret-able. A streaming algorithm is proposed to learn the relevant active sets for a given parameter distribution, and a classifier is employed to predict the optimal active set. The approach is demonstrated on the DC Optimal Power Flow problem on a large range of test cases.

3 - Modeling, Analysis and Prediction of Weather-induced Outages Using Graph Convolutional Networks

Rui Yao, Argonne National Laboratory, Lemont, IL, 60439, United States, yaorui.thu@gmail.com, Feng Qiu, Jie Chen

Adverse weather is a major threat to the security of electric power systems because it can cause widespread power outages. However, the weather-induced outages are complex in nature and are difficult to model. In this work, we demonstrate the modeling and prediction of weather-induced outages with machine learning techniques. With the real customer outage data with geographical information and the weather data records, we use the graph convolutional network (GCN) and recurrent neural network (RNN) to model the spatio-temporal interdependency of the outages under the weather influence in the power grid. We also demonstrate the prediction of weather-induced outages based on the trained models.

4 - Learning the Weather Impacts on Power System Outage

Xinda Ke, Pacific Northwest National Laboratory, Richland, WA, United States, Qiuhua Huang

In this talk, we will first give a overview of machine learning and its applications in power systems (smart grid). Then, we will present a specific case study of applying various machine learning and data analytic techniques to analyze and quantify the impacts of weather, in particular severe weather conditions, on power system outages. Our study is based on realistic power system outage data and weather data collected in the Northwest region of the U.S. over the last 20 years.

1 - Fifteen Years of Capital Budgeting, a Literature Review of Resource Allocation Problems

Erich D. Morman, Naval Postgraduate School, Monterey, CA, 93940, United States

The capital budgeting problem is universal across all institutions. Whether examining problems of providing quality healthcare service, purchasing military assets, improving manufacturing, or investing in research and development, decision makers must make difficult choices with limited resources to determine which projects within their organization will receive funding and which projects will not. This literature survey takes a closer look at fifteen years of capital budgeting: 2004 to 2018. The research provides an examination of the most recent capital budgeting methodologies and an investigation into how current scholars are modeling the different components of capital budgeting.

1 - Fairness Without Demographics in Repeated Loss Minimization

Hongseok Namkoong, Stanford University, Stanford, CA, 94305, United States, Tatsunori Hashimoto, Megha Srivastava, Percy Liang

Machine learning models (e.g., speech recognizers) are trained to minimize average loss, which results in representation disparity—-minority groups (e.g., non-native speakers) contribute less to the training objective and thus tend to suffer higher loss. Worse, as model accuracy affects user retention, a minority group can shrink over time. We show that empirical risk minimization (ERM) amplifies representation disparity over time, which can even make initially fair models unfair. Distributionally robust optimization controls the risk of the minority group at each time step, in the spirit of Rawlsian distributive justice, while remaining oblivious to the identity of the groups.

2 - On the Impacts of Tail Model Uncertainty in Rare-event Estimation

Henry Lam, Columbia University, New York, NY, United States, khl2114@columbia.edu

Rare-event probabilities and risk measures can be sensitive to the accuracy of the underlying input models, especially regarding their tail behaviors. We investigate how the lack of tail information of the input can affect the output extremal measures, in relation to the level of data that are needed to inform the input tail. We argue that heavy-tailed problems are much more vulnerable to input uncertainty than light-tailed problems. We explain this phenomenon via their large deviations behaviors, and substantiate with some numerical experiments.

3 - Probability Functional Descent Algorithms

Carson Kent, Stanford University, Stanford, CA, 94305, United States, Jose Blanchet, Peter W. Glynn

Many optimization and estimation problems of interest can be abstracted into a form which involves optimizing a functional over the space of probability measures on a given a domain. Examples of these formulations include variational inference, Markov decision processes, and optimal transport costs. We present gradient descent algorithms which are shown to achieve fast convergence guarantees for these problems. Our results include duality results of independent interest which have implications in the context of distributionally robust optimization.

4 - Risk-sensitive Inference

Harsha Honnappa, Purdue University, West Lafayette, IN, United States, honnappa@purdue.edu, Prateek Jaiswal, Vinayak Rao

We consider a single-stage stochastic optimization problem, where the stochastic variable is only known through a parametrized predictive model. Operating in a Bayesian setting, we study the interplay between posterior estimation and decision-making through a “risk-sensitive” lens by leveraging dual representations of convex risk measures. We prove finite sample probabilistic bounds on an oracle regret function and illustrate these results through simulations on an example problem. Time permitting, we will discuss extensions of the methodology to non-Bayesian and multi-stage problems.

1 - Optimal Dynamic Futures Portfolios

Yang Zhou, University of Washington, Seattle, WA, 98105, United States, Tim Leung

We study the problem of dynamically trading a portfolio of futures contracts under a number of stochastic multi-factor models. A utility maximization approach is developed to determine the optimal futures trading strategies. Applications to volatility and oil futures are discussed.

2 - Interpretable Sparse Proximate Factors for Large Dimension

Markus Pelger, Stanford University, Stanford, CA, 94305, United States, Ruoxuan Xiong

This paper approximates latent statistical factors with sparse and easy-to-interpret proximate factors. Latent factors in a large dimensional factor model can be estimated by principal component analysis, but are usually hard to interpret. By shrinking factor weights, we obtain proximate factors that are easier to interpret. Proximate factors consisting of 5-10% of the cross-section observations with the largest absolute weights are usually sufficient to almost perfectly replicate the population factors, without assuming a sparse structure in loadings. We provide analytical asymptotic bounds for the correlation of proximate factors with population factors based on extreme value theory.

3 - Conditional Importance Sampling for Event Timing

Alex Shkolnik, UCSB, UCSB, Santa Barbara, CA, United States

This article develops a conditional important sampling (IS) for a wide range of stochastic point process models of event counting processes. We contribute to the event timing simulation literature by designing, implementing and testing a simple and practically efficient IS scheme for tail probabilities. Our approach to the design of the scheme is nontrivial and is of independent interest. Numerical results demonstrate its application to estimating rare-event probabilities and pricing interest rate derivatives with efficient performance. Joint work with Baeho Kim.

4 - The Gorin-Shkolnikov Identity and its Random Tree Generalization

David Clancy, University of Washington, Seattle, WA, United States

The recent work of Gorin and Shkolnikov (2018) have shown the area under normalized Brownian excursion minus half the integral of its total local time squared is a centered Gaussian with variance 1/12. Hariya (2016) gave a path-wise proof of the same result. Gaudreau Lamarre and Shkolnikov (2017) generalized this to reflected Brownian bridges and asked for a combinatorial interpretation. We provide a combinatorial interpretation as the limit of the difference of two quantities on random forests on n nodes. We further generalize this to other forest models outside of a Brownian setting.

Chair: Seyed Emadi

1 - Menu Costs and the Bullwhip Effect: Supply Chain Implications of Dynamic Pricing

Robert Louis Bray, Kellogg School of Management, Northwestern University, Evanston, IL, 60202, United States, r-bray@kellogg.northwestern.edu

We study the supply chain implications of dynamic pricing. Specifically, we estimate how reducing menu costs—-the operational burden of adjusting prices—-would affect supply chain stability. We estimate that removing menu costs would stabilize the supply chain by attenuating order batching. Specifically, we estimate that removing menu costs would cut the average batch size by 5.0%, which would decrease the average standard deviation of orders by 3.9%

2 - Machine Learning in Demand Estimation with Long Tail Data

Fanyin Zheng, Columbia University, Columbia Business School, 412 Uris Hall, New York, NY, 10027, United States, Pu He

Discrete choice demand estimation is an important tool of empirical studies in operations management, economics, and marketing. The most commonly adopted framework is introduced by Berry, Levinsohn, and Pakes (1995, BLP). One disadvantage of BLP is that it exhibits major limitations when the customer choice data has long tails-i.e., when many products and services offered have zero demand or very low demand at a given period of observation. In this paper, we show that the common practice of dropping products and services with zero and low sales introduces substantial bias in BLP estimates. We propose a solution to correct for the bias using a two-stage estimator.

3 - An Empirical Study of Caller Behavior under a Callback Option

Brett Hathaway, UNC Chapel Hill, Chapel Hill, NC, 27514, United States, brett_hathaway@kenan-flagler.unc.edu, Seyed Emadi, Vinayak V. Deshpande

While call centers have recently invested in callback technology, the impact of this innovation on caller behavior and call center performance is not clearly understood. Using call center data from a US commercial bank, we perform an empirical study of the callers’ decision-making process in the presence of a callback option.

4 - Intended and Unintended Consequences of Drug Price Regulations

Andrew Wu, Assistant Prof of Technology, Operations, Finance, Ross School of Business, University of Michigan, Ann Arbor, MI, United States, andydiwu@umich.edu, Jun Li

To curb rising drug prices, regulators in many countries have implemented, or plan to implement, various forms of price regulation, including mandated price ceilings for individual drugs. We exploit a major policy shift in the Chinese pharmaceutical market — the elimination of longstanding ceilings on retail drug priciest — to examine the impact of price regulations on drug prices. We find that overt drug price regulation, such as price ceilings, could lead to the unintended consequence of inflated prices, potentially due to asymmetric information and focal point pricing.

Co-Chair: Danielle Morais, Universidade Federal de Pernambuco, Recife - PE, 52020-212, Brazil

1 - Modeling Social Distance and Altruism in Systems of Shared Mobility as a Multi-Criteria Decision Problem

Dmitry Gimon, Park University, Parkville, MO, United States, dmitry.gimon@park.edu

Shared mobility systems allow people to increase the efficiency of infrastructure use. We consider shared infrastructure use as a complex collective decision problem, where users make decisions on how to use the system. Altruism drives individuals to act in the interest of others. In this study, we modeled individual decision making as a multi-criteria problem. We applied a model of altruism as a function of the social distance between the users in order to study the benefit of connecting shared mobility users to each other. As a decrease in social distance results in increases of altruism, we studied how this change affects the efficiency of sharing. We used simulations to test the proposed model.

2 - A Multicriteria Group Decision Approach to Define Maintenance Policies under Resource Constraints

Alexandre Alberti, Brazil, alexandre.emc091@gmail.com, Cristiano Cavalcante, Danielle Morais

We present a group decision approach for the definition of maintenance policies in contexts involving multiple sectors, which share the resources available for asset maintenance. Each sector has its specific characteristics and operating requirements and is represented by a decision maker (DM), who considers the criteria that he deems pertinent to make decisions on maintenance. However, the amount of resources for maintenance may be a constraint to maximizing all the DMs' satisfaction, and then we present an approach that can be used to seek better solutions for the group as a whole.

3 - Applying VFT and Fitradeoff for Multicriteria Group Decision Making in the Context of Brazilian Federal Police Operational Activities

Carla P. Cunha, Universidade Federal de Pernambuco, Recife, Brazil, cunhacarla1976@gmail.com, Caroline Miranda Mota, Adiel Teixeira De Almeida, Eduarda Frej

Under an investigative aspect, the duties of Brazilian Federal Police are innumerous. In this context, considering that the driving force of the decision-making process should be the set of organizational values, this work intends to demonstrate the significant decision support that may come from the application of the Value-Focused Thinking (VFT) method in the identification of values and objectives of the Federal Police and subsequent application of the FITradeoff method for multicriteria group decision making (MCGDM), in order to make the judicial police of the Federal Union more efficient.

4 - Multicriteria Group Decision Making (MCGDM) Processes with Flexible and Interactive Tradeoff Elicitation

Adiel Teixeira De Almeida, Universidade Federal de Pernambuco, Recife PE, 50630-970, Brazil, Eduarda Frej, Lucia Reis Peixoto Roselli

A decision support system is presented for MCGDM with FITradeoff method, which uses partial information for criteria aggregation by an additive model in MAVT scope. For choice, it explores potential optimal alternatives. For ranking, it searches for dominance relations between alternatives. The DSS presents flexibility to help agreements about the best alternative for the group of DMS. The process is enhanced by using graphical visualization, whose design has been improved by using neuroscience experiments, which also produces insights for the analyst when interacting with DMs. The DSS is easily available at www.fitradeoff.org and has been applied in many situations.

Sponsored Session

Chair: Luyi Yang, Johns Hopkins University, Baltimore, MD, 21202, United States

1 - Ride Solo or Pool: Designing Price-service Menus for a Ride-sharing Platform

Jagan Jacob, University of Rochester, Simon Business School, Rochester, NY, 14627, United States, Ricky Roet-Green

A ride-sharing platform (RSP) such as Uber or Lyft, can sometimes offer passengers an option to share (pool) the ride with fellow passengers. On the one hand, a passenger who pools benefits from paying a lower fare and the RSP benefits from increasing occupancy-per-car, thereby serving more passengers. On the other hand, a passenger who pools takes more time on average to reach her destination and may have to share the ride with a stranger, and the RSP gets a lower profit margin per passenger compared to solo rides. We develop a queueing model to find the RSP's optimal revenue at equilibrium when passengers are strategic and drivers are independent agents.

2 - A Queueing Model and Analysis for Autonomous Vehicles on Highways

Neda Mirzaeian, PhD Candidate, Carnegie Mellon University, Pittsburgh, PA, 15217, United States, mneda@andrew.cmu.edu, Soo-Haeng Cho, Alan Scheller-Wolf

Autonomous vehicles (AVs) have a potential to significantly improve highway congestion, since these vehicles are able to maintain smaller inter-vehicle gaps, and travel together in larger platoons (or batches) than human-driven vehicles (HVs). We model a multi-lane highway segment as a queueing system, and analyze two policies: the designated-lane policy (designating one lane to AVs) and the integrated policy (allowing both AVs and HVs in any lane). After calibrating our model to data, we compare the performance of these two policies that depend on the proportion of AVs and the highway load.

3 - Economic Behavior of Information Acquisition: Impact on Peer Grading in Moocs

Dongyuan Zhan, University College London, School of Management, Gower Street, London, WC1E 6BT, United Kingdom, d.zhan@ucl.ac.uk, Onesun Steve Yoo

A critical issue in operating Massive Open Online Courses (MOOCs) is the scalability of providing feedback. Since it is infeasible for instructors to grade large number of students' assignments, MOOCs employ peer-grading systems. We investigate how the economic behavior of student graders impacts the accuracy of peer grading. We characterize grading as the process of acquiring information about the quality of the assignment, present the economic tradeoff facing each student grader, and analyze the unique equilibrium grading behavior of a homogeneous group of students. We identify the condition under which peer grading fails, namely when each grader submits uncorrelated grades in equilibrium.

4 - Invite Your Friend and You'll Move Up in Line: Optimal Design of Referral Priority Programs

Luyi Yang, Johns Hopkins University, Baltimore, MD

This paper studies the optimal design of referral priority programs, in which customers on a waitlist can jump the line by inviting their friends to also join the waitlist. Recent years have witnessed a growing presence of referral priority programs as a novel customer acquisition strategy for firms that maintain a waitlist. Different variations of this scheme are seen in practice, raising the question of what should be the optimal referral priority mechanism. We build an analytical model that integrates queueing theory into a mechanism design framework, where the objective of the firm is to maximize the system throughput, i.e., to accelerate customer acquisition. Our analysis shows that the optimal mechanism has one of the following structures: full-priority, partial priority, first-in-first-out (FIFO), and strategic delay.

Chair: He Wang, Georgia Institute of Technology, Atlanta, GA, 30332-0205, United States

1 - Pricing for Online Truckload Shipping Platforms

Yufeng Cao, Georgia Institute of Technology, Atlanta, GA, 30080, United States, yufeng.cao@gatech.edu, Anton J. Kleywegt, He Wang

Recent startups are moving truckload brokerage online and smooth the matching process with technology innovation. Nevertheless, challenges exist for these online truckload matching platforms: (a) randomness on both sides of the market; (b) limited control over the resource.

Our study explores operations management problems in these platforms and provides new managerial insights on two-sided marketplaces. We propose a mathematical model that captures stochastics on both sides of the market. We study the optimal pricing policy in different settings and develop heuristics to achieve near-optimal performance. We also suggest ways to improve matching outcomes in these platforms.

2 - Optimal Service System Design with Flexible Servers and Priority Customers

Xuan Wang, Hong Kong University of Science and Technology, School of Business and Management, LSK 4079, Kowloon, Hong Kong, xuanwang@ust.hk, David Chen, Ruoran Chen, Rowan Wang

We study a non-preemptive service system with two priority classes and two flexible servers with heterogeneous service rates. We give a complete characterization of the optimal service policy for this system, which is a threshold type with strategic idling. We develop an algorithm to compute the optimal thresholds that minimize the long-run average waiting cost. In comparison to a benchmark policy where a dedicated server is assigned to customers with a higher priority, we find that the optimal policy in our proposed flexible configuration always performs better in terms of the long-run average waiting cost as well as the probability that a new arrival has to wait for both classes of customers.

3 - Robust Online Resource Allocation: a Competitive Analysis of Service Reservations with Heterogeneous Types

Jinglong Zhao, Massachusetts Institute of Technology, 77 Massachusetts Avenue, Cambridge, MA, 02139, United States, Will Ma, David Simchi-Levi

Our model is motivated by an industry partner's supply chain. A manufacturing plant, having some initial stock capacity, receives a sequence of orders which request some fraction of that stock. The plant must decide whether to fulfill the order using its stock, or reject it. Orders cannot be split and if there is not enough stock left to fulfill the entire order size, then the order must be rejected. The plant is trying to maximize its final utilization. We propose a randomized threshold policy, which has a 0.432-competitive ratio on a single knapsack. We further generalize our results to multiple knapsacks.

4 - Dynamic Pricing in Two Sided Queuing Systems

Sushil M. Varma, PhD Student, Georgia Institute of Technology, Atlanta, GA, United States, sushil@gatech.edu, Pornpawee Bumpensanti, Siva Theja Maguluri, He Wang

We studied two-sided queuing systems in which, unlike the traditional queuing systems, customers and server both arrive and wait in the queue until they are matched. As soon as a customer is matched with a server, they leave the system and the service is assumed to be complete instantaneously. We make the system positive recurrent by employing the idea of dynamic pricing. We formulated our system as an average cost Markov decision process to maximize the revenue earned by the system operator. We proved some structural properties of the pricing policies and extended these ideas to a system with multiple types of customers and servers.

Empirical Studies in Operations Management

Sponsored: Manufacturing & Service Oper. Mgmt/Supply Chain

Sponsored Session

Chair: Serguei Netessine, The Wharton School, Philadelphia, PA, 19104, United States

1 - Do Performance Nudges Work for Driving Performance? Evidence from A Field Experiment

Vivek Choudhary, INSEAD Business School, Singapore, vivek.choudhary@insead.edu, Masha Shunko, Serguei Netessine

Can non-monetary interventions improve driving behavior when real-time feedback with monetary incentives fail (Choudhary et al. 2018)? Conducting a randomized field experiment with >1050 drivers, we investigate this question. Using a telematics smartphone application, we provide real-time feedback to the drivers and nudge them to improve. We use three types of performance nudges - personal best, personal average and latest score nudge. Our results show that not all types of nudges work. Personal best and average performance nudges found to be more effective. Our work contributes to the literature by providing evidence that a costless intervention can be effective in changing behavior.

2 - When the Crowd Grows Restless: Managing Interventions on Crowdfunding Platforms

Philipp Benjamin Cornelius, Rotterdam School of Management, Mandeville Building T09-10, Burgemeester Oudlaan 50, Rotterdam, 3062 PA, Netherlands

Crowdfunding has become a cornerstone of entrepreneurial finance, but it also exposes companies to significant reputational risk from crowds that quickly turn hostile if they feel ignored or if the campaign does not progress as expected. Companies have several options to intervene in such cases, however certain interventions can aggravate the situation while others are costly. We empirically study the efficacy of different intervention strategies.

3 - Decoupling Learning Rates Using Empirical Bayes

Sareh Nabi, University of Washington, Seattle, WA, United States, snabi@uw.edu

Two often-faced challenges in Management Science applications are the absence of informative priors, and the inability to control parameter learning rates. We propose an Empirical Bayes approach that addresses both challenges. Our method learns empirical priors from data itself and uses them to decouple the learning rates of any feature grouping in a Generalized Linear Model. We apply our method to a standard optimization problem as well as an online combinatorial optimization problem in a contextual bandit setting in an Amazon production system. Our method shows marked improvements, especially in cases of small traffic and can be applied to any problem instance modeled as a Bayesian framework.

4 - Inconvenience, Liquidity Constraints, and the Adoption of Off-grid Lighting Solutions

Serguei Netessine, The Wharton School, Philadelphia, PA, Bhavani Shanker Uppari, Ioana Popescu, Rowan P. Clarke'

A significant proportion of world's population does not have access to grid-based electricity, and so relies on off-grid lighting solutions. Rechargeable bulb technology is becoming prominent as an alternative off-grid-lighting model in developing countries. In this paper, we explore the consumer behavior and the operational inefficiencies that result under this model. Specifically, we are interested in measuring the impact of inconvenience (of travel to recharge the bulb) {which is a peculiar feature of this model {along with the impact of liquidity constraints on bulb usage. We also discuss the efficacy of strategies that address these factors.

CC- Room 307

Supply Chain Bargaining

Sponsored: Manufacturing & Service Oper. Mgmt/Supply Chain

Sponsored Session

Chair: ZHUO Feng, Dalian University of Technology, Dalian, 116024, China

1 - Negotiation in Competitive Supply Chains: The Kalai- Smorodinsky Bargaining Solution

Yuanchen Li, Purdue University, 2192 Tortuga Lane, West Lafayette, IN, 47906, United States, li1820@purdue.edu, Qi Feng, J. George Shanthikumar

We study bargaining in a two-tier supply chain with supply or retail competition. We allow the negotiations to be parallel or sequential. We also distinguish the situation with contingency from those without. Compared to previous studies in which the Nash bargaining solution is widely applied, we adopt an alternative solution, the Kalai-Smorodinsky (KS) bargaining solution, and establish its connection to the Nash bargaining solution. We observe that the Nash solution may not be appropriate for the studies involving channel competition and contingency terms. The KS solution generally grants the retailer more bargaining power, except for the case of the sequential bargaining with contingency.

2 - Coordinating Stochastic Projects Through Bilateral Negotiations

Chengfan Hou, Tsinghua University, Beijing, 100084, China, Mengshi Lu, Tianhu Deng

Project outsourcing has been a pronounced trend in many industries, but is also recognized as a major cause for project delays. We study how companies can coordinate outsourced projects with uncertain completion times through bilateral contract negotiations. We model project contract negotiations as a multi-unit bilateral bargaining game and derive the conditions such that bilateral negotiations can achieve system coordination. Our study uncovers how the coordination of project outsourcing is impacted by the contract form, bargaining power structure, network topology, and payment timing and highlights the importance of bargaining modeling in project contracting.

3 - A Nash Bargaining Framework in Public-Private Partnerships

Zhuo Feng, Dalian University of Technology, Dalian, 116024, China, zhfeng@dlut.edu.cn, Shiliang Cui, Yiwen Zhang

Public-private partnerships (PPPs) are widely used for infrastructure projects in developing countries. Under PPP, a private company finances and constructs a government project for a share of the later operating revenue of the project in return. We propose a Nash bargaining framework in PPPs which is missing in the existing literature, despite the fact that the government and the private company almost always carry out negotiations for PPP contracts.

4 - Strategic Inventories in Supply Chains with Bargaining

Lucy Gongtao Chen, Associate Professor, National University of Singapore, Singapore, bizcg@nus.edu.sg, Weijia Gu, Qinshen Tang

We investigate the existence and effect of strategic inventories for a supply chain under a bargaining framework and compare the results to those under a Stackelberg game. We then introduce supply chain competition into the system and study how the impact of strategic inventories changes. We find that while bargaining can eliminate the existence of strategic inventories, the competition between supply chain may reintroduce strategic inventories.

Going Beyond the Beer Game: Collaborative & Competitive Supply Chain Simulations

Sponsored: Education

Sponsored Session

Chair: Yao Zhao, Rutgers University, Newark, NJ, 07102-1895, United States

Co-Chair: Kwon Gi Mun, Fairleigh Dickinson University, Fort Lee, NJ, 07024, United States

1 - The Flower Game - Online Collaborative and Competitive Supply Chain Simulation

Yao Zhao, Rutgers University, SCMMS Department, Newark, NJ, 07102-1895, United States, yaozhao@business.rutgers.edu

Beer game ignores the conflict of interest among trading partners and the resulting delusion and conspiracies. We design a flower game to simulate multiple competing supply chains where firms in each supply chain must collaborate to win the competition, meanwhile defend themselves against their worst enemy: their partners.

2 - Hunger Chain Simulation – A Competitive Gaming for Supply Shortages

Kwon Gi Mun, Fairleigh Dickinson University, Fort Lee, NJ, 07024, United States, kwongimun@gmail.com

Action-based simulation, named as Hunger Chain Simulation, is developed for allowing students to learn Inventory Management actively by doing. Instructor can keep students engaged and can deliver OM/SCM concepts and principles effectively to the classroom. We discuss the interactive teaching materials and the effectiveness of it to allow students to practice principles and skills.

CC- Room 309

Learning and Strategic Incentives

Sponsored: Manufacturing & Service Oper. Mgmt/iFORM

Sponsored Session

Chair: Jussi Keppo, National University of Singapore, Singapore, 119245, Singapore

1 - Delegated Testing of Design Alternatives

Jochen Schlapp, Frankfurt School of Finance & Management gGmbH, Adickesallee 32-34, Frankfurt am Main, 60322, Germany

Design testing is an integral part of any new product development initiative as it enables firms to identify the best possible designs for their new products. The desired testing results are typically collected by (teams of) experts who need to be incentivized to not only exert effort in testing their designs, but also to truthfully reveal their findings. But how many of these experts should a firm employ, and how should the firm orchestrate their efforts? Our analysis establishes the firm's optimal testing strategy as well as the optimal incentive structures, and it also reveals how exactly delegation distorts the firm's testing process.

2 - Knowledge Sharing and Learning among Smallholders in Developing Economies: Implications, Incentives, and Reward Mechanisms

Shihong Xiao, University of Minnesota, Minneapolis, MN, United States, xiaosh@umn.edu, Ying-Ju Chen, Christopher S. Tang

Recently, knowledge-sharing platforms emerge to facilitate knowledge exchange among smallholders so as to enhance farmers' productivity. Putting altruism aside, we examine economic implications for farmers to share knowledge with others under (implicit) competition. We find that farmers with high knowledge are reluctant to share, and consequently the voluntary sharing level is suboptimal in maximizing farmer welfare. In view of the inadequacy of knowledge sharing, we propose a quota-based reward mechanism that can entice farmers to share more knowledge voluntarily, maximizing farmer welfare.

3 - Strategic Reviews

James Siderius, Massachusetts Institute of Technology, Cambridge, MA, 02134, United States, Mohamed Mostagir, Asuman Ozdaglar

Reviewers on online platforms (e.g. Yelp) can exert considerable influence on the decisions of future buyers. This can create perverse incentives for a business to offer influential reviewers side payments ("bribes") in exchange for favorable reviews. While accepting bribes increases the direct payoff to a reviewer, it imposes the cost of potentially damaging her reputation and losing sustained influence. We study the equilibrium properties of the game between reviewers and consumers and show which policies can help a platform curb the negative outcomes of review manipuation.

4 - Higher Moments of Expert Herding

Yanwei JIA, National University of Singapore, Singapore, jia_yanwei@u.nus.edu, Jussi Keppo, Ville Satopaa

Morris and Shin (2002) analyze experts' point forecasts under herding and find that increased precision of public information is not always beneficial to social welfare. We extend their model to distributional forecasts, which are common in many applications such as inflation forecasting. Our unique equilibrium is expressed in closed-form and coincides with theirs in the first moment. However, the increased precision of public information reduces the variance of experts' forecasts and improves welfare in our model. It implies that the negative welfare effect of public information disclosure does not need to exist if experts report both point forecasts and their associated uncertainties.

Issues in Agricultural and Food Supply Chains

Sponsored: Manufacturing & Service Oper. Mgmt/Sustainable Operations

Sponsored Session

Chair: Adem Orsdemir, University of California-Riverside, Riverside, CA, 92521, United States

Co-Chair: Eda Kemahlioglu Ziya, North Carolina State, Raleigh, NC, 27695-7229, United States

1 - The Impact of Input- vs. Output-based Farm Subsidies on Farmer Welfare and Income Inequality in Developing Economies

Ming Zhao, University of Electronic Science and Technology of China, M628, Li Ka Shing Tower, Hung Hom, Chengdu, China, Christopher S. Tang, Yulan Wang

To alleviate farmer poverty and reduce income inequality in developing economies, we study two common farmer subsidy schemes that are either input-based or output-based. By analyzing a stylized model that captures yield heterogeneity across farmers, we find that these two schemes generate different effects. First, although both types of subsidies can reduce the aggregate income inequality in terms of Gini coefficient, the input-based subsidy scheme can narrow the income gap between farmers under mild conditions, and the output-based scheme always widens this gap. Second, the low-yield farmers prefer input-based subsidies, while high-yield farmers prefer output-based subsidies.

2 - Optimal Agricultural Supply Planning under Extreme Weather Conditions

Utku Serhatli, INSEAD, Constance de le Boulevard, Fontainebleau, 77590, France, utku.serhatli@insead.edu, Andre Du Pin Calmon, Enver Yucesan

We analyze the optimal production decisions of a seed manufacturer who faces increasing incidences of extreme weather events, making its production more costly and uncertain. We propose a stochastic dynamic optimization model to describe this setting and examine the sensitivity of optimal production decisions to changes in extreme event probability and intensity. Our analysis shows that a minor increase in present or future extreme event probability can lead to major shifts in both seed production and assortment decisions. Furthermore, low-margin markets (usually developing countries) may see a significant decrease in average seed availability as extreme events become more likely.

3 - Sustainable or Not? Role of Valuation Uncertainty and Operational Flexibility in Product Line Design

Iva Rashkova, Washington University in St. Louis, St. Louis, MO, United States, Lingxiu Dong

Increasing consumer interest in healthy and eco-friendly food production (i.e., sustainability) has led food companies to rethink their product line design and strike a balance between the taste and sustainability product quality dimensions. The paper investigates the effects of uncertain consumers' willingness-to-pay for sustainability and operational costs - both R&D and production - on the firm's optimal product line length and product quality commitments. We explore the effect of the company's optimal strategy on development waste, consumer surplus and the level of investment in sustainability.

4 - Agricultural Cooperative Pricing of Premium Product

Burak Kazaz, Professor, Syracuse University, Whitman School of Management, Syracuse, NY, 13244, United States, bkazaz@syr.edu, Nur Ayvaz-Cavdaroglu, Scott Webster

We consider the problem of price setting by a cooperative for purchase of an agricultural product with the following characteristics: (1) the pricing policy is published prior to the growing season and (2) the value of the farmer's harvest is affected by his investments during the growing season. We propose two alternative pricing policies that are new to the agricultural literature, both of which can coordinate farmer decisions with the system but differ in terms of ease of implementation and susceptibility to risk aversion.

5 - Farmers Market vs. Grocery Store: A Theory of Local Food Marketplace and Food Waste

Bing Bai, Washington University in St. Louis, St. Louis, MO, United States, Lingxiu Dong

Each year twenty percent of vegetables and fruits grown in US goes to waste because of imperfect looking. Grocery stores usually have aesthetic standard to increase consumer's shopping valuation. While in farmers market, imperfect produce are generally carried. We study the effect of consumer purchasing behavior on channel competition and characterize its influence on food waste.

CC- Room 3A

Managing Risk and Uncertainty

Sponsored: Decision Analysis

Sponsored Session

Chair: Youngsoo Kim, University of Alabama, Tuscaloosa, AL, United States

1 - Applying A Discount Rate for Project Risk Analysis in Practice

Samuel E. Bodily, Darden School of Business, University of Virginia, Charlottesville, VA, 22903, United States, bodilys@virginia.edu

The performance of the recently-introduced adjusted discount rate ra is studied in practical project evaluation examples compared to the standard finance NPV and the correct, yet more-difficult-to-use certain return equivalent, ro. The examples studied exhibit a variety of structures of time dynamics and uncertainty. The finance approach misses some risk nuances in the varied structures although ra and ro produce similar certainty equivalent results. Because it accounts for risk preference without involving the simulation of an alternative portfolio of stocks and treasuries, ra has great promise for use in practice.

2 - Managing Multi-level, Correlated Supply Risks

Nickolas K. Freeman, University of Alabama, Tuscaloosa, AL, 35405, United States, nkfreeman@cba.ua.edu, Ming Zhao

Companies are increasingly facing the task of managing correlated supply disruption risks due to globalization and outsourcing. However, correctly estimating the correlations that prevail among available suppliers is difficult and mistakes can be costly. We consider distributionally robust models for managing supply disruption risks when suppliers are ambiguously correlated and may experience multiple disruption levels. Analysis of these models offers several insights that can help buyers determine how to direct efforts that aim to improve understanding of the prevailing correlation structure.

3 - Collaboration and Fair Labor Practices: Risk, Reputation, and Profit

Matthew J. Sobel, William E. Umstattd Professor Emeritus, Case Western Reserve University - Retired, Department of Operations, Cleveland, OH, 44106-7235, United States, matthew.sobel@case.edu, Susan A. Slotnick

The reputation and sales of a multinational buyer are hurt if its offshore supplier flagrantly violates fair labor practices. In this paper the buyer manages the reputational and financial risk of an adverse labor event at the supplier by offering the supplier financial incentives to treat its labor fairly. The underlying model of risk and reputation over time is a dynamic Stackelberg game in which the buyer has a long-run perspective while the supplier is myopic. The talk reports analytical and computational results. The buyer's risk posture plays a basic role in determining the financial incentives.

4 - Operational Risk Management: Team Based Incentive Bonus and Effort Coupling

Lingjiong Zhu, Florida State University, Tallahassee, FL, 32306, United States, lz465@nyu.edu, Yuqian Xu

We consider a financial firm that offers bonus to its employees to provide incentives to reduce operational risk losses. We characterize the optimal incentive bonus based on a team of employees, and then explore the impact of team characteristics and effort coupling among team members on the optimal bonus. We discuss when the optimal strategy is to offer bonus to one employee and when it is optimal to offer bonuses to multiple employees and present the ordering policy of the incentive bonuses. We subsequently extend our model to characterize the employees' effort coupling effect.

CC- Room 3B

Inaugural Flash Session II (Decision Analysis)

Sponsored: Decision Analysis

Sponsored Session

Chair: Allison C. Reilly, University of Maryland, Washington, DC, 20017, United States

1 - Should Hospitals Incentivize and Influence Physicians' Diagnostic Imaging Decisions?

Christian Wernz, Virginia Commonwealth University - VCU, Richmond, VA, 23298, United States, cwernz@vcu.edu, Aditya Umesh Kulkarni, Yongjia Song, Danny R. Hughes

Public reporting of hospital quality data intends to help patients make better consumer choices. However, this public quality signal motivates hospitals to try to achieve certain metric goals. In response, hospitals may choose to influence, incentivize or nudge physicians to change their medical decisions. We developed a decision-theoretic model to analyze the decision processes of hospitals and physicians, and explore the implications of hospitals interfering with physicians' decisions.

2 - Rumor Tracking and Strategic Decision-making During Disasters Using Supervised Machine Learning and Game Theory

Puneet Agarwal, University at Buffalo, Buffalo, NY, United States, puneetag@buffalo.edu, Kyle Hunt, Ridwan Al Aziz, Jun Zhuang

Social media is being increasingly utilized to spread breaking news and updates during disasters of all magnitudes. Unfortunately, due to the unmoderated nature of social media platforms, rumors and misinformation are able to propagate widely. Our studies investigate the interplay between rumor spreading and debunking on social media platforms using Machine Learning and Game Theory. We present an automated framework based on state-of-the-art machine learning techniques to track rumors that are spread online during disasters. We also model the strategic interactions between official agencies and social media users during rumor spreading and debunking using game-theoretic approach.

3 - Learning About and From Models: A Decision Science Approach

Michael Gerst, University of Maryland, Washington, DC, 20010, United States, mgerst@umd.edu

Models are ubiquitous in science and aiding of decision-making. Despite the frequency of their use, little progress has been made in generalizing how modelers and model users translate knowledge learned about a model to broader learning from a model. This can be a problem because (i) different scientific disciplines often use differing epistemic norms and (ii) learning consists of a chain of decisions that can be subject to cognitive biases and heuristics. We develop a framework that guides model builders and model users through the process of learning about and from a model in a way that minimizes error introduced by biases and heuristics and aids in choosing a model that maximizes learning.

4 - Cyber Deterrence OR: How We Learned to Stop Worrying and Love the Signal

Jonathan W. Welburn, RAND Corporation, Santa Monica, CA, 15213, United States, Justin Grana, Karen Schwindt

Traditional deterrence theory may not hold for cyber conflict. The cyber domain obscures actions and removes common knowledge on the ability of actors to attack, defend, & retaliate. Motivated by these features, we examine a game of deterrence between an attacker and a defender. The sequential-move game features imperfect information, uncertain attribution, and (noisy) signaling. We reveal cases where the defender can use signaling to deter an attacker. We also uncover a counter-intuitive "ant-deterrent" result that illustrates how the defender can increase its expected utility by inducing attack. The new contributions of this approach have important implications for cyber policy.

5 - Using Virtual Reality to understand Renewable Energy Preferences

Zana Cranmer, Bentley University, Waltham, MA, 02452, United States, acranmer@bentley.edu

Immersive virtual experiences can enhance the understanding of non-experts on unfamiliar topics. Building new energy infrastructure often involves interaction with the public to elicit preferences and constraints. When the public has no experience with a type of power plant, like a wind turbine, expressing preferences can be difficult. Providing an immersive, virtual experience with a wind turbine may help respondents better gauge and express their opinions about such facilities. This is especially important for wind energy, which is often subject to myths and misinformation.

6 - Ecosystem-scale Selenium Modeling and Decision Making

Karen Jenni, U.S. Geological Survey, Wheat Ridge, CO, 80033, United States, kjenni@usgs.gov

Modeling the environment is at the core of environmental laws that regulate the mining industry. USGS modelers have developed mechanistic models of the responses of ecosystems to geologic sources of Selenium exposed by ground disturbances such as mining activities. We propose here an integrated strategy that encompasses current mechanistic knowledge, modeling ability, and templates for decision-making to resolve questions related to site-specific Se protection as mining areas continue to expand and ecosystems are altered.

7 - Enabling Preemptive Planning and Increased Community Resilience through Post-Disaster Temporary Housing Decision Analysis

Daniel Perrucci, Graduate Researcher, Vanderbilt University, Nashville, TN, United States, daniel.v.perrucci@vanderbilt.edu, Hiba Baroud

Over the last three decades, the severity and frequency of natural disasters has experienced an increasing trend which drives the post-disaster displaced populations to unprecedented levels. A multi-objective decision analysis (MODA) will provide government entities the ability to analyze temporary housing alternatives in advance of the disaster displaced population. This prior planning reduces the supply chain uncertainty, and therefore, increases community resilience during the disaster recovery.

CC- Room 401

Prediction and Mechanism Design

Sponsored: Auction and Market Design

Sponsored Session

Chair: Michael Albert, University of Virginia, Durham, NC, 27708, United States

1 - An Equivalence Between Wagering and Fair-Division Mechanisms

Rupert Freeman, Microsoft Research, New York, NY, United States, rupert.freeman@microsoft.com

We draw a surprising and direct mathematical equivalence between the class of allocation mechanisms for divisible goods studied in the context of fair division and the class of weakly budget-balanced wagering mechanisms designed for eliciting probabilities. The equivalence rests on the intuition that wagering is an allocation of financial securities among bettors, with a bettor's value for each security proportional to her belief about the likelihood of a future event. The equivalence leads to theoretical advances and new practical approaches for both fair division and wagering.

2 - Novel Results for Multi-task Peer Prediction

Jens Witkowski, Frankfurt School of Finance & Management, Adickesallee 32-34, Frankfurt, 60322, Germany

Peer prediction mechanisms elicit private information from rational respondents without the requirement that ground truth is eventually revealed. In recent years, the peer prediction community has increasingly focused on the setting, where the center elicits reports on several questions. We present new mechanisms for this multi-task setting as well as tighter analyses of previous work.

3 - Finite Properties for Scoring Rules and Mechanism Design

Ian Kash, University of Illinois at Chicago, Microsoft Research, Chicago, IL, CB1 2FB, United States

I will discuss an application of a model of truthful elicitation which generalizes and extends mechanisms and scoring rules to understanding settings where the set of allocations (mechanisms) or reports (scoring rules) is finite. This yields a new proof of a result in mechanism design due to Saks and Yu.

4 - understanding Market Functionality and Trading Success

David Rothschild, Microsoft Research, New York, NY, 10011, United States, davidmr@microsoft.com

We examine individual-level trading data from several markets to determine what strategies correlate with financial success. Various regulations and frees limit traders to retail investors. Our data includes all orders and trades from every trader across several markets. We are able to fully reconstruct the markets and tie traders both within and between markets. We show that understanding how markets and trades works is more important to financial success than proxies for (1) confidence or funding (2) information or objectivity in trading. The work should be a call-to-action in simplifying trading for exchanges, their markets and contracts, aimed at retail investors.

5 - Minimum Revenue Socially Efficient Mechanisms under Correlated Valuations

Michael Albert, University of Virginia, Charlottesville, VA, 27708, United States, albertm@darden.virginia.edu

In many situations of interest there is a shared resource that needs to be distributed fairly to agents that have private information about their value of that resource. Traditionally, this is distributed using an auction based mechanism requiring payments. In some situations (such as in federated server farms), there is no natural party to receive payments, and therefore, these mechanisms cannot be implemented leading to a loss in social welfare. In this work, we demonstrate how to take advantage of correlation in bidder behavior in a repeated setting to learn mechanisms with zero expected payments for all participants by learning the optimal, minimum revenue mechanism.

CC- Room 4C-1

E-commerce

Contributed Session

Chair: Zhijun Zheng, Xi'an Jiaotong University, Xi'an, 710049, China

1 - The Impact of Social Interaction on Live-streaming Shopping

Xiabing Zheng, University of Science and Technology of China, Hefei, China, Jinqi Men, Xiao Shi

Social interaction (electronic word of mouth and observational learning) is an essential factor for the success of online commerce. The new technology of live streaming has changed how social interaction affects consumers. This study investigates how electronic word of mouth and observational learning influence consumers' perceptions on live-streaming shopping platforms. In addition, this study views consumers' perception (individuals' relationship bonding) as dynamic factor. The results of this study will contribute towards IS literature by understanding social interaction and its effect on consumers' perceptions and behavior in live-streaming shopping context.

2 - Analyzing Travel Behavior Impacts of Automated Vehicles and Mobility Services

Parastoo Jabbari, University of Washington, Seattle, WA, United States, jabbari@uw.edu, Andisheh Ranjbari, Don MacKenzie

In this study, we explore how automated vehicles may affect travel behavior in the future, particularly as self-driving vehicles are deployed in mobility-as-a-service fleets. We collected data through stated preference experiment that was designed based on each respondent's typical workday in real-time. Through several discrete choice models, impacts of different factors on users' decision making and choices (e.g. mode choices and car ownership decision) and the trade-offs users make between different factors were quantified.

3 - Inside the Learning Curve: The Mediating Role of Technological and Procedural Knowledge in High-tech After-sales Services

Fêdde S. Zijlstra, Eindhoven University of Technology, Eindhoven, Netherlands, f.s.zijlstra@tue.nl, Alex Alblas, Fred Langerak

By providing after-sales services, high-tech firms can learn about their products, services, and customers. The question is, through what mechanisms does after-sales experience impact performance? Based on 10 years of data from a high-tech firm we demonstrate how the creation of technological and procedural knowledge act as learning mechanisms. Specifically, we open the black box of the learning curve, by testing the mediating effects of technological and procedural knowledge. These findings contribute to a better understanding of learning in after-sales services.

4 - Supplementary Service Strategy of Online Marketplace: Authorized Service or Un-authorized?

Zhijun Zheng, Xi'an Jiaotong University, Xi'an, China, zhengzhijun@stu.xjtu.edu.cn, Gang Li

Supplementary services that support the core product are becoming important in consumers'purchasing decisions. In this paper, we explore the service strategy for the online marketplace, as well as the sellers. Three kinds of services, third-party authorized service (TAS), marketplace self-built authorized service (SAS), and the unauthorized service(UAS) are addressed. We find that when the commission rate of the marketplace is low (high), the seller will provide TAS (UAS). Besides, we show that the marketplace tends to provide SAS rather than TAS when the commission rate is too low or too high. The seller's price of product bundled with TAS (SAS) increases (decreases) with the commission.

Decision Problems in Sharing-economy

Sponsored: Service Science

Sponsored Session

Chair: Zhiwei Qin, DiDi Research America, Walmart Labs, Mountain View, CA, 95117, United States

1 - Optimal Dynamic Matching with Impatient Demand and Patient Supply

Yun Zhou, McMaster University, 1280 Main Street West, Hamilton, ON, L8S 4M4, Canada, zhouy185@mcmaster.ca, Zhiyuan Chen, Ming Hu

We consider a centralized platform's problem of dynamically matching heterogeneous types of impatient demand and patient supply. Demand and supply types are vertically differentiated with either high or low-quality level. We characterize the structure of the optimal matching policy for maximizing the long-run average matching rewards minus holding costs and also explore exact and approximate methods to compute the solution. We also compare the centralized matching system with its decentralized counterpart.

2 - A Deep Value-network Based Approach for Multi-driver Order Dispatching

Zhiwei (Tony) Qin, DiDi Research America, Mountain View, CA, 95117, United States, Xiaocheng Tang, Fan Zhang, Zhaodong Wang, Zhe Xu, Yintai Ma, Hongtu Zhu, Jieping Ye

In this work, we propose a deep reinforcement learning based solution for order dispatching and we conduct large scale online A/B tests on DiDi's ride-dispatching platform. To improve the stability of the value iteration with nonlinear function approximators, we propose Cerebellar Value Networks (CVNet) with a novel distributed state representation layer. We further derive a regularized policy evaluation scheme for CVNet that penalizes large Lipschitz constant of the value network for additional robustness against adversarial perturbation and noises. Finally, we adapt transfer learning to CVNet for increased learning adaptability and efficiency across multiple cities.

3 - Where to Find Next Passengers on E-hailing Platforms? A Markov Decision Process Approach

Zhenyu Shou, Columbia University, Columbia University, New York, NY, 10027, United States, zs2295@columbia.edu, Sharon Di, Jieping Ye, Hongtu Zhu, Hampshire Robert

E-hailing drivers exhibit different behaviors from traditional taxi drivers because they do not need to actually search for passengers. This study aims to develop a Markov Decision Process model to incorporate the new behavioral characteristics of e-hailing drivers and thus derive an optimal policy. To account for the competition among drivers, a dynamic adjustment strategy of the order matching probability is devised and calibrated by using a massive dataset collected from more than 50,000 Didi drivers in Beijing. The validation results show that drivers' rate of return and the utilization rate of the vehicle can both be increased by about 10% if the driver had followed the policy.

4 - Reinforcement Learning and Optimization in Ride-sharing Dispatching Task

Fei Feng, UCLA, Los Angeles, CA, United States, fei.feng@math.ucla.edu

Ride-sharing services are significant parts of the sharing economy. To guarantee the well-functioning and profits of ride-sharing services, a good order-dispatching strategy is to be learned. We discuss several reinforcement learning approaches to attacking this problem, analyze their advantages and disadvantages, and present a new method of solving the order-dispatching task.

5 - Algorithms for Network Inventory Management

Deniz Akturk, University of Chicago, Chicago, IL, United States, akturk@chicagobooth.edu, Ozan Candogan, Varun Gupta

We consider the problem of rebalancing in a bike-sharing network. When designing our rebalancing policies, we explicitly take into account operational considerations such as the transportation, shortage, and holding costs. We provide new structural results for the rebalancing problem, and obtain policies with accompanying performance bounds. For certain network structures, we show that our policies are asymptotically optimal. We also provide numerical examples to show the effectiveness of our algorithm in rich settings.

Smart Service Modeling, Design, and Application

Sponsored: Service Science

Sponsored Session

Chair: Robin Qiu, Penn State (The Pennsylvania State University), Malvern, PA, 19355, United States

1 - Deep Learning based Multiple-Disease Risk Predictive Modeling

Robin Qiu, Penn State (The Pennsylvania State University), 30 E. Swedesford Road, Malvern, PA, 19355, United States, robinqiu@psu.edu

This talk presents multiple disease risk predictive models to assess a discharged patient's future disease risks. We propose a novel framework that relies on deep learning techniques to substantially enhance the performance of multiple disease risk predictive modeling.

2 - Analysis of Power Grid Operation Accident Based on Causal Network Model

Chuanmin Mi, Assistant Dean, Nanjing University of Aeronautics and Astronautics, Nanjing, China, cmmi@nuaa.edu.cn, Yuanyuan Qian, Zhipeng Zhou, Qing Zhang

Internet borrowing presents different risk characteristics due to imperfect information disclosure and long tail effect. This paper constructs a network model between online lending platforms from the expected channels, and uses the SIS model to simulate the risk transmission of online lending platforms. The research results show that the network loan platform network has the characteristics of scale-free and small world, and the risk is easy to spread through the expected channels. The speed of risk transmission and the scope of transmission between the online loan platforms are affected by the risk of infection, cure rate and risk impact.

Auctions and Market Design

Sponsored: Auction and Market Design

Sponsored Session

Chair: Martin Bichler, Technische Universitat-Munchen, Munich, 85748, Germany

1 - Computing Prices in the Product-Mix Auction

Martin Bichler, Technical University of Munich, Department of Informatics, Boltzmannstr. 3, Munich, 85748, Germany

We develop an efficient algorithm to find Walrasian equilibrium prices in multiunit, multi-item product mix-auctions in which participants express strong substitutes preferences. Our algorithms are based on DC programming,where the difference of two convex functions is minimized. We develop a DC algorithm to find global optima necessary for Walrasian prices in theproduct-mix auction and show that the problem is dual to minimizing the Lyapunov function.

2 - Combinatorial Exchanges for Transportation

Robert Day, University of Connecticut, Storrs, CT, 06269-1041, United States, Bob.Day@business.uconn.edu, Mohsen Emadikhiav

We study efficient combinatorial exchange mechanisms, proposing an electronic transportation market as a means of profitable collaboration among transportation providers (carriers) supplying to a single shipper (or single conglomeration of shippers). We propose a compact bidding language and solve the combinatorial winner determination problem optimally, influenced by practical constraints such as driver hour limitations and existing backhaul opportunities. Moreover, carriers may exchange lanes to improve allocative efficiency, in addition to typical contract procurement. We implement different payment rules to analyze the economic outcomes of this transportation market.

3 - Estimating Approximate Incentive Compatibility

Ellen Vitercik, Carnegie Mellon University, Computer Science Department, CMU, Pittsburgh, PA, 15213, United States, vitercik@cs.cmu.edu, Maria-Florina Balcan, Tuomas Sandholm

In practice, most mechanisms for selling, buying, matching, voting, and so on are not incentive compatible. We show how to estimate the extent to which an agent can improve his utility by misreporting his type, given samples from the agents' type distribution. We apply our tools to the combinatorial first-price auction, generalized second-price auction, discriminatory auction, uniform-price auction, and second-price auction with spiteful bidders. To our knowledge, these are the first guarantees for estimating approximate incentive compatibility from the mechanism designer's perspective.

4 - Markets for Information About Markets

Arnob Ghosh, Indian Institute of Technology-Delhi, Delhi, 47907, India, ghosh39@purdue.edu, Randall Berry

Motivated by the recently established recently established framework for using the 3.5 GHz band of wireless spectrum, we consider a scenario in which there is an upstream market for information (namely spectrum availability) that impacts the downstream competition among firms (i.e. wireless service providers). We consider different models for how the down-stream firms share wireless resources and different models for pricing the upstream service.

Supply Chain, Humanitarian Logistics

Contributed Session

Chair: Afshin Ghassemi, University of Illinois at Chicago, Chicago, IL, 60614, United States

1 - An Approach to Identify Donor Behavior in Humanitarian Food Supply Chains

Shubhra Paul, North Carolina A&T State University, Greensboro, NC, United States, spaul1@aggies.ncat.edu, Lauren B. Davis

Humanitarian food supply chains consist of a network of donors, food bank warehouses, and agencies like soup kitchens, food pantries. These supply chains primarily function based on the goodwill of donors who provide a needed source of monetary and in-kind supplies. Donors range from individuals to retailers, farmers, and governmental entities. Contribution amounts of donors vary significantly over time in quantity, quality, and food type. We propose an approach to identify the behavioral attributes of donors and cluster them based on those attributes. We show the impact of our clustering approach by comparing the forecasts with and without donor clustering attributes considered.

2 - Facility Location Problem with Restricted Recourse

Esra Koca, Sabanci University, Istanbul, Turkey, ekoca@sabanciuniv.edu, Nilay Noyan, Hande Yaman

We study the two-stage stochastic uncapacitated facility location problems where the location and allocation decisions are made under uncertainty, while the allocation decisions may be changed in response to the realizations of the uncertain parameters. We quantify the deviations between the first and second stage allocation decisions by using a dispersion measure and control it by enforcing an upper bound on it. We devise Benders-type scenario decomposition algorithms and develop efficient methods to construct the optimal solutions of the Benders subproblems. This study is supported by the Scientific and Technological Research Council of Turkey (TUBITAK) Career Award [218M782].

3 - Optimal Design of the Hybrid Reactive Distillation System for Formic Acid Production Using Genetic Algorithm

Xiaolong Ge, Assitant. Prof. Dr., Tianjin University, Tianjin, China, g_xiaolong1@126.com, Botong Liu, Botan Liu

Hybrid reactive distillation is proposed to overcome the energy and capital intensivity in methyl formate (MF) hydrolysis production. the optimization variables of FA process includes stage number in each column sections, reflux ratios, the ratio of water and MF, the product flow rate, which turns out to be a mixed integer mathematical programming problem(MINLP). Genetic algorithm embedded in MATLAB was coupled with simulation software ASPEN plus to find the optimal solution. The energy efficiency of the process and conversion of MF could be significantly increased, while lower capital cost was achieved because of lower operating pressure in hydrolysis reaction.

4 - A New Robust Approach to Develop an Integrated Energy-water Nexus System

Afshin Ghassemi, University of Illinois at Chicago, Chicago, IL, United States, aghass2@uic.edu, Michael J. Scott

An energy-water nexus is an interconnected system including the energy subsystem, the water subsystem, and the connection between them. A new robust mixed-integer linear mathematical integrated approach is proposed to investigate the energy and water system planning. When there is a limitation on water resources, the new approach leads to lower cut-off time in comparison to the traditional separated planning approach. Moreover, the robust planning decisions provide a reliable system performance under uncertainty for demands.

Tutorial: Structural Econometric Models

Emerging Topic: Tutorials

Emerging Topic Session

1 - Tutorial: Structural Econometric Models

Yong Tan, University of Washington, Seattle, WA, 98195-3226, United States, Yan Huang, Stephanie Lee

In this tutorial, we discuss the concept of structural econometric models and their applications in business and management research. Structural models are constructed by grounding on economic and related theories and attempt to accurately reflect underlying data generating processes. One unique advantage of structural models is their capability to simulate user or firm strategic behaviors under new policies and measure the effectiveness of these proposed policies, and hence generate convincing managerial suggestions. We present three representative classes of structural models: demand estimation using aggregate data, dynamic choice models, and two-sided matching models, to demonstrate model specification, assumptions, and estimation procedures.

Military and Security Decision Analysis

Sponsored: Military and Security

Sponsored Session

Chair: Gregory S. Parnell, University of Arkansas, Fayetteville, AR, 72701, United States

1 - Informing Requirements and Design Through Set-based Design

Eric Specking, PhD Candidate, Univeristy of Arkansas, Fayetteville, AR, 72701, United States, especki@uark.edu, Gregory S. Parnell, Edward A. Pohl

Traditional design methods find a single “good” or several Pareto solutions to investigate further. These designs sometimes become infeasible with new information or requirement changes. Set-based design (SBD) is an alternative design method that considers a large number of alternatives and is not a new field. SBD literature lacks established quantitative techniques to define, evaluate, and selects sets. Additionally, the literature discusses the team-based component of SBD, but does not describe how to integrate it with analysis. This presentation will describe a methodology that performs and facilitates team-based SBD in early system design. An UAV case study demonstrates the methods.

2 - Supporting Efficient Resource Allocation to Mitigate Terrorist Risks During Sport Mega-events

Marcelo Zawadzki, AFIT, Wright-Patterson AFB, OH, United States, Marcelo.Zawadzki.BR@afit.edu

Sports events have proved to be a frequent target for terrorists. Protecting these events with limited resources is a challenge for security forces. The finite horizon time and the chance to heighten the security to discourage the attacker, are interesting features in this situation. We present a Stackelberg game and suggest a partially enumerative algorithm, to simplify the solution of the game. The optimal solution is guaranteed and the defense may use the algorithm to support resource allocation when trying to discourage an attack. A preliminary case study, revisiting the counterterrorism planning for the Brazilian Olympic Games, in 2016, illustrates the application of the proposed algorithm.

3 - Using Decision Analysis to Inform Agile Development Decisions

Gregory S. Parnell, University of Arkansas, Fayetteville, AR, 72701, United States, gparnell@uark.edu, Edward A. Pohl

Stage and Gate is an effective product development process when the requirements are understood. Decision analysis informs gate decisions in many domains. For many products, especially software development, the requirements become known after prototypes are provided. Agile Development was advocated as an alternative to Stage and Gates. The Agile Manifesto principles emphasize designing software that creates value for users and stakeholders. To organize the planning, agile divides the development into spirals and the spirals into sprints. We use decision analysis techniques to guide the quantification of value and risk to inform spiral and sprint decision making.

4 - A Model Centric Approach to Set-Based Design

Nicholas Shallcross, DoD/University of Arkansas, Fayetteville, AR, 72701, United States

Model based systems engineering (MBSE) methodologies offer a means to effectively and efficiently execute Set-Based Design (SBD) of complex systems in geographically dispersed organizations. We present a methodology for implementing SBD in support of complex system engineering programs to inform improved and resilient design decisions. Using Phoenix Integration’s ModelCenter® as the MBSE integration platform, we demonstrate the use of multiple variable fidelity physics and cost models in exploring, analyzing, and refining the design space as part of a multiobjective analysis of alternatives (AoA). We outline the potential benefits of our methodology and provide our future research focus.

1 - Building Analytics Organizations - From Insights to Impact

Katie Wrenn and MaryJo Robinson, Booz Allen Hamilton, McLean, VA

Booz Allen Hamilton (Booz Allen) is one of the largest providers of analytics, data science, and machine learning services to the Federal Government, commercial institutions, and international organizations. While many early adopters agree that these capabilities have the potential to transform business or mission delivery over time, there are common challenges that organizations face that analytics and operations research leaders should understand and put into their strategies to truly scale and sustain analytics. For example: To centralize or not? How to build the right talent base? How to create a reputation and brand for technical expertise and social good? With over 4,000 practitioners, we have faced these questions for ourselves and helped clients navigate their own journeys to data-driven decision-making. In this talk, we will share our lessons learned in areas including training programs, partnerships, catalysts, and common challenges to building and sustaining a scaled analytics organization. We will also discuss how these lessons learned have translated into tangible impact for the clients we serve on a daily basis.

Pyomo II

Sponsored: Optimization/Computational Optimization and Software

Sponsored Session

Chair: Qi Chen, Carnegie Mellon University, PA, United States

1 - Tailored Numerical Algorithms in Pyomo with the Pynumero Extension Package

Carl Laird, Sandia National Laboratory / Purdue University, Fayetteville, AR, 47907, United States, Bethany Nicholson, Jose Santiago Rodriguez, Mary Jo Robinson

Emerging needs of science and engineering push the size and complexity of optimization problems that need to be addressed. To tackle these large-scale, but inherently structured problems, there is a need for tools that allow for rapid development of new algorithms in high-level languages without loss of computational performance. In this presentation, we will discuss the PyNumero package that provides a Python-based api for development of serial and parallel numerical optimization algorithms. We will demonstrate the ease of use and performance of this package on several parallel decomposition-based examples.

2 - Pyomo.FlexibilityAnalysis - A Modeling Framework for Optimization under Uncertainty

Maria Paz Ochoa, PhD, Carnegie Mellon University, Pittsburgh, PA, United States, Anuja Deshpande, Ignacio E. Grossmann

Pyomo.FlexibilityAnalysis is an open source Python-based modeling framework that allows the application of the flexibility analysis. In the flexibility analysis literature, many methods have been proposed. First, the vertex enumeration method, where the model is evaluated at each vertex of the uncertain parameter set. Then, the active set strategy proposes to replace the lower level of the bilevel problemt by its KKT and complementarity conditions. Recently, the dual based flexibility analysis was proposed, where the lower level problem is replaced by its dual problem. The package is a collection of modules, which contain functions that automatically apply the mentioned methods

3 - Nested Decomposition Algorithm for Large-scale Multi-period and Multistage Stochastic MIP Models

Cristiana L. Lara, Carnegie Mellon University, Pittsburgh, PA, 15201, United States, Ignacio E. Grossmann

Nested Benders Decomposition is particularly appropriate for multi-period/multistage models in which each period/node can be decomposed into a subproblem. We propose a Nested Decomposition algorithm based on Nested Benders for deterministic multi-period problems with mixed-integer recourse. Additionally, we extend the Stochastic Dual Dynamic integer Programming to also handle mixed-integer recourse in multistage stochastic programs, and parallelize the algorithm. We test both the deterministic and the stochastic frameworks by solving a Generation Expansion Planning problem for a case study in the ERCOT region with instances up to quadrillions of variables and constraints.

4 - Advances in Pyomo.gdp: An Ecosystem for Nonlinear Disjunctive Programming Modeling and Optimization Development

Qi Chen, PhD Candidate, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, qichen@andrew.cmu.edu, Romeo Valentin, Sunjeev Kale, Johnny Bates, David Esteban Bernal, Michael Lee Bynum, John Siirola, Ignacio E. Grossmann

We present new capabilities for nonlinear disjunctive programming problems formulated as Generalized Disjunctive Programming (GDP) models. Global optimization of these problems requires strategies that exploit model structure. We present a new nonlinear disjunctive B&B solver, GDPbb, and an interface to the Z3 SMT solver to screen node feasibility. We introduce a global variant of the logic-based outer approximation solver GDPopt. GDPopt calls upon the MC++ toolset to construct rigorous affine cuts. GDPopt also exploits logical structure for range reduction in disjunctive scopes. We demonstrate these solution strategies with a GDP model test library alongside traditional MINLP solvers.

Sponsored Session

Chair: Andres Gomez, University of Pittsburgh, Pittsburgh, PA, 15217, United States

1 - Intersection Disjunctions for Reverse Convex Sets

Jim Luedtke, University of Wisconsin-Madison, Madison, WI, United States, jim.luedtke@wisc.edu, Eli Towle

We present a framework to obtain valid inequalities for a reverse convex set, which is a set of points in a polyhedron that lie outside an open convex set. Intersection cuts are a well-known method for generating valid inequalities for a reverse convex set from a basic solution in the convex set. We propose a framework for deriving valid inequalities for such sets from basic solutions that lie outside the convex set. We begin by proposing an extension to intersection cuts that defines a two-term disjunction. We refer to such a disjunction as an intersection disjunction. Next, we generalize this analysis to a multi-term disjunction by considering the convex set's recession directions.

2 - Sparse Cutting Planes for Nonconvex Quadratically Constrained Quadratic Programs

Aleksandr Kazachkov, Polytechnique Montreal, Montreal, QC, Canada, Santanu Dey, Andrea Lodi, Gonzalo Munoz

Nonconvex quadratically-constrained quadratic programs (QCQPs) arise in a wide variety of real-life applications. However, interior point solvers struggle with the semidefinite programming relaxations for large instances, whereas using linear relaxations provides a scalable path forward. However, how to properly use such relaxations remains poorly understood. We investigate how to systematically incorporate sparse cuts in the solution process for nonconvex QCQPs, analyze how to appropriately select sparse linear relaxations depending on the instance, and present results of preliminary experiments illustrating the precise tradeoffs between sparsity and strength.

3 - Sufficient Conditions for Exact SDP Reformulations of Quadratic Programs

Alex L. Wang, Graduate Student, Carnegie Mellon University, Pittsburgh, PA, United States, alw1@andrew.cmu.edu, Fatma Kilinc Karzan

Quadratically constrained quadratic programming (QCQP) is a fundamental problem that is well-known to be NP-hard in general. In this talk we review and extend known sufficient conditions under which the standard semidefinite programming (SDP) relaxation of QCQP is tight. In particular, we analyze two new conditions depending on the multiplicity of the eigenvalues in the quadratic forms. We additionally give an explicit description of the convex hull of the QCQP epigraph in the original space under similar conditions.

4 - Integer Programming Through Lexicography

Yiran Zhu, Clemson University, Clemson, SC, United States, yiran@g.clemson.edu

In this work, we propose new polyhedral methods for a pure integer program (IP) over a compact set which may not be polyhedral or even convex. Our polyhedral relaxations are based on ordering the lattice points under some monomial order on integer vectors. Furthermore, for a binary program, we establish a new converging hierarchy for the integral hull of the feasible region being of packing or covering type.

OPT Integer/Uncertainty: Integer Programming under Uncertainty

Sponsored: Optimization/Integer and Discrete Optimization

Sponsored Session

Chair: Amy Burton, Clemson University, Townville, SC, 29689, United States

1 - A Strong Branch-and-Cut Framework for Robust Integer Programming with Budget Uncertainty Sets

Timo Gersing, RWTH Aachen University, Pontdriesch, Germany, gersing@math2.rwth-aachen.de, Arie Koster, Christina Büsing

Since their introduction by Bertsimas and Sim in the early 2000s, budget uncertainty sets have received a lot of attention in the literature. This is not least due to the existence of a compact robust reformulation for linear programs. Despite its compactness, the reformulation performs poorly when solving robust integer problems due to its weak LP relaxation. We propose a Branch-and-Cut framework that addresses this problem by strengthening the LP relaxation with each branching. Our computational results show that the approach outperforms the sole use of the reformulation by far.

2 - A Mean-risk Stochastic Mixed-integer Program for Network Protection

Amy Burton, Clemson University, Townville, SC, 29689, United States, aburto2@g.clemson.edu, Akshay Gupte

Two-stage stochastic programs are often used to model network resource allocation when there is uncertainty in future performance. We propose a mean-risk mixed integer nonlinear program for network protection that hedges against future extreme events. The model is implemented with coherent risk measures on a transportation network in which the first stage minimizes total retrofitting cost and the second minimizes expected future travel cost. We use perspective relaxations and conic quadratic constraints to derive a convex reformulation of the nonlinear, non-separable second stage. Benders Decomposition is used to solve the model and computational results are presented.

3 - Airline Schedule Planning Using Risk-Averse Two-Stage Stochastic Programming Approach

Saravanan Venkatachalam, Wayne State University, Detroit, MI, 48377, United States, Sujeevraja Sanjeevi

Fleet assignment model (FAM) assigns an aircraft to scheduled flights considering demand, cost, revenue and other operational constraints. We propose a mean-risk two-stage stochastic programming approach under demand uncertainty for FAM. The mean-risk models pose computational challenges. In this talk, we present column generation based decomposition algorithms and computational results.

4 - Optimal Crashing of an Activity Network with Disruptions

Haoxiang Yang, Northwestern University, Evanston, IL, 60208, United States, haoxiangyang2019@u.northwestern.edu

We introduce a general type of sequential decision problem under uncertainty, where the uncertainty consists of a small number of disruptions, both the magnitude and the timing of which can be random. We consider a special case: a project crashing problem under a single disruption. When a disruption occurs, the duration of an activity which has not started could change. The magnitude of the activity duration change and the timing of the disruption can be random. We formulate a stochastic mixed integer programming (SMIP) model with second stage a mixed integer program. We propose a learning-based branch-and-bound algorithm and evaluate the computational performance of our approach.

Recent Advances in Planning and Scheduling under Uncertainty

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Karmel Shehadeh, MI, United States

1 - Joint Job Sequencing and Due-date Determination with Limited Distributional Information

Yuli Zhang, Beijing Institute of Technology, Beijing, China, zhangyuli@bit.edu.cn, Lun Ran, Zuo-Jun Max Shen

Uncertainty is an inevitable element in manufacturing systems and has a significant impact on the system performance. Recently distributionally robust optimization (DRO) has been recognized as an effective approach to minimize the adverse impact of uncertainty. This paper studies the joint job sequencing and due-date determination problem with limited distributional information. We derive a closed-form expression for the DRO model and show the optimality of the smallest-variance-first rule under special cost structures. We further provide an equivalent mixed 0-1 quadratic conic programming reformulation and design efficient algorithms for problems with general cost structures.

2 - Scenario Generation and Cutting Planes for Stochastic Integer Programming, with Applications to Air Traffic Management

Alexandre Jacquillat, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, ajacquil@andrew.cmu.edu, Kai Wang

We formulate a two-stage stochastic integer program to jointly optimize flight scheduling (at the strategic level) and ground holding operations (at the tactical level) in airport networks. We develop a cutting plane algorithm based on new optimality cuts obtained from the dual relaxation of the second-stage problem, and a neighborhood search to trade off exploration and exploitation. We also propose a data-driven scenario generation approach for stochastic programming. The solution approach provides optimal, or near-optimal solutions in reasonable computational times, and outperforms baseline approaches based on existing algorithms and heuristic scenario generation procedures.

3 - Appointment Systems under Service Level Constraints

Zhenzhen Yan, Assistant Professor (PhD), Nanyang Technological University, School of Physical and Mathematical Sciences, Singapore, Singapore, yanzz@ntu.edu.sg

We consider a new model of appointment scheduling where customers are given the earliest possible appointment times under the service level constraint that the expected waiting time of each individual customer or the probability of long waiting cannot exceed a certain threshold. We apply the theory of majorization to analytically characterize the structure of the optimal appointment schedule. We show the monotonicity of the optimal inter-appointment times and study the limiting behaviour of the appointment system. We also extend our analysis to systems with multiple servers.

4 - A Distributionally Robust Optimization Approach for Outpatient Colonoscopy Scheduling

Karmel S. Shehadeh, University of Michigan, Ann Arbor, MI, 48109, United States, Amy Cohn, Ruiwei Jiang

We present a distributionally robust (DR) optimization approach for colonoscopy scheduling under the coexisting uncertainties of pre-procedure bowel preparation (prep) quality and the procedure duration. Using historical colonoscopy appointment data of a large outpatient procedure center, we infer structural relations between procedure duration and prep adequacy. Accordingly, we propose a new DR sequencing and scheduling model that incorporate these two uncertainties using limited distributional information. From extensive case studies based on real data, we derive interesting managerial insights of colonoscopy scheduling.

Chair: Harsha Gangammanavar, Southern Methodist University, Dallas, TX, 75275, United States

Co-Chair: Halit Uster, Southern Methodist University, Dallas, TX, 75275-0123, United States

1 - Prescriptive Scenario Reduction for Stochastic Optimization

Nishanth Mundru, Massachusetts Institute of Technology, Cambridge, MA, United States, Dimitris Bertsimas

We consider stochastic optimization problems when the sample average approximation approach is computationally expensive. We introduce a novel measure, called the Prescriptive divergence which takes into account the decision quality of the scenarios, and consider scenario reduction in this context. We demonstrate the power of this optimization-based approach on various examples.

2 - Parametric Scenario Optimization under Limited Data: A Distributionally Robust Optimization View

Fengpei Li, Columbia University, New York, NY, 10027, United States, fl2412@columbia.edu, Henry Lam

We discuss how to leverage parametric information and the power of Monte Carlo simulation to obtain and certify feasible solutions for chance-constrained optimization problems under limited data. Our approach makes use of distributionally robust optimization (DRO) that translates the data size requirement in scenario optimization into a Monte Carlo size requirement drawn from what we call a generating distribution. We show that, while the optimal choice of this generating distribution is in a sense the one eliciting the data or the baseline in a distance-based DRO, it is not necessarily so in the parametric case, and leads us to some procedures that improve upon these basic choices.

3 - An Adaptive Sequential Sample Average Approximation Framework for Solving Two-stage Stochastic Programs

Yongjia Song, Clemson University, Clemson, SC, 29634, United States, yongjis@clemson.edu, Raghu Pasupathy

In this talk, we present a new adaptive sequential sampling approach for solving two-stage stochastic programs. The adaptive sequential sampling procedure solves the SAA problem of a certain sample size up to an adaptively chosen precision in each iteration, depending on the sampling error corresponding to the candidate solution. Stopping criteria developed in the literature of sequential sampling for stochastic programs are applied to construct asymptotically valid confidence intervals on candidate solutions with high probability. Numerical results on an extensive set of instances on two-stage stochastic linear programs with fixed recourse will be reported.

4 - Adaptive Cluster Sampling-based Approximation for Two-stage Stochastic Programs

Siavash Tabrizian, Southern Methodist University, Dallas, TX, 75206, United States, stabrizian@smu.edu, Harsha Gangammanavar, Halit Uster

We present an adaptive clustering based sampling technique for two-stage stochastic programs, and we discuss its performance for estimating the recourse function. We also present a decomposition algorithm design for solving two-stage stochastic programs and demonstrate its efficiency through numerical experiments on classical test instances.

Chance Constrained Programming and its Applications

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Jianqiang Cheng, University of Arizona, Tucson, AZ, 85721, United States

1 - Distributionally Robust Chance Constrained Set Covering with a Wasserstein Ambiguity Set

Haoming Shen, University of Michigan, Ann Arbor, MI, United States, Ruiwei Jiang

We consider distributionally robust chance constrained set covering problem with a Wasserstein ambiguity set, in which decision variables and uncertainties are both binary-valued. We derive exact reformulations of the chance constraints. In addition, we derive valid inequalities for the resulting mixed-integer feasible region. Experiments based on randomly generated test instances show the effectiveness of our reformulation and the strength of the valid inequalities.

2 - Chance Constrained Programming in Power Systems: Limited Controllability & Model Uncertainties

Kenneth Bruninx, KU Leuven, Belgium, kenneth.bruninx@kuleuven.be

We discuss two specific applications of chance constrained programming in power system models. First, we study the impact of the limited controllability of demand response resources on an aggregator's interaction with its consumers and the wholesale electricity market. Second, we discuss how modeling inaccuracies (e.g., the approximation of nonlinear pump/turbine performance curves) and model uncertainties (e.g., due to limited knowledge the underground cavity's geometry and hydraulic properties) can be included in the scheduling problem of a underground pumped hydro energy storage system.

3 - A Mixed-integer Distributionally Robust Chance-constrained Model for Optimal Topology Control in Power Grids with Uncertain Renewables

Payman Dehghanian, Assistant Professor, George Washington University, Washington, DC, 20052, United States, payman@gwu.edu, Mostafa Nazemi

We propose a distributionally robust chance-constrained (DRCC) optimization model for optimal topology control in power grids overwhelmed with significant renewable uncertainties. A distributionally robust optimization (DRO) formulation is proposed to guarantee the robustness of the network topology control plans against all uncertainty distributions defined within the moment-based ambiguity set. The DRCC problem is reformulated into a tractable mixed-integer second-order cone programming problem (MISOCP) which can be efficiently solved. Numerical results on the IEEE 118-bus test system verify the effectiveness of the proposed methodology under uncertainties.

4 - A Framework for Solving Chance-constrained Linear Matrix Inequality Programs

Roya Karimi, University of Arizona, Tucson, AZ, 85719, United States, royakarimi1993@email.arizona.edu, Jianqiang Cheng, Miguel Lejeune

In this talk, we present a partial sample average approximation (PSAA) framework to solve chance-constrained linear matrix inequality (CCLMI) problems with random technology matrix and with random right-hand side. We also present computationally tractable PSAA-based approximations, analyze their properties, and derive sufficient conditions ensuring convexity. We derive several semidefinite programming PSAA-reformulations efficiently solved by off-the-shelf solvers and design a sequential convex approximation method for the PSAA formulations. To demonstrate the superiority of this framework, we carry out a comprehensive numerical study on three practical CCLMI problems.

Sponsored: Railway Applications

Sponsored Session

Chair: Seyed Mohammad Nourbakhsh, BNSF Railway, University of Illinios-Urbana, Fort Worth, TX, 61820, United States

1 - Robust Tactical Crew Scheduling under Fluctuating Demand

Christian Raehlmann, University of Cologne, Albertus-Magnus-Platz, Cologne, 50931, Germany, Felix Wagener, Ulrich Thonemann

We investigate a freight railway crew scheduling problem under fluctuating demand in which the start and end times of duties must be determined four weeks before operations. We seek to find a recoverable-robust schedule that is capable to absorb the structural changes induced by significant changes in train-demand such that the guaranteed on- and off-times of the train drivers are not violated. We decompose the problem twice using a column generation approach. We test our model on several real data sets and show that significantly less stand-by-duties are necessary in order to meet the adjusted demand compared to the nominal crew scheduling problem.

2 - A Heuristic-based Tactical Crew Sizing Model for Freight Railroad

Kiran Chahar, Sr. Manager, Norfolk Southern Corporation, Atlanta, GA, 30309, United States, Kiran.Chahar3@nscorp.com, Clark Cheng

Norfolk Southern (NS) has developed a crew planning tool to optimize the sizes of crew boards while maintaining an on-time train performance. While determining the optimal board sizes, the model simulates federal government regulations and complex crew call rules such as crew rotation, crew tie-up, rest hours, mark-off, carded or assigned jobs, show-up jobs, detention, deadheading, extraboard, and re-crew. The model runs weekly to monitor the crew pool and extraboard sizes. In addition, the model allows what-if analysis using different train plans to ensure that the right number of crews are in place to operate trains.

3 - Scheduling and Routing Roaming Conductors to Support Single-person Crew Operations on North American Freight Railways

Tyler Dick, U. of Illinois at Urbana-Champaign, Urbana, IL, 61801, United States

This research investigates the feasibility of reducing freight train crew sizes by assigning train work events to roaming conductors. Various heuristic routing and scheduling approaches are developed to minimize the number of roaming conductors while assigning them to work events. Results suggest that under different performance standards, operating conditions and practical assumptions, the total number of roaming conductors may be less than the number of on-board conductors required for two-person crews. Under these conditions, roaming conductors can facilitate a net decrease in operating personnel, while still performing all required work events for mainline freight trains.

4 - Railway Crew Rescheduling with Flexible Start and End Times

Felix Wagener, University of Cologne, Cologne, Germany, Ulrich Thonemann

In freight railway crew scheduling employees mostly do not know their work schedule more than a week in advance. This paper presents a model that allows the company to announce a rough schedule, with start and end times that lie within predefined time windows, some weeks in advance by slightly increasing operating cost. We present a trade-off that allows the company to decide either to decrease total cost or to increase the stability for the train drivers. The trade-off helps to find a solutios that create better work conditions for train drivers.

5 - Strategic Passenger Railway Timetabling

Gert-Jaap Polinder, Erasmus University-Rotterdam, Rotterdam, Netherlands

This paper proposes a method to develop strategic timetables, which can help decide on future line plans. This is done by integrating passenger flows with timetabling. Computational results of real life studies are presented.

Supply Chain, Competition, and Retail Management

Contributed Session

Chair: Xinyi Ren, University of Maryland, College Park, MD, 20742, United States

1 - Effects of Manufacturer-to-Consumer Rebates in Competitive Environments

Qin Wang, School of Information Management,Central China Normal University, WuHan, China, 13387561952@163.com, Pengyu Chen

In four competitive supply chains, we examine effects of manufacture-to-consumer rebates on prices and production quantities decisions, considering strategic inventories. We find that M-to-C rebates and strategic inventories can benefit manufacturers, retailers, and consumers alike in competitive environment with low holding cost. We also analyze how optimal solutions are influenced by the intensity of competition or complementarity.

2 - Sharing Commitment and Capacity Allocation under Supply Competition

Hongyan Xu, Chongqing University, Chongqing, China, xuhongyan@cqu.edu.cn, He Huang, Xiaomin Liu

We analyze the implication of demand information sharing in a supply chain with one manufacturer sourcing from two capacity-constrained suppliers. Two suppliers compete for both the manufacturer's order and a mature market share. Two rules are examined for the manufacturer to allocate its order, fixed allocation rule and proportional allocation rule. Our results show that under the proportional allocation rule, the manufacturer may have the incentive to share demand information with both suppliers, but always has no incentive to share information under fixed allocation rule.

3 - Buyer's Strategic Demand Information Disclosure to an Upstream Echelon under Entry Threat

Kenji Matsui, Kobe University, Kobe, Japan, kmatsui@b.kobe-u.ac.jp

This paper investigates the information sharing problem of whether a buyer purchasing products from a supplier should disclose its demand information. Contrary to a conventional insight in the literature, the present paper demonstrates that the buyer can increase its own profit by fully disclosing information when there exists not only an incumbent supplier currently operating, but also a potential alternative supplier. This result provides the practical implication that a buyer in a supply chain can strategically reveal demand information, which is seemingly disadvantageous to the buyer, to improve its profit through encouraging entry of another supplier as an alternative source of products.

4 - Retailers' Return Policy Strategies under Competition

Ozgun Caliskan Demirag, Penn State Erie, The Behrend College, Erie, PA, United States, ozc1@psu.edu, Delong Jin, Frank Y. Chen, Min Huang

We investigate retailers' strategic decisions on the adoption of buy-online, return-to-physical store (BORP) policy from a competitive perspective. We find that the adoption of the BORP policy by one or both retailers can be sustained in equilibrium if the retailers are sufficiently differentiated and when they can recover significantly larger salvage values from items returned in-store than those returned online. We fully characterize the equilibrium outcomes and explore several model extensions.

5 - Order Fulfillment Policies for Ship-from-Store Implementation in Omni Channel Retailing

Armagan Bayram, University of Michigan Dearborn, Dearborn, MI, United States, Bahriye Cesaret

We consider an omni-channel retailer having both online and store operations and implementing ship-from-store fulfillment model. We investigate dynamic fulfillment decisions in ship-from-store implementation, specifically from which location to fulfill an online order. We incorporate the uncertainty both in demand and in the cost of shipment to individual customers. We develop a stochastic dynamic programming framework and present some analytical and numerical findings on optimal fulfillment strategies.

6 - The Effect of Pop-up Stores on Customer Retention & Acquisition: Evidence from a Quasi-field Experiment

Xinyi Ren, PhD Candidate, University of Maryland, College Park, MD, United States, xinyi.ren@rhsmith.umd.edu, Philip Evers, Robert Windle

With the increasingly uncertain future of brick-and-mortar retailing, companies are exploring new ways to avoid the high costs associated with traditional full-service stores. One solution, pop-up stores remain a relatively new form of offline retailing. Using industry data collected from a leading North American retailer between 2014 and 2017, we empirically study the impact of opening a pop-up store on sales across multiple channels during and after the opening of a pop-up store. Also, we compare this effect to the opening of a traditional, full-service store by the same retailer.

CC- Room 610

Conic Optimization in Energy

Contributed Session

Chair: Richard Weinhold, Berlin Institute of Technology, Berlin, 10623, Germany

1 - Convex Inner Approximation of Feeder Hosting Capacity Limits on Dispatchable Demand

Nawaf Nazir, Graduate Research Assistant, University of Vermont, Burlington, VT, United States, mnazir@uvm.edu, Mads Almassalkhi

This paper presents a method to obtain a convex inner approximation that aims to improve the feasibility of optimal power flow (OPF) models in distribution feeders. Inaccuracy in linearized OPF models may lead to under and over voltages when dispatching flexible demand, at scale, in response to whole-sale market or grid conditions. In order to guarantee feasibility, this paper obtains an inner convex set in which the dispatchable resources can operate, based on their real and reactive power capabilities, that guarantees network voltages to be feasible. Test simulations are conducted on standard IEEE distribution test networks to validate the approach.

2 - Data-Driven Security Constrained Optimal Power Flow

Spyros Chatzivasileiadis, Technical University of Denmark, Kgs. Lyngby, Denmark, spchatz@elektro.dtu.dk, Andreas Venzke, Lejla Halilbasic, Florian Thams

Current electricity market clearing uses linear approximations of security constraints that are either too conservative or inaccurate, leading to costly redispatching actions . We unify security considerations with electricity market operations. Using data-driven techniques, we extract an accurate representation of the non-convex security region, and incorporate it as conditional linear constraints in an optimization problem. We capture both static and dynamic stability constraints, while being less conservative. Our approach is scalable can eliminate costs of millions of euros every year.

3 - A Cluster-based Approach to Synchronize Electricity Load Profiles in Buildings

Seyyed Danial Nazemi, PhD Student, Rutgers University, Piscataway, NJ, United States, danial.nazemi@rutgers.edu

In this study, a novel cluster-based approach is proposed to synchronize aggregate load profile of a building based on different control actions of end-uses. In this regard, using wavelet transform, a Multi-Resolution Clustering (MRC) algorithm is applied to load profiles to make clustering more accurate. By applying X-means clustering to the spectral components, ans also using our proposed Multi-Objective Optimization (MOO) model based on the results of clustering, the optimal load profiles for each end-use can be found, and then, the smoothest possible aggregate load profile for a building is calculated.

4 - Reduction of Transmission-Grid Constraints for Computationally Efficient N-1 Secure Optimal Power Flow

Richard Weinhold, TU Berlin, Berlin, Germany, riw@wip.tu-berlin.de, Robert Mieth

Power flows and thus electricity market outcomes are constrained by physical transmission system constraints and its security requirements such as the N-1 criterion.Internalization of this criterion in optimal power flow (OPF) analyses often leads to prohibitive computational complexity even for linearized (DC) power flow equations.We present a methodology to obtain a minimal set of linear constraints that yields an exact N-1 secure DC-OPF solution that can be leveraged in multi-period economic analyses. The reduction process depends only on time invariant parameters and needs to be performed only once.The effectiveness of the method is shown on a large-scale real world power system.

Graph Algorithms and Applications I

Sponsored: Optimization/Network Optimization

Sponsored Session

Chair: Golshan Madraki, PhD., Clarkson University, Potsdam, NY, United States

1 - Interdicting Layered Physical and Information Flow Networks

N. Orkun Baycik, Shenandoah University, School of Business, Winchester, VA, 22601, United States, Thomas Sharkey, Chase Rainwater

We study the interdiction of layered networks that involve a physical flow and an information flow network. There exist dependencies between these networks since components of the physical flow network are operational should their counterparts in the information flow network receive enough demand. This leads to a network interdiction problem over these layered networks. For the case where the information supply arcs are uncapacitated, we apply a novel multi-step, dual-based reformulation technique. We apply this technique to the application of combating illegal drug trafficking and cyber-physical system security.

2 - Max-min Diversity Problem with Non-identical Facilities

Saeed Chavoshi, North Carolina State University, Dept of Industrial Engineering, Raleigh, NC, 27695-7906, United States, schavos@ncsu.edu, Yahya Fathi

We consider the max-min diversity problem in which there is a weight associated with each facility and we wish to locate a collection of p facilities on a given set of n nodes (n larger than or equal to p) so as to maximize the minimum weighted pairwise distance among the located facilities. We propose an iterative algorithm for solving this problem and propose effective methods for solving the corresponding IP model at each iteration. We also present the results of a limited computational experiment.

3 - Block-structure Based Time-series Models for Graph Sequences

Mehrnaz Amjadi, UIC, Chicago, IL, United States, Theja Tulabandhula

Although the computational and statistical trade-off for modeling single graphs, for instance, using block models is relatively well understood, extending such results to sequences of graphs has proven to be difficult. In this work, we take a step in this direction by proposing two models for graph sequences that capture: (a) link persistence between nodes across time, and (b) community persistence of each node across time. For both of these proposed models, we provide statistically and computationally efficient inference algorithms, whose unique feature is that they leverage community detection methods that work on single graphs.

4 - Learning Steady-States of Iterative Algorithms Over Graphs

Le Song, Georgia Institute of Technology, Atlanta, GA, 30332, United States, Hanjun Dai

Many graph problems can be solved via iterative algorithms where the solutions are often characterized by a set of steady-state conditions. Different algorithms respect to different set of fixed point constraints, so instead of using these traditional algorithms, can we learn an algorithm which can obtain the same steady-state solutions automatically from examples, in an effective and scalable way? How to represent the meta learner for such algorithm and how to carry out the learning? We propose an embedding representation for iterative algorithms over graphs, and design a learning method which alternates between updating the embeddings and projecting them onto the steady state constraints.

5 - Interdicting Interdependent Contraband Smuggling, Money and Money Laundering Networks with Uncertain Information

Yeming Shen, Rensselaer Polytechnic Institute, Troy, NY, United States, sheny15@rpi.edu, Thomas Sharkey, Boleslaw Szymanski, William A. Wallace

This paper focuses on the problem of interdicting the interdependent contraband smuggling, money and money laundering (ICSML) networks of a transnational criminal organization (TCO). There are four interdependencies among these networks: money flows from the contraband smuggling network to the money network, support from the money network flows to the smuggling network, money flows from the money network to the laundering network and incentives from the laundering network flow to the smuggling and money networks. Our computational analysis focuses on the impact of inaccurate or incomplete information about the TCO on our interdiction decisions.

Data-driven Decision Making and Decision Diagrams

Sponsored: Computing

Sponsored Session

Chair: Amin Hosseininasab, Carnegie Mellon University, Pittsburgh, PA, 15217, United States

1 - Integrating Decision Diagrams into Generative Adversarial Networks for Data-driven Decision-making

Willem-Jan Van Hoeve, Carnegie Mellon University, Tepper School of Business, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, vanhoeve@andrew.cmu.edu, Yexiang Xue

Many decision-making problems aim to maximize (implicit) user preferences for which no algebraic or rule-based description exists. This makes it challenging to directly apply classical optimization technologies such as integer programming or constraint programming. An alternative is to generate solutions from a neural network that represents the preferences, but these solutions often fail to satisfy operational constraints. We present a hybrid approach, DDGAN, that embeds Decision Diagrams into Generative Adversarial Networks. It filters the solutions generated from the neural network through a decision diagram to ensure feasibility. We evaluate DDGAN on routing/scheduling problems.

2 - Reward Potentials for Learned Neural Networks

Buser Say, University of Toronto, Toronto, ON, M6K 0B4, Canada, bsay@mie.utoronto.ca, Scott Sanner, Sylvie Thiébaux

Optimal planning with learned neural networks (NNs) in continuous action/state spaces is a challenging task for branch-and-bound solvers due to the poor linear relaxation of the underlying mixed-integer linear programming (MILP) model. For a given set of features, potential heuristics provide an efficient framework for computing bounds on reward functions. We model the problem of finding an optimal potential heuristic for learned NNs as a bilevel program, and solve it with constraint generation. We then strengthen the linear relaxation of the MILP model by valid constraints to bound the reward function based on the precomputed potentials, and show results on efficiency and runtime improvements.

3 - Decision Diagrams for Real-Time Routing Applications

Ryan J. O’Neil, nextmv, Philadelphia, PA, United States, ryan@nextmv.io, Karla L. Hoffman

Decision Diagrams are a rapidly developing optimization technology with many attractive qualities for real-time routing in industry. These include fast discovery of high quality solutions, inherent testability and interpretability, and low communication overhead for parallelization. We examine the use of Decision Diagrams for meal delivery and ride sharing, present computational results, and give some recommendations regarding their implementation.

4 - Structure Mining for Interpretable Data-driven Sequential Decision Making

Amin Hosseininasab, Carnegie Mellon University, Pittsburgh, PA, 15217, United States, aminh@andrew.cmu.edu, Willem-Jan Van Hoeve, Andre Augusto Cire

Learning algorithms are generally evaluated by prediction accuracy, which has entailed the development of complex highly nonlinear models. Unfortunately, the complexity of such predictors is a barrier to their adaption in many decision making problems. This has led to increasing interest in interpretable algorithms for management science applications, albeit with lower accuracy. In this talk, we present a systematic approach towards generating interpretable but also accurate knowledge for sequential decision making problems. We show the benefits of our approach using an example in marketing, where we investigate methods to reduce the skip rate of users in online music streaming platforms.

Joint Session ICS/DM: Optimization in Machine Learning II

Sponsored: Computing

Sponsored Session

Chair: John W Chinneck, Carleton University, Ottawa, ON, K1S 5B6, Canada

1 - Approximating L1-Norm Best-Fit Lines

J. Paul Brooks, Virginia Commonwealth University, School of Business, Richmond, VA, 23284, United States, jpbrooks@vcu.edu, Jose Dula

Fitting subspaces is a fundamental task in data analysis techniques such as linear regression and principal component analysis and for applications including ranking and recommendation. L1-norm best-fit subspaces provide benefits including outlier insensitivity, but can be difficult to compute. We derive sufficient conditions for L1-norm line fitting and in doing so reveal the algorithm with the best-known approximation factor having the lowest computational complexity.

2 - Mixed-integer Conic Programming for Learning Directed Acyclic Graphs from Continuous Data

Hasan Manzour, University of Washington, Seattle, WA, 98195, United States, hmanzour@uw.edu, Simge Kucukyavuz, Ali Shojaie

We study sparse directed acyclic graph (DAG) learning of a Bayesian network from continuous observational data. This problem is commonly modeled using a standard big-M constraint in the associated mixed-integer program. However, this strategy leads to poor continuous relaxations because there is no natural upper bound for the arc weights. To circumvent this deficiency, we reformulate the problem as a mixed-integer second-order cone program (MISOCP), which entails tighter continuous relaxation compared to the existing formulations based on big-M constraints. Our numerical results demonstrate that the MISOCP clearly outperforms the existing big-M formulations.

3 - Solving Map Estimation via Mixed-integer Quadratic Optimization and Customized Branch-and-bound

Pitchaya Wiratchotisatian, Worcester Polytechnic Institute, Worcester, MA, 01609, United States, pwiratchotisatia@wpi.edu, Patrick Flaherty, Andrew C. Trapp

We study maximum a-posteriori (MAP) estimation for the Gaussian mixture model. This problem features challenging nonconvex and non-separable components in which existing approaches often sacrifice global optimality for quick convergence. We formulate MAP as a mixed-integer quadratic program using piecewise linear approximation. Even so, this NP-hard problem may require significant running time to find a global optimum. We develop custom branch and bound methods that accelerate convergence to global optimality, and compare the efficiency and quality of solutions with standard MAP methods.

4 - On the Cluster-wise Supervised Learning: A New Framework and Globally Convergent Algorithm

Weijun Xie, Virginia Tech, Department of Industrial and Systems Engineer, Blacksburg, VA, 24061, United States, Shutong Chen

In supervised learning, there might be hidden structures in the dataset, which require unsupervised learning techniques to improve the results. Therefore, this paper integrates the clustering with supervised learning, to simultaneously find the best clusters of the data points and minimize the empirical loss function within each cluster. We develop a novel regularized alternating projection method with global convergence. Our numerical study demonstrates both the efficiency and effectiveness of the proposed method compared to the existing ones (e.g., random forests).

1 - Sublinear Time Linear Algebra for Structured Matrices

David P. Woodruff, PhD. in Computer Science, Carnegie Mellon University, Pittsburgh, PA, 15213, United States

There are a number of approximation algorithms for NP-hard versions of low rank approximation, such as finding a rank-k matrix B minimizing the sum of absolute values of differences to a given matrix A. These error measures are special cases of the following general entrywise low rank approximation problem: given an arbitrary function g, find a rank-k matrix B which minimizes the entrywise g-function loss. A natural question is which functions g admit efficient approximation algorithms. We give approximation algorithms for every function g which is approximately monotone and satisfies an approximate triangle inequality, and we show both of these conditions are necessary.

2 - Convex Optimization for Overlapping Community Detection

Jimit Majmudar, University of Waterloo, Waterloo, ON, Canada, jmajmuda@uwaterloo.ca, Stephen Vavasis

In the community detection problem, the goal is to recover communities in a graph. “Communities” are defined as cliques or dense subgraphs, and we may assume that the graph is generated according to some specified generative model. This problem is well-studied in the situation in which the communities do not overlap. For the case of overlapping communities, Arora et al. (2011) provide a combinatorial approach and Anandkumar et al. (2014) provide a tensor factorization approach for recovery. In this work, we provide the first convex optimization approach for recovering overlapping communities. Our method is also robust to reasonable noise in the input graph.

3 - An Optimal-storage Approach to Semidefinite Programming Using Approximate Complementarity

Lijun Ding, Cornell University, Ithaca, NY, 14850, United States

This talk develops a new storage-optimal algorithm that provably solves generic semidefinite programs (SDPs) in standard form. This method is effective for weakly constrained SDPs. The key idea is to formulate an approximate complementarity principle: Given an approximate solution to the dual SDP, the primal SDP has an approximate solution whose range is contained in the eigenspace with small eigenvalues of the dual slack matrix. This result suggests an algorithmic strategy that can be implemented with minimal storage: (1) Solve the dual SDP approximately; (2) compress the primal SDP to the eigenspace with small eigenvalues of the dual slack matrix; (3) solve the compressed primal SDP.

4 - Bundle-type Methods for Dual Atomic Pursuit

Zhenan Fan, The University of British Columbia, Vancouver, BC, Canada, zhenanf@cs.ubc.ca

The aim of structured optimization is to assemble a solution, using a given set of (possibly uncountably infinite) atoms, to fit a model to data. A two-stage algorithm based on gauge duality and bundle-type methods is proposed. The first stage discovers the optimal atomic support for the primal problem by solving a sequence of approximations of the dual problem using a bundle- type method. The second stage recovers the approximate primal solution using the atoms discovered in the first stage. The overall approach leads to implementable and efficient algorithms for large problems.

Parking Behavior and Management

Sponsored: Transportation Science & Logistics/Intelligent Transportation Systems (ITS)

Sponsored Session

Chair: Xinlian Yu, University of Massachusetts-Amherst, Amherst, MA, 01003, United States

1 - Location of Parking Facilities in the Era of Autonomous Vehicles

Mahmood Tarighati Tabesh, Graduate Research Assistant, Purdue University, West Lafayette, IN, United States, mtarigha@purdue.edu, Mohammad Miralinaghi, Samuel Labi

Drivers in metropolitan downtown areas continue to face challenges in finding parking locations. In an era of Autonomous Vehicles (AVs), it is expected that travelers can directly travel to their destination and dispatch their AVs to park at distant locations. For a mixed fleet (AV and human-driven vehicles) environment that will characterize the AV transition period, this study presents a general framework for locating parking facilities. We formulate the problem as a mixed-integer nonlinear problem and use the well-known Bender's decomposition method to solve it. The findings can help transportation planners to address parking issues associated with the AV transition period.

2 - Puzzle-based Parking

Parag Siddique, University of Louisville, Louisville, KY, United States, parag.siddique@louisville.edu, Kevin Gue

The potential for remote control of autonomous cars suggests new ways to increase parking density for urban settings. We describe a general model for very high density parking based on the popular sliding block puzzle Rush Hour. Our designs suggest improvements of 70-80% are possible.

3 - Operation of Shared Autonomous Vehicle Systems: Optimal Fleet Sizing and Depot Deployment

Xinlian Yu, University of Massachusetts-Amherst, Amherst, MA, 01003, United States, Alireza Khani

Autonomous vehicles (AVs) can relocate themselves automatically to any traveler's location upon request, and thus potentially improve the efficiency of vehicle sharing system, as they can relocate themselves automatically to any traveler's location upon request. This study aims to develop a systematic approach for planning and operating a fleet of shared AVs by addressing a number of practical challenges: the fleet sizing, depot deployment and capacity, as well as routing and relocating algorithms.

4 - The Morning Commute of Traditional Vehicles with Considering a Parking Space at Network Level

Reza Ansari Esfe, University of Calgary, Calgary, AB, Canada, Lina Kattan

The morning commute problem has been studied with different assumptions in a single bottleneck. At the first time, the morning commute problem was discussed by Vickery (1969) to investigate the trip of people having identical behavior preferences in the morning with a single and fixed capacity bottleneck. Then, it is discussed by considering homogenous and heterogeneous preferences, with one parking and multiple parking zones or without parking space and with an autonomous or traditional vehicle. However, modeling the network level is much more realistic. In this study, we talk about the user equilibrium in the network level by considering parking space constraint near the workplace. We use Speed-MFD to model the congestion and consider the traditional vehicle. To define the morning commute in this study, a number of commuters travel through the downtown network and reach their destination. The desired arrival time is identical for all commuters. There parking spaces near commuter's destination with infinite capacity Np. In addition, we assume the real-time speed of each commuter, which is changing by the variation of the commuters' number in the network, that is in contrast with the studies considering a fixed speed, departing speed or arrival speed, therefore; this assumption helps us to make a more realistic model.

Sponsored Session

Chair: Shahab Derhami, Georgia Tech-ISYE, Atlanta, GA, 30332, United States

1 - Assortment Planning in Interconnected Retail Networks

Shahab Derhami, Georgia Tech, 755 Ferst Drive, NW, Atlanta, GA, 30332, United States

In this talk, we propose a mixed integer programming model to solve the assortment planning problem in an interconnected network of retailers distributing high-value substitutable products such as cars and recreational vehicles, where retail centers exploit on-demand inventory transshipment to satisfy the demand for out-of-stock products. The model finds the optimal assortment to maximize the total profit under uncertain demand, customer substitution, long order-to-delivery lead time, and obsolescence cost.

2 - Assessing Time-Sensitive Availability of Substitutable Products Across Downstream Supply Chains and Retail Networks

Benoit Montreuil, Georgia Institute of Technology, Industrial & Systems Engineering, Atlanta, GA, 30332-0205, United States, Shahab Derhami

We introduce a product availability performance indicator measuring the current capability of a retail center to meet demand from customers for each of the products in its offer portfolio. It accounts for customer time-based service expectations, product demand share estimates, product substitution, product transfers from other retailers in the network as well as other supply chain sources. We demonstrate using Product Availability Ratio (PAR) for a large North American network of high-value products, highlighting key insights and impacts.

3 - Showcasing Optimization in Omnichannel Retailing

Iman Dayarian, University of Alabama, Tuscaloosa, AL, 35487, United States, idayarian@cba.ua.edu, Ji Soo Park, Benoit Montreuil

We focus on a setting in which customers prefer to visit an offline showroom to experience the products in person to gain sufficient confidence in their potential purchase. An order is placed next and the product is delivered to the customer. We propose a quantitative approach to optimize the showcasing value for a retailer to maximize the exposure of the features that customers expect to experience from a visit to a showroom. The numerical results of a case study on data obtained from dealerships of our industrial partner show that the showcasing value for a retailer can significantly increase, even in the presence of spatial and/or budget constraints.

4 - Providing Menus of Choices for Crowdsourced Suppliers in Open Platform Systems

Jennifer Pazour, Rensselaer Polytechnic Institute, Troy, NY, 12180-3522, United States, pazouj@rpi.edu, Hannah Horner, John E. Mitchell

Open platform systems, in which decentralized suppliers provide access to their resources to fulfill demand requests, are becoming common in distribution and logistics. We propose and evaluate a new hierarchical approach to coordinate decentralized resources by recasting the platform's role as one providing personalized menus of requests for decentralized suppliers to choose from.

1 - High-capacity Ride-pooling with Electric Vehicles

Matthew Zalesak, Cornell University, Ithaca, NY, United States, mdz32@cornell.edu, Samitha Samaranayake

We study the effects of using electric vehicles in online ride-pooling systems. Prior work has shown that online algorithms perform well for high capacity ride-pooling systems. We propose an mixed integer linear program to extend these algorithms to the electric vehicles setting, with the primary objective of maximizing the number of requests satisfactorily served. Then we show a faster, scalable algorithm with similar performance that is practical for large-scale systems. Our contributions show the importance of having knowledge and estimates of future demand even when operating in the online setting.

2 - Estimating Primary Demand in Bike-sharing Systems

Chiwei Yan, Uber Technologies, San Francisco, CA, United States, University of Washington, Seattle, WA, United States, Chong Yang Goh, Patrick Jaillet

We consider the problem of estimating the primary or first-choice demand for a bike-sharing service using trip and inventory data. To account for choice substitutions, we propose a rank-based demand model that treats each observed trip as the best available option in a latent ranking over origin-destination pairs. We then solve a high dimensional estimation problem using algorithms that (i) find sparse representations of the parameters efficiently, and (ii) constrain trip substitutions spatially according to the bike-share network. Our method is effective in recovering the primary demand and computationally tractable on a city scale, as we demonstrate on a bike-sharing service in Boston.

3 - Relocation Optimization for Empty Vehicles on Shared Transportation Platforms

Hai Wang, Singapore Management University, School of Information Systems, Singapore Management University, Singapore, 178902, Singapore, Carnegie Mellon University, Pittsburgh, PA, United States, Zhengli Wang

Due to stochastic demand, supply, and their imbalance on shared transportation platforms, the relocation guidance for empty vehicles (idle drivers) is very important to improve passenger service level, driver income, and platform revenues. In this paper, we study the empty vehicles relocation guidance problem using a two-stage model. First, we propose a general idealised relocation policy and its theoretical guarantee assuming that all travel times between regions are equal within a time unit; second, we study the specific relocation optimization considering practical general travel times among regions and provide performance bounds both theoretically and numerically.

4 - Reservation vs. On-demand Ride-hailing Platforms

Ziwei Cao, University of Maryland, College Park, MD, 20740, United States, Michael O. Ball

We consider a market where a dominant firm provides an Uber-like on-demand service and a startup provides reservation service. Customer valuations are differentiated based on preference for the service offered by different platforms. We study how the reservation platform makes pricing, wage and expansion decisions under competition.

1 - The Impact of Bolsa Familia on Unhealthy Behaviors

Fernanda Araujo Maciel, PhD Candidate, Bentley University, Waltham, MA, United States, fmaciel@bentley.edu

The objective of this paper is to assess the impact of Brazil's Bolsa Familia conditional cash-transfer program on unhealthy behaviors, which is measured by expenses with ultra-processed foods, alcohol, and smoking products. Applying Machine Learning methods to improve Propensity Score Matching, I analyze the intensive margin, extensive margin, and overall effect. Results show that program participants increase the expenditure of food, food away from home, and cookies. Among households that purchase soda or smoking products, the amount spent on these products reduces.

2 - Attitudes Toward Risk and Cost Pass-through under Uncertainty

Phat Luong, Rutgers University, Newark, NJ, United States, Xiaowei Xu

This paper takes into account the difference in risk-aversion of producers to explain the degree of cost pass-through. Each producer can be either risk-neutral or risk-averse, characterized by a CARA utility function. We find that the maximal pass-through differentiation structure arises if one supplier is risk-neutral (e.g., a Chinese state-owned enterprise) but the other is risk-averse (e.g., a domestic private enterprise). Contrarily, if both suppliers are similarly risk-averse (e.g., American vs. European producers), then the pass-through rates stay in the range of 40%-60% at market equilibrium. We also find that tariff is inefficient to promote the competitiveness of domestic producer.

3 - Mathematical Model for Ridesharing Matching Algorithm Optimization

Luiza Marques Fonseca dos Santos, Texas Tech University, Lubbock, TX, United States, luiza.santos@ttu.edu, Jia Li

Isolation in rural areas creates the Last Mile problem. Ridesharing systems can fill this gap, but it relies on the matching mechanism for its efficiency. This paper tries to identify the matching algorithms which ensure the consistency of the ridesharing systems. We propose that ridesharing stability is related to the size of the market. We expand optimization models found in the literature by introducing the characters of drivers and passengers relating to maximum waiting time and spatial distribution.

4 - Characterizations for DTA Modelling under User Equilibrium Conditions and Convergence of Solutions for Some Stochastic DTA Cases

Ricardo de la Paz Guala, PhD Student, Universidad de Chile, Santiago, Chile, delapaz8866@gmail.com, Cristian Eduardo Cortes, Pablo Andres Rey

When studying the factors that affect traffic, analyzing how demand is assigned (Traffic Assignment) among routes is fundamental. Currently, the Dynamic Traffic Assignment (DTA) problem, which faces the time dependency of route choice under conditions as User Equilibrium (UE) and, particularly, the Stochastic DTA (SDTA) problem, which integrates uncertainty on route choice, have become determinant tools for this type of analysis. We present characterizations of fundamental functions that fully define DTA for some general cases and prove that, for some of this cases, the solution of SDTA, with a logit route choice model, converges to the solution of its equivalent DTA.

5 - Facility Location Decisions from Public Data

Muge Tekin, Imperial College Business School, London, United Kingdom, m.tekin@imperial.ac.uk, Kalyan Talluri

Econometric analysis is challenging for the restaurant industry since it includes taste, quality and value that are unobservable. To tackle the challenges, we make use of social media, demographic and geographic data to infer an operational decision: the optimal location and design for a restaurant considering the long term benefits.

Joint Session AAS/TSL Air/Practice Curated: Airline Scheduling

Sponsored: Aviation Applications

Sponsored Session

Chair: Bruno F. Santos, TU Delft, Delft, 2629 HS, Netherlands

1 - Integrated Flight Scheduling and Fleet Assignment with Improved Supply-demand Interaction Modeling

Sebastian Birolini, PhD Student, Department of Management, Information and Production Engineering, University of Bergamo, Dalmine (BG), Italy, sebastian.birolini@unibg.it, António Pais Antunes, Mattia Cattaneo, Paolo Malighetti, Stefano Paleari

This paper presents an alternative approach to deal with supply-demand interactions in flight scheduling and fleet assignment optimization models. Different from demand correction terms, the proposed approach simultaneously solves the demand generation and allocation problems allowing for flexible itinerary-utility specifications. Computational testing reveals that the model can handle mid-size hub-and-spoke networks to optimality in reasonable time. The benefits that can be derived from the application of the approach are illustrated for a major European airline.

2 - Dynamic Evaluation of Airline Crew Flight Requests

Bruno F. Santos, Assistant Professor, TU Delft, Faculty of Aerospace Engineering, Delft, 2629 HS, Netherlands, b.f.santos@tudelft.nl, Lennart Scherp, Maud Beulen

In airline crew rostering, crew members' requests to operate specific flights need to be evaluated efficiently to avoid inefficient schedules. This is a dynamic problem, in which requests are submitted while others have already been granted and pre-assigned. We propose a neural-network algorithm to evaluate flight requests, providing a systemic way of assessing flight requests. To train and test this algorithm, we developed an innovative rolling rostering framework that solves a linear programming crew rostering method in multiple time periods with the help of a column-generation algorithm. The framework is tested in a case study with a major European airline.

3 - A Strategic Multistage Tactical Two-stage Stochastic Optimization Model for the Airline Fleet Management Problem

Luis Cadarso, Rey Juan Carlos University, Camino del Molino s/n, Fuenlabrada, 28943, Spain, luis.cadarso@urjc.es, Adrian Serrano, Javier Faulin

This work proposes stochastic optimization for the airline fleet management problem, considering uncertainty in the demand, operational costs, and fares. In particular, a multistage tree is proposed, compounded of strategic and tactical nodes. At the former ones, fleet composition decisions are made, while at the latter ones, aircraft assignment decisions are formulated. Computational experiments are based on a network with seven strategic nodes and fourteen tactical nodes (i.e., seasons) where two fleet types are available. The results provide the optimal fleet mix and assignment at both strategic and tactical scopes.

4 - Reducing Crew Split in Multi-rank Pairing Optimization Problems

Yogesh Dashora, Sabre Corp., Southlake, TX, United States, yogesh.dashora@sabre.com, Olof Damberg, Tomas Karlsson

Airlines having multi base operations across various countries have always been troubled with the problem of keeping their crew together for the entire length of trip while still maintaining the manpower limitations and costs minimal. Although there are various restrictions that can be placed in the optimization system to try to achieve these goals, recently we have tried techniques for reducing the number of different bases, number of different pairing types, or number of pairings covering a set of flight legs within our optimization framework. We intend to provide overview of the mathematical complexity while keeping the business aspect of the problem in the highlight.

5 - An Innovative and Efficient Solution Methodology to Integrated Fleet Assignment Problem

Shahram Shahinpour, Sabre Inc., Fort Worth, TX, 76155, United States, Sergey Shebalov Shebalov, Peter Sun

Fleet assignment deals with assigning an equipment type to a flight to best match seat capacity with passenger demand in order to maximize profit. Fleet assignment models (FAM) that consider origin and destination effect and integrate other aspects of demand forecasting systems have been proven to be very hard to solve. In this talk we explore the root cause for the intractability of such problems and propose a solution methodology to origin and destination fleet assignment and extensions to integrated FAM. Numerical experiments with real datasets from airlines show significant benefits of the proposed method.

Data-driven Decision-making in Pricing and Ordering

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Boxiao (Beryl) Chen, University of Illinois at Chicago

1 - Online Learning Algorithms for Multi-product Inventory Systems with Point of Sales Data

Xiangyu Gao, The Chinese University of Hong Kong, RM909 Cheng Yu Tung Building, Shatin, Hong Kong, Hong Kong, Huanan Zhang

We consider a periodic-review multi-product inventory system where each consumer's demand is affected by the product availabilities. In this model, the total sales are affected by the arrival sequence and preferences of consumers. When the full distributional information of the demand is not available, the decision-maker has to learn the information on-the-fly, through the partial and censored feedback of customers. We introduce a UCB-based algorithm to balance the learning and earning tradeoff. Due to the high-dimensionality of the policy space, we propose two methods to improve the efficiency of our algorithm.

2 - Data-driven Approximation Schemes for Joint Pricing and Inventory Control Models

Hanzhang Qin, Massachusetts Institute of Technology, Cambridge, MA, 02142, United States, hqin@mit.edu, David Simchi-Levi, Li Wang

We study the classic multi-period joint pricing and inventory control problem in a data-driven setting. We propose a data-driven approximation algorithm, which uses the past demand data to solve the joint pricing and inventory control problem. We assume the retailer does not know the noise distributions or the true demand functions; instead she only has access to demand hypothesis sets that contain the true demand functions. We prove the algorithm's sample complexity bound, the number of data samples needed to guarantee a near-optimal profit. A simulation study suggests that the data-driven algorithm solves the dynamic program effectively.

3 - Tailored Base-Surge Policies in Dual-Sourcing Inventory Systems with Demand Learning

Boxiao (Beryl) Chen, University of Illinois-Chicago, Chicago, IL, 60607, United States, bbchen@uic.edu, Cong Shi

We consider a periodic-review dual-sourcing inventory system, in which the expedited supplier is faster and more costly, while the regular supplier is slower and cheaper. Under full demand distributional information, it is well-known that the optimal policy is extremely complex but the celebrated Tailored Base-Surge (TBS) policy performs near optimally. In this paper, we assume that the firm does not know the demand distribution a priori, and makes adaptive inventory ordering decisions in each period based only on the past sales data. We develop the first nonparametric learning algorithm that admits the best possible convergence rate.

4 - Discontinuous Demand Functions: Estimation and Pricing

N. Bora Keskin, Duke University, Fuqua School of Business, Durham, NC, 27708-0120, United States, bora.keskin@duke.edu, Arnoud Victor den Boer

In random utility models, customer utility distributions exhibit point masses in the presence of income effects, transportation costs, and network effects. These point masses naturally result in discontinuities in the expected demand as a function of price. Motivated by this, we consider a dynamic pricing-and-estimation problem with an unknown and discontinuous demand function. We show that ignoring such discontinuities results in substantial loss of revenues, and construct near-optimal policies that can handle demand discontinuities.

Learning in Strategic Environments

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Santiago Balseiro, Columbia University, New York, NY, 10027, United States

Co-Chair: Daniel Russo, Columbia University, New York, NY, 60208, United States

1 - Learning and Earning in Competitive Environments

John R. Birge, University of Chicago, Chicago, IL, 60637, United States, John.Birge@ChicagoBooth.edu

Competition can dramatically change decisions regarding exploration and learning. This talk will discuss conditions for such incomplete learning.

2 - Bid Prediction in Repeated Auctions with Learning Agents

Vasilis Syrgkanis, Microsoft Research, Cambridge, MA, 02142, United States, vasy@microsoft.com

We consider the problem of bid prediction in repeated auctions from past bidding data. We formulate two models of learning behavior, one based on mean field asymptotics and one based on no-regret learning. We propose an econometric approach to estimation of the structural parameters of both the type of the player and the learning algorithm. We subsequently solve the bid prediction problem by forward simulation. We evaluate our approach on a real-world data set from sponsored search auctions in Bing. We find that bid prediction based on gradient descent style behavioral assumptions outperforms most machine learning approaches that treat the problem as a pure time series problem.

3 - On the Futility of Dynamics in Robust Mechanism Design

Anthony Kim, Columbia University, New York, NY, United States, aek2185@columbia.edu, Santiago Balseiro, Daniel Russo

We consider a broad class of problems in which a principal repeatedly interacts with a strategic agent over a finite discrete-time horizon. In each round, the agent privately observes idiosyncratic shocks drawn independently and identically from a distribution known to him but not to the principal. When the principal commits to a dynamic mechanism, the agent best-responds to maximize his aggregate utility over the rounds. We show the minimax regret is linear in the time horizon and repeatedly implementing a single-round mechanism is optimal without any meaningful dynamics. Outside the class of problems, we construct an example in which a dynamic mechanism can provably outperform static mechanisms.

4 - No Regret Learning on Games with Imperfect Information

Zhengyuan Zhou, Stanford University, Stanford, CA, 94305, United States

We discuss some of the recent results in learning on games, where each player employs a no-regret learning algorithm to update its action in an unknown, time-varying environment that consists of other agents who are simultaneously engaged in a similar online decision making process.

Online Advertising and Digital Marketplace Platforms

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Sami Najafi

1 - Distributionally Robust Convex Regression

Zhengqing Zhou, Stanford University, Stanford, CA, United States, Jose Blanchet, Peter W. Glynn

Convex regression recognizes non-linearities that are often a part of problem settings in which linear regression is used mostly because of tractability considerations. This work presents a natural distributionally robust optimization formulation for convex regression analysis which has many advantages relative to standard formulations. First, the underlying convex function is easier to fit than in standard least-square algorithms. Second, it is more robust, not only by design but also in terms of empirical performance. Statistical rates of convergence guarantees are also supplied, which are not-worst than those obtained in current estimators.

2 - Customer Choice Models Versus Machine Learning: Finding Optimal Product Displays on Alibaba

Jacob Feldman, Olin Business School, Saint Louis, MO, 63108-1291, United States, jbfeldman@wustl.edu, Dennis Zhang

We compare the performance of two approaches for finding the optimal set of products to display to customers landing on Alibaba's two online marketplaces, Tmall and Taobao. Both approaches were placed online simultaneously and tested on real customers for one week. The first approach we test is Alibaba's current practice. This procedure embeds thousands of product and customer features within a sophisticated machine learning algorithm that is used to estimate the purchase probabilities of each product for the customer at hand. Our second approach uses a featurized multinomial logit (MNL) model to predict purchase probabilities for each arriving customer.

3 - Managing Digital Advertising Campaigns

Sami Najafi Asadolahi, Santa Clara University, Leavey School of Business, Santa Clara, CA, 95053, United States, snajafi@scu.edu, Naren Agrawal, Stephen A. Smith

Advertising agencies manage numerous ad campaigns for multiple clients in real-time. Because of uncertainties in the demand from campaigns for viewers, and the rate at which the target viewers visit websites, ensuring that campaigns proceed according to plan is a difficult challenge. We describe a methodology to manage such campaigns.

4 - Extended Sampled Trees for Classification and Regression

Omar Skali, Massachusetts Institute of Technology, Cambridge, MA, United States, oskali@mit.edu, Georgia Perakis, Divya Singhvi

Our objective is to develop a Machine Learning model for classification and regression that is interpretable, scalable, suitable for a learning framework and that is competitive in terms of accuracy. In particular, we propose an Extended Sampled Trees (XSTrees) algorithm, which extends linearly the splits of individual tree-based methods such as CART, then introduces a Bayesian distribution over this tree space. We prove probabilistic guarantees, and benchmark it against state-of-the-art methods on synthetic data, publicly-available datasets, and a real-world case study.

Revenue Management in Online Marketplaces

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Negin Golrezaei, Google Inc., Google Inc., Cambridge, MA, 02142, United States

Co-Chair: Vahideh Manshadi, Yale University, New Haven, CT, 06511, United States

1 - Product Ranking on Online Platforms

Negin Golrezaei, MIT, Massachusetts Institute of Technology, Cambridge, MA, 02142, United States, golrezae@mit.edu, Mahsa Derakhshan, Vahideh Manshadi, Vahab Mirrokni

On online platforms, consumers face an abundance of options that are displayed in the form of a ranking. Only products placed in the first few positions are readily accessible to the consumer, and she needs to exert effort to access more options. For such platforms, we develop a two-stage search model, wherein the first stage, the consumer sequentially screens positions to learn the preference weight of some products and forms a consideration set. In the second stage, she learns the additional idiosyncratic utility of the products in her consideration set. For this model, we characterize the optimal search policy of consumers. We then study how platforms with objectives should rank products.

2 - Matchings in Ride Sharing Platforms: A Two Stage Robust Optimization Approach

Oussama Hanguir, Columbia University, New York, NY, 10025, United States, oh2204@columbia.edu, Omar El Housni, Vineet Goyal, Clifford Stein

We consider the problem of matching riders to drivers in ride sharing platforms where such matchings need to be made in the presence of uncertainty for both agents. We consider a two-stage robust optimization approach to model the problem where we decide on the matching between the given agents in the first stage before observing the second-stage (adversarially chosen) scenario of agents. The goal is to select a first-stage matching such that the worst-case total cost is minimized. We show that this problem is NP-hard even with two scenarios. We consider myopic and threshold policies to approximate the problem and show that a myopic policy gives a good approximation for the case of metric distances.

3 - Surge Pricing and its Spatial Supply Response

Francisco Castro, Columbia University, Columbia School of Business, New York, NY, 10027, United States, Omar Besbes, Ilan Lobel

We study the pricing problem faced by a ride-hailing platform. We propose a two-dimensional framework in which a platform selects prices for different locations, and drivers respond by choosing where to relocate in equilibrium based on prices, travel costs and driver congestion. The general structure of an optimal pricing policy creates a menu of locations. In some, prices are set so that supply and demand are matched; over-congestion is induced in others, and some less profitable ones are indirectly priced out. We also study a family of models characterized by a demand shock. In this case, the platform will use prices to balance supply and demand around the shock, but also to induce movement away from it.

4 - Ridesharing and the Use of Public Transportation

Katherine Hoffman Pham, NYU Stern School of Business, New York, NY, United States, khoffmann@stern.nyu.edu, Panos Ipeirotis, Arun Sundararajan

We investigate the relationship between on-demand ridesharing via platforms like Uber/Lyft and the use of public transit systems. Our study uses trip count data on ridesharing, taxi, shared bike, and subway usage in New York City. Exploiting a series of exogenous shocks to the system (the closing of subway stations) to isolate substitution effects, we find that the average shock is associated with a 2.8-3.3% increase in the use of ridesharing. This shows that on-demand ridesharing acts as infrastructure that helps smooth unexpected supply and demand surges, but the effect is small relative to the estimated average number of subway rides displaced per zone and four-hour period.

Logistics Models for Disaster Response and Public Health Emergencies

Sponsored: Public Sector OR

Sponsored Session

Chair: Ashlea Millburn

1 - A Data-driven Optimization Approach for Multi-period Location-specific Resource Allocation in Cholera Outbreak

Nan Kong, Purdue University, Biomedical Engineering, West Lafayette, IN, 47906-2032, United States, nkong@purdue.edu, Mu Du, Aditya Sai

We consider a multi-period location-specific intervention resource allocation problem of cholera outbreak with missing local disease state information. We propose a data-driven optimization approach to determine the optimal intervention strategy in a rolling-horizon manner, which can make decisions with progressively incoming observations. We integrate model parameter fitting and scenario-based stochastic programming at each period. We conduct comparative studies to assess the performance of our approach and offer insights into intervention policy development.

2 - Locating Emergency Shelters in Consideration of Spatial and Aspatial Elements of Accessibility

Ashlea Bennett Milburn, University of Arkansas, 4207 Bell Engineering Center, Fayetteville, AR, 72701, United States, ashlea.bennett@uark.edu, Justin Taylor

Disaster response shelters should be located so as to maximize their accessibility by impacted populations who need them. A variety of spatial and aspatial factors influence shelter accessibility, such as the relationship between supply and demand in an area, and the levels of mobility and health care needs of people living in an area. This research creates a shelter accessibility metric inclusive of these components and formulates a linear program for locating shelters to maximize this new measure. The metric and optimization model are demonstrated for a case study based on Hurricane Florence.

3 - What Explains State Variations in the Number of Deaths from Opioid Overdose?

Negar Darabi, PhD Student, Virginia Tech, Blacksburg, VA, United States, darabi@vt.edu, Niyousha Hosseinichimeh

The number of deaths from opioid overdoses has increased dramatically over the last 16 years in the United States. Because of the severity of the opioid epidemic in the year 2017, this issue was announced as the “National Emergency”. We constructed a state-level panel data for 50 states of the U.S. plus the District of Columbia from 2008 to 2017 and we used a fixed effect regression model to explore the association between death from opioid overdose and a number of explanatory variables across different states. Our independent variables include insurance type, unemployment rate, income level, education level, and state policies on opioid prescription.

Sponsored Session

Chair: Hongcheng Liu

1 - Computational Evaluation of New Mixed Integer Programming Models for Tree Ensembles Optimization

Bijan Taslimi, University of Florida, Gainesville, FL, 32603, United States, b.taslimi@ufl.edu, Jean-Philippe P. Richard, Jongeun Kim, Mohit Tawarmalani

Tree ensemble models are widely used to predict the value of a dependent variable as a function of independent variables. When the independent variables are controllable, the value of the dependent variable can be optimized by adjusting the values of the independent variables. Mixed Integer Programming models have recently been proposed for such tree ensembles optimization problems. In this presentation, we consider new MIP formulations for this problem and compare their computational characteristics. We also present heuristic algorithms that can obtain near-optimal solutions efficiently.

2 - Training Prediction Models for Two-stage Linear Programs with Uncertain Right-hand Sides

Alexander Stewart Estes, University of Minnesota, 2929 University Ave SE, Apartment 606, Minneapolis, MN, 55414, United States, este0100@umn.edu, Jean-Philippe P. Richard

Consider a two-stage linear programming problem where the right-hand side of the second stage is unknown, and we are interested in fitting a regression model to predict these unknown quantities. Oftentimes, the prediction model is trained to minimize a standard loss function, such as mean square error, that is not directly related to the objective function of the optimization problem. We instead provide a convex loss function that is aligned with the objective function, and we demonstrate how to train models using this loss function.

3 - A Two-stage Optimization Algorithm to Learn Parameters of a Kernel Smoother

Sam Davanloo Tajbakhsh, The Ohio State University, 210 Baker Systems Building, 1971 Neil Ave, Columbus, OH, 43210, United States, sam.tajbakhsh@gmail.com, Necdet Serhat Aybat, Enrique Del Castillo

Learning parameters of a kernel smoother requires solving a nonconvex optimization problem. The problem is aggravated in high-dimensional settings for anisotropic kernels where the number of parameters scales with the dimension. In this work, we propose a two-stage optimization algorithm to learn kernel parameters. First, a convex likelihood-based problem regularized with a weighted l_1 norm is solved to get a sparse inverse covariance matrix. Second, the kernel parameters are estimated by solving a least-square problem. Theoretical error bounds for the proposed estimator are provided. Some numerical studies supporting the proposed algorithm will be provided.

10:30-11:15 SAS / 11:15-12:00 Frontline Systems, Inc.

Vendor Tutorial

1 - Building and Solving Optimization Models with SAS

Ed Hughes, SAS, Northants, United Kingdom, Rob Pratt

SAS provides a broad and deep array of data and analytic capabilities, including data integration, statistics, data and text mining, econometrics and forecasting, and operations research. The SAS optimization, simulation, and scheduling features coordinate easily and fully with other SAS strengths in data handling, analytics, and reporting.

OPTMODEL from SAS provides a powerful and intuitive algebraic optimization modeling language and unified support for building and solving LP, MILP, QP, NLP, CLP, and network-oriented models. And because the OPTMODEL optimization modeling language is contained within the OPTMODEL procedure, a SAS software module, it integrates seamlessly with the entire family of SAS functions, procedures, and macros. We'll demonstrate how you can use OPTMODEL to solve both basic and advanced problems, highlighting its newer capabilities and its support for both standard and customized solution strategies.

2 - Using Analytic Solver® Cloud for Teaching

Daniel H. Fylstra, Frontline Systems, Inc., Incline Village, NV, 89450-4288, United States

Introduced in May 2019 and now widely used, Analytic Solver® Cloud solves the biggest problems that faculty members experience when teaching analytics, especially to business students. Excel for Macintosh, Excel for Windows, and Excel Online are all fully supported. Setup is easier than ever: No download or Setup program is needed, and all students are using the same software version at all times. Requirements are just a current Office 365 subscription (free for students from Microsoft) and continuous Internet access. Supporting multiple leading textbooks, with responsive tech support for faculty and students, Analytic Solver Cloud simplifies your life when teaching.

Chair: Antonio Pievatolo

1 - Monitoring of Count Data Time Series: Cumulative Sum Change Detection in Poisson Integer Valued GARCH Models

Arda Vanli, Florida State University, Department of Industrial Eng., Tallahassee, FL, 32310, United States, oavanli@eng.fsu.edu, Rupert Giroux, Eren Erman Ozguven, Joseph J. Pignatiello

In this talk we present a new cumulative sum (CUSUM) monitoring approach for count-data time series. A seasonal integer valued generalized autoregressive conditional heteroscedasticity (INGARCH) time series model with Poisson deviates is used to develop a likelihood ratio test formulation to detect changes in the process accounting for temporal correlations and seasonality. The approach is applied for monitoring traffic crash counts and roadway safety improvement.

2 - Minimal Aliasing Optimal Designs for Non-Linear Models

Anna Errore, Carlson School of Management, University of Minnesota, Minneapolis, MN, United States, aerrore@umn.edu, R. Dennis Cook, Christopher J. Nachtsheim

Foldover designs induce statistical independence between first order linear effects and two-factor interactions in designs for linear models, so that linear main effects estimates are not biased by two-factor interactions effects. We use constrained optimization to explore the construction of designs for non-linear models with the same property. Our primary goal is to maximize the efficiency for a first order logistic regression model, subject to a constraint on the bias induced by the omission of two-factor interactions. To operationalize this optimization, we attempt to construct designs with parameter orthogonality between the parameters associated with the first and second order models.

3 - Applying SPC and DoE Methods in Continuous Processes under Feedback Control

Francesca Capaci, Luleå University of Technology, Lulea, Sweden, francesca.capaci@ltu.se

Standard statistical process control (SPC) and design of experiments (DoE) methods rely on the assumption that processes operate in open-loop. Continuous processes often work under engineering process control as in the case of feedback controllers. Accordingly, SPC and DoE methods need to be adapted when applied in these production environments. This talk explores potential challenges of using SPC and DoE methods in processes under feedback control. Simulated examples using the Tennesse Eastman process simulator under a decentralized feedback control strategy show how an analyst may adapt and use SPC and DoE methods for quality improvement efforts.

4 - Bayesian Virtual Age in Repairable Systems

Didem Egemen, National Cancer Institute - NIH, Alexandria, VA, 22315, United States, Fabrizio Ruggeri, Refik Soyer

Repairable systems are subject to different repair protocols upon each failure of the system. These include minimal, imperfect and perfect repairs. We are proposing a unifying virtual age model, which combines all three repair types and introduce generalizations of the repair models existing in the literature. Virtual age concept differentiates between the operational age and the current condition of the repairable system. The introduced models under the unifying model structure are extended further based on the dependence structure between the repair actions. For statistical inference, a Bayesian framework is considered and Markov Chain Monte Carlo methods are used for inference.

1 - Unsupervised Anomaly Detection in Presence of Embedded Low Dimensional Manifold

Imtiaz Ahmed, Texas A&M University, College Station, TX, 77840, United States, imtiazavi@tamu.edu, Travis Galoppo, Yu Ding

In higher dimensional space, data points are more likely to embed a complicated structure thus leading to a nonlinear manifold. In the presence of such complicated space structure, the direct Euclidean distance between two points does not represent their intrinsic distance anymore. Minimum Spanning Tree (MST), a graph-based measure can help us to approximate these true geodesic distances among points. In this work, we apply MST metric to measure the similarities of neighborhood points and use it as a regularizer to assist the machine learning techniques to obtain proper low dimensional representation in latent space which can in turn be used into detecting anomalies.

2 - Functional Gaussian Directed Graphical Models

Ana M. Estrada, PhD. Student, Georgia Institute of Technology, Atlanta, GA, 30332, United States, ameg3@gatech.edu, Kamran Paynabar, Massimo Pacella

A directed graphical model aims to represent the probabilistic relationship between variables in a system. Several methods have been developed for graphical models with low-dimensional variables. However, the case in which the variables are high-dimensional has not been studied thoroughly. This paper proposes a novel methodology to learn the structure and predict in the functional setting. When the structure of the network is known, function-to-function regression is used to estimate the parameters of the graph. When the goal is to learn the structure, a penalized least square loss is employed. Through simulations and a case study, the advantage of the proposed method is proven.

3 - A Deep Forest-based Supervised Learning Approach for High Dimensional Data Analysis

Chen Kan, University of Texas-Arlington, Arlington, TX, 76039-6215, United States, chen.kan@uta.edu, Chenang Liu, Jihoon Chung

High-dimensional data provide a great opportunity for process monitoring but pose significant challenges in modeling and analysis. Recently, deep learning (DL) is increasingly used to handle these data and extract pertinent information about process dynamics. However, most DL models, including CNN, contain too many hyperparameters and the performance is highly dependent on parameter tuning, which is very time consuming and may lead to suboptimal results. To address this problem, this study introduces and improves a deep forest approach for the analysis of high-dimensional data. Experimental results show the proposed approach is more robust compared with widely used DL models.

4 - Nonparametric Change-point Detection with Parsimonious Smoothing for Real-time Process Monitoring

Shenghan Guo, Rutgers University, Piscataway, NJ, 08854, United States, sg888@scarletmail.rutgers.edu, Weihong (Grace) Guo

Machine faults and systematic failures are revealed by pattern changes in manufacturing data. Early recognition of such changes can preclude issues that cause severe profit loss. Change-point detection identifies the time when abnormal patterns occur, thus ideal for pattern recognition in manufacturing processes. In this paper, we develop an innovative change-point detection method based on Parsimonious Smoothing. An effective and efficient criterion is proposed for change-point selection, whose explicit upper/lower bound is given by a solid theoretical framework.

5 - Bootstrap Distributionally Robust Optimization

Xue Wang, Pennsylvania State University, University Park, PA, 16802, United States, wxie91@gmail.com, Changcheng Li, Tao Yao, Runze Li

A board class of machine learning problems involves optimizing an expectation which the exact underlying distribution is unknown. One popular approach to address the distributional uncertainty, distributionally robust optimization (DRO), is to optimize the problem with respect to the worst distribution in the uncertainty set. The key ingredient of DRO is the uncertainty set construction. The inappropriate uncertainty set can lead to an unnecessary conservative solution. In this paper, we propose a novel DRO framework, Bootstrap DRO (BDRO), in which we applied the bootstrap technique. In addition, we design the computation algorithm solves the BDRO problem.

1 - Data Driven Fatigue Modeling of Additive Manufactured Parts by Establishing Process Property Relationship

Linkan Bian, Mississippi State University, Industrial and Systems Engineering Department,Mississippi State University, MS, 39762, United States, bian@ise.msstate.edu, Seyyed Selfi, Wenmeng Tian, Aref Yadollahi, Haley Doude

One major barrier for broader adoption of additive manufacturing is inferior fatigue properties of the final products, caused by the presence of internal defects. We propose a data-driven methodology to predict the size and location of porosities based on in-situ process signatures, i.e. thermal history. Size as well as location of pores highly affect the resulted fatigue life where near-surface and large pores, compared to inner or small pores, significantly reduces the fatigue life. The model proposed is validated using a thin wall fabricated by a direct laser deposition process and the multistage fatigue (MSF) modelsimulations.

2 - Designed Experiments on Additive Manufacturing Systems for Inference on Interference in Shape Deviations

Arman Sabbaghi, Purdue University, West Lafayette, IN, 47907, United States, sabbaghi@purdue.edu

Additive manufacturing (AM) is a promising manufacturing technique marred by geometric shape deviations. Control of shape deviations in an AM system can be achieved based on statistical deviation models. However, little attention has been paid to performing inference on interference in shape deviations, or incorporating interference in deviation models. We investigate interference with designed experiments on an AM system that involve in-plane deviations for different types of cylinders and different settings of a stereolithography machine. Our work illustrates a principled framework for detecting, inferring, and modeling interference via designed experiments on an AM system.

3 - Feasible Design Region Identification in Additive Manufacturing via Surrogate Modelling of Design Rules

SungKu Kang, Virginia Polytechnic Institute and State University, Blacksburg, VA, 24060, United States, kangsungku@vt.edu, Xinwei Deng, Ran Jin

Additive manufacturing provides great design flexibility for personalized product realization. However, as the flexibility yields complicated design space, it is time-consuming to identify feasible design candidates with conventional simulation-based design exploration. To address the issue, we propose the feasible design region identification method via surrogate modelling of design rules, much more efficient than simulation. We elaborate the method from microbial fuel cell anode design and demonstrate that feasible regions can be quickly identified for efficient design exploration. The method can contribute to timely product realization cycle adapting to mass personalization.

4 - Leveraging Additive Manufacturing Qualification Data During the Design Process

Paul Witherell, National Institute of Standards and Technology (NIST), Gaithersburg, MD, United States

With the maturation of Additive Manufacturing (AM) as a production process, AM parts are increasingly being operationally deployed to meet unique design requirements. However, part designs are being accepted only after strenuous testing and qualification of the material, process, and part for a given design. Each part requires its own acceptance procedures, often including the delivery of large amounts of data to instill a level of quality assurance. This presentation discusses the types of data being generated and curated during the AM process, the analytics opportunities being created, and initial efforts to incorporate this data back into the design decision-making process.

Sponsored Session

Chair: Ilbin Lee

1 - Capturing Natural Progression of Amyotrophic Lateral Sclerosis (ALS) Based on Static and Dynamic Risk Factors

F. Safa Erenay, University of Waterloo, Waterloo, ON, N2N 0A2, Canada, ferenay@uwaterloo.ca, Ozden Onur Dalgic, Haoran Wu, Mustafa Y. Sir, Kalyan Pasupathy, Osman Ozaltin, Brian Crum

We proposed a tollgate-based staging system for capturing natural progression of ALS. Using data from Mayo Clinic-Rochester, we applied classification methods to convert a large ALS dataset from PROACT database into tollgate information. Using the longitudinal data of over 3000 ALS patients, we predicted the timing of key tollgate events (e.g., needing a wheel chair, needing feeding tube, loosing functionality in both arms) and analysed statistically significant static/dynamic factors. We then use a Markov Process based prescriptive model to determine timing of assistive device interventions to maximize quality of life.

2 - Is Separately Modeling Sub-populations Beneficial for Medical Decision-making?

Ilbin Lee, University of Alberta, School of Business, University of Alberta, Edmonton, AB, T6G 2R6, Canada, ilbin@ualberta.ca

In recent applications of Markov decision processes, transition probabilities and rewards are often estimated from large-scale sequential data. In health applications, sequential data are collected from a population where each sequence corresponds to a person. Thus, there may be sub-populations that exhibit heterogeneous transition patterns. In this work, we study the benefit of making optimal decisions separately for different subpopulations and derive a theoretical bound on the benefit. We also suggest a method to estimate the benefit and empirically illustrate it. Lastly, we discuss several intuitions derived from the theoretical and empirical analyses.

3 - Determining the Optimal Timing of Diabetic Retinopathy Screening Exams

Taewoo Lee, University of Houston, Houston, TX, 77204-4008, United States, Poria Dorali

Diabetic retinopathy (DR) is the leading cause of blindness in American adults. While timely treatment can prevent up to 98% of DR-related blindness, only 30-60% of the patients are screened on a yearly basis due to high cost and inconvenience. Teleretinal screening is receiving increasing attention as an affordable and moderately accurate technique, yet little is known how it should be implemented for different patient subgroups to maximize clinical benefits. In this study, we propose discrete even simulation and POMDP approaches to determine the optimal timing of DR teleretinal and in-clinic screening exams using data from a screening program in Harris County.

4 - A Data-driven Framework for Personalizing Patient Encounters for Diabetes Care

Han Ye, U. of Illinois at Urbana-Champaign, Champaign, IL, 61820, United States, hanye@illinois.edu, Ujjal Mukherjee, Dilip Chhajed

We consider a data-driven approach to personalize encounters for diabetes patients. We first use machine learning models to predict future diabetes risks for individual patients, with patient-level clinical, demographic, and encounter data, as well as zip-code level socioeconomic information. We then use the predicted risks as inputs to build a decision model to optimally allocate encounters to individual patients.

5 - Monitoring HIV Treatment under Different Resource Settings

Huaiyang Zhong, Stanford University, Stanford, CA, 94305, United States, hzhong34@stanford.edu, Margaret L. Brandeau

In order to achieve viral load suppression for HIV infected individuals, treatment should be closely monitored to identify the correct time to change treatment regime since drug resistance/treatment failure is detected. Under different resource settings, we need to adapt the monitoring strategy to data and infrastructure we can access. Our work develops an integrated machine learning and partially observed Markov decision process to identify the best treatment monitoring strategy.

Healthcare Delivery: Models, Data, and Applications

Sponsored: Health Applications

Sponsored Session

Chair: Mabel Chou, National University of Singapore, Singapore, 118699, Singapore

1 - Optimal Stopping for Medical Treatment with Predictive Information

Zhichao Zheng, Singapore Management University, Lee Kong Chian School of Business, Singapore, 178899, Singapore, danielzheng@smu.edu.sg, Guang Cheng, Jingui Xie

The availability of data and development in machine learning techniques enable accurate prediction of patient future condition. We develop (partially observable) Markov decision process models incorporating (imperfect) predictive information to support medical treatment continuation decisions. We characterize the structure of the optimal policies and show that knowing even moderately accurate predictive information can lead to more personalized policies and significantly improved medical outcomes. We calibrate and test our model for the extubation problem in the intensive care unit using a patient-level dataset of more than 3,000 cases.

2 - On the Design of Customized Colorectal Cancer Screening Policies to Improve Screening Guideline Compliance

Yini Gao, Singapore Management University, Lee Kong Chain School of Business #4031, Singapore, 178899, Singapore, yngao@smu.edu.sg, Zhichao Zheng, Yan He

As one of the leading causes of cancer-related deaths in many countries, nowadays, colorectal cancer is actually curable but the key lies in its early detection and treatment. Undergoing regular screening (pre-tests followed by colonoscopy) can significantly increase the chance of earlier detection and reduce cancer mortality. Despite that fact that the accuracy of colonoscopy is nearly 100%, the compliance rate of taking colonoscopy is far below desired. Our study aims to design more effective and customized initial screening guidelines so that the compliance rate (the probabilities of taking colonoscopy given at least one positive pre-test result) can be improved.

3 - A Robust Approach to Study Multiple Treatments: Hierarchical Contrast-specific Propensity Score

Shasha Han, National University of Singapore, NUS Business School, Singapore, shashahan@u.nus.edu, Joel Goh, Fanwen Meng, Donald Rubin

To prevent or delay the onset of the complications for diabetic patients is challenging, in part because healthcare providers lack treatment guideline at clinic operational level. In this study, we are motivated by this setting, specifically, a provider has to decide among three treatment options: no-medication and two classes of medications (statins and fibrates) to control cholesterol for a newly-diagnosed diabetic patient. We develop a new approach that obtains causal effects of multiple treatments from observational data. We discuss how our approach overcomes several limitations of existing methods; in particular, the approach enjoys robustness to some model misspecifications.

4 - Data Analytics for Hospital Capacity Planning

Mabel C. Chou, National University of Singapore, Singapore, 118699, Singapore

We study a portering system with the goal of improving the porters' performance and the stability of the system. The porters' performance is indicated by their KPI fulfilment rate, while the stability of the system is indicated by the magnitude and occurrences of variability in various response timings. We carry out performance and demand analysis to identify the worst performing day and task time, as well as to seek insights on the stability of the demand. Our results help to identify bottlenecks for the system and provide insights on how to achieve better capacity management in such a system.

5 - Does Ownership Conversion from Nonprofit to For-profit Benefit the Public? Evidence from U.S. Nursing Homes

Susan F. Lu, Purdue University, West Lafayette, IN, 47907, 4-United States, lu428@purdue.edu, Lauren Xiaoyuan Lu

Employing a large panel dataset of U.S. nursing homes from 2006 to 2015, we conduct a difference-in-differences analysis on converted facilities' financial performance, operating policies, and quality of care. We observe that converted facilities significantly increased their post-conversion profit margins, compared to propensity-score-matched controls.

Sponsored Session

Chair: Janiele Custodio

1 - Response Time Optimization for Drone-Delivered Automated External Defibrillators

Justin J. Boutilier, University of Wisconsin - Madison, Madison, WI, 53706, United States, Timothy Chan

Out-of-hospital cardiac arrest (OHCA) is a time-sensitive medical emergency claiming over 400,000 lives each year and an automated external defibrillator (AED) is one of the only effective methods for treating OHCA. In this paper, we propose an integrated location-queuing model to minimize the total number of drones required to meet an average response time goal while guaranteeing a sufficient number of drones are located at each base. We develop a novel reformulation technique that allows us to solve real-world instances and determine the optimal deployment of AED-enabled drone resources using eight years of data covering 26,000 square kilometers around Toronto, Canada.

2 - Relieving Congestion and Improving Patient Welfare for the Case of Compassionate Dialysis

Farnaz Nourbakhsh, Southern Methodist University, Dallas, TX, 75243, United States, Olga Bountali, Sila Cetinkaya

Modeling the compassionate dialysis process motivated by a real life application at a county hospital, we analyze congestion mitigation policies motivated by alternative routing and prioritization schemes and inspired by queueing theory. Our approach provides policy alternatives informing medical personnel and government decision makers.

3 - Improving Patient Transfer Protocols for Regional Stroke Networks

Beste Kucukyazici, Michigan State University, East Lansing, MI, H3A 1G5, United States, Amir Ardestani Jaafari

We develop an analytical framework to enrich stroke routing decisions that incorporates spatial variation in population density, time and severity of stroke, and congestion levels at the hospitals. We develop predictive models to estimate outcomes associated with given stroke-network and optimize patient allocations under stochastic demand and congestion-dependent service time.

4 - Minimization of the Response Time of Queuing-based Drone Delivery Models with Decision-dependent Uncertainty

Janiele Custodio, Geoge Washington University, Washington, DC, 20011, United States, janiele@gwu.edu, Miguel Lejeune

Drones are emerging technologies with a wide range of applications. One of its potential use is to reduce the delivery time of automated external defibrillators (AEDs) to cardiac arrest occurrences. This research presents second-order cone programming reformulations of queuing-based optimization models for drone network delivery of AEDs. The problem is a stochastic-location allocation model with decision dependent uncertainty. We use queuing theory to model the congestion of the system. We show the equivalent convex reformulation for two cases: discrete facility location and facility location on the plane.

Applications of OR & Analytics in Healthcare

Sponsored: Health Applications

Sponsored Session

Chair: Vedat Verter, McGill University, Montreal, QC, H3A 1G5, Canada

1 - Machine Learning for the Opioid Prescription Epidemic

Alireza Boloori, Assistant Professor, Michigan State University, East Lansing, MI, United States, aboloori@asu.edu, Soroush Saghafian, Stephen J. Traub

Opioid epidemic has been largely attributed to the over-prescription of opioid painkillers. As a result, many medical guidelines have recently urged healthcare providers to lessen opioid prescriptions in their medical practices. This, however, could negatively affect those patients who suffer from acute or chronic pain symptoms. Utilizing commercial insurance claims and encounters data, we first analyze the trade-off between the opioid epidemic and pain management. Based on our results, we then provide recommendations for both policymakers and healthcare providers.

2 - Optimization Model for Staff Scheduling

Kimia Ghobadi, Johns Hopkins University, Baltimore, MD, United States, kimia@jhu.edu, Sauleh Ahmad Siddiqui, Scott R. Levin, Eric Hamrock

We consider the scheduling of support staff (e.g., nurses) in healthcare environments. The workload predictors for support staff are frequently different from the providers (e.g., medically stable but distruptive patients increase the workload for nurses but not necessarily for providers). In this work, we consider short-term staffing based on patient census prediction and workload prediction to inform a series of optimization problems. The model finds an optimal staffing assignment that is robust against patient variability and the uncertainty in the prediction simulation.

3 - Managing Telemedicine Platforms with Independent Physicians

Xianyi Wang, Renmin University of China, Beijing, China, 2016102585@ruc.edu.cn, Xiaofang Wang, Frank Y. Chen

In a telemedicine platform, quality of service typically depends on the service rate. Thus, in addition to the quality and speed trade-o , the manager needs to decide the wage paid to physicians who make individual decisions whether or not to join the platform with the help of mobile Internet. In a strategic queueing framework, we study how a telemedicine platform make the optimal service fee, wage and service rate decisions. We show several insights with respect to social welfare and the e ects of regulation policies.

4 - Optimal Ranges for Personalized Treatment Planning

Wesley J. Marrero Colon, University of Michigan, Ann Arbor, MI, United States, wmarrero@umich.edu, Mariel Sofia Lavieri

We present a method to obtain ranges of near-optimal treatment choices based on reinforcement learning and multiple comparisons theory. Reinforcement learning is used to provide a general framework on how to find approximately optimal treatment plans when the standard dynamic programming assumptions are not met. We model the ranges of near-optimal treatment choices as simultaneous confidence intervals on the difference of the approximate value functions using a bootstrap approach. Our methodology is applied for the management of cardiovascular diseases.

5 - Technology Assessment for Blood Pressure Measurement

Vedat Verter, McGill University, Faculty of Mgmt, Montreal, QC, H3A 1G5, Canada, vedat.verter@mcgill.ca, Manaf Zargoush, Mehmet Gumus

Applanation Tonometry (AT) is more accurate than the traditional blood pressure measurement technique. Since it is also more invasive and costly, the value of the provided information is scrutinized by physicians. Employing machine learning, we assess the value of AT from the patients' perspective, based on real life data.

Recent Advances in Process Monitoring of Complex Data

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Kai Yang

1 - Process Monitoring of Short-range Serially Correlated Data

Peihua Qiu, University of Florida, Gainesville, FL, 32610, United States, pqiu@ufl.edu

In practice, serial data correlation almost always exists in sequential data. It has been well demonstrated in the literature that control charts designed for independent data are unstable for monitoring serially correlated data. In this talk, we present our recent methodologies for monitoring serially correlated data, which do not impose restrictive assumptions on data correlation and data distribution.

2 - Dissimilarity-Based Variation Identification for Point Cloud Data

Anh Tuan Bui, Virginia Commonwealth University, Technological Institute,Richmond, VA, 60208, United States, Daniel Apley

Point cloud (PC) data from laser scanners provide rich information about the surface geometry of the scanned parts. We develop a method for identifying part-to-part variation using PC data. We propose a novel, computationally efficient dissimilarity measure between PCs based on kd-tree concepts, and use manifold learning on these dissimilarities to discover a low-dimensional parameterization of the part-to-part variation patterns. Visualizing how the parts change as the manifold parameters are varied helps build an understanding of the physical characteristic of each variation pattern. Our approach clearly reveals the nature of the variation patterns in PC data of several examples.

3 - An Effective Method for Online Disease Risk Monitoring

Lu You, University of Florida, Gainesville, FL, 32611, United States, you3939@ufl.edu, Peihua Qiu

Many diseases can be prevented or treated if they are detected early. Disease early detection and prevention (DEDAP) thus has a great impact on health improvement of our society. In this paper, we suggest a novel and effective new method for DEDAP. To detect a disease by this method, a patient's risk to the disease is first quantified at each time point, and then the longitudinal pattern of the risk is monitored sequentially over time. A signal will be triggered by a large cumulative difference between the risk pattern of the patient under monitoring and the risk pattern of a typical person without the disease in concern. Both theoretical arguments and numerical studies show that it works well in practice.

4 - Online Sequential Monitoring of Disease Incidence Rates

Kai Yang, University of Florida, Gainesville, FL, 32611, United States, yklmy1994121@ufl.edu, Peihua Qiu

Online sequential monitoring of disease incidence rates is critically important for public health. For disease surveillance purposes, conventional CUSUM and EWMA charts are usually included in numerous biosurveillance systems. However, these charts require many assumptions about the data structure of the observations. In practice, these assumptions are hardly valid, making the results from the conventional charts unreliable. Motivated by an application to monitor the Florida influenza-like illness data, we develop a new online monitoring approach, which can accommodate the dynamic nature of disease incidence rates, spatio-temporal data correlation, and arbitrary data distribution.

1 - Improving the Expected Improvement Algorithm

Chao Qin, Columbia Business School, New York, NY, United States, CQin22@gsb.columbia.edu, Daniel Russo, Diego Klabjan

The expected improvement (EI) algorithm is a popular strategy for information collection in optimization under uncertainty. EI is widely known to be too greedy, but nevertheless enjoys wide use due to its simplicity and ability to handle uncertainty and noise in a coherent decision theoretic framework. To provide rigorous insight into EI, we study its properties in a simple setting of Bayesian optimization. In this framework, one can show formally that EI is far from optimal. To overcome this shortcoming, we introduce a simple modification of EI. Surprisingly, this simple change results in an algorithm that is asymptotically optimal, and provably outperforms standard EI by an order of magnitude.

2 - Information Relaxation and a Duality Based Learning Approach for Stochastic Dynamic Programs

Nan Chen, Chinese University of Hong Kong, Shatin N.T, Hong Kong, nchen@se.cuhk.edu.hk, Xiang Ma

We use the information relaxation technique to develop a duality based recursive approach to obtaining and improving confidence interval estimates for the true value of stochastic dynamic programming problem with finite time horizon. In addition to the advantage that the dual gap can help us assess the quality of the current control policy, the new proposed method also uses it to guide policy exploration in order to address the trade-off between exploration and exploitation.

3 - Extreme Event Estimation via Distributionally Robust Optimization

Yuanlu Bai, Columbia University, New York, NY, United States, yb2436@columbia.edu, Henry Lam

A bottleneck in analyzing extreme events is that, by their own nature, tail data are often scarce. Conventional approaches fit data using justified parametric distributions, but often encounter difficulties in confining both estimation biases and variances. We discuss approaches using distributionally robust optimization as a nonparametric alternative that, through a different conservativeness-variance tradeoff, can mitigate some of the statistical challenges in estimating tails. We explain the statistical connections and comparisons of our framework with conventional extreme value theory.

4 - Optimal Transport Based Distributionally Robust Optimization

Fan Zhang, Stanford University, Stanford, CA, 94305, United States, fzh@stanford.edu, Jose Blanchet, Karthyek Murthy

In this talk, we explain why optimal transport based Distributionally Robust Optimization (DRO) is an important class of stochastic optimization problems by showing that it encompasses a large class of estimators in machine learning. Our discussion will motivate a more general and powerful class of machine learning estimators and DRO formulations. We will provide optimal algorithms for the solution of these general DRO formulations. Finally, we will demonstrate empirically that our proposed methodology is able to improve upon a wide range of popular machine learning estimators.

1 - How to Model City Soundscape Using Machine Learning

Alireza Rostamzadeh, Uber Technologies Inc., San Francisco, CA, United States, rostamzadeh.ar@gmail.com

Once Aerial Ride-sharing is deployed at scale, noise becomes the most important bottleneck in limiting the number of operations. To plan ahead, we developed the first-ever ML-based prediction model that can predict noise levels in dB for any given time and location. We collected training data in Dallas area using our custom-made noise sensors and used internal and external datasources to generate the most important and relevant features. Our model has a good accuracy and will be incorporated in our decision making process.

2 - Assessing Induced Demand for Metropolitan Air Service: A First-order Approach

Hani S. Mahmassani, Northwestern University, Transportation Center, Evanston, IL, 60208-4055, United States, masmah@northwestern.edu, Haleh AleAhmad, Ying Chen

Major congestion discourages many travelers from participating in important activities they wish to engage in at the locations they prefer. We present a first-order approach to estimate the potential induced demand for air service at the metropolitan area level. A supply side analysis is performed to identify travel corridors most likely to experience service improvement. The elasticity of demand with respect to travel time is estimated, and applied to predict the potential induced demand for different air service network configurations.

1 - Assessing Cooperative and Competitive Strategies Between Transit Agencies and Transportation Network Companies Using an Integrated ABM-DTA Software

Omer Verbas, Argonne National Laboratory, Lemont, IL, United States, omer@anl.gov, Joshua Auld, Michael Hyland, Felipe de Souza

In this study, we will model the potential short- and long-term responses by transit agencies in a world of connected and autonomous technologies and transportation network companies (TNC). The short-term responses comprise schedule optimizations in order to coordinate with TNCs better or compete against them better. The long-term responses comprise major changes e.g. adding/removing routes or modifying existing routes. The optimized scenarios will be tested in a unified framework using POLARIS; an agent-based ABM-DTA software consisting of an activity-based model integrated with multimodal routing, assignment and simulation.

2 - A New Adaptive Simulation Framework for Resilience Analysis of Interdependent Critical Infrastructures

Leili Soltanisehat, University of Oklahoma, Norman, OK, United States, leili.soltanisehat@ou.edu, Shima Mohebbi

We propose a hybrid simulation-optimization framework to assess the resilience of interdependent water, transportation, and cyber (traffic management system) critical infrastructures under random failure scenarios. The proposed framework consists of bottom-up (agent-based modeling) and top-down (system dynamics) methods to capture different layers of resiliency including physical and organizational resiliency. The main contributions of this research are: a) adding heterogeneity to the transportation network using Bayesian Inference method, and b) proposing a new cascading failure algorithm which considers functional and spatial interdependencies between networks.

3 - On the Performance of Consensus Algorithms in Blockchain

Sichao Yang, CEO and Co-Founder, Nakamoto & Turing Labs, New York, NY, United States, ysc@ntlabs.io, Lei Zhang, Chong Li

Consensus algorithm, by which agents in a blockchain consent on the order of transactions, is one of the key components to the security. As the advance of blockchain technologies, variant consensus algorithms have been proposed for different purposes. In consensus algorithms design, there are tradeoffs among security, decentralization, and performance. The capacity of a blockchain system is not only limited by the physical constraints, but also by the performance of consensus algorithms. We use agent-based model as a tool for simulating many types of consensus algorithms, and compare them by presenting analytical and simulation results, which is instrumental to the design of blockchains.

4 - Agent-Based Tree Search

Abdullah Konak, Penn State Berks, Tulpehocken Road, Reading, PA, 19610, United States, konak@psu.edu

An agent-based simulation model is proposed to explore an unknown tree with arbitrary edge distances by a set of agents which are initially located at the root of the tree and expected to return back to the root after all nodes are explored. The proposed algorithm depends only on local information stored at nodes using a bookkeeping token left at nodes by agents.

1 - "Un"fair Machine Learning Algorithms

Runshan Fu, Carnegie Mellon University, Pittsburgh, PA, 15217, United States, runshan@cmu.edu, Manmohan Aseri, Param Vir Singh, Kannan Srinivasan

Several new fairness notions have been proposed in response to the concern on the bias against certain demographics in algorithm-based decisions. In this paper, we model a data driven decision making process and compare optimal decisions for a firm under different fairness constraints, including the current law of equal treatment and two other popular notions, equal opportunity (EO) and demographic parity (DP). We show that, EO and DP, despite being conceptually appealing, can make everyone worse off, including the very group they aim to protect. This is because under these constraints, the firm would choose lower levels of learning effort and therefore be more conservative in selecting candidates.

2 - Is More Always Merrier? Procuring Impressions from Multiple Ad-exchanges

Leila Hosseini, The University of Texas at Dallas, Richardson, TX, 75080, United States, Shaojie Tang, Vijay S. Mookerjee

In this study, we analyze a procurement model for an ad-firm. There are two key decisions that the firm needs to make. First, it needs to select the set of mobile ad-exchanges to obtain its supply. Each mobile ad-exchange is characterized by specific supply uncertainties, location dependent win-curves, and a participation constraint. Second, for each ad-exchange and location, the ad-firm needs to determine its bidding policy, i.e., how much to bid for each bid-request.

3 - Reveal or Conceal? An Analysis of Inventory Reveal Policy in Online Flash Sales

Zibo Liu, University of Washington, Seattle, WA, 98105, United States, zibol@uw.edu, Shi Chen, Kamran Moinzadeh, Yong Tan

Inventory management is an important factor for companies to optimize their profit. Herding effect, scarcity effect and time pressure are essential ways that consumers' strategic behavior affect firms' decision. In this paper, we focus on inventory reveal policy on online flash sales platforms. Many flash sales platforms reveal inventory at all time, while others reveal inventory information only when the product has low inventory level. We build a model on inventory reveal problem and study three different inventory reveal policies: always conceal, always reveal, and a threshold policy. We compare their performance and find out how much the optimal policy can make the firm better off.

4 - Technological Disruption That Redefines Consumption: An Examination of Digital Camera Market Through Diffusion Lens

Geng Sun, University of Texas at Dallas, Richardson, TX, United States, gengs@utdallas.edu, Byungwan Koh, Srinivasan Raghunathan

The simultaneous decline in sales of digital cameras and boom of smartphones in recent years have triggered an intensively debatable question among industry experts: whether smartphones will replace digital cameras? Drawing from multi-generation diffusion literature, we show that smartphones are not a subsequent generation of digital cameras in general; however, smartphones disrupt the digital camera industry in a unique way that they have taken away the demand of compact digital cameras that could have migrated to dedicated digital cameras. In addition, we find that the rise of photo-sharing apps lately alleviates the disruption of smartphones.

5 - Commercializing Software Applications under Perpetual

Licensing: Is Seeding Still Relevant in the Age of Time-limited Freemium?

Hao Hu, Georgia Institute of Technology, Atlanta, GA, 30309, United States, Hao.Hu@scheller.gatech.edu, Marius Florin Niculescu, Yifan Dou, Dongjun Wu

The seeding strategy is losing its popularity to the time-limited freemium (TLF) in the software industry. This study seeks to answer when seeding is still relevant for practitioners. We compare seeding with TLF in a two-period game theoretical model, incorporating social learning, individual depreciation, and imperfect self-learning altogether. The findings suggest that seeding is optimal only if the majority of consumers significantly underestimate the software a priori. This finding is robust under different levels of imperfect self-learning and social learning.

3 - Multi-Period Inventory Management with Budget Cycles: Rational and Behavioral Decision Making

Michael Becker-Peth, Rotterdam School of Management, Erasmus University, Burgemeester Oudlaan 50, Rotterdam, 3062 PA, Netherlands, Kai Hoberg, Margarita Protopappa-Sieke

We examine inventory decisions in a multiperiod newsvendor model. In particular, we analyze the impact of budget cycles in a behavioral setting. We derive optimal rational decisions and characterize the behavioral decision-making process using a shortsightedness factor. We test the aforementioned effect in a laboratory environment. We find that subjects reduce order-up-to levels significantly at the end of the current budget cycle, which results in a cyclic pattern during the budget cycle. This indicates that the subjects are shortsighted with respect to future budget cycles. To control for inventory that is carried over from one period to the next, we introduce a starting-inventory factor and find that order-up-to levels increase in the starting inventory.

1 - Show Me Your ``Shares": Stochastic Social Promotion for Influence Maximization

Shaojie Tang, University of Texas at Dallas, McKinney, TX, 75071-5138, United States, shaojie.tang@utdallas.edu

Recent days have witnessed a boom of online firms that offer a ``Shares for Gifts" contest to users who need to share the product information with their friends in social network to gain rewards. During this campaign, the firm is faced by the problem of determining the set of initial users and the amount of rewards offered to each of them. In this paper, we formulate this problem as a stochastic social promotion problem. Our objective is to strategically offer rewards to some ``initial users" so as to maximize the influence spread.

2 - The Value of Alternative Data in Credit Risk Prediction: Evidence from a Large Field Experiment

Tian Lu, Carnegie Mellon University, Pittsburgh, PA, United States, tianlu@andrew.cmu.edu, Yingjie Zhang, Beibei Li

This paper conducts a comprehensive evaluation of the value of alternative data on microloan platforms with a large field experiment. Our machine-learning analyses demonstrate that alternative data can significantly improve the prediction accuracy of borrowers' default behavior and increase platform profits. Moreover, we find that our framework helps financial institutions extend service to more lower-income and less-educated loan applicants from less-developed geographical areas. Our study demonstrates the tremendous potential of leveraging alternative data to alleviate such inequality in the financial service markets, while in the meantime achieving higher platform revenues.

3 - A Recurrent Multivariate Marked Point Process Model for Player Engagement in Video Game

Junming Yin, University of Arizona, Management Information Systems Department, Tucson, AZ, 85721, United States, Zisu Wang, Tianyu Gu, Yong Liu

The strategic management of game development relies on the understanding of the behavior dynamics of players. In this study, we propose an innovative approach combining marked point processes and recurrent neural network to capture players' activity dynamics. Applying our model to an American football video game data set, we find that players' previous game sessions are a major driver for their future activities, whereas previous purchases only account for a small portion of influence for their future engagement. Out-of-sample prediction results further demonstrate that our model can achieve better performance in predicting the time, type, and side-information of players' future activities.

4 - Cold Start and Hard Stop Recommendation: A Dynamic Graph Neural Network Approach

Meizi Zhou, University of Minnesota, Minneapolis, MN, United States, zhou0793@umn.edu, Yicheng Song, Zhuoxin Li, Chunmian Ge

Online personalized recommendation for time-constrained products (e.g. news, short video, flash sale,...) is a highly challenging problem due to the dynamic nature of continuous influx of new items into the market and fade out after limited life cycle. In such markets, the recommender system faces constant cold start problems as well as the need to take prompt actions before the items expire. To address these challenges, we propose a dynamic graph neural network recommendation framework, which aims to explicitly model the sequential user-item interaction to incrementally update the bipartite graph between user and item using recurrent neural network.

5 - Network Embedding Based Recommendation with a Neural Attention Model

Yuheng Hu, University of Illinois-Chicago, Chicago, IL, 60607, United States, Tengteng Ma, Yingda Lu, Sid Bhattacharyya

Heterogeneous information has been widely used to extract context information in modeling recommender systems. Although some recent work has achieved performance improvement to some extent, when it comes to model interactions between entities, they still resorted to matrix factorization. By developing a novel deep neural network based on network embedding and involving attention mechanism, we present a framework that can model complex context information and provide interpretations for the recommendation.

1 - Network Planning for Connectivity at Facebook

Birce Tezel, Facebook, Menlo Park, CA, United States, btezel@fb.com, Erik Zawadzki

Facebook Connectivity aims to bring more people online to a faster internet. In Advanced Network Planning, we build automated planning tools to help our partners create desirable plans in minutes that previously would have taken days. Dense urban planning designs 60 GHz wireless mesh networks that provide fiber speed connectivity at a fraction of the deployment cost. The tool has been helpful for Terragraph deployments in Georgetown. Fiber planning involves solving graph subset problems based on right-of-way graphs. One of our tools solves a form of the survivable network design problem. We use a heuristic that has good empirical performance and is able to scale to large cities like Lagos, Nigeria.

2 - Tetris Planner: Optimizing Facebook Data Warehouse Data Placement

Han Fang, Data Scientist, Facebook, Seattle, WA, United States, Dorian Jaminais, Delia David, Jeff Tian, Martin Valdez-Vivas, Amol Desai, Waqar Malik

Facebook's data warehouse has 9+ data centers around the world, which hosts exabytes of data for analytics and machine learning. Due to uneven growth of namespaces, there were a mix of highly loaded and half empty clusters w.r.t storage, compute, IO, and network. We built Tetris Planner, a system to plan for load rebalancing through daily table placement instructions and partitions moves. The core of Planner is the optimization algorithm with mixed integer linear programming. It tries to solve the minimax optimization problem, as to minimize the maximum utilization across multi-objectives. Planner was deployed to all Facebook's data centers and successfully rebalancing petabytes of data daily.

3 - Planning Spare Parts in Data Center

Tianke Feng, Research Scientist, Facebook, Inc., Menlo Park, CA, United States, Jingyang Xu, Bowen Hua

A challenge to provide high availability and low latency service in modern data centers is to handle the bursts of part failures. To minimize service disruption, certain quantity of spare parts must be planned beforehand, with proper trade-off between the risk of shortage and the cost of overstocking. Part failures are highly uncertain, complicated by the quality of service, correlation across parts, temperatures, load balancing, etc. In this work, we analyze the patterns of part failures and discusses machine learning based forecasting models and the inventory control policies.

4 - Matching Algorithms for Blood Donation

Duncan McElfresh, Facebook, Menlo Park, CA, United States, dmcelfre@math.umd.edu, Christian Kroer, Sergey Pupyrev, Eric Sodomka, John P. Dickerson

Managing the blood supply chain has been a topic of research for decades; we focus on an aspect of this problem rarely studied in the literature: coordinating blood donors to meet demand. We model this problem as a matching market: donors are matched to donation centers by a central planner, who prompts individual donors (e.g., via push notification) to donate to a preferred center or centers. Donors may have constraints or preferences that can be taken into account. We present an initial analysis of policies for matching potential blood donors to donation centers under these constraints and preferences, and under simple models of stochastic demand.

Flash Session II

Flash Session

Chair: Barbara Fasolo, London School of Economics, Department of Management, Houghton Street, London, WC2A 2AE, United Kingdom

1 - Architecting A Real-time Optimization Framework for Driver Positioning

Hao Yi Ong, Lyft, San Francisco, CA, United States, hong@lyft.com

Personal Power Zones (PPZs) are Lyft's real-time supply-shaping incentive that proactively repositions drivers in anticipation of demand. This paper describes a positioning algorithm for PPZs that balances between optimizing ride throughput and driver retention subject to uncertainty in the supply and demand distributions and response. The algorithm generates moneyed driver bonuses and guidance, and is based on solving a series of convex programs. The method scales well and positions drivers efficiently, generating significant incremental rides for both drivers and their markets.

2 - Bekaert Predicts Total Market Demand Using Macroeconomic Indicators to Improve the Tactical Sales Forecast

Gylian Verstraete, Researcher/Consultant, Ghent University, Ghent, Belgium, gylian.verstraete@ugent.be, El-Houssaine Aghezzaf, Bram Desmet

Traditional forecasting methods extrapolate historical patterns to predict future sales. These forecasting models are incapable of anticipating macroeconomic changes. To account for these, literature suggests including leading macroeconomic indicators in this process. Events that result in market share fluctuations often hinder this process. Furthermore, companies upstream in the supply chain are unable to segment their sales based on the end-market. We address this by forecasting total market demand. We decompose the market demand after which the extracted trend is forecasted using macroeconomic indicators. The demand is used as an indicator for predicting the company sales.

3 - Classifying Seat Pan Contours Using Principal Component Analysis and Density-based Clustering

Joan Martinez, Western Michigan University, Kalamazoo, MI, United States, Steven Butt, Tycho Fredericks

Numerous studies on sitting comfort/discomfort have been conducted over the years, but knowledge about the influence of seat pan parameters (e.g., surface, geometry) on comfort/discomfort is still inconclusive. Research was conducted to investigate the influence of a user-adjustable seat pan during a seated computer-task environment. Two hundred and forty-four user-adjusted seat pan contours were obtained and analyzed using principal component analysis and density-based clustering techniques. Four distinct shapes of seat pan contours were obtained based on type of sitter. Future research aims to investigate factors that could explain seat pan contour preferences by subjects.

4 - Defaults: Do They Save Every Life Equally?

Barbara Fasolo, London School of Economics, Department of Operational Research, Houghton Street, London, WC2A 2AE, United Kingdom, Elena Reutskaja

Opt-out defaults applied to healthcare save lives - but do they save every life equally? Our artefactual field experiment on hospital choice and simulations with knee replacement mortality ratios show that defaults create a disconcerting inequality: citizens with higher ability to use numbers ("numeracy") are saved more than low numerates. This finding is critical for world-wide healthcare managers and policy makers.

5 - A Stochastic Model for Casualty Transportation in Large Scale Disasters: An Application for Istanbul

Sule I. Satoglu, Professor, Istanbul Techical University, Istanbul, Turkey, onbaslis@itu.edu.tr, Nadide Caglayan

Casualty transportation is a vital issue in cases of large scale disasters. In this study, a two-stage stochastic model is proposed, where the number injured people (from each triage category) transported from each triage point to the hospitals and temporary medical centers, the number of tours of ambulances and number of casualty could not be served are decided, according to each scenario. The model is solved for the expected Istanbul Earthquake, especially for Kartal district of Istanbul, based on real population, expected casualty, hospital location and capacity data.

Operations Management IV

Contributed Session

Chair: Jianjun Xu, Dongbei University of Finance and Economics, Dalian,, 116025, China

1 - Optimal Timing and Rollover Strategy of New Product Introduction: Newsvendor Perspective

Jian Li, Northeastern Illinois University, Chicago, IL, United States, j-li3@neiu.edu, Panos Kouvelis

This paper studies the optimal timing of a new product introduction and the optimal product rollover strategy. Our focus is on characterizing the optimal policy, identifying the environments each strategy works best, and estimating numerically the impact of other factors on the benefit of Dynamic.

2 - Product Assortment and Space Allocation Strategies to Attract Loyal and Non-loyal Customers

Anna Timonina-Farkas, Postdoctoral researcher, EPFL, TOM, Lausanne, Switzerland, anna.farkas@epfl.ch, Argyro Katsifou, Ralf W. Seifert

Assortment planning has received much attention from practitioners and academics due to its direct impact on retailers' commercial success. We focus on the increasingly popular retail practice of using combined product assortments consisting of regular "standard" products and more fashionable "variable" products, included to increase the store traffic and to drive up the sales. We address the assortment planning as a bilevel optimization problem, where the retailer's binary decision about product inclusion influences the distribution of product's demand, i.e. we focus on decision-dependent uncertainties.

3 - Optimal Sourcing Strategies Based on a Real Option

Jae Hyeok Jo, Master's Course, KyungPook National University, DaeGu, Korea, Republic of, Sung Su Kim

Evaluation of outsourcing suppliers is one of complex business problems because of uncertainty and dynamic changes of operating environments. A firm should continuously assess its partners from multiple aspects to be competitive. At the same time, its supply chain should be agile enough to implement sourcing strategies derived from assessments of partners. We propose a model for an optimal sourcing strategy based on a real option. The model considers environmental and firm-specific factors which are related to cost. Uncertainties are modeled using Brownian motion and Monte Carlo simulation.

4 - Decision Making in the Context of Flexible Demand

Sepideh Alavi, PhD Candidate-Supply Chain & Operations Management, University of Wisconsin Milwaukee, Milwaukee, WI, United States, alavi@uwm.edu, Matthew Petering, Xiaohang Yue

We consider applications of the concept of flexible demand in various domains. In an inventory setting, we study a cyclic coordinated supply and replenishment problem with batch supplies and flexible demand. The decisions include the timing and sizes of batches delivered by the suppliers to the buffer and the timing and amounts by which demanders are replenished in order to minimize total cost. We also introduce the Vehicle Routing Problem with Flexible Demand (VRP-FD). Math models and heuristic methods are presented and discussed.

5 - Display and Product Positioning Optimization for Online Retailers

Alara Tascioglu, Koç University, Istanbul, Turkey, atascioglu17@ku.edu.tr, Gurhan Kok, Selcuk Karabati

Consumers face a long list of products when searching for a product online. The location of a product in the page layout affects the customer choice process. Thus, an optimized product positioning can potentially increase consumer satisfaction as well as company profits. We develop a display location based Multinomial Logit model to determine product positions in the first page of an online store. We compare our results with commonly used heuristics.

6 - Optimal Dual Sales and Stock Replenishment by Flexible Contracts with Spot Markets

Jianjun Xu, Associate Professor, Dongbei University of Finance and Economics, Dalian,, China, xujianjun@dufe.edu.cn, Mustafa Çagri Gurbuz, Youyi Feng, Shaoxiang Chen

We consider a company that uses two channels for trading: long-term contracts and spot markets. A fixed setup cost is incurred in each instance of buying or selling in the spot market. This paper considers very general inventory-related (not necessarily convex) costs, and demand is random following a one-sided Polya distribution. We show that the optimal policy can be characterized by five critical points. We also characterize optimal procurement from the contract supplier under certain conditions. Moreover, we show that our results also apply to uniform demand, and numerical tests assuming uniform demand are performed to discern which factors are most important and to gain managerial insights.

Scheduling II

Contributed Session

Chair: Ayaka Yamamoto, Kansai University, 3-3-35, Yamate-cho, Suita-city, Osaka, 5648680, Japan

1 - Learning Dispatching Rules from Optimal Schedules for Single Machine Scheduling Problems

Sungbum Jun, Purdue University, West Lafayette, IN, United States, Seokcheon Lee

Designing efficient and robust dispatching rules is crucial to respond to changes on the shop floor. However, due to the increasing volume of data from multiple sources, it is difficult to capture implicit rules intuitively. Therefore, we propose a novel approach for single machine scheduling based on a decision tree expressed in a set of IF-THEN rules. The proposed approach generates a dispatching rule from optimal schedules that contain the knowledge of why one job is dispatched ahead of another. Also, genetic programming is applied to extract new features by combining attributes. The major contribution of this study is discovering understandable dispatching rules with less human intervention.

2 - Online Scheduling on a Single Parallel Batch Machine with a Temporary Interruption

Ran Lin, Northwestern Polytechnical University, Xi'an, China, pacpos.rlin@gmail.com, Junqiang Wang

We consider the online scheduling problem on a single parallel batch machine with a temporary interruption. Jobs arrive over time, and the information of jobs becomes known at its arrival time. A parallel batch machine can process at most b jobs simultaneously. When the interruption occurs at time T, the processing of jobs has to be stopped and restarted after time T. Our goal is to minimize the makespan. We prove that there is no deterministic online algorithm with a competitive ratio less than 2 for the arbitrary positive integer b. Furthermore, we provide a best online algorithm H(b). When b=1, 2 and $b \geq n$, we show that H(b) is best possible. When $3 \leq b < n$, we prove that the competitive ratio of H(b) is 2.5.

3 - Scheduling in Permutation Flowshops to Obtain an Optimal Solution/ A Lower Bound with the Consideration of the Makespan of Jobs

Thamarassery Abdul Jaleel Jessin, Research Scholar, Indian Institute of Technology Madras, Chennai, India, tajessin2008@yahoo.co.in, Chandrasekharan Rajendran, Sakthivel Madankumar

This paper focuses on developing lower bounds/optimal solutions for N-job M-machine permutation flowshop scheduling problems with the objective of minimizing makespan using Lagrangean Relaxation technique. We develop an MILP based Lagrangean Relaxation model with the consideration of benchmark problem instances to evaluate the performance of the model. It is observed that the proposed method gives encouraging good results.

4 - Makespan Minimizing for a Sequence-dependent Flowshop with Machine Deterioration and Maintenance Events

Fatma Alkhabbaz, Kuwait University-Kuwait, Kuwait, M'Hallah Rym

This paper addresses the two-machine permutation flowshop scheduling problem, where idle time is allowed on the second machine. The objective minimizes the makespan of a set of jobs whose processing times are sequence-dependent. The machines are subject to deterioration but may be restored to a perfect state via maintenance events. The maintenance duration is fixed and known. This paper models the problem as a non-linear mixed integer program that can solve small instances. For larger instances, the paper proposes four heuristics. Each heuristic constructs a sequence using a priority rule and inserts maintenance events using a mixed integer program.

5 - Process Innovation of Synchrotron Radiator Using Time Indexed Single-machine Scheduling

Myungho Lee, POSTECH IME, Nam-gu, Pohang-si, Korea, Republic of, Kangbok Lee, Jiang Xiao Juan

Synchrotron radiator is a microscope used for a variety of research areas such as biology and material science. In spite of its increasing importance, there is no research on how to operate it. This research provides an optimization method for a synchrotron radiator scheduling problem, called a beamline management. We formulate it as a time-indexed MIP model for a realistic setting and solve it optimally in a short time. We also find and analyze an important criterion of robustness against an unexpected disaster, which minimizes the maximum weight of jobs affected by a disaster with a certain length. We formulate this special problem, develop algorithms, and prove optimality for some special cases.

6 - Tunnel Maintenance Scheduling for Leveling Annual Cost in Japan

Ayaka Yamamoto, Kansai University, Osaka, Japan, k900324@kansai-u.ac.jp, Hiroshige Dan, Hiroaki Tanaka-Kanekiyo, Masakazu Sakou, Naoki Satou

In Japan, when tunnel maintenance is conducted, the guideline which was established by the Japanese government must be followed. Japanese local governments prefer to level the annual cost as much as possible, since local governments generally adopt the single-year budget system and imbalance of annual costs may cause a shortage of the annual maintenance cost. In this research, we propose an optimization model for making maintenance schedule of tunnels to reduce the imbalance. Also we conducted some numerical experiments with the practical data and confirmed the effectiveness of the model.

Joint Session DEA/Practice Curated: Applications in DEA II

Emerging Topic: Productivity, Efficiency and Data Envelopment Analysis

Emerging Topic Session

Chair: Timothy R Anderson, Portland State University, Portland, OR, 97201, United States

1 - Sustainability and Energy Efficiency in Indian Manufacturing

Kankana Mukherjee, Babson College, Economics Division, Wellesley, MA, 02481, United States, kmukherjee@babson.edu

A major crisis facing the Indian economy is in terms of significant energy shortage. Given the supply constraints and heavy dependence on imports for energy, a sustainable growth path for the manufacturing sector depends on achieving efficiency in energy use. This paper examines the energy intensive industries in India over the period 2008-09 through 2015-16 and utilizes Data Envelopment Analysis to study sustainability and energy efficiency in Indian manufacturing. The roles of technical efficiency of production, capacity utilization, adoption of energy efficient technology and other factors in determining energy efficiency and a sustainable growth path for these industries are analyzed.

2 - Output Attributes and Hedonic Prices: An Analysis of Airfares

Charles Howell, Autonomous University of Barcelona, Barcelona, Spain, Charles.Howell@uab.cat, Emili Grifell-Tatjé

The man objective of the paper is to study the effect of product differentiation on price formation in the airline industry. For this purpose, we introduce a Konüs (1939) type index of output attributes as a measure of the level of product differentiation in a market. The definition of the Konüs output attribute index is based on cost functions, which capture the cost differential of providing varying levels of output attributes. We then use the Konüs output attribute index, along with measures of market power, to explore how adding market characteristics to a hedonic price model can improve the usability of results. The model is empirically tested on US domestic airfare data.

3 - Regulation under Asymmetric Information in Road Transport Networks

Jung You, California State University-East Bay, Hayward, CA, 94542, United States, jung.you@csueastbay.edu

This paper is concerned with the analysis of regulations on a monopolistic public enterprise. We construct a game-theoretical contract model between the government and a public enterprise where the regulated firm holds private information about its cost-efficiency. Based on the theoretical model, we evaluate the welfare consequences of regulatory policies in road transport network. Our empirical analysis is to estimate our structural contract models including the travel demand function, cost function, and optimal subsidy function, and use the estimates to study the welfare implications of price and subsidy-based regulation policies.

4 - Exploring the Impact of Noise on DEA

Maoloud Dabab, Portland State University, Portland, OR, 97219, United States, dabab@pdx.edu, Timothy Anderson

The impact of random production values is explored in DEA using an application of baseball batting through historical data. Varying patterns of noise across time are shown and related to application characteristics.

1 - Response Surface Analysis of Genomic Prediction Accuracy Values Using Quality Control Covariates in Soybean

Reka Howard, University of Nebraska-Lincoln, 342B Hardin Hall, Lincoln, NE, 68583, United States

An important tool in plant breeding programs is genomic prediction (GP). In GP molecular marker information and phenotypic data are used to predict the phenotype of individuals for which only marker data are available. Higher prediction accuracy can be achieved by using quality data. The quality control of marker data includes the elimination of markers with certain level of minor allele frequency (MAF), missing marker values and the imputation of missing marker values. We evaluated accuracy in terms of the combination of 12 MAF values, 27 different percentages of missing marker values, and 2 imputation techniques. We constructed a response surface of prediction accuracy values using soybean data.

2 - Using Harshness to Identify Stable Plant Varieties

Hanisha Vemireddy, Iowa State University, Ames, IA, United States, hanisha@iastate.edu, Sigurdur Olafsson

One of the important aspects in plant breeding is to understand the quality of an environment in which plant varieties are planted. In this paper, we propose an empirical harshness index for different environments based on phenotype data, and develop visualizations to use this index to better support advancement decisions.

3 - Crop Stress Classification Using Deep Convolutional Neural Networks

Saeed Khaki, Iowa State University, Ames, IA, 50010, United States, skhaki@iastate.edu

As one of the winning teams in 2019 Syngenta Crop Challenge, we designed a two-step approach to classify 2,452 corn hybrids as either tolerant or susceptible to heat and drought stresses. First, we designed a deep convolutional neural network that took advantage of state-of-the-art modeling techniques to extract stress metrics for each type of stress. Then, we conducted a linear regression of the yield of hybrids against each stress metric, and classified the hybrids based on the slope the regression line, since the slope of the regression line showed how sensitive a hybrid was to a specific environmental stress. Our results suggested that only 14% of hybrids were tolerant to at least one type of stress.

4 - Multi-trait Genomic Selection Methods for Crop Improvement

Saba Moeinizade, Iowa State University, Ames, IA, 50014, United States, sabamz@iastate.edu, Aaron Kusmec, Guiping Hu, Lizhi Wang, Patrick Schnable

Productivity in plants depends on more than one trait. Hence, the decision-maker should consider several characteristics to decide which individuals are the most valuable ones to be parents of the next generation. Finding the best selection strategies to reach breeding goals in a Multi-trait Genomic Selection (MTGS) framework is a key issue in plant breeding. This research introduces an approach for MTGS problems by optimizing the main goal of a breeding project (i.e. high yield) while making sure other traits fall into a desirable range. We design a new MTGS algorithm using optimization and simulation techniques and examine the effectiveness of the algorithm compared to the conventional methods.

5 - New Algorithms for Detecting Multi Effects and Multi Ways Epistatic Interactions

Javad Ansarifar, Iowa State University, Ames, IA, United States, ansarifar.javad@gmail.com, Lizhi Wang

Detection of epistasis, which is the phenomenon of genetic interactions, is extremely challenging problem due to the combinatorial nature of the problem. We propose three new algorithms for multi-effect and multi-way epistases detection, with one guaranteeing global optimality and the other two being local optimization oriented heuristics. The comparison of computational performance of the proposed heuristic algorithm with several state-of-the-art methods revealed the proposed heuristic algorithm was much more effective and efficient than others at finding a close-to-optimal solution.

Teams and Innovation Management

Sponsored: Technology, Innovation Management & Entrepreneurship

Sponsored Session

Chair: Nilam Kaushik, Boston, MA, 02115, United States

1 - Parallel Innovation Contests

Ersin Korpeoglu, University College London, 1 Canada Square, London, E14 5AA, United Kingdom, C. Gizem Korpeoglu, Isa Emin Hafalir

We study innovation contests where multiple organizers seek solutions from agents, and the quality of an agent's solution depends on her effort and uncertainty. We find that when uncertainty is sufficiently large, organizers benefit from agents' entry to multiple contests. An organizer's profit is unimodal in the number of contests, and the optimal number of contests increases with uncertainty. Thus, practitioners who seek innovative (resp., low-novelty) solutions may benefit from running multiple parallel contests and from encouraging (resp., discouraging) agents' entry to multiple contests.

2 - The Interplay Between Physical and Social Space on Collaboration

Manuel E. Sosa, Associate Professor, INSEAD, Singapore, 138676, Singapore, manuel.sosa@insead.edu, Massimo Maoret

Previous studies on collaboration have emphasized the role that intra-organizational networks play on organizational performance. Yet, these studies overlook the role that physical spaces, and in particular inter-personal distance, play in determining the effect of network structure on collaborative performance. We close this salient gap by taking advantage of a quasi-natural experiment, in which a global pharmaceutical firm relocated two of their regional offices onto new sites. By capturing both social network and inter- personal distances prior and after the moves, we study the interplay of social network structures and physical spaces on inter-personal collaborative performance.

3 - Communication Patterns At Academic Events Related to Scientific Collaboration Patterns

Jacqueline Lane, Harvard University, Boston, MA, United States, jnlane@hbs.edu

Good ideas often result from combining innovative ways of thinking from one field with those of another. We propose that academic networking events offer a context to "engineer" serendipitous encounters. To advance understanding, we designed and executed a research symposium at a leading research university held in conjunction with a grant opportunity. Scientists who engaged in "information sharing" networking sessions were more likely to collaborate with one another on the grant proposal. The extent of boundary-spanning ties in scientists' communication networks are also related to breadth in research interests.

4 - Gender-based Preferences for Tech Work: Field Experimental Evidence from an Internet-of-things Platform

Nilam Kaushik, Indian Institute of Management, Bangalore, 02115, India, Kevin Boudreau

We report on a large field experiment in which 112,770 U.S. university-educated individuals from all fields and career stages were given the opportunity to participate in a technologically intensive area of learning and innovation, the Internet-of-Things (IoT).

Optimization Methods for Design and Operation of Energy Systems

Sponsored: Energy, Natural Res & the Environment/Natural Resources Petrochemicals

Sponsored Session

Chair: YIFU Chen, University of Wisconsin Madison, Madison, WI, 53705, United States

1 - An Energy-water Nexus Approach for Energy Infrastructure Planning

Efstratios Pistikopoulos, Texas A&M Energy Institute, 1617 Research Parkway, 3rd Floor, Giesecke Engineering Research Bldg, College Station, TX, 77843-3372, United States, stratos@tamu.edu, R. Cory Allen, Styliani Avraamidou

Due to rapid global population and economic growth, the demand for energy and water is dramatically increasing. To address this challenge, we have developed an integrated capacity planning and operational scheduling framework for power generating and water treatment systems. The mixed integer programming model allows for the creation of additional water treatment facilities, power plants, and large-scale energy storage facilities to account for the intrinsic stochastic nature of renewable generators. We illustrate the effectiveness of the infrastructure expansion framework through the use of a case study that spans the ERCOT region of Texas.

2 - Optimization of Inter-regional Flows in Petrochemical Supply Chains

Arul Sundaramoorthy, BP, 150 W. Warrenville Road, Naperville, IL, 60563, United States

The petrochemical supply-chain network consists of production sites, demand locations and optional suppliers in various regions across the globe. The core demand of each region is typically assigned to production sites in that region. The spot demands are treated as common marketplace for all regions. The product can be stored at production sites with limited capacity. Given the costs of production and logistics as well as product prices, the goal of multi-period optimization model is to maximize the variable contribution margin for the entire network. The key decisions in each period include which site should produce how much, stock position in each location and optimal inter-regional flows.

3 - Data-driven Strategies for Optimization of Integrated Chemical Plants

Kaiwen Ma, Carnegie Mellon University, Pittsburgh, PA, United States, Nikolaos Sahinidis, Sreekanth Rajagopalan, Satyajith Amaran, Scott Bury

Operation optimization over large-scale integrated chemical plants is inherently a difficult problem for a system of such size and complexity. We propose two novel methodologies to exploit the available Aspen flowsheets and plant data. In the first approach, we develop and solve a data-driven optimization model. The impact of the level of detail of the model is investigated. In the second approach, we apply derivative-free optimization (DFO) with a novel decomposition framework. Our proposed framework significantly extends the scope of current DFO solvers to larger-scale problems. Both methodologies are studied and compared over the dimethyl ether/diethyl ether production case study.

4 - Variable Bounds Tightening for Multiperiod Blending Problem

YIFU Chen, University of Wisconsin Madison, Madison, WI, 53705, United States, Christos T. Maravelias

We introduce an algorithm for variable bounds tightening using multiple constraints in the context of Multiperiod Blending Problem, which is typically formulated as a nonconvex MINLP. We propose a reformulation for the variables involved in the bilinear terms through lifting and an algorithm to tighten the bounds on the lifted variables using linear constraints. The selection of constraints and the sequence of variable bounds to be tightened are based on the understanding of the physical system. We introduce RLT constraints that utilize the bounds to further tighten the formulation. We demonstrate the effectiveness of our methods through an extensive computational study.

Analytical Work on Food Waste

Sponsored: Energy, Natural Res & the Environment/Environment & Sustainability

Sponsored Session

Chair: Dorothee Honhon, University of Texas at Dallas, Richardson, TX, 75080, United States

1 - Strategic Stockpiling in the Presence of Waste Cost

Benny Mantin, University of Luxembourg, Luxembourg, L-1511, Luxembourg, benny.mantin@uni.lu

We model the stocking decisions of a seller and its customers, who face uncertainty about their own consumption rates for a perishable good over a two-period horizon. We characterize the conditions leading to strategic consumer stockpiling and evaluate the impact of waste cost on consumers' and sellers' inventory decisions.

2 - How Do Minimum Life on Receipt (MLOR) Agreements Impact Food Supply Chains?

Sara Martins, INESC TEC and Faculty of Engineering, University of Porto, Porto, Portugal, Pedro Amorim, Bernardo Almada-Lobo

In food supply chains, retailers usually impose a minimum life on receipt (MLOR) to perishable products, which specifies the minimum shelf-life the retailer is willing to accept in the inbound. While these agreements are common in practice, there is a lack of literature on this criterion and how it impacts the supply chain, especially the food waste generated. Practical reports show that the mean MLOR is 85%, but there is no difference amongst products. This study models an agreement between a retailer and a manufacturer, considering different settings and MLOR values, assessing their impact in the supply chain. The goal is to analyze how the MLOR should be defined for distinct product categories.

3 - Implications of Eliminating Grading in Food Supply Chains

Karthik Murali, Assistant Professor, Oregon State University, Corvallis, OR, United States, karthik.murali@oregonstate.edu, Isil Alev

Motivated by the practice of grocery retailers beginning to sell ugly produce alongside conventionally aesthetic produce, we study production and distribution decisions in an agricultural supply chain to determine the social and environmental consequences of this global food movement. Our results identify profitability and sustainability implications of product-line decisions for grocery retailers and their consequences for upstream farmers.

4 - The Race for Product Renewal

Xabier Barriola, IESE Business School, Barcelona, 08034, Spain, xbarriola@iese.edu, Victor Martínez de Albéniz

Product renewal has been criticized for increasing waste. While consumers enjoy novelty in settings where product utility decays over time, it is not clear how firms should take renewal decisions when there are fixed costs associated with a new launch. In this work, we build a model where consumers decide to renew their products as a function of releases, and firms optimize features, pricing, and launches. We determine closed form optimal launch decisions in the case of a single firm, and derive equilibrium decisions under competition. We find that a monopolist internalizes inter-product cannibalization and sets efficient launch decisions, while competition results in an oversupply of new products.

New Challenges in Energy

Sponsored: Energy, Natural Res & the Environment/Electricity Sponsored Session

Chair: Ali Daraeepour, Princeton University, Princeton, NJ, 08544, United States

1 - Remuneration of Flexibility in Non-convex Electricity Markets: A PJM Case Study

Ali Daraeepour, Princeton University, 016 ACEE Building, 086 Olden St, Princeton, NJ, 08544, United States, a.daraeepour@princeton.edu

Continued growth in penetration of Variable Renewable Electricity (VRE) increases the demand for operational flexibility in electricity markets. Paradoxically, the price formation may not effectively remunerate the flexibility attributes of conventional generating units. While electricity markets are inherently non-convex, conventional pricing mechanisms assume convexity that results in prices that may not properly incent operational flexibility. This study evaluates the implications of conventional and convex hull marginal pricing mechanisms for the ability of markets in incenting flexibility with growing penetration of wind resources in PJM.

2 - A Mathematical Optimization Approach to Enhanced Renewable Energy Forecasting and Trading

Juan M. Morales, Associate Professor, University of Malaga, Malaga, Spain, juan.morales@uma.es, Miguel A. Muñoz, Salvador Pineda

In this talk, we describe a mathematical optimization approach to improve the day-ahead forecasts of stochastic renewable energy production, by exploiting information on auxiliary variables that may have some predictive power on such a production. Our approach is based on a data-driven reformulation of the well-known newsvendor problem and can be easily tailored to enhance the performance of renewable energy producers in a dual-price balancing market. We illustrate our approach using a realistic case study based on data from the Danish power system, where the auxiliary information our approach leverages corresponds, e.g., to the predicted renewable energy generation in neighboring regions.

3 - Absence of Spurious Local Trajectories in Time-varying Optimization

Cédric Josz, Le Kremlin-Bicetre, 14 A. Avenue du Docteur Antoine Lacroix, Le Kremlin-Bicetre, 94270, France

We study the landscape of optimization problems where the input data vary over time. To this end, we introduce the notion of spurious local trajectory as a generalization to the notion of spurious local solution in nonconvex optimization. As a case study, we consider the problem of optimal power flow in electrical networks with real-world and time-varying input data. We show that, despite the existence of spurious local solutions at every time, the time-varying landscape of the problem is free of spurious local trajectories. Inspired by this example, we propose an ordinary differential equation to study this phenomenon. (Joint work with S. Fattahi, R. Mohammadi, J. Lavaei, S. Sojoudi).

4 - Incentives for More Flexible Power Plant Operation under Different Market Designs

Christoph Weber, University Duisburg-Essen, Essen, Germany, christoph.weber@uni-due.de

Higher shares of variable renewables in power markets induce higher ramping needs and higher deviations between day-ahead schedules and actual production. To cope with these challenges, conventional power producers need to provide flexible response. Based on a stylized two-stage setting including both flexible and inflexible units, we analyze the pricing and the resulting incentives occurring in ISO-based American markets with complex, cost-based bids making use of convex hull pricing. We compare the incentives to those arising in European-style markets with simple bids and self-scheduling.

5 - The Impact of Renewable Energy Forecast Errors on Imbalance Volumes and Electricity Spot Prices

Shadi Goodarzi, University of Texas Austin, Austin, CA, United States, Derek W. Bunn, H. Niles Perera

Using data from the German electricity market, we investigate the effect of wind and solar energy forecasts' errors on imbalance volumes and intraday spot electricity prices. We use OLS and quantile regressions and autoregressive moving averages to identify these relationships using variables that have a quarter-hourly data granularity.

Resilience in Energy and its Interdependent Systems

Sponsored: Energy, Natural Res & the Environment/Energy Sponsored Session

Chair: Charalampos Avraam, Johns Hopkins University, Baltimore, MD, 21218, United States

1 - Irrigation and Hydropower Tradeoff at the Intersection of Food-energy-water Nexus

Ying Zhang, Johns Hopkins University, Baltimore, MD, 21215-2623, United States, ying.zhang@jhu.edu, Prathibha Juturu, Sriram Sankaranarayanan, Carson Drew, Ben Zaitchik, Sauleh Ahmad Siddiqui

The Grand Ethiopian Renaissance Dam (GERD) will be the largest hydroelectric dam in Africa when complete. The great irrigation potential upstream may be explored to improve food security in climate-vulnerable Ethiopia, while the effects on downstream hydropower generation remain unknown. We focus on the tradeoff between upstream irrigation and downstream hydropower generation and the corresponding influences on the food-energy-water nexus with a coupled modeling framework - a multi-player microeconomic partial equilibrium (MME) food system model coupled with a water/crop model and a hydropower model.

2 - Advancing Science Through Multisector Dynamics Modeling Innovation

Chris R. Vernon, Pacific Northwest National Laboratory, Richland, WA, United States, chris.vernon@pnnl.gov, Casey D. Burleyson, Jennie S. Rice, Ian P. Kraucunas, W. Dave Millard, Jon Weers

The U.S. Department of Energy's Integrated Multi-sector, Multi-scale Modeling (IM3) project aims to improve understanding of the dynamics of human-Earth systems, including how different stressors might affect system vulnerability and resilience over multi-decadal time horizons. IM3 integrates previously autonomous, process-rich models from a range of sectors, such as energy, water, land, and population, with varying spatial and temporal resolutions. The IM3 Framework-Software-Data (FSD) team provides embedded guidance and develops standards and capabilities to help collaborators explore how different model configurations of varying complexity influence simulation fidelity.

3 - A 3-level Nested Decomposition Framework for Multi-year Power Systems Planning under Policy Uncertainty

Nestor Andres Sepulveda, Massachusetts Institute of Technology, Cambridge, MA, 02142, United States, nsep@mit.edu, Juan Pablo Vielma

This work develops a capacity expansion planning framework for power systems able to solve for the optimal investment strategy/pathway subject to uncertain policies such as CO2 limits and/or renewable energy mandates over several year into the future while accounting for detailed operation at an hourly resolution. The framework integrates Stochastic Dual Dynamic Integer Programming, Benders Partitioning and Dantzig-Wolfe decomposition in order to decouple and parallelize different levels and stages of the problem. The framework is implemented using the Julia general purpose programming language and its mathematical programming extension JuMP.

4 - The Role of Cross-border Energy Infrastructure in Resilience to Natural Gas Price Shocks in North America

Sauleh Ahmad Siddiqui, Johns Hopkins University, Baltimore, MD, 21218, United States, siddiqui@jhu.edu, Charalampos Avraam, Maxwell Brown

We investigate the role of cross-border infrastructure — natural gas pipelines and electricity transmission lines — on energy resilience in North America. We couple the North American Natural Gas Model (NANGAM); a partial-equilibrium model for natural gas production, transport, storage, consumption, and infrastructure; with the Regional Energy Deployment System (ReEDS 2.0); a high-fidelity, high-spatial resolution model that determines regional capacity expansion and dispatch for electricity; in order to understand the dynamics of this cross-border infrastructure development under different scenarios of shocks to natural gas supply.

Chair: Soobin Lee, Yonsei University, Yeonhui-ro, Seoul, 03716, Korea, Republic of

1 - The Effects of Portfolio Group Constraints in Estimation Risk

Luis Chavez-Bedoya, Universidad Esan, Lima, Peru, lchavezbedoya@esan.edu.pe, Francisco Rosales

Group constraints limit the fraction invested in certain subsets of assets and generate portfolios covering the spectrum between the 1/N portfolio and the optimal portfolio fully invested in risky assets. In this paper, under the expected loss function of Kan and Zhou (2007), we determine the impact on out-of-sample performance when group constraints are considered. The resulting optimal portfolio rule combines the risk-free asset with M+1 sample portfolios: M portfolios satisfying each of the group constraints and a zero-exposure portfolio. We show that adding group constraints , and individually estimating each of the portfolios, have an important impact in reducing estimation risk.

2 - Comparison Study of Portfolio Insurance Strategies: CPPI Versus VTPI

Olga Biedova, Bentley University, Waltham, MA, United States, obiedova@bentley.edu

We compare two portfolio insurance strategies: Constant Proportion Portfolio Insurance (CPPI) and Volatility Target Portfolio Insurance (VTPI), an option based portfolio insurance strategy with an embedded option linked to a Volatility Target portfolio. We rely on numerical simulations and use the main ideas of the stochastic dominance theory. The bootstrapping approach allows us to relax the assumptions on the risky asset price dynamics. We present an extended comparative quantitative analysis of strategy performances in various market scenarios and within a range of input parameter values.

3 - Evaluating the Investment Performance of the 1/N Portfolio Based on the Euclidean Distance

Soonbong Lee, Yonsei University, Seoul, Korea, Republic of, tnsqhd94@gmail.com, Hongseon Kim, Seongmoon Kim

This study newly illuminates the excellence of the 1/N portfolio through its Euclidean distance, a new portfolio evaluation measure based on the vector distance. First, this study proves that the 1/N portfolio's diversification strategy decreases the Euclidean distance's upper limit. Furthermore, we empirically compare the 1/N portfolio and five representative portfolio-selection models in terms of performance measures related with returns and the Euclidean distance. The results of the analysis lead to the conclusion that the 1/N portfolio can achieve investment performance as excellent as the other portfolio models' due to the superiority of its Euclidean distance.

4 - Comparative Analysis on Investment Performance According to the Accuracy in Market Forecast

Soobin Lee, Yonsei University, Seoul, Korea, Republic of, Hongseon Kim, Seongmoon Kim

In this paper, comparison of performance of the Optimal portfolio model by accuracy in prediction is presented. To do this, the accuracy of input variables for the Optimal portfolio is adjusted using the convex combination of in-sample and out-of-sample data. The performance of portfolio is evaluated by several criteria including Euclidean Distance from in-sample portfolio, which is considered as optimal standard portfolio in this paper. Through this study, we expect to show how much the performance of the optimal portfolio is affected by the accuracy control of the input variable.

5 - An Omega Model with Stochastic Dominance Efficiency Approach

Chen Chang, National Chi Nan University, Nantou, Taiwan, ccjeff85@hotmail.com, Jing-Rung Yu, Paul W. Chiou, Ming-Yi Huang

This study advances the Omega portfolio model by integrating a nonparametric method, the stochastic dominance efficiency approach. Though it grants flexibility by considering a return threshold set by investor, the Omega model tends to be over-optimistic and overweight the low price stocks of high variance in returns. This can lead to loss and uncertainty in the portfolio performance. By selecting the portfolio that stochastically dominates the benchmark, the proposed Omega model yield more stable performance. We provide the empirical results using the daily returns of two data sets, the Exchange Traded Funds and the S&P 500 composite stocks.

Advanced Analytics for Manufacturing and Health

Emerging Topic: Advanced Manufacturing

Emerging Topic Session

Chair: Trung Le, North Dakota State University, Fargo, ND, 58102, United States

Co-Chair: Om Yadav, PhD, North Dakota State University, Fargo, ND, United States

1 - Deep Learning for Distortion Prediction of Additive Manufacturing

Linkan Bian, Mississippi State University, Industrial and Systems Engineering Department, Mississippi State University, MS, 39762, United States

Laser-Based Additive Manufacturing (LBAM) is a fabrication process that is a key aspect of Industry 4.0, which aims to employ many sensors for continuous process control. One current challenge in LBAM is the geometric inaccuracy of fabricated parts. To increase accuracy, accurate predictions of distortion are needed. Here we develop a novel Deep Learning approach that accurately predicts distortion well within LBAM tolerance limits by considering the local heat transfer for pointwise distortion prediction. Our Deep Learning approach not only gives highly accurate predictions but also fits into the Industry 4.0 framework of analyzing big data with manysensors.

2 - Validation Framework for Sleep Stage Scoring in Wearable Sleep Trackers and Monitors

Trung (Tim) Le, North Dakota State University, North Dakota State University, Fargo, ND, 58102, United States, trung.q.le@ndsu.edu

The increasing trend in transforming point-of-care sleep tracking devices to polysomnographic (PSG) alternatives has necessitated evaluation and validation frameworks. We proposed a quantitative evaluation framework to assess the performance of wearable sleep tracking devices relative to the PSG gold standard. The proposed framework compares sleep features epoch-by-epoch in all N1, N2, N3, REM and wake stages. The evaluation of sleep tracking devices with PSG included the wake-sleep analysis, sleep staging distribution comparisons, and localized analysis.

3 - Probabilistic Graphical Model of Acute Disorder Pathogenesis for Patient-specific Preventive Treatment

Phat K. Huynh, Doctoral Student, North Dakota State University, Fargo, ND, United States, phat.huynh@ndsu.edu

Disease pathogenesis has not been encoded in machine learning models because of its complex temporal dependencies and inter-patient stochastic variability. This paper proposes a pathogenesis probabilistic graphical model (PPGM) that incorporates pathogenetic domain knowledge to capture mechanisms leading to disease onsets. PPGM model consists of a static Bayesian network of patient attributes and a pathogenetic temporal model of pathogenetic dynamics. The PPGM model presents an inference paradigm for conditional patient queries and k-step onset forecasting. The model was evaluated by two case studies: Obstructive Sleep Apnea (OSA) and Paroxysmal Atrial fibrillation (PAF).

4 - Scheduling Medical Interpreters: A Data-driven Optimization Model

Abdulaziz Ahmed, Assistant Professor, University of Minnesota, Business Dept, Crookston, MN, 56716, United States, aahmed20@umn.edu

According to the American Community Survey (ACS), twenty-four million people in the United States are not able to speak English well or do not speak English at all. Offering interpreting service for patients who cannot speak English (limited English Proficiency patients (LEPPs)) in hospitals is mandatory according to Title VI of the Civil Rights Act of 1964. In addition, interpreting service significantly affects the quality of medical service. This research develops a data-driven optimization model for scheduling medical interpreters in medical centers. The model minimizes the total costs of full-time as well as part-time interpreters and maximizes interpreter performance rating.

5 - Nonparametric Moments Estimation for Li-ion Batteries Degradation Data

Hon Keung Tony Ng, Southern Methodist University, Department of Statistical Science, Dallas, TX, 75275-0332, United States, Lochana K. Palayangoda

In this paper, we propose the use of nonparametric empirical saddlepoint approximation to estimate the moments of the lifetime distribution based on degradation data. The major advantage of the proposed method is that it does not require the knowledge about the underlying random distribution of the degradation process. The performance of the proposed approach is compared to some existing parametric approaches for the prediction of end of performance of lithium-ion batteries by means of Monte Carlo simulation. A lithium-ion batteries degradation dataset from a lab experiment at different currents is used to illustrate the proposed method.

Financial Risk and Regulation

Sponsored: Finance

Sponsored Session

Chair: Hamed Amini

1 - A Theory for Measures of Tail Risk

Fangda Liu, Assistant Professor, University of Waterloo, Waterloo, ON, Canada, Ruodu Wang

The notion of "tail risk" has been a crucial consideration in modern risk management and financial regulation. In this work, we carry out an axiomatic study for tail risk measures which quantify the tail risk. The two popular classes of regulatory risk measures in banking and insurance, the Value-at-Risk and the Expected Shortfall, are prominent, yet elementary, examples of tail risk measures. We establish a connection between a tail risk measure and a corresponding law-invariant risk measure, and investigate their joint properties. We explore relevant issues on tail risk measures, such as bounds, distortion risk measures, risk aggregation, and elicitability.

2 - Market-making Costs and Liquidity: Evidence from CDS Markets

Stathis Tompaidis, University of Texas-Austin, McCombs School of Business, IROM Department, Austin, TX, 78712-1179, United States, Stathis.Tompaidis@mccombs.utexas.edu, Mark Endel Paddrik

We provide a stylized model to study the implications of dealer costs on dealer behavior and market liquidity. In an empirical study of the single-name CDS market between 2010-2016, we find that transaction prices between dealers and clients have recently become more dependent on the inventories of individual dealers; that the volume with clients decreases, but that interdealer volume decreases much more; and that dealers with large inventories become more likely to trade with clients. Our results are consistent with the view that recent regulatory reforms increased the cost of holding inventory for dealers, and the cost of interdealer trading.

3 - Capital Regulation and Dynamic Financial Contagion

Zachary Feinstein, Stevens Institute of Technology, Hoboken, NJ, 63130, United States

In this talk we construct a continuous time model for price-mediated contagion precipitated by a common exogenous stress to the banking book of all firms in the financial system. In this setting, firms are constrained so as to satisfy a risk-weight based capital ratio requirement. We use this model to find analytical bounds on the risk-weights for assets as a function of the market liquidity. Under these appropriate risk-weights, we find existence and uniqueness for the joint system of firm behavior and the asset prices. Numerical case studies are provided to demonstrate various implications of this model.

4 - Cascading Losses in Reinsurance Networks

Ariah Klages-Mundt, Cornell University, Ithaca, NY, United States, aak228@cornell.edu, Andreea Minca

We develop a model for reinsurance cascades by which primary losses spread via general contracts, such as typical excess of loss (XL). We show that existing proportional contract models greatly underestimate risk. We characterize fixed points in our model and exotic cases of network structure that cause network effects to dominate overall payments. We develop efficient algorithms and apply them to data on real reinsurance networks. Our simulations demonstrate (1) extreme parameter sensitivity, which makes risk measurement difficult and incentivizes firms to cooperate to prevent fraud, and (2) nonlinearities from XL contracts obfuscate risks and can cause excess costs in a real network.

1 - On the Solution of Scheduling Uninterruptible Services with Stochastic Duration: A Distributionally Robust Optimization Approach

Ana Celeste Batista, Research Intern, Skolkovo Institute of Science and Technology, Moscow, Russian Federation, abatista@uc.cl, David Pozo, Jorge Vera

We introduce a mixed integer optimization model for dealing with uninterruptible services with random duration, i.e., once the service is scheduled it should remain schedule until it is finished. The duration of the service is assumed to be stochastic. The underlying stochastic process service duration is ambiguous. Thus, we consider that known information is limited only to the first moment and the support of the true probability distribution. We present a distributionally robust optimization (DRO) framework for describing this problem. We present numerical simulations to study the admission planning problem assuming limited distributional information of the patient's stay duration.

2 - Planning and Scheduling Operating Room Using Modified Block Scheduling Strategy with Considering the Surgical Team and Post-operative Units Constraint

Motahareh Tavakolikashi, Student, Suny at Binghamton, Binghamton, NY, United States, Nasser Salmasi

Operating room is the most important facility in hospital since it causes about 33% of total costs and produce about 67% of total revenue. Managing operating room is complicated due to many resource constraints and conflicts. Managers are interested in decreasing the costs while increasing patient's satisfaction level. We proposed a novel two phases model for planning and scheduling operating rooms. In this model, several modified block scheduling strategies are implemented and anesthesiologist constraints and post-operative units constraints are considered. The result shows this new model can solve reasonable size problems in a reasonable time.

3 - The Impact of Competition on Hospital's Technology Adoption

Varun Gupta, Penn State Erie, The Behrend College, Erie, PA, United States, vxg15@psu.edu, Ozgun Caliskan Demirag, Xin (David) Ding

In this paper, we examine how competition in local hospital service area drives hospitals' decision to adopt technology using secondary data. Additionally, we develop a series of hypotheses based on game theory and test the hypotheses with the performance data in econometric models.

4 - Designing Master Surgical Schedules

M'Hallah Rym, Kuwait University, Kuwait, rymmha@yahoo.com

This paper designs a master surgical schedule (MSS) of a fixed planning horizon for a pediatric hospital. The MSS determines the specialty associated with each operating room session of the planning horizon with the objective of minimizing the expected waiting times of elective surgeries, guaranteeing access to the operating theatre for each specialty, and optimizing the use of downstream resources. Using the optimized MSS in lieu of the fixed grid currently used by the hospital increases the throughput of the operating theatre by as much as 10%.

5 - Identification of Disparities Associated with Maternal Morbidity in Arkansas: A Bayesian Network Analysis

Mandana Rezaeiahari, Assistant Professor, University of Arkansas for Medical Sciences, Little Rock, AR, United States, Clare C. Brown

Although women of every race and ethnicity are affected by maternal mortality, in Arkansas, maternal mortality among black mothers is more than 2.5 larger than among white mothers. In this study, risk factors that are most likely to contribute to the higher risk of morbidity among racial minorities are identified using Bayesian networks. The probability of conditional dependencies of demographic and clinical characteristics to the maternal morbidities will be learned using unsupervised machine learning algorithms. Based on the result of our predictive algorithms, proper interventions can be proposed to slow down or stop the target condition at an identified stage of pregnancy.

Mean Field Games and Large Stochastic Systems

Sponsored: Finance

Sponsored Session

Chair: Xin Guo

1 - Beyond Mean Field Limits: Large Sparse Networks of Interacting Processes

Daniel Lacker, Columbia University, New York, NY, United States, dl3133@columbia.edu

We study large systems of stochastic processes (particles), in discrete or continuous time, in which each particle is associated with a vertex in a graph and interacts only with its neighbors. It is known that when the graph is complete and the number of particles grows to infinity, the system is well-approximated by a nonlinear (McKean-Vlasov) process, which describes the behavior of one typical particle. For general graphs, however, the system is no longer exchangeable, and the mean field approximation fails. Nevertheless, for a broad class of locally tree-like graphs, we show that a single particle and its nearest neighbors are characterized by an autonomous evolution we call the "local dynamics."

2 - Hierarchical Preferential Attachment Models: Statistical Analysis and Applications

Wenpin Tang, UC Berkeley, Berkeley, CA, United States

In this talk I will discuss various preferential attachment models, including the Buckley-Osthus model and hierarchical PA models. The degrees of these graph models are known to be power-law distributed. I will focus on the statistical analysis of these models: the MLEs are shown to be consistent and asymptotically normal. The theoretical results are corroborated with simulations and real world data.

3 - Portfolio Diversification and Model Uncertainty: A Robust Dynamic Mean-variance Approach

Xiaoli Wei, University Paris Diderot, Paris, France, tyswxl@gmail.com

This paper is concerned with a dynamic multi-asset mean variance portfolio selection problem under model uncertainty. We develop a continuous time framework for ambiguity aversion about both expected return rates and correlation matrix of the assets, and their effects on portfolio diversification. We prove a separation principle, which allows us to reduce the determination of the optimal strategy to the parametric computation of the minimal risk premium. Our results provide a justification for under-diversification, as documented in empirical studies. Moreover, time-dependent ambiguity sets may explain why a under-diversification becomes a well-diversification over time and verse versa.

4 - MFGs for Partially Reversible Investment

Haoyang Cao, University of California, Berkeley, CA, 94709, United States, Xin Guo, Joon Seok Lee

This paper analyzes a class of MFGs with singular controls motivated from the partially reversible investment problem. It establishes the existence of the solution when controls are of bounded velocity, solves explicitly the game when controls are of nite variation, and presents sensitivity analysis to compare the single-player game with the MFG. Our analysis shows that MFGs, when appropriately formulated, can demonstrate genuine game eects even without heterogeneity among players and additional common noise.

Sponsored Session

Chair: Ismail Capar, Texas A&M University, College Station, TX, 77843-3367, United States and Bowling Green State University, Bowling Green, OH, 43403, United States

Co-Chair: Yudai Honma, The University of Tokyo, Tokyo, 153-8505, Japan

1 - Distance Distribution of Shortest Travel Route that Includes a Visit to a Facility on a Continuous Network

Ken-ichi Tanaka, Keio University, Yokohama, Japan, ken1tnk@ae.keio.ac.jp, Kazuki Tanno

We focus on a continuous network in which origin and destination of trips are continuously distributed along links of the network, and present a method to derive the distance distribution of trips that includes a visit to a facility on the way to destination. It is assumed that every traveler chooses a shortest route in visiting a facility that minimizes the sum of the distance from origin to a facility and the distance from the facility to destination. We apply the proposed method to an actual road network and evaluate accessibility to a facility.

2 - Spacing of Intersections in Hierarchical Road Networks with Inward, Outward, and Through Traffic

Masashi Miyagawa, University of Yamanashi, 4-4-37, Takeda, Kofu, 400-8510, Japan, mmiyagawa@yamanashi.ac.jp

This paper develops a continuous network model for examining the spacing of intersections that connect different levels of roads in a hierarchical network. An analytical expression for the total travel time is obtained for a grid road network with two road types: minor and major roads. The travel time is defined as the sum of the free travel time and the delay at intersections. The optimal pattern of intersections that minimizes the total travel time is then obtained. The result shows how the road length, the intersection delay, the travel speed, and the traffic composition affect the optimal intersection pattern.

3 - Drone Base Location Planning for Disaster Relief

Hozumi Morohosi, National Graduate Inst Policy Studies, Tokyo, Japan, morohosi@grips.ac.jp, Takehiro Furuta

In this work we study a location problem of drone bases for disaster relief in a large region. Despite its rapidly growing technology, a drone is still suffering from short flight time allowance. This causes us to need multiple drones to cover whole a large area, and transport them by means of mass transportation such as a truck. Suppose several potential hazard areas are scattered in a large region and each area assumes the number of drones necessary for the search, we consider a problem where to build drone bases and how many drones should be allocated to each base in terms of covering location problem.

4 - Evaluating Impact of Flow Refueling Objectives on Transportation Corridor Deployment

Ibrahim Capar, Bowling Green State University, Bowling Green, OH, 43403, United States, icapar@bgsu.edu, Ismail Capar, Sevgi Erdogan, Mohammad M. Nejad

We consider a decision maker who focuses on creating EV corridor to maximize the number of EV served. While flow refueling location model (FRLM) literature uses flow and vehicles miles traveled objectives, these objectives do not prioritize an EV corridor. In this research, we introduce two new objective functions to prioritize charging station deployment on an EV corridor. The first model maximizes the total flow on an EV corridor. The second model maximizes the weighted total flow where weight is based on the distance on the EV corridor. We test models on Maryland transportation network.

Stochastic Models & Machine Learning: Applications to Healthcare

Sponsored: Manufacturing & Service Oper. Mgmt/Healthcare Operations

Sponsored Session

Chair: Fernanda Bravo, UCLA Anderson School of Management, Los Angeles, CA, 90024, United States

Co-Chair: Yaron Shaposhnik, University of Rochester, Rochester, NY, 14627, United States

1 - Provider Schedules with No Shows

Vera Tilson, University of Rochester, Rochester, NY, 14627, United States, Vera.Tilson@simon.rochester.edu

We address the problem of scheduling patient appointments in a family medicine clinic. A significant barrier to a clinic's sustainability is under-utilization of the medical providers it employs. Practically all patient appointments are scheduled some time in advance (from an hour to months ahead), and under-utilization happens because some patients do not keep their appointments and do not provide sufficient notice for the clinic to reschedule another patient into the freed slot. Using a stylized simulation model we investigate an algorithm for appointment capacity release that increases provider utilization.

2 - Simple Rules for Predicting Congestion Risk in Queueing Systems: Application to ICUs

Yuting Yuan, Simon Business School, University of Rochester, Rochester, NY, United States, yuting.yuan@simon.rochester.edu, Fernanda Bravo, Cynthia Rudin, Yaron Shaposhnik

We study the problem of predicting congestion risk in service systems. We define "high-risk states" as system states that are likely to lead to a congested state in the near future, and strive to formulate simple rules for determining whether a given system state is high-risk. We show that for simple queueing systems, such as the $M/M/\infty$ queue with multiple customer classes, such rules could be approximated by linear and quadratic functions on the state space. For more general queueing systems, we develop a computational framework and demonstrate through extensive computational study its effectiveness. We also show that in many cases linear classifiers provide very accurate prediction rules.

3 - Sparse Flexible Design: A Machine Learning Approach

Timothy Chan, University of Toronto, Mechanical and Industrial Engineering, Toronto, ON, M5S 3G8, Canada, Benjamin Potter

For a general production network, state-of-the-art methods for constructing sparse flexible designs are heuristic in nature, typically computing a proxy for the quality of unseen designs and using that estimate in a greedy manner to modify a current design. In this talk, we develop two machine learning-based approaches to constructing sparse flexible designs that leverage a neural network to accurately and quickly predict the performance of large numbers of candidate designs. Using small benchmark instances and a large case study of the flexibility of linear accelerators that deliver radiation to treat cancer, we demonstrate that our approach meets or beats the state-of-the-art.

4 - An Integrated Learning and Optimization Approach to Reduce Cancellations in the Operating Room

Nadia Lahrichi, Polytechnique Montreal, Montreal, QC, H3C3A7, Canada, nadia.lahrichi@polymtl.ca, Arnaud Augustin, Philippe Jouvet, Andrea Lodi, Louis-Martin Rousseau

In this talk, we propose a novel approach to deal with the integration of the intensive care unit to the (long term) surgical case assignment problem. The approach is based on graphical model optimization that includes the probability of canceling cases at each state. We use the practical case of the teaching hospital Sainte-Justine (CHUSJ), in Montreal and show that prioritizing patients during this process only increases the quality of the schedule without decreasing the occupancy rate of the OR.

Time-Inconsistent Decision Problems

Sponsored: Finance

Sponsored Session

Chair: Nan Chen, Chinese University of Hong Kong, Shatin N T, Hong Kong

Co-Chair: Xuedong He, The Chinese University of Hong Kong, Shatin, Hong Kong

1 - Failure of Smooth Pasting Principle and Nonexistence of Equilibrium Stopping Rules under Time Inconsistency

Wei Wei, Waterloo University, Mathematics 3, Waterloo, ON, N2L 3G1, Canada, weiw1422@gmail.com, Xunyu Zhou, Ken Seng Tan

This paper considers a time-inconsistent stopping problem in which the inconsistency arises from non-constant time preference rates. We show that the smooth pasting principle may fail under time-inconsistency. We prove that the smooth pasting principle solves a time-inconsistent problem if and only if certain inequalities are satisfied. By a stopping model which is commonly used in real options approach, we show that the violation of these inequalities can happen even for very simple non-exponential discount functions. Moreover, we demonstrate that the stopping problem does not admit any intra-personal equilibrium whenever the smooth pasting principle fails.

2 - Forward Rank-dependent Performance Criteria: Time-consistent Investment under Probability Distortion

Moris Strub, The Chinese University of Hong Kong, Engineering Building, Hong Kong, NT, Hong Kong

We introduce forward rank-dependent performance processes and thereby extend the framework of forward criteria to include probability distortions. A fundamental challenge is how to reconcile the time-consistent nature of forward performance criteria with the time-inconsistency stemming from probability distortions. Our main results are an equivalence of definitions based on preservation of the performance value and time-consistency of policies, a full characterization of viable probability distortions by means of a bifurcation-type result and the introduction of an auxiliary, distorted financial market leading to a construction method for forward rank-dependent criteria.

3 - On the Strategies of Naive and Sophisticated Agents with Weighted Average Risk Preferences in Continuous Time

Sang Hu, The Chinese University of Hong Kong, Shenzhen, Shenzhen, 518172, China, husang@cuhk.edu.cn, Xuedong He

In the recent two papers by Ebert and Strack (2015, 2018), the authors show that under certain conditions, naïve agents never stop gambling while sophisticated agents never start to do so, when their risk preferences are characterized by cumulative prospect theory. In this paper, we investigate the strategies of the above-mentioned types of agents, whose risk preferences are induced by a weighted average of expected utility theory and cumulative prospect theory. Furthermore, we employ the definition of weak equilibrium to study the strategies of sophisticated agents. Our results then generalizes the ones by Ebert and Strack (2015, 2018).

4 - Non-Concave Utility Maximization without the Concavification Principle

Shuaijie Qian, National University of Singapore, Singapore, Singapore

The problems of non-concave utility maximization appear in many areas of finance and economics, such as in behavior economics, incentive schemes, aspiration utility, and goal-reaching problems. Existing literature solves these problems using the concavification principle. We provide a framework for solving non-concave utility maximization problems, where the concavification principle may not hold and the utility functions can be discontinuous. In particular, we find that adding bounded portfolio constraints, which makes the concavification principle invalid, can significantly affect economic insights in the existing literature. Theoretically, we give a new definition of viscosity solution and show that a monotone, stable, and consistent finite difference scheme converges to the solution of the utility maximization problem.

Kidney Allocation & Exchange

Sponsored: Health Applications

Sponsored Session

Chair: Joris Van de Klundert, Erasmus University-Rotterdam, Ridderkerk, 2983 HE, Netherlands

1 - Equitable Deceased Donor Kidney Allocation through Network Flows

Joris Van de Klundert, Professor, Mohammad bin Salman College, King Abdullah Economic City, 23964, Saudi Arabia, jklundert@mbsc.edu.sa

In the USA, the wait times for decease donor kidney transplants are long and inequitable. For instance, disparities exists between blood types and races. We analyze how transplant organs can be allocated (most) equitably, and characterize under which conditions equity can be achieved. The analysis is based on queuing theory and network flow formulations. The analysis will be illustrated using UNOS data, the results of which suggest concrete policy improvements.

2 - Maximum Matchings in Graphs for Allocating Kidney Paired Donation

Michal Mankowski, King Abdullah University of Science and Technology, Jeddah, Saudi Arabia, michal.mankowski@kaust.edu.sa, Sommer Gentry, Michael T.S., Dorry Segev

Kidney paired donation matches one patient and his incompatible donor with another patient and donor in the same situation for an organ exchange. Let patient-donor pairs be the vertices of an undirected graph G, with an edge connecting any two reciprocally compatible vertices. A matching in G is a feasible set of paired donations. We propose an edge-weighting of G which guarantees that every matching with maximum weight also has maximum cardinality, and also maximizes the number of transplants for an exceptional subset of recipients.

3 - A Centralized Allocation Mechanism for Public Housing

Weihua Zhang, University of British Columbia, Vancouver, BC, V5G 1Z2, Canada, weihua.zhang@sauder.ubc.ca, Yichuan Ding, Daniel Granot

In 2014, US programs of federal rental assistance helped nearly five million families. We model the affordable housing allocation problem as a centralized decision problem. The Housing Authority strives to accommodate move-in requests as well as requests of transfer between housing types. We assume that households list the housing types that they would accept without specifying their complete preference order. We further assume that the housing units of each type are homogeneous. For minimizing vacancy rate and maximizing portability (the responsiveness of the HA to households' accommodation requests), we formulate the problems as network flow problems and characterize the optimal solutions.

4 - Challenges in Match Offer Acceptance in the OPTN Kidney Paired Donation Pilot Program

Ruthanne Leishman, RN, MPH, UNOS, Seattle, WA, United States, Ruthanne.Leishman@unos.org

The OPTN KPD program offers hundreds of matches each year. Despite this, only about 45 transplants occur annually. A 92% match failure rate is the biggest challenge to achieving transplants. Hospitals refused 233/562 match offers from Jan17-Jun18. Another 257 matches failed due to a refusal in the same exchange. Donor related issues accounted for 39.9% of refusals, candidate issues 24.5%, HLA 26.6%, and other 26.1%. KPD data entered by hospitals screens donors and candidates for optimal matching, however, many refusals are behavioral. For example improperly entered unacceptable antigens (19.3%) or donor preferences (8.5%) and failure to remove candidates unavailable for transplant (22.3%).

5 - Scalable Robust Kidney Exchange

John P. Dickerson, Assistant Professor, University of Maryland, College Park, MD, United States, john@cs.umd.edu, Duncan McElfresh, Hoda Bidkhori

In barter exchanges, participants trade their endowed goods in a constrained economic setting without money. Transactions in barter exchanges are often facilitated via a central clearinghouse that must match participants even in the face of uncertainty—e.g., over participants, existence and quality of potential trades. Leveraging robust combinatorial optimization techniques, we address uncertainty in kidney exchange, a real-world barter market where patients swap (in)compatible donors. We provide two scalable robust methods to handle two distinct types of uncertainty in kidney exchange—over the quality and the existence of a potential match, along with preliminary experiment results.

Joint Session MIF/OPT: Stochastic Programming Methods and Applications

Sponsored: Minority Issues

Sponsored Session

Chair: Lewis Ntaimo, Texas A&M University, College Station, TX, 77843, United States

1 - Pathways Modeling and Scheduling for Connected Community Health under Uncertainty

Jiangyue Gong, Texas A&M University, College Station, TX, 77354, United States, gongjiangyue@gmail.com, Lewis Ntaimo

Pathways Modeling and Scheduling for Connected Community Health under Uncertainty Speaker: Jiangyue Gong [gongjiangyue@gmail.com] Co-Author: Lewis Ntaimo [ntaimo@tamu.edu] Affiliation: Texas A&M University, College Station, U.S.A

Pathways are structured and time-framed guidelines used by health-related services to detail essential steps of a process with a specific outcome. In this talk, we present a stochastic programming model for connected community health to schedule clients and resources for each step of the pathway under uncertainty in resource availability. The goal of the model is to optimize clients wait-time while providing workload balance among resources of the same type.

2 - Multistage Decision Making During Large-scale Wildfires

Brittany Segundo, Texas A&M University, College Station, TX, 77845, United States, brittany.segundo@tamu.edu, Lewis Ntaimo

Large-scale wildfires that have escaped initial containment efforts require a coordinated response from numerous agencies. While stochastic programming has been used to pre-position firefighting resources in advance of a fire season, we employ a multistage stochastic program to inform the allocation of resources during the course of a wildfire and its progression. Decision-makers face volatile fire growth and intensity as a result of uncertain weather changes, but previous response efforts also impact the fire progression. We approximate this multistage program with endogenous uncertainty using a rolling horizon approach.

3 - Risk-averse Multistage Stochastic Programs with Expected Conditional Risk Measures

Maryam Khatami, Texas A&M University, College Station, TX, 77840, United States, maryam.khatami@tamu.edu, Thuener Silva, Bernardo Kulnig Pagnoncelli, Lewis Ntaimo

We present a study of decomposition algorithms for risk-averse multistage stochastic programs with expected conditional risk measures (ECRMs). ECRMs are time-consistent, and we show that solving risk-averse problems in this case is as complex as solving risk-neutral ones. We consider ECRMs for both quantile and deviation mean-risk measures, deriving the Bellman equations in each case. We illustrate our results with extensive numerical computations for a hydrothermal scheduling and a portfolio selection problem.

4 - Stochastic Programing and Climate Data Analytics for Planning and Operating Distributed Generation Systems

Clara Novoa, Associate Professor, Texas State University, San Marcos, TX, 78666, United States, cn17@txstate.edu, Temitope Runsewe, Tongdan Jin

We present a non-linear model to find the optimal capacities and locations of wind turbines that minimize the lifecycle cost of a distributed generation system considering loss-of-load probability and thermal constraints. Volatilities on the wind turbines power generation are modeled through scenarios for the wind speed across the turbine blades. The cost of bringing energy from the grid and the income from selling back green energy are considered as recourse actions. Data analytics on wind speed for different cities permits to estimate the probability distribution for the power output. Sensitivity analysis reveals that the system has still affordable cost if fluctuations in the loads occur.

Joint Session DEI/MIF: A Panel Discussion on the Role of the Professional Organization in Gender Harassment Mitigation

Emerging Topic: Diversity, Equity, and Inclusion

Emerging Topic Session

Chair: Julie Simmons Ivy, North Carolina State University, Raleigh, NC, 27695-7906, United States

Co-Chair: Christine Grant, North Carolina State University

1 - A Panel Discussion on the Role of the Professional Organization in Gender Harassment Mitigation

Julie Simmons Ivy, North Carolina State University, Raleigh, NC, 27695-7906, United States

There is an emerging national dialogue about aspects of diversity, equity and inclusion in STEM fields. The conduct of STEM colleagues in the workplace and at national conferences is a critical component of mitigating sexual and gender harassment. In this session, we will present (i) an overview of the National Academy of Engineering report on Gender Harassment, (ii) introduce the Societies Consortium on Sexual Harassment in STEMM (science, technology, engineering, mathematics and medicine) and (iii) review the INFORMS Meeting Code of Conduct Policy. This session opens the dialogue within INFORMS regarding sexual and gender harassment, the operationalization of code of conduct policies within professional organizations, and the role that organizations like INFORMS can play in creating safe spaces.

Panelists

- Christine Grant, North Carolina State University, Raleigh, NC, United States
- Michael P. Johnson, University of Massachusetts Boston, Department of Public Policy & Public Affairs, Boston, MA, 02125-3393, United States
- Shengfan Zhang, University of Arkansas, Department of Industrial Engineering, Fayetteville, AR, 72701, United States

Machine Learning in Finance

Sponsored: Data Mining

Sponsored Session

Chair: Gavin Feng

1 - Deep Learning in Asset Pricing

Markus Pelger, Stanford University, Stanford, CA, 94305, United States, mpelger@stanford.edu, Jason Zhu, Luyang Chen

We estimate a general non-linear asset pricing model with deep neural networks applied to all U.S. equity data and a substantial set of macroeconomic and firm-specific information. Our crucial innovation is the use of the no-arbitrage condition as part of the neural network algorithm. We estimate the stochastic discount factor that explains all asset prices from the conditional no-arbitrage moment constraints. Our model finds the key factors that drive asset prices, identifies mis-pricing of stocks and generates the mean-variance efficient portfolio. Our optimal portfolio has an annual out-of-sample Sharpe Ratio of 2.6.

2 - Risk Factors That Matter: Textual Analysis of Risk Disclosures for the Cross-Section of Returns

Alejandro Lopez-Lira, The Wharton School, University of Pennsylvania, Philadelphia, PA, United States, joselop@wharton.upenn.edu

Using unsupervised machine learning, I introduce interpretable and economically relevant risk factors that characterize the cross-section of returns better than the leading factor models, furthermore, I do not use any information from the past returns to select the risk factors. I exploit natural language processing techniques to identify from the firms' risk disclosures the types of risks that firms face, quantify how much each firm is exposed to each type of risk, and employ the firms' exposure to each type of risk to construct a 4-factor model. The risk factors roughly correspond to Technology and Innovation Risk, Demand Risk, Production Risk and International Risk.

3 - Smart Betas: A Machine Learning Perspective

Jianeng Xu, University of Chicago Booth School of Business, Chicago, IL, United States, Shentao Yang, Guanhao Feng, Nicholas Polson

Empirical studies in "smart beta" mostly focus on identifying stock winners via security sorting. In this paper, we study machine learning classification for "Beta v.s. Return" in the sorting perspective of Black, 1993. Classification conveniently takes multiple inputs (betas and firm characteristics) while sorting faces difficulty. In our comparative analysis, machine learning improves classification and annual performance. We identify the best methods (support vector machine and deep learning) and betas (net equity issues, asset growth, and operating profitability). Machine learning methods also tend to recommend similar stocks while security sorting portfolios are more diversified.

4 - A Machine Learning Approach to Estimating Large Positive Definite Covariance Matrix of High Frequency Data

Liyuan Cui, City University of Hong Kong, Hong Kong, Hong Kong, liyuan.cui@cityu.edu.hk

This paper proposes a novel covariance estimator via a machine learning approach. Our method simultaneously provides a consistent estimation in a one-step procedure. Moreover, in the presence of microstructure noises and asynchronous trading, the covariance estimator is guaranteed to be positive definite with the optimal rate of convergence. We provide a data-driven algorithm to select the optimal tuning parameters in practice. We apply the proposed estimator to vast portfolio allocations, which enjoy significantly enhanced out-of-sample portfolio risk and Sharpe ratios. The success of our approach helps justify the role that machine learning techniques play in finance.

Predictive Analytics in Healthcare

Sponsored: Data Mining

Sponsored Session

Chair: Zhang Qingpeng

1 - Predicting Depressive Disorders in the Elderly with Multitask Recurrent Neural Network

Qingpeng Zhang, City University of Hong Kong, Kowloon, 12180, Hong Kong, qingpeng.zhang@cityu.edu.hk, Zhongzhi Xu, Mingyang Li

This research aims to develop a state-of-the-art deep learning model for the individualized prediction of depressive disorders with a 22-year longitudinal survey data among elderly people in the United States. The experiments indicate that (a) machine learning models can provide an accurate prediction of the onset of depressive disorders for elderly individuals; (b) the temporal patterns of risk factors are associated with the onset of depressive disorders; and (c) the proposed multitask deep learning model exhibits superior performance as compared with baseline models.

2 - A Bayesian Non-parametric Approach to Modeling Multi-dimensional and Heterogeneous Disability Progression of Older Adults

Suiyao Chen, University of South Florida, Tampa, FL, 33617, United States, suiyaochen@mail.usf.edu, Hongdao Meng, Nan Kong, Kathryn Hyer, Mingyang Li

Predictive modeling of disability progression of older adults allows better understanding of their evolving needs on various healthcare settings (e.g., nursing home, hospital) and further development of more proactive preparedness decisions. Conventional modeling approaches often consider univariate disability progression with simplified modeling assumptions (e.g., homogenous population). This work proposes a Bayesian non-parametric approach to characterizing multi-dimensional and heterogeneous disability progression of older adults by relaxing the conventional modeling assumptions and further developing effective estimation algorithms.

3 - Temporal and Spatial Analysis of Mental Health on Social Media: Take U.S. as an Example

Jiaojiao Wang, The State Key Laboratory of Management and Control for Complex Systems, Institute of Automation, Chinese Academy of Sciences, Beijing, China, jiaojiao.wang@ia.ac.cn Jiaojiao Wang, Shenzhen Artificial Intelligence and Data Science Institute (Longhua), Shenzhen, China, jiaojiao.wang@ia.ac.cn, Junjie Lin, Qingpeng Zhang, Wenji Mao, Dajun Daniel Zeng

Geotweets data from May 11 to October 2 in 2014 on more than 60 hashtags related to mental health have been collected on Twitter social media platform. The correlation between the number of tweets and users related to mental health and deaths, sociodemographic indicators has been measured. Time series decomposition and forecasting method was applied to evaluate the seasonality, periodicity, trend of mental health related tweets. Temporal evolution and spatial analysis of the number of mental health related tweets and users on social media could help to implement novel digital public health surveillance methodologies for supporting policy makers in fighting the mental health epidemic.

4 - Hidden Markov Models for Sleep Identification via Commercial Wrist-worn Device

Kwok-Leung Tsui, City University of Hong Kong, City University of Hong Kong, Hong Kong, Jiaxing LIU, Yang Zhao

The use of wrist-worn devices to track and measure sleep cycle objectively grows increasingly popular. Existing algorithms for sleep/wake identification in these devices are mainly based on activity data inference and require expensive training or threshold setting.Our study proposed an unsupervised and personalized algorithm to infer sleep and wake states using both heart rates and step counts based on hidden Markov models. The proposed algorithm agreed mostly to Fitbit's scorings but enabled identifying more afternoon naps and earlier sleep onset in real-world case studies. Moreover, the estimated HMM parameters can reflect different behavior and circadian patterns among individuals.

5 - Parallel Computing for Large Scale Linear/Nonlinear Programming Based on Microservice Infrastructure

Jing He, Swinburne University of Technology, Victoria University, Hawthon, Australia

This talk will introduce a parallel algorithm and architecture to efficiently solve linear/nonlinear programming models with single-objective function and/or multiple-objective functions. The proposed Gradient Flow method for both single and multiple criteria programming will be implemented in a general distributed computing environment with the microservice infrastructure. The analytical performance of the proposed algorithm and the other well-known method, including the speedup upper bound and lower bound limits, will be derived. Numerical experiments and real-time applications will also be provided in order to verify the complexity of the proposed algorithm and architecture. The empirical results will demonstrate that the speedup of this parallel algorithm and architecture approaches linearity, which means that it can take full advantage of both the proposed algorithm and the distributed computing power as the size of the mathematical programming problem increases.

1 - A Continuous-time Perspective of Quasi-newton Methods

Honglin Yuan, PhD. Candidate, Stanford University, Stanford, CA, United States, Junzi Zhang, Stephen P. Boyd

In this work, we studied the continuous-time limit of Quasi-Newton methods.

2 - A Convex Optimization Approach to Radiation Treatment Planning with Dose Constraints

Anqi Fu, PhD Candidate, Stanford University, Stanford, CA, United States, anqif@stanford.edu, Baris Ungun, Lei Xing, Stephen P. Boyd

We present a method for handling dose-volume constraints as part of a convex programming framework for inverse treatment planning. Since these constraints are non-convex, we replace them with a convex restriction. To mitigate the restriction's impact on clinical objectives, we develop a two-pass planning algorithm that allows each dose-volume constraint to be met exactly on a second pass if its corresponding restriction is feasible on the first pass. In another variant, we add slack variables to prevent the problem from becoming infeasible when the user specifies an incompatible set of constraints. Finally, we introduce ConRad, a Python software package for convex radiation treatment planning.

3 - Ode Analysis of Stochastic Gradient Methods with Optimism and Anchoring for Minimax Problems and Gans

Ernest Kang Ryu, Assistant Adjunct Professor, University of California, Los Angeles, Los Angeles, CA, 90024, United States, eryu@math.ucla.edu, Kun Yuan, Wotao Yin

Despite empirical success, training dynamics of generative adversarial networks (GAN), which involves solving a minimax game using stochastic gradients, is still poorly understood. In this work, we analyze last-iterate convergence of simultaneous gradient descent (simGD) and its variants under the assumption convex-concavity. First, we show simGD, as is, converges with stochastic sub-gradients under strict convexity in the primal variable. Second, we generalize optimistic simGD to accommodate an optimism rate separate from the learning rate and show its convergence with full gradients. Finally, we present anchored simGD, a new method, and show convergence with stochastic subgradients.

4 - Distributional Robust Kelly Gambling

Qingyun Sun, PhD. Candidate, Stanford University, Department of Mathematics, Stanford, CA, United States, Stephen P. Boyd

In classic Kelly gambling, bets are chosen to maximize the expected log growth,under a known probability distribution.In this note weconsider the distributional robust version of the Kelly gambling problem, in which the probability distribution is not known, but lies in a given set of possible distributions.The bet is chosen to maximize the worst-case (smallest) log growth among the distributions in the given set.This distributional robust Kelly gambling problem is convex, but in general need not be tractable. We show that it can be tractably solved in the case of a finite number of outcomes,and some useful sets of distributions.

5 - Calibrating Multivariate L\'evy Processes with Neural Networks

Kailai Xu, PhD Candidate, Stanford University, Stanford, CA, 94305, United States, kailaix@stanford.edu, Eric Darve

Calibrating a L\'evy process requires characterizing its jump distribution. Traditionally this problem has been solved with nonparametric estimation using the empirical characteristic functions (ECF). For multivariate L\'evy processes and less smooth L\'evy densities, the problem becomes challenging as ECFs decay slowly and have large uncertainty because of limited observations. We solve this problem by approximating the L\'evy density with a parametrized functional form; the characteristic function is then estimated using numerical integration. In our benchmarks, we used deep neural networks and found that they are robust and can capture sharp transitions in the L\'evy density.

1 - The Role of School-Based Programs in Minimizing Health-Compromising Behaviors: An Optimization Approach

Banafsheh Behzad, Assistant Professor, California State University, MS 8506, Long Beach, CA, 91101, United States, banafsheh.behzad@csulb.edu, Niloofar Bavarian, Sheena Cruz

School health programs are united by their desire to promote health and health-related outcomes amongst youth. They are also united by the fact that their success is contingent on successful program implementation, which is often impeded by a multitude of real-world barriers. We present a detailed example of the first known application of Linear Programming to Positive Action (PA). Our findings from this exploratory study support the utility of applying LP during the program planning and implementation processes of school health programs.

2 - Predicting Risk of Opioid Use Disorder by Leveraging Massachusetts All Payer Claim Data

Muhammad Noor-E-Alam, Northeastern University, Boston, MA, United States, md.alam@northeastern.edu

Given the magnitude of ongoing opioid crisis across the US, we utilized Massachusetts All Payer Claims Data (MA APCD) to assess the long-term opioid usage pattern of opioid-naïve patients and reveal the underlying risk factors that lead such a naïve patient towards Opioid Use Disorder. Outcome of this research is anticipated to combat the opioid addiction epidemic by ensuring judicious use of prescription opioids for patients who genuinely require them.

3 - Identifying Potential Cancer Victims on Twitter through Text Mining

Anton Ivanov, PhD, University of Illinois at Urbana–Champaign, Champaign, IL, United States

Health surveillance data often lacks temporal and spatial precision. Social media may offer new inexpensive and effective solutions that can complement current surveillance practices. Using the theoretical foundation related to language exhibited by those afflicted by cancer, we train a neural network capable of identifying language cues that are similar to those used by self-identified cancer patients. We use a multisource dataset that includes community characteristics, cancer registries, and text data from Twitter. We benchmark performance of several algorithms. Our testing indicated 88% accuracy, and predicted scores showed a moderate (.53) correlation with observed incidence rates.

1 - How Vivid Explanation Impacts User Trust on Explainable Artificial Intelligence

Xiaocong Cui, Georgia State University, Atlanta, GA, United States, xcui4@gsu.edu

AI has revealed remarkable predictive capabilities in many domains. However, how human interpret and evaluate the AI solutions have been lack of research. By drawing on research from the explanation literature, we find explanation presentation form and individual characteristics are two factors that influence user's perceived explanation quality. Specifically, we investigate how explanation with vividness impact user's perception on AI. Furthermore, we infer that individual characteristics can moderate the relationship between information vividness and trust. We will conduct an online experiment to verify our research model.

2 - Marketing Strategy from Customer Review Mining

Yi Lin, University of Miami, Coral Gables, FL, United States, lucky_plus1@163.com, Rame Tang

More and more companies do marketing strategic decision by means of online customer review data mining. In this research we will go into the question how firms benefit from onlinr customer review mining. We will focus mainly on the working mechanism of customers behaviors online on their purchase decision.

3 - The Value of Two-sided Platform Innovations

Shaoling Katee Zhang, University of North Carolina Wilmington, Wilmington, NC, United States, Tanya Tang

Two-sided platform innovation is a significant driver to platform sustainability. Yet how a two-sided platform innovates remains virtually unexplored in literature. Drawing on the principle of platform design, this study classifies two-sided platform innovations around the core interaction enabled by the platform, including innovation in participants, innovation in value unit, and innovation in interaction process (i.e., filter, match, facilitate, and curate). This study links these innovations to platform sustainability and examines how their impact changes across a platform's lifecycle stages.

4 - Effect of Consumers' Online Community Participation Sentiments on Purchase Behaviors: From the Perspective of Peer Influence

Xuehua Liao, School of Economics and Management of Fuzhou University, Fuzhou, 510275, China, liaoxueh@mail2.sysu.edu.cn, Jinghua Xiao, Kang Xie, Changbao Lu

There are some mixed findings of the rescent research on the effect of consumers' online community participation on purchase behaviors. And most of them are taken from perspectives of information research, information processing, perception of affiliation and customer satisfaction. This research deliberates the mixed findings from the perspective of peer influence. In-depth discussions will be taken on the basis of differentiating peer types and sentiment bias types by means of data mining. Furthur, different time distance of future purchase behaviors will be taken into account. Construal level theory will be used to interpret the results.

1 - Debugging Natural Language Models

Marco Tulio Ribeiro, PhD, Microsoft Research, Seattle, WA, United States

Machine learning models for NLP often exhibit puzzling bugs, such as making different predictions for input instances that are semantically equivalent or making logically inconsistent predictions. While such behaviors are very hard to find manually, I will present two different techniques for discovering these bugs automatically in any black box model. I'll present user studies to validate that what is discovered with these techniques really are bugs, and to compare the automated techniques with human experts trying to debug on their own. Finally, for both techniques, a simple data augmentation procedure mitigates the bugs with little or no discernible impact in accuracy.

2 - A Glimpse into the Role of Data Science in Google's Healthcare Efforts

Valeria Espinosa, Google, Mountain View, CA, United States

We'll discuss a few examples of health care related projects that data scientist at Google work on.

3 - Modeling of Language, Social, and Behavioral Abstractions for Microblog Political Discourse Classification

Kristen Johnson, Purdue University, IN, United States

Social media microblogs, specifically Twitter, allow politicians to communicate with the public as events unfold and shape public discourse on various issues. By selectively using framing techniques and political slogans, politicians are able to express or conceal their stances, as well as their underlying political ideologies and moral views on policies and issues. In this talk, I will present my approach for identifying and modeling adaptable abstractions of language and behavior which can handle the ambiguous and context-independent nature of political tweets, for the prediction and classification of ideological stances, policy frames, and moral foundations present in tweets.

4 - Generalized Predictive Comparisons for Interpreting Complex Models

Marcos O. Prates, UFMG, Belo Horizonte, Brazil

Machine learning algorithms, in general, offers a class of models that are a black boxes on the capacity to understand and interpret the insights and patterns discovered. This issue can be crucial in many scenarios, as interpretability helps not only in the better understanding and in the gain of knowledge to improve processes but also in the verification of model's correctness and adequacy. We propose a methodology to interpret multiple inputs and interesting functional forms of them to learn and interpret patterns that are inferred by complex models. We demonstrate the broad scope and significance of our methodology by case studies that utilize complex models such as BART, and neural networks.

5 - Statistical and Data Envelopment Analysis of Banks Operating in India

Badri Toppur, Rajalakshmi School of Business, Kuthambakkam Post, Chennai, 600124, India, badri.toppur@rsb.edu.in

We have compared the cost efficiency and operational efficiency of nationalized banks with those of private sector banks. The pool consists of 21 public sector banks, and 21 private banks. The analysis used is Statistical analysis and Data Envelopment Analysis, on the most recent data available (for financial year 2018) with the regulatory bank - Reserve Bank of India. The DEA reports and graphs have been obtained using Frontier Analyst software.

1 - Machine Learning and Internal Audio Spectrogram Based Data Analytics for Advanced Manufacturing

Martin Byung-Guk Jun, PhD, Purdue University, West Lafayette, IN, 47907, United States, mbgjun@purdue.edu, Huitaek Yun, Hanjun Kim

This paper uses audio spectrogram and autoencoder-based machine leanring algorithm as an alternative sensing method to detect anomaly situations for manufacturing equipment. An industrial robot is used to test the method. The audio signals of a 6-axis industrial robot arm were collected. Then, spectrograms are used and then analyzed by applying Autoencoder architecture to discriminate anomalous status. To simulate normal and anomaly status, different load conditions were assigned on the robot end-effector. Two audio sensors were attached on the wrist and the base of the robot. After training, the features both from normal and anomalous status signals were tested based on reconstruction errors.

2 - Calibration of Multiple Physics-based Simulation Models with Unobservable Variables

Alaa Elwany, Associate Professor, Texas A&M University, College Station, TX, 77843, United States, elwany@tamu.edu

Physics-based modeling and simulation have been identified as high priority needs in metal additive manufacturing. Statistical calibration of these computer models using physical observations is a vital task without which one cannot confidently rely on the simulation model predictions. We address an important problem for the case when multiple physics-based simulation models are integrated, but experimental observations needed for calibration is not available for every model. We employ Bayesian networks to capture the relationship between the multiple simulation models and present a framework based on tuning variables to account for lack-of-data for the models with unobservable output.

3 - Efficient Prediction of High-fidelity Simulation Results Based on Low-fidelity Simulation in Additive Manufacturing

Lening Wang, Virginia Tech, Blacksburg, VA, 24061, United States, Xiaoyu Chen, SungKu Kang, Xinwei Deng, Ran Jin

Finite element analysis (FEA) has been widely adopted to model the thermal-field in additive manufacturing (AM) to validate the design and provide engineering insights. However, a high-fidelity FEA is usually time-consuming and cannot be readily approximated by a low-fidelity FEA due to a large disagreement. Reducing this disagreement merely based on low-fidelity FEA can significantly reduce the huge computation intensity introduced by high-fidelity FEA. This research proposes an efficient data-driven model to predict high-fidelity FEA results based on a low-fidelity FEA with satisfactory accuracy. A case study in three fused deposition modeling processes validates the proposed model.

4 - Distortion Model Transfer Between Materials in Laser Based Additive Manufacturing Systems via Bayesian Neural Networks

Arman Sabbaghi, Assistant Professor of Statistics, Purdue University, West Lafayette, IN, 47907, United States, sabbaghi@purdue.edu, Jack Francis, Ravi Shankar, Morteza Ghasri-Khouzani, Linkan Bian

Distortion in laser-based additive manufacturing (AM) systems is a critical quality control issue that is known to be material-dependent. One key challenge in AM systems is learning distortion models for new materials given past experiments on distinct materials. We present a Bayesian neural network methodology to transfer distortion models across different materials in an AM system, thereby leveraging past experiments to learn distortion models for new materials. We demonstrate the utility of this method with case studies on disks additively manufactured using Ti-6Al-4V and 316L stainless steel.

1 - A Deep Learning Application for Traffic Condition Estimations by Utilizing Data from Connected and Autonomous Vehicles

Daisik Nam, University of California, Irvine, Irvine, CA, 92617, United States, daisikn@uci.edu, Riju Lavanya, Jayakrishnan R., Inchul Yang, Woo Hoon Jeon

This paper develops techniques and algorithms to estimate various traffic indices for continuous flow by applying machine learning methodologies to data collected from Connected and Autonomous Probes. We propose a new model that considers the correlation of temporal traffic patterns between links in a network. The design attributes of the proposed algorithm make it suitable for accepting input data from multiple sensors on multiple links. Numerical experiments indicate that the proposed model can better estimate traffic condition than a model based on Edie's definition.

2 - Integrating Autonomy into Urban Systems

Cathy Wu, MIT, Cambridge, MA, United States

Self-driving cars are not expected to reach full adoption for at least another 35 years. In the meantime, how will self-driving cars change urban mobility? Leveraging and advancing techniques in model-free deep reinforcement learning and control theory, the talk explores and quantifies the potential impact of a small fraction of automated vehicles on low-level traffic flow dynamics such as congestion on a variety of important traffic contexts. Together, these optimization methods and empirical findings demonstrate how small changes in vehicles, sensors, and infrastructure can be harnessed for significant impact on urban mobility, and shed light into the future study of mixed autonomy systems.

3 - An Efficient Learning-based Network Contraction Approach for Optimal Path Finding Problem in Dynamic Stochastic Networks

Fatemeh Fakhrmoosavi, Michigan State University, East Lansing, MI, United States, moosavi@egr.msu.edu, Ali Zockaie, Khaled Abdelghany, Hossein Hashemi

The study aims to develop a network contraction approach to reduce the network size of each specific origin and destination (OD) pair in stochastic time-dependent networks. The network contraction is based on the comparison of optimistic and pessimistic solutions resulting from minimum and maximum travel time realizations of a Monte-Carlo simulation-based (MCS) approach. In this respect, the researchers propose a learning approach to utilize the information of the realizations in the initial iterations of the MCS approach. Implementation of this approach is in place for two real-world large-scale applications with significant computational improvements and an acceptable accuracy level.

4 - A Balanced Trip-based Graph Partitioning Algorithm for Dynamic Peer-to-peer Ridesharing

Amirmahdi Tafreshian, University of Michigan, Ann Arbor, MI, 48109, United States, atafresh@umich.edu, Neda Masoud

Ridesharing systems connect drivers who use their personal vehicles to travel with riders who are in need of transportation. Since each driver/rider may have several potential matches, the rideshare operator needs to make the matching decision based on a global view of the system that includes all active riders and drivers. However, the underlying ride-matching problem can become computationally expensive, when such systems operate over a large region. This research proposes a partitioning algorithm to decompose the matching problem into multiple subproblems with the goal of reducing the overall computational complexity of the problem while providing high-quality solutions in real time.

5 - Identfying Failure Reasons in Aviation Operations with Machine Learning

Burak Cankaya, Embry Riddle Aeronautical University, Daytona Beach, FL, 43235, United States

Aviation failures have the greatest impact of all transportation modes because of the vital role and economic impact. In this reseach we utilise multiple Machine Learning Algorithms to find the root causes of Aviation failures from public databases.

6 - Strategic Fleet and Crew Planning Business Applications

Aaron Glassman, Embry-Riddle Aeronautical University, Daytona Beach, FL, United States

Airline travel is growing over the time over the world. Airline operators keep growing to serve to the demand by passengers. One of the main parameters that define the size of the company are the number of aircrafts and the number of pilots working for the company. Training a pilot is one of the most time consuming type of professions. Pilots are currently in high demand and airline operators have hardships to optimize the number of pilots they have for their different fleets. It is even harder for companies to plan their future fleet and align their internal and external pilot trainings to meet the future pilotage need. In this study a mathematical model will be developed to optimally plan the future aircraft need for a commercial airline and plan the pilot training to serve to today's pilot need and future pilot needs. The research problem is very common for many commercial airlines because of the competitive demand for pilots and time consuming nature of future fleet planning and aircraft delivery and the mathematical model will serve to solve the actual need and theoretical baseline for government and private aviation industries.

AI/ML Novel Applications

Emerging Topic: Artificial Intelligence & Machine Learning

Emerging Topic Session

Chair: Sebastian Souyris

1 - Image-based Sales Forecasting for Fast-fashion Industry

Recep Yusuf Bekci, McGill University, Montréal, QC, Canada, Mehmet Gumus

In fashion industry, the image is the key motive of the preferences of customers. Our intention in this study is to leverage product images and come up with more accurate forecasts and assortments. We utilized computer vision techniques, more specifically, convolutional neural networks for retrieving the information from images and deep learning and other machine learning methods for predictions. We used e-commerce data from one of the largest Fast-Fashion retail companies in Eastern Europe.

2 - Machine Learning to Predict Audience and Schedule Shows in Television

Jaime Miranda, Universidad de Chile, Diagonal Paraguay, Santiago, 8330015, Chile, jmirandap@fen.uchile.cl, Sebastian Souyris

We predict audience television and schedule shows using ML and Integer Programming methods. Our algorithms are used by leading US networks. We present how the prediction and scheduling connect to maximize revenue.

3 - AI and Large Scale Dynamic Discrete Choice Models

Sebastian Souyris, The University of Texas at Austin, Austin, TX, 10028, United States, sebastian.souyris@utexas.com

The estimation of Dynamic Discrete Choice Models is typically very time consuming. We discuss methods to alleviate the computational burden with AI.

Methods and Models for Big Network Data Problems

Sponsored: Artificial Intelligence

Sponsored Session

Chair: Bin Zhang, University of Arizona, Tucson, AZ, 85721, United States

1 - Would Users Post More? A Hidden Markov Model of Reviewer Learning Dynamics in User-generated Content Platform

Zheng Fang, Purdue University, West Lafayette, IN, United States, Jinyang Zheng, Karthik Kannan, Guopeng Yin

Review-in-review (RIR) is a function that information technology companies apply to collect users' valuation of the generated content. Users could click "helpful", "unhelpful" button or write "review" in the form of text to the content they read. It makes RIR a method for users to express their opinion and to measure the quality of content before they read. The introduction of RIR would reshape the content generating process since users' participation in the platform would be influenced by the RIR of other users. To evaluate the effectiveness of our idea, we root our research in the context of a movie review platform. In this study, we implement the Hidden Markov Model (HMM) to capture the learning dynamics of users based on their unobserved learning patterns. We estimate the learning state of users on a daily basis and it shows significant evidence that RIR would influence users' content generating process.

2 - Prescriber and Pharmacy-Sharing Effect on Prescription Opioid Abuse: A Large-Scale Social Network Analysis

Yongcheng Zhan, University of Arizona, Tucson, AZ, 85719, United States, Bin Zhang

The misuse of and addiction to opioids is a serious national crisis that affects public health as well as social and economic welfare. The state-run prescription drug monitoring programs (PDMPs) play an important role in opioid misuse identification and prevention. We innovatively used social network analysis techniques to study PDMP data in Arizona and found there existed a statistically significant network autocorrelation effect on patients' opioid high-dose status. We found some of the prescribers were systematically more easily to prescribe opioid to patients. The identification of these prescribers with potential risky prescribing behavior may improve patient and drug safety.

3 - Predicting Cryptocurrency Movement: Analysis of Blockchain Transaction Graph

Yuxin Zhang, University of Texas at Austin, Austin, TX, United States, yuxin.zhang@utexas.edu, Rajiv Garg, Patrick L. Brockett, Linda Golden

We propose an iterative learning model to predict the evolution of blockchain transactions based on its entire transaction history. We develop various patterns of transaction subgraphs and use those to predict volume and amounts of transaction graphs in future blocks. We further develop the insights to predict the exchange rate for the cryptocurrency using the identified transaction subgraphs. Additionally, we provide discussion on how framework is valuable in understanding anomalies in blockchain enabled supply chain.

4 - Time-space Network Model and Solution Algorithm for a Variety of Vehicle Routing Problem with Backhauls

Daiki Saito, Waseda University, Tokyo, Japan, Takashi Hasuike

Multi-Trip Split-Service Vehicle Routing Problem with Backhauls is investigated in this study. This variant of the MT-VRPB allows two or more vehicles to serve a single customer with its linehaul or backhaul order. The problem is modelled on a Time-Space Network, and solved with a heuristic approach involving general-purpose numerical solver.

5 - A Network's Gender Composition and Communication Pattern Predict Women's Leadership Success

Yang Yang, Research Assistant Professor, Kellogg School of Management, Evanston, IL, United States, yang.yang@kellogg.northwestern.edu, Nitesh V. Chawla, Uzzi Brian

We use social network information drawn from 4.5 million email correspondences among hundreds of students who were placed directly into leadership positions to understand the link between graduate school social networks and placement into leadership. Using a quasi-experiment and IV2SLS regression, we find that for men, the higher centrality in the network, the higher his leadership placement will be. While centrality also predicts women's placement, high-placing women have a distinctive inner circle of women. Women whose networks resemble those of high-placing men are low-placing, despite having leadership qualifications comparable to high-placing women.

Joint Session SMA/Practice Curated: Optimization Methods in Social Media Analytics

Sponsored: Social Media Analytics

Sponsored Session

Chair: Theodore T Allen, Ohio State University, Columbus, OH, 43210-1271, United States

1 - Mapping Educational Effects from Public Service YouTube Advertising

Theodore T. Allen, Ohio State University, Columbus, OH, 43210-1271, United States, allen.515@osu.edu, Tengmu Hu

Working with an educational nonprofit called factSpread, we study the effects of advertising on YouTube with visual displays mapping topic selection, sentiment, and key word dispersion across the USA Obama-Trump counties in swing states. Levels are divided by statistical confidence. The levels of knowledge are compared before and after interventions as well as viewership.

2 - The Good, the Bad, and the Social Media: Financial Implications of Social Media Reactions to Firm-Related News

Julie Zhang, University of Massachusetts-Lowell, Lowell, MA, 01854, United States

We study the relationship between press news, user generated content, enterprise generated content, and firm performance. Employing data from press news articles, financial information, twitter posts of firms and microbloggers, we examine whether social media content reduces information asymmetry and provide additional information value to the public on news event days. Our analysis reveals several interesting findings. We find an interplay between press news articles, firm tweets, and user tweets; where firms are more active on social media and tweet more often when positive news is released on the firms than negative news.

3 - Social Media Optimization Using Deep Reinforcement Learning

Michel Ballings, University of Tennessee, Knoxville, TN, 37996, United States, Brandon Bell, Senne Van Steelandt

The goal of this study is to find an optimal social media policy. At any point in time the system recommends the next best social media action based on an online deep learning system. We devise and compare custom reward signals, and different architectures. Our system takes into account a large number of variables, including shares, likes, number of comments, content of comments, posted images, posted videos, and posted text.

4 - Acquisition Modeling in the Nonprofit Sector Based on Facebook Data

Lisa Schetgen, Ghent University, Belgium, lisa.schetgen@ugent.be, Matthias Bogaert, Matthijs Meire, Dirk Van den Poel

This research investigates whether Facebook data can be used to predict donation behavior. On the basis of individual specific Facebook data (i.e. Facebook groups, pages, and page categories), we build an acquisition model that predicts an individual's likelihood to become a donor. Three different classification algorithms are being compared, namely Bagging, Random Forest and Adaboost. Furthermore, by constructing different models, we assess the value of different Facebook features as predictors of donation behavior.

Centralized and Decentralized Control of Queueing Systems

Sponsored: Applied Probability

Sponsored Session

Chair: Philipp Afeche, University of Toronto, Toronto, ON, M5S 3E6, Canada

1 - Control of Queueing Systems with Distorted Customer Types

Dongyuan Zhan, University College London, School of Management, Gower Street, London, WC1E 6BT, United Kingdom, d.zhan@ucl.ac.uk, Arturo Estrada, Rouba Ibrahim

We study queueing systems where customers may distort their true types to shorten their waiting. For example, such systems arise in healthcare settings where patients exaggerate their own symptoms in order to be seen faster, or with public housing applications where applicants may lie on their applications to jump the queue. We investigate optimal joint inspection and routing policies in such a setting. An inspection reveals some additional information about the true types of the customer, but is costly to the inspector, and a routing policy classifies customers according to different priority levels, thus resulting in different, priority-dependent, waiting times.

2 - Dynamic Matching and Centralized Relocation in Ridesharing Platforms

Nasser Barjesteh, University of Chicago, Chicago, IL, 60615, United States, barjesteh@chicagobooth.edu, Baris Ata, Sunil Kumar

This paper studies dynamic controls in ridesharing platforms. We focus on the dynamic matching of customers and driver and centralized relocation of drivers from one area to another. We model the ridesharing system as closed stochastic processing network. We focus on the heavy traffic analysis of the network and obtain a limiting singular control problem. We solve this control problem numerically and interpret it as a pre-limit policy for the ridesharing system.

3 - Pricing, Service Design and Contracting for On-demand Public Transit

Ankur Mani, University of Minnesota, MInneapolis, MN, 63108-2432, United States, amani@umn.edu, Philipp Afeche, Sherwin Doroudi, Varun Gupta, Daniel F. Silva, Alexander Vinel

Municipalities worldwide are looking to improve the service-quality/cost trade-off for public transit by adding on-demand options to fixed-route/fixed-schedule services. Cities typically contract on-demand service operations to third-party providers. This raises the following question that we explore in this talk: How to tailor pricing, service design, and contracting decisions to a city's demand characteristics, operating objectives and constraints?

4 - Ride-hailing Networks with Strategic Drivers: The Impact of Platform Control Capabilities on Performance

Zhe Liu, Imperial College London, London, 10027, United Kingdom, Philipp Afeche, Costis Maglaras

We study the performance impact of two operational controls, demand-side admission control and supply-side repositioning control, in ride-hailing networks with strategic drivers. We characterize the system equilibria for various control regimes, show how the performance gains from these controls depend on the capacity and the network demand imbalance, and provide new results on how admission control affects drivers' repositioning decisions.

Joint Session APS/I-Sim: Advances in Simulation and Stochastic Optimization

Sponsored: Applied Probability

Sponsored Session

Chair: Henry Lam, Columbia University, New York, NY, 10027, United States

1 - Central Limit Theorems for Variance-Reduced First-Order Schemes

Uday Shanbhag, Penn. State, State College, PA, United States, udaybag@psu.edu, Jinlong Lei

We consider variance reduced stochastic gradient, accelerated gradient, and momentum methods for strongly convex stochastic programs. Under suitable assumptions on batch-sizes, we establish CLTs for each scheme. In addition, we provide an avenue for constructing confidence regions for the optimal solution .(joint work with Jinlong Lei).

2 - A New Family of Output Sensitivity Measures

Wendy X. Jiang, Northwestern University, Evanston, IL, United States, XiJiang2020@u.northwestern.edu, Barry L. Nelson, Jeff Hong

How sensitive is your simulation output to your simulation input models? Even constructing a rigorous formulation of this question is not easy. In this talk we propose a new family of output-with-respect-to-input sensitivity measures and identify two particularly useful members of it. A further benefit of this family is that there is a simple estimator of any member of the family with no additional simulation effort beyond the nominal experiment. Numerical examples are provided.

3 - A Monte Carlo Algorithm for Solving Perron-Frobenius Eigenvalue Problems

Peter W. Glynn, Stanford University, Stanford University, Stanford, CA, 94305-4026, United States

We discuss the use of sampling-based methods that exploit regenerative representations for the Perron-Frobenius eigenvalue, eigenfunction, and eigenmeasure for an irreducible non-negative operator. We discuss the central limit theory for these estimators, and their implications for rates of convergence and construction of confidence intervals. This work is joint with Paritosh Desai.

4 - Optima Transport Relaxations

Saied Mahdian, Stanford University, Stanford, CA, 94305, United States, smehdian@stanford.edu, Jose Blanchet, Peter W. Glynn

We propose a class of relaxations for the optimal mass transport problem. These relaxations involve adding an extra optimization step over a small region around one of the marginal measures and they regularize the problem. We prove the tractability of this formulation for a wide class of cost functions. We also prove out-of-sample generalization results. Our formulation provides computationally tractable algorithmic insights involving the training of Wasserstein GANs. For example, we derive, using optimality principles, a threshold-based criterion which indicates that the generating networks should be trained less often while the actor-critic iterations are increased.

1 - A Deep Learning Approach to Estimating Fill Probabilities in a Limit Order Book

Muye Wang, Columbia Business School, New York, NY, 10027, United States, Ciamac Cyrus Moallemi

Deciding between the use of market orders and limit orders is an important question in practical optimal trading problems. An important ingredient in making this decision is understanding the uncertainty of execution a limit order, that is, the fill probability or equivalently the distribution of the time-to-fill. We propose a data-driven approach based on recurrent neural networks to estimate the distribution of time-to-fill for a limit order conditional on the current market conditions. Using a historical data set, we demonstrate the superiority of this approach to several benchmark techniques.

2 - Unbiased Monte Carlo Estimator for Jump-Diffusions

Guanting Chen, Stanford University, Stanford, CA, United States, guanting@stanford.edu, Alex Shkolnik, Kay Giesecke

We develop and analyze an unbiased Monte Carlo estimator for functionals of jump-diffusion process with state-dependent drift, volatility, jump intensity and jump size. Under regularity conditions on the coefficient functions as well as the functional, we prove the unbiasedness and the finite variance property of the estimator.

3 - Optimal Execution in the Presence of a Limit Price

Seungki Min, Columbia Business School, 3260 Henry Hudson Parkway, The Arbor 3LB, New York, NY, 10463, United States, smin20@gsb.columbia.edu

We consider an optimal execution problem in the presence of a limit price. Here, the decision maker seeks to sell (respectively, buy) a given quantity of stock as quickly as possible, but is not allowed to trade at a price that is lower (resp., higher) than a given limit price. We characterize the optimal policy for this problem, and illustrate our results with numerical experiments.

1 - Is Simplicity the Ultimate Sophistication? The Superiority of Linear Pricing

Behrooz Pourghannad, University of Minnesota, Rochester, MN, 55901, United States, behrooz@umn.edu, Guangwen Kong, Tony H. Cui

This paper studies a manufacturer's choice of the contract when facing a boundedly rational retailer. In a supply chain with a fully rational retailer, a wholesale price contract cannot perform better than buy-back and revenue sharing contracts. When the retailer is boundedly rational, we find that a wholesale price contract can dominate both buy-back and revenue sharing contracts. We characterize the condition under which a wholesale price contract is the optimal choice of the manufacturer. Our findings are supported by laboratory experiments in which human suppliers choose a contract to offer to computerized boundedly rational retailers.

2 - Service Design of Non-profits that Serve Distressed Individuals: under Earmarked Funds

Priyank Arora, University of Massachusetts Amherst, Amherst, MA, 01003, United States, parora@isenberg.umass.edu, Morvarid Rahmani, Karthik Ramachandran

Non-profit organizations that serve distressed individuals are driven to not only offer a variety of services, but also engage in advisory activities to minimize mismatches between services clients receive and their true needs. We investigate the effect of earmarked funds (that can be used only for the delivery of a specific type of service) on the portfolio and service design decision of resource-constrained NPOs.

3 - Content Sharing as a Competitive Strategy in the Age of Big Data

Mariia Petryk, University of Florida, Florida, FL, United States, mariia.petryk@ufl.edu, Emre M. Demirezen, Subodha Kumar

Competition becomes more collaborative in the era of big data. Businesses reduce the accessibility barriers to their content and integrate with peers. We explore the setting of two competing firms which are both hardware and content-platform providers. We find that cross-platform integration and content-sharing may result in higher satisfaction for the customer and additional profit streams for participating firms.

Negotiation Models and Analysis of Negotiators

Sponsored: Group Decision Making and Negotiation

Sponsored Session

Chair: Danielle Morais, Universidade Federal de Pernambuco, Recife - PE, 52020-212, Brazil

Co-Chair: Adiel Teixeira De Almeida, Universidade Federal de Pernambuco, Recife PE, 50630-970, Brazil

1 - Negotiation Protocol Based on Ordered Weighted Averaging

José Leão Silva Filho, Universidade Federal de Pernambuco, Caruaru, Brazil, zeleao@gmail.com, Danielle Morais

This study proposes a Negotiation Support framework to provide the negotiator with recommendations on making decisions in a negotiation process. To input this idea into negotiation protocols, this paper suggests the use of some concepts based on OWA (Ordered Weighted Averaging), where its weights are used to evaluate rankings of offers evaluation which depends only on its ranking position (from the higher to lower). It is expected that the support provided will aid the negotiator to make decisions during the negotiation process, to learn from the elicitation and his own behavior, in other words, the results obtained can help the negotiator improving his skills in the negotiation process.

2 - Development of an Integrative Negotiation Model for the Definition of Individual Actions in the Reverse Flow Channel

Marcele Elisa Fontana, Universidade Federal de Pernambuco, rua Governador Lopo Garro, Engenho do Meio, Caruaru, 50730-285, Brazil, marcelelisa@gmail.com, Wesley Douglas Silva

An integrative negotiation model was developed to define a set of individual actions in a shared responsibility view of waste management in the reverse flow channel. The Strategic Options Development and Analysis (SODA) and Soft Systems Methodology (SSM) methods were added to structure the problem, stimulate collaboration and integrate stakeholder perspectives and preferences into a learning process. Meanwhile, linear multi-objective programming (LMOP) has found a subset of individual actions. The model reached the Pareto Frontier solution satisfactory for all stakeholders simultaneously, which allowed the strengthening of the engagement between the parties.

3 - Assessing Negotiators' Preferences with Partial Information and Flexible Elicitation

Eduarda Frej, Universidade Federal de Pernambuco, Avenida Flor de Santana 148, Recife, Brazil, eafrej@cdsid.org.br, Danielle Morais, Adiel Teixeira De Almeida, Gregory E. Kersten

The aim of this work is to incorporate preferences elicitation with partial information to negotiation processes conducted with the INSPIRE system. Negotiators preferences would be evaluated considering a structured elicitation procedure based on the FITradeoff method during the offer exchanging process, which would help them to propose their offers to the other side. The idea is to improve the actual way in which preferences are assessed in the INSPIRE system, which is based on direct rating and consequently leads to inconsistencies in the results. The FITradeoff method uses partial information about the individual's preferences to build a recommendation, which results in time and effort saving.

4 - Supporting the Negotiation Process for Watershed Committees with Value-focused Thinking Application and Neurodecision Insights

Ana Luiza Andrade, Universidade Federal de Pernambuco, Recife, Brazil, analuiza93@hotmail.com, Marcella Maia Urtiga, Danielle Morais

Members from watershed committees (WSC) in Brazil need to make decisions regarding water allocation considering the availability of water and the rainwater accumulated in the reservoirs. A framework based on Value-focused Thinking is proposed to assist decision-makers (DMs) on structuring a water allocation problem, identifying issues to be negotiated which represent the interests of different sectors of society and behavioral decision making is explored by suggesting how neuroscience tools might be used to help the decision process. The framework promotes cooperation and reduces conflicts by having DMs interact with the purpose of increasing the beneficial results of the negotiation.

Emerging Topics in Service Operations

Sponsored: Manufacturing & Service Oper. Mgmt/Service Operations

Sponsored Session

Chair: Mor Armony, New York University, New York, NY, 10012, United States

1 - The Customer May Not Always Be Right: Customer Compatibility and Service Performance

Ryan Buell, Harvard Business School, Boston, MA, United States, rbuell@hbs.edu, Dennis Campbell, Frances X. Frei

This paper investigates the impact of customer compatibility - the degree of fit between the needs of customers and the capabilities of the operations serving them - on customer experiences and firm performance. Customers interacting with retail banks and quick service restaurants report relatively consistent satisfaction across transactions with specific firms, but some customers are habitually more satisfied than others. Further analysis reveals these customer-level differences in satisfaction are explained in part by differences in customer compatibility, and that the compatibility of a firm's customer base has meaningful implications for its long-run performance.

2 - Data-driven Priority Policies to Enhance Customer Service and Revenue Opportunities Using Past Customer Interaction Information

Seyed Emadi, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, Seyed_Emadi@kenan-flagler.unc.edu, Vinayak V. Deshpande, Brett Hathaway

While companies are increasingly customizing their offerings based on their customers' history of interactions, to our knowledge, the benefits of exploiting customer history in service systems to enhance customer service or revenue opportunities has not been demonstrated empirically. We fill this gap by using call center data to study history-based priority policies, which prioritize callers based on their predicted abandonment and redialing behavior. We find that compared to a first-come, first-served policy, certain history-based priority policies can simultaneously improve average waiting times and opportunities for agents to cross-sell additional products.

3 - What's in a Constraint? on the Ambiguity of Standard Delay Targets

Itai Gurvich, Cornell Tech, New York, NY, 10044, United States, gurvich@cornell.edu, Seung bum Soh

Service providers often formulate staffing problems as satisfization ones, where staffing is minimized subject to quality of service constraints. These constraints are an indirect mechanism to model customers' disutility from delay or, at least its structure (monotone, convex and so on). Standard satisfization formulations, we show are ambiguous-they have multiple solutions, each consistent with a different delay-disutility structure. Yet, practitioners (and researchers), in choosing one out of these multiple solutions and, implicitly impose a delay disutility structure. We seek to give a principled basis for these choices.

4 - When to Send a Patient Home? The Effect of Infection Risk on Hospital Length-of-stay

Mor Armony, New York University, New York, NY, 10012, United States, marmony@stern.nyu.edu, Galit Yom-Tov

Following treatment hematology patients face an increased risk of developing an infection. If a patient remains at the hospital his risk of catching an infection is higher than at home, but once an infection develops the mortality risk at the hospital is lower than at home due to quick access to appropriate treatment. We study the problem of dynamically determining discharge times for hematology patients subject to capacity constraints. We show that in an overloaded operating regime this dynamic problem reduces to a static problem with a simple solution of two-class two-discharge thresholds. We characterize the specific optimal solutions under empirically driven time-to-infection distributions.

MSOM ServOps/Spatial Service Systems: Ride-Hailing

Sponsored: Manufacturing & Service Oper. Mgmt/Service Operations

Sponsored Session

Chair: Ilan Lobel, New York University, New York, NY, 10012, United States

Co-Chair: Francisco Javier Castro, Columbia University, New York, NY, 10027, United States

Co-Chair: Omar Besbes, Columbia University, New York, NY, 10027, United States

1 - Dynamic Spatial Pricing in Ride-hailing Markets

Chen Chen, Duke University, Durham, NC, 27708-0120, United States, cc459@duke.edu, Santiago Balseiro, David Brown

We study dynamic pricing of resources distributed over a network of locations. Customers with private willingness-to-pay sequentially request to relocate one resource, and a revenue-maximizing service provider sets a price for each request. We focus on networks with a hub-and-spoke structure, and develop a dynamic pricing policy based on a Lagrangian relaxation. We show the policy loses no more than $O(\sqrt{(\ln n/n)})$ in performance when the number of spokes n and the number of resources grow at the same rate. Finally, we extend the approach to general networks with multiple hubs and spoke-to-spoke connections. We observe strong empirical performance on realistic examples based on data from RideAustin.

2 - Optimal Subscription Design for Ride-sharing Platforms

Shreyas Sekar, Harvard University, Cambridge, MA, 02138, United States, ssekar@hbs.edu, Hongyao Ma, David C. Parkes

In ridesharing platforms with dynamic pricing, there has been widespread interest in subscription mechanisms that offer riders a locked-in price. Yet, we lack an understanding of how such schemes can co-exist with a spot market. In this work, we present a systematic investigation of subscription pricing in ridesharing. We propose a two-period model where uncertain riders choose between subscribing in advance or participating upon realization of value. Our results present many insights on the use of subscription prices. We establish conditions under which subscription mechanisms improve the social welfare at equilibrium and develop a prescriptive framework for optimally setting these prices.

3 - Information Design for Spatial Resource Competition

Pu Yang, Cornell University, Ithaca, NY, 14850, United States, py75@cornell.edu, Krishnamurthy Iyer, Peter Frazier

Information design arises in economic settings where a better-informed sender designs mechanisms to share information with a group of agents to improve their total welfare. Motivated by ride-sharing, we study a setting where agents competing for a resource decide whether to explore a new location with unknown resource level. We (i) characterize the equilibrium strategies of agents under public and private information sharing mechanisms; (ii) study the structure of the optimal public and private mechanisms and (iii) demonstrate via analysis and numerical examples that randomized mechanisms achieve higher welfare than deterministic ones when agents' behaviors have negative externalities.

4 - Spatial Capacity Planning

Francisco Castro, Columbia University, Columbia School of Business, New York, NY, 10027, United States, Omar Besbes, Ilan Lobel

We study the link between capacity and performance for a service firm with spatial operations such a ride-hailing platform. We propose a state-dependent queueing model that captures spatial frictions and spatial economies of scale through the service rate. We find that SRS staffing does not balance server utilization and customer wait times in spatial systems. In them, pickup times increase the system load, and are an endogenous source of extra workload that leads the system to only operate efficiently if there is enough supply-demand imbalance. In heavy traffic, we show that to balance utilization and wait times a higher safety factor is required, proportional to the offered load to the power of 2/3.

Sponsored Session

Chair: Robert Swinney, Duke University, Durham, NC, 27708, United States

1 - Designing Rewards-based Crowdfunding Campaigns for Strategic Contributors

Soudipta Chakraborty, Duke University, Durham, NC, 27708, United States, sc390@duke.edu, Robert Swinney

We study a model of rewards-based crowdfunding via a platform like Kickstarter. The creator of a crowdfunding campaign solicits pledges from contributors, and if total pledges exceed a pre-determined threshold, the campaign is successful, the creator receives all pledges and each contributor receives a reward. Otherwise, the campaign fails and contributors are refunded their pledges. We determine how a creator should design her campaign when the uncertainty of receiving the reward makes contributors behave strategically.

2 - Pricing and Prioritizing Differentiated Services When Customers Learn Socially

Gad Allon, University of Pennsylvania, Philadelphia, PA, 19104, United States, gadallon@wharton.upenn.edu, Koushiki Sarkar, Achal Bassamboo

Dissemination of information via social networks play a critical role in modern decision-making. We model the effects of social information in service differentiation under a queuing setting. We consider a profit-maximizing firm serving two groups of customers, where the customers observe service reviews from a subset of customers in each period and use that information to decide their action for the coming period. We study the equilibrium to which the system converges under social learning and compare it to the equilibrium under individual learning.

3 - Predicting Human Discretion to Adjust Algorithmic Prescription: A Large-scale Field Experiment in Warehouse Operations

Jiankun Sun, Northwestern University, Evanston, IL, 60201, United States, jiankun-sun@kellogg.northwestern.edu, Dennis Zhang, Haoyuan Hu, Jan A. Van Mieghem

Conventional optimization algorithms that prescribe order packing instructions focus on bin volume utilization yet tend to overlook human behavioral biases. We observed the order fulfillment operations at Cainiao, the logistics division of Alibaba. We found that for more than 5.8% of packages, workers deviated from the algorithmic prescriptions typically by switching to a larger bin than recommended. This switch increases packing time as well as material and environmental costs. We identify such behavioral biases, and propose a new algorithm that predicts human discretionary behavior using machine learning techniques to pro-actively adjust the algorithmic prescription.

4 - Verification of Truth in News: Crowd Sourcing vs. Platform Intervention

Jiding Zhang, The Wharton School, University of Pennsylvania, Philadelphia, PA, 19104, United States, jiding@wharton.upenn.edu, Senthil Veeraraghavan, Laurens G. Debo

Fake news and unverified information reduce new quality, and informedness of citizenry. One possible way of controlling the spread of fake news is encouraging readers to inspect and flag fake news. In this paper, we model readers as Bayesians who update their belief of a news article being untrue, based on the total readership and the time of the news being alive (not yet flagged). They are strategic in deciding whether to inspect the news. The platform inspects the news at the same time. We examine conditions where the inspection from the crowd/platform is more effective.

CC- Room 307

New Topics on Inventory Management

Sponsored: Manufacturing & Service Oper. Mgmt/Supply Chain

Sponsored Session

Chair: Shan Li, City University of New York, New York, NY, 10010, United States

1 - The Guaranteed Service Model as a Heuristic for the Stochastic Service Model

Yinan Liu, Lehigh University, Bethlehem, PA, 19144, United States, Lawrence V. Snyder

The stochastic service model (SSM) and the guaranteed service model (GSM) are the two most widely used models for optimizing base-stock levels in multi-echelon inventory systems. The SSM is generally more realistic but the GSM is more tractable. We study the question of whether the GSM is a good heuristic for systems that operate under SSM conditions. We conclude that the GSM usually a good heuristic in serial and assembly systems but may perform poorly in distribution systems. We also examine the question of how to set the demand truncation bound in the GSM, a critical parameter that has a large effect on the performance but is often overlooked in the modeling analysis.

2 - Optimizing Inventory in a Two-stage System

Kangye Li, Lehigh University, Bethlehem, PA, United States, kangyeli92@gmail.com, Lawrence V. Snyder

We formulate a two-stage inventory model with stochastic demand. Our model optimizes the inventory decisions at the downstream stage, assuming that the upstream stage follows its own policy and may experience stockouts. Using dynamic programming, we optimize the inventory policy numerically. We also consider a special case in which the upstream stage follows a base-stock policy and discuss the theoretical implications for the optimal policy at the downstream stage. Our study is motivated by the more complex problem of optimizing inventory in a multi-stage supply chain when some stages do not follow the optimal policy, as in the beer game.

3 - Stockout Risk Estimation and Repair Expediting for Repairable Spare Parts

Mustafa Hekimoglu, Kadir Has University, Istanbul, Turkey, mustafa.hekimoglu@khas.edu.tr, Gurhan Kok, Mustafa Sahin

Stockouts of repairable spares usually lead to downtime costs of capital products. Advance indicators of future stockouts combined with optimal repair expediting policies are crucial for achieving target service levels with reasonable costs. In this study, we first developed an advance stockout risk quantifier for repairable spare parts. Tests with empirical data indicate that the method is accurate in 83% of cases. Second, we developed an parameter optimization algorithm for a threshold-type repair expediting policy under minimum service level and maximum expedited demand constraints. The algorithm is proved to be efficient for finding optimum policy parameters in our empirical tests.

4 - The Commitment Conundrum of Inventory Sharing

Shan Li, City University of New York, Baruch College, New York, NY, 10010, United States, shan.li@baruch.cuny.edu, Kay-Yut Chen

In recent years, inventory sharing, in addition to the traditional within-firm model, also appears in the sharing-economy model where different firms can share their inventory via an internet platform. Two prominent issues, shaping the behaviors of inventory sharing systems, are the commitment of the transfer price and the commitment to share. In this paper we investigate, through a behavioral lens, the decisions of transfer price, order quantity and the resulting supply chain efficiency in different transshipment commitment scenarios. This study provides implication on the design of the commitment rules in decentralized inventory sharing platforms.

What You Need to Know to be a Scholarly Teacher

Sponsored: Education

Sponsored Session

Chair: Joseph Szmerekovsky, North Dakota State University, Fargo, ND, 58108-6050, United States

Co-Chair: Tim O Peterson, North Dakota State University College of Business, Fargo, ND, 58108, United States

1 - What is Scholarly Teaching?

Tim O. Peterson, Professor of Management, North Dakota State University, Faro, ND, United States, tim.o.peterson@ndsu.edu

This portion of the session will define scholarly teaching as compared to the scholarship of teaching. Next the idea of scholarly teaching will be applied to observed Teaching><Learning Connections which are problems or opportunities seen in a learning environment. I will share two examples from my teaching experience. One of those experiences was a problem in the learning process. The other was an opportunity to improve on the Teaching><Learning Transaction.

2 - What You Need to Know About Adult Learning to Be a Scholarly Teacher

Claudette M. Peterson, Associate Professor, North Dakota State University, Fargo, ND, United States, claudette.peterson@ndsu.edu

Academics and other professionals in operations research and analytics can increase the impact of their research, knowledge, and technical training by optimizing how they share that knowledge with others. Technical education usually does not include courses related how adults learn. This portion of the session will apply principles of adult learning to scholarly teaching in order to more effectively interpret and communicate the meaning of information for others. In addition, I will share research-based findings regarding the development of emerging adults (traditional college students) and how learning changes according to their stage of development.

3 - Scholarly Teaching to Support Systems Thinking and Information Systems

Jon W. Beard, Iowa State University, Ames, IA, United States, jwbeard@iastate.edu

In recent years we have become swamped with information. A thoughtful, systematic, yet flexible, approach is needed to cope with this wealth of information. This portion of the session uses Systems Thinking to explore scholarly teaching as a context to organize, interpret, and work with the information available and to recognize where gaps exist in our knowledge and understanding. A more systematic approach is especially important in this era of wide and growing use of information systems. Both real-world examples and material from the management literature are used to explore ways to employ scholarly teaching to support teaching, learning, and decision making.

4 - Scholarly Teaching in Transportation Science and Technology

Raj Bridgelall, Assistant Professor & Program Director, North Dakota State University, Fargo, ND, United States

Transportation systems has recently been undergoing a rapid transformation that integrate advancements in sensing, artificial intelligence, and communications technologies. The motivations classify into push and pull factors that drive business gains and address societal needs, respectively. In the context of scholarly teaching, the instructor developed a new push-pull-impedance framework to motivate and organize learning about factors that affect the evolution and adoption of smart transportation. The author will provide a specific example of using the framework to demonstrate learning about the potential societal impacts and implications of connected vehicle technology.

Emerging Topics in Supply Chain Risk Management

Sponsored: Manufacturing & Service Oper. Mgmt/iFORM

Sponsored Session

Chair: Panos Kouvelis, Washington University in St. Louis, Saint Louis, MO, 63130-4899, United States

Co-Chair: Danko Turcic, Washington Univ. in St. Louis, St. Louis, MO, 63130, United States

1 - Retailer Initiated Inventory-based Financing

Weiming Zhu, IESE Business School, Avenida Pearson 21, Barcelona, 08034, Spain, wzhu@iese.edu, Wei Luo

We study an innovative financing scheme in which a large retailer, such as JD.com, provides inventory-based lending to a small retailer selling through her own brick-and-mortar channel. We analyze the effectiveness of such financing scheme through a Stackelberg game, and explore its impact on operational decisions and contract design. Using datasets obtained from JD Finance, we provide evidence for small retailer's stockpiling behavior and verify the predictions from the theoretical results through reduced-form analysis.

2 - Operational Risk Management: Optimal Inspection Policy

Yuqian Xu, University of Illinois at Urbana-Champaign, Champaign, IL, 61820, United States, Youngsoo Kim

This paper studies the design of optimal inspection policy for financial service firm that aims to mitigate operational risk losses. The firm takes recurring inspections to check operational risk events, and the employee exerts efforts to avoid paying penalty for operational risk events. Both random and deterministic policies are considered.

3 - An Investigation of the BMW Supply Chain

Danko Turcic, Washington Univ. in St. Louis, Olin Business School, St. Louis, MO, 63130, United States, Panos Markou, Panos Kouvelis, Daniel S. Corsten

This paper develops a theory that explains how automakers apportion raw material cost fluctuations that their suppliers face, and empirically tests that theory using a unique data set of procurement contracts at BMW.

4 - Hedging Input Commodity Price Risk: An Equilibrium View

Stathis Tompaidis, University of Texas-Austin, McCombs School of Business, IROM Department, Austin, TX, 78712-1179, United States, Stathis.Tompaidis@mccombs.utexas.edu, Hamed Ghoddusi, Sheridan Titman

We present a model of a commodity processing chain with endogenously determined input and output prices and characterize the effectiveness of hedging policies that employ forward contracts on the price of the input. The minimum variance hedge depends on operational characteristics, such as the convexity of the production function, and on economic variables - the elasticity of supply and demand and the relative magnitude of input and output risks. The hedge can change over time as capacity utilization in the industry changes. We evaluate the effectiveness of our model for the crude oil to refined products supply chain.

CC- Room 310

Joint Session MSOM/SUS/Practice Curated: Operations Management and the Sustainable Development Goals

Sponsored: Manufacturing & Service Oper. Mgmt/Sustainable Operations

Sponsored Session

Chair: Andre Du Pin Calmon, INSEAD, Fontainebleau, 77300, France

Co-Chair: Gonzalo Romero, University of Toronto, Rotman, Toronto, ON, M4K 3H6, Canada

1 - Eliminating Lead Poisoning through Value Chain Innovation

Erica Plambeck, Stanford University, Graduate School of Business, Knight Management Center, Stanford, CA, 94305-7298, United States

Informal recycling of lead acid batteries and coloring (adulteration) of turmeric with lead chromate cause widespread lead poisoning in Bangladesh. Profitable value chain innovation could largely eliminate that lead poisoning.

2 - Non-ownership Business Models for Solar Energy

Safak Yucel, Georgetown University, Georgetown University, Washington, DC, 20057, United States, safak.yucel@georgetown.edu, Vishal Agrawal, Beril L. Toktay

In addition to the traditional sales model, solar power companies, such as SolarCity and Sunrun, have introduced innovative non-ownership business models: leasing and power purchase agreements. We study a solar power company's business model decisions and how they affect the environment, customers, and utility firms.

3 - Effective Distribution Models for the Base of the Pyramid

Olumurejiwa Fatunde, MIT, Cambridge, MA, United States, Andre Du Pin Calmon, Joann de Zegher, Gonzalo Romero

We partner with Essmart, a social enterprise distributing life-improving durable goods to Base of the Pyramid (BoP) consumers in India, to gather data and examine the current behavior of BoP retailers. Our goal is to conduct a field experiment to test the effectiveness of various distribution models.

4 - Timely After-sales Service and Technology Adoption: Evidence from the Off-grid Solar Market in Uganda

Amrita Kundu, London Business School, Regent's Park, PhD Office - MSO, London, NW1 4SA, United Kingdom, akundu@london.edu, Kamalini Ramdas

We empirically examine the extent to which timely after-sales service impacts technology adoption in emerging markets. We find: (1) Timely after-sales service is a strong driver of technology adoption in emerging markets, (2) Customers share their service experience with others in their network. This word-of-mouth mechanism explains our first result.

CC- Room 3A

Bayesian Learning and Decision Making

Sponsored: Decision Analysis

Sponsored Session

Chair: Canan Ulu, Georgetown University, Washington, DC, 20057, United States

1 - Learning and Information Spillover in a Technology Supply Chain

Wenxin Xu, The Hong Kong Polytechnic University, M507n, Hong Kong, Hong Kong, wenxin.v.xu@polyu.edu.hk, Dharma Kwon, Wenjie Tang

We consider a setting where one technology provider introduces her new technology to two manufacturers, who adopt this technology into their products. The manufacturers then release their products to the same consumer market and price compete with each other. The success of the new technology is uncertain, but the manufacturers can learn the profitability from some public speculations of how acceptable products carrying the new technology might be to the consumer market, or the performance of an earlier adopter. We examine the adoption timing strategies of the manufacturers as well as the pricing strategy of the technology provider.

2 - Markdown Policies for Demand Learning with Forward-looking Customers

Hongfan Chen, University of Chicago, Chicago, IL, 60615, United States, hongfan.chen@chicagobooth.edu, John R. Birge, N. Bora Keskin

We consider the markdown pricing problem of a firm that sells a product to a mixture of myopic and forward-looking customers. The firm faces an uncertainty about the customers' forward-looking behavior, arrival pattern, and valuations for the product, which we collectively refer to as the demand model. Over a multiperiod sales season, the firm sequentially marks down the product's price and makes demand observations to learn the underlying demand model. Contrary to common intuition, we show if the customers are forward-looking, the firm's profit loss due to demand model uncertainty can asymptotically vanish.

3 - Learning from Clickstream Data in Online Retail

Bharadwaj Kadiyala, University of Utah, Clear Water Bay, Kowloon, Salt Lake City, UT, United States, Dorothee Honhon, Canan Ulu

E-tailers now have the resources to record the sequence of clicks their online customers make, also known as their clickstream. Such detailed browsing information reveals customer preferences and, as such, can be used to improve product assortment and display decisions over time. In this paper, we consider a Bayesian framework to study how an e-tailer can draw inferences about customer preferences using clickstream and sales data, for utilitarian and hedonic product categories.

4 - Decision Making under Impending Regime Shifts

Canan Ulu, Georgetown University, Washington D.C., DC, United States, Sreyaa Guha, Matthias Seifert

We study insurance and asset pricing in dynamic environments when there is an impending regime shift. Risk attitudes and probability judgments of a regime shift occurring affect such pricing judgments. Integrating prospect theory with system neglect hypothesis to evaluate pricing judgments we predict distinct patterns of under- and overreaction in stable environments with noisy signals and in unstable environments with precise signals, which, we argue, are driven by the fourfold pattern of risk attitude postulated by prospect theory and by system neglect in probability judgments, respectively. We identify desirability of regime shifts as a critical factor that contributes to these patterns.

Judgments and Forecasts

Sponsored: Decision Analysis

Sponsored Session

Chair: Asa Palley, Indiana University, Bloomington, IN, 47405, United States

1 - Is It Better to Elicit Quantile or Probability Judgments to Estimate a Continuous Distribution?

Saurabh Bansal, Penn State University, 405 Business Building, State College, PA, 16801, United States, sub32@psu.edu, Asa Palley

Two elicitation methods are commonly used to obtain subjective probability distributions from experts: (i) quantile judgments, and (ii) cumulative probability judgments, but a consensus on which format yields more accurate distribution estimates has not been reached. We report results from a series of experiments conducted with participants with a range of quantitative backgrounds to compare these elicitation formats for a variety of variables. We find that quantile judgments provided more accurate estimates of the full distribution, and identify the mechanism that drives this relative performance benefit.

2 - Naturalistic Noisy Signals

Blair Flicker, University of South Carolina, Columbia, SC, 75208, United States, blair.flicker@moore.sc.edu, Elena Katok

Private information (an important operational concept) is often conveyed via noisy signals in models and experiments. The typical "mechanical" implementation (adding mean-zero noise to a quantity of interest) does not reflect how many signals are conveyed. We propose a method for sending "perceptual" signals in laboratory experiments via informative images.

3 - Individual and Group Weighting in Crowd Forecast Aggregation

Pavel Atanasov, Pytho LLC, Brooklyn, NY, 19103, United States, pavel@pytho.io, Stephen Bennett, Andres Abeliuk, Mark Himmelstein, Fred Morstatter, Aram Galstyan, David Budescu, Mark Steyvers

Weighting individual estimates based on past performance has proven effective in improving the accuracy of aggregated forecasts. We examine nested designs, in which forecasters belong to groups that may vary in average accuracy. Using data from forecasting tournaments and related simulations, we examine algorithms that simultaneously infer weights at the individual and the group level, and define the conditions in which nested weighting improves accuracy compared to individual-only weighting. In general, nested weighting is expected to produce an accuracy boost when performance varies widely across groups, and when individual accuracy measures are sparse or unreliable.

4 - Leveraging Group Discussion to Boost the Wisdom of Crowds

Chengcheng Zhai, Kelley School of Business, Bloomington, IN, United States, zhaic@iu.edu, Asa Palley, Ruth Beer

Combining information from multiple individuals can improve judgment accuracy. We leverage a stylized analytical model of information to derive candidate aggregation procedures under different assumptions about how information is shared before and after a group discussion, and study these methods in an experiment.

5 - 20 Years of Expert-elicited Probability Assessments at Eli Lilly: Approach and Analysis of Performance

Charles Persinger, Senior Research Advisor, Eli Lilly & Company, Lilly Corporate Center, Indianapolis, IN, 46285, United States, cpersinger@lilly.com

Assessments of the probability of success of projects in drug development inform individual project decisions and portfolio management. Since 1997 Lilly has used an expert panel to assess these probabilities using an approach informed by the field of Decision Analysis. We discuss Lilly's approach and present analyses of more than twenty years of data from these probability assessments.

Applications in Big Data Analytics

Emerging Topic: Practice Curated Track

Emerging Topic Session

Chair: Grace Lin, Asia University, Wufeng, 41354, Taiwan

Co-Chair: Roger R Gung, University of Phoenix, Phoenix, AZ, 85048, United States

1 - Big Data Analytics-Based Pricing and Revenue Management

Roger R. Gung, University of Phoenix, Phoenix, AZ, 85048, United States, Chun-Che Huang

Using big data for better pricing is a critical strategy for revenue management. Nowadays commodity and service industries have been developing big data analytics-based pricing systems to optimize profit or return on investment. In this talk, we present a general methodology for pricing and revenue management using big data analytics. The methodology includes statistical models for predicting customer buying behavior and an optimization framework for optimizing profit or return on investment.

2 - Optimize Teaching Performance Using Big Data Analytics

Roger R. Gung, University of Phoenix, Phoenix, AZ, 85048, United States, Jixiang Fang

Evaluating teachers' effectiveness in the educational industry is difficult, because teachers might be assigned with high or low performing students. In order to filter out the impact of student quality factor, we developed the mixed effect model using student attributes as fixed effect and teacher impact as random effect. Based on the model outputs, teachers' performance ranking is used to guide the classroom assignment, so as to optimize overall student learning outcome. The variable ranking is used as the training guidance for low performing teachers.

3 - A Supply Chain Based Credit Rating Methodology

Grace Lin, Asia University, Wufeng, 41354, Taiwan, Han-Chao Lee, Ko-Yang Wang

Traditional credit rating methodology is mostly based on financial data. Due to limited financial data availability, it's been very challenging for small and medium businesses to get loans from financial organizations. In this talk, we will present a new credit rating methodology based on a combination of financial information and the supply chain information as well as other market and environmental information. We will also share the design of our 3rd party blockchain based supply chain financing platform.

E-marketing

Contributed Session

Chair: Xin Wang, Stonehill College, Easton, MA, 02357, United States

1 - Enabling the Smart Grid Services with the Decentralized Blockchain Architecture

Lida Haghnegahdar, SUNY, Binghamton, NY, United States, Zahra Amjadi

Advanced forecasting, future energy storage, dynamic pricing, load management, and responding to the demands of the energy market are some of the characteristics of a smart grid. A reliable, service-oriented, secure, efficient, and cost-effective the modern smart grid system is always desired. One way to achieve these objectives is to implement a blockchain approach, with the emphasis of smart grid data flow monitoring and data center management. Such an approach provides a suitable environment with tools to manage and access data effectively. The objective of this paper is to introduce the power blockchain model: an energy system model based on enabling accessible service to computing resources.

2 - Complaint Handling in Consumer Finance – The Case of the Three Credit Bureaus

Zsolt Ugray, Associate Professor, Utah State University, Logan, UT, United States, zsolt.ugray@usu.edu, Xiaoyan Xu

Consumers are often mistreated by large financial companies. The three large credit bureaus are a special case by themselves as no citizen can avoid dealing with them if they want to participate in any mortgage, loan, bank, credit card or other financial transactions. Using quantitative and text analysis methodologies, we investigate how the three large credit bureaus respond to consumer complaints.

3 - Service Investment Strategy for Competing Online Retailers with Social Network in Multiple Periods

Ruiqi Hou, Dr., University of Science and Technology of China, Hefei, China, qiqimath@gmail.com

We investigate the impact of investments in service with two competing online retailers. Customers diffuse between different markets, based on purchasing experience and under the effect of social network. At the beginning of a period, the firms decide on investments costs. We distinguish two variants: one where both firms decide autonomously (Nash equilibrium) and a leader-follower (Stackelberg game) case. For both cases, the optimal investment cost, optimal profit per unit time and the effect on market share are calculated. We also solve the two cases without social network. Numerical analysis shows that both firms invest more when social network exists and higher profits are gained.

4 - A Social Media Analysis of Measles' Outbreak in 2018-2019

Xin Wang, Stonehill College, 320 Washington Street, Easton, MA, 02357, United States, Zhong Justin Ren

We apply social media analytics to study public reactions to the recent measles outbreak. The social media analytics methodologies employed include descriptive, content and network analyses. The descriptive analysis describe the users' characteristics and basic behavior profiles. The content analysis reveal the major topics and extract the hidden semantics from the text. The network analysis explore the degree of a user's connections as well as help identify the most influential users. This research not only will provide insights on public sentiments toward vaccination but also shed light on how policy makers can understand and influence public attitude toward disease prevention measures.

CC- Room 4C-2

E-commerce

Sponsored: Service Science

Sponsored Session

Chair: Jingran Zhang, Marshall University, Huntington, WV, 25755, United States

1 - Third-party Sellers Strategic Decision-making in E-commerce Platform

Jingran Zhang, Marshall University, Huntington, WV, 25755, United States, zhangjin@marshall.edu

E-commerce has grown rapidly. Leading online retailers, such as Amazon and JD.com, has changed the traditional retailing models, along with the remarkable sales growth. Online retailer platform provides three strategies to process and fulfill customer orders: sell by and ship from the first party retailer, sell by third-party sellers and ship from the first-party website or sell by and ship from the third-party retailers. A strategic decision model between the last two methods is established by forecasting demand and the value of replenishment and quick response to customer orders to maximize the profit of third-party sales and order fulfillment performance.

2 - Assigning Online orders to Fulfillment Centers for Optimal Inventory Positioning

Sevilay Onal, University of Illinois Springfield, Springfield, IL, United States

Online orders have been assigned to fulfillment centers based on the proximity of the delivery location. We analyzed methods to improve multi-period fulfillment performance by forecasting future orders for optimal inventory positioning.

3 - The Digital Marketplace: The Past, Present and Future Future

Lasse Mitronen, Aalto University School of Business, Espoo, Finland, lasse.mitronen@aalto.fi, Mikko Hänninen, Stephen K. Kwan

We are now witnessing increased disintermediation in the retail value-chain as new entrants, like digital marketplaces, are applying advances in information technology to create novel combinations of value to end-customers, simultaneously converging the front and backstage activities in the service system. We develop an understanding of how digitalization is enabling firms to integrate the online and offline channels and succeed in creating a more coherent and personalized customer experience. We argue that a new stage in the service system is emerging where the online and offline domains are converging to create a more coherent customer experience.

4 - Managing Queues with Static Delivery Guarantees

Mehdi Hosseinabadi Farahani, University of Texas at Dallas, Richardson, TX, United States, mehdi@utdallas.edu, Milind Dawande, Ganesh Janakiraman

We study the problem of managing queues in online food ordering services where customers, who place the order online and pick up at the store, are promised a common due-date lead time. The objective is to minimize the long-run average earliness and tardiness costs incurred by the customers. Due to the difficulty of implementing sophisticated policies in practice, we investigate the performance of easily-applicable heuristic policies. Our results show that a simple policy, that starts serving a customer as soon as the time remaining to the due date falls below a threshold, yields near-optimal solutions.

5 - Scheduling Truck Docking Times and Package Loading for Outbound Operations

Daniel Chen, Amazon.com, Seattle, WA, United States, chonglic@amazon.com, Mehmet Tolga Cezik

In a warehouse, packages are sent to the outbound dock and require loading onto trucks going to the appropriate destination with deadlines. These packages can be loaded directly (preferable but less flexible), or stacked for later loading. Loading can only occur when trucks are docked at a limited number of doors. We propose a MIP to assign trucks to doors and schedule both types of loading. The MIP solves quickly on real-world problems for an online retailer. Under some simplifying assumptions, the formulation simplifies to one with a totally unimodular constraint matrix, which implies that the LP relaxation is integral. We further investigate various other improvements and extensions to the model.

Stochastic Models of Manufacturing & Service Operations Management

Sponsored: Service Science

Sponsored Session

Chair: Xu Sun, University of Florida, Gainesville, FL, 10027, United States

1 - Beyond Safety Drivers: Staffing a Teleoperations System for Autonomous Vehicles

Andrew Monroe Daw, Cornell University, Ithaca, NY, 14853, United States, amd399@cornell.edu, Robert Hampshire, Jamol Pender

Driverless vehicles promise a host of societal benefits including improved safety, increased accessibility, greater productivity, and higher quality of life. As this new technology approaches widespread public deployment, both industry and government are making provisions for teleoperations systems in which remote human agents provide assistance to driverless vehicles, including via human-in-the-loop artificial intelligence systems. We address the problem of staffing such a remote support center. By establishing a novel connection from queueing models to storage processes, we determine staffing levels by calculating the probability that the workload in the system exceeds capacity.

2 - Perfect Sampling for Hawkes Queue

Xinyun Chen, Chinese University of Hong Kong, Shenzhen, Shenzhen, China, chenxinyun@cuhk.edu.cn

Motivated by the applications in social media, healthcare and financial systems, queueing models with autoregressive arrivals, such as the Hawkes or shot-noise-driven arrivals, have been studied in several recent works. So far, there is no analytic approach to compute the stationary distribution of single-server queues. In this talk, we propose a perfect sampling algorithm that generates i.i.d. samples exactly following the stationary distribution of single-server queues with autoregressive arrivals.

3 - Generalized Fractional Brownian Motion as Scaling Limits of Nonstationary Shot Noise Processes

Guodong Pang, Penn State University, Industrial and Manufacturing Engineering, University Park, PA, 16802, United States, Murad Taqqu

We introduce generalized fractional Brownian motions which preserve the self-similarity property but instead have non-stationary increments. They are defined via the integral representations with respect to Gaussian random measures. They arise naturally as scaling limits for a class of nonstationary shot noise processes with power-law variances. The proof of weak convergence relies on new maximal inequalities for stochastic processes in the space D whose upper bounds involve finite set functions with a superadditive property, instead of finite measures in the classical results (Billingsley, 1999). (This is joint work with Murad Taqqu at Boston University.)

4 - Differentiating the Quality of Service in Multiclass Queues: A Queue-ratio-based Scheduling Policy

Xu Sun, Assistant professor, University of Florida, Gainsville, FL, United States, Yunan Liu

Motivated by large-scale service systems, we study a multi-class queueing system having time-varying arrivals. Our objective is to devise appropriate staffing and scheduling policies to achieve differentiated service levels for each customer class. For this purpose, we propose new staffing and scheduling policies that are both time dependent (coping with the time variability in arrival pattern) and state dependent (capturing the stochastic variability in service times and arrival times). Effectiveness of our proposed staffing and scheduling policies is substantiated by heavy traffic limit theorems (as the system scale increases).

Forecasting II

Contributed Session

Chair: Zhengde Zhao, University of Washington, Seattle, WA, 98105, United States

1 - Employment Analysis Based on Panel Data in the Background of Industry 4.0

Rongyan ZHOU, CentraleSupélec, Université Paris-Saclay, Gif-sur-Yvette, France, rongyan.zhou@centralesupelec.fr, Julie Stal-Le Cardinal

Although Industry 4.0 will bring a great of convenience to our lives, the unemployment brought by new technologies is concerned by the public. Whether the new jobs created by the industry 4.0 can make up for the losses caused by technical unemployment; what is the difference in the new job opportunities created by investment of industry 4.0 in different regions is focused in this paper. The panel data is applied in the study, and the study found that the EU faced the most serious unemployment problem brought by the industry 4.0 technologies, followed by NAFTA, then SAARC and East Asia. Furthermore, the study describes the possible reasons of the difference and proposes future research directions.

2 - An Adaptive Event Prediction Clustering Algorithm Based on Bayesian Network

Xing Yang, Tsinghua University, Beijing, China

Forecasting events requires expressing event temporal-causal relationships and capturing event temporal natures. First, different event types perform variously in temporal property. Second, relative time and absolute time should exist together to express them. Third, small data requires clustering for precise prediction in some cases. To address them, we present an adaptive clustering algorithm based on Bayesian network by measuring the event similarities, and divide events into two types, timing events and random events. Experimental results show that by clustering similar events and classifying event types, the proposed model leads to a significantly improved performance.

3 - Demand Forecasting of New Products Based on Model-driven Clustering and Feature-based Classifying

Yun Zhou, School of Management, Zhejiang University, Hangzhou, China, zhouyun2015@zju.edu.cn, Weihua Zhou, Hongyan Dai

This paper proposes a forecasting framework for new products based on model-driven clustering. Traditional studies generally adopted feature-, category-based or data-driven clustering to group products for model training. However, these frameworks mainly focus on operationalizing "similarity" between products, which is not necessarily between the model of products. We attempt to approach model "similarity" by leveraging the correlation vector with each component generated from the pair of demand and a single feature for clustering and feature-based classifying. The results indicate that the proposed clustering algorithm significantly outperforms other extant clustering methods.

4 - HHT-enhanced Machine Learning Methods for Financial Time Series

Zhengde Zhao, PhD Student, University of Washington, Seattle, WA, United States, zdzhao16@uw.edu, Tim Leung

In this paper, Hilbert-Huang transform (HHT), consisting of empirical mode decomposition (EMD) and Hilbert spectral analysis, is modified to analyze non-stationary financial time series, and is integrated into machine learning techniques, such as support vector machine (SVM), to identify useful features for prediction. Examples show that HHT-enhanced method can significantly improve the accuracy of prediction.

Tutorial: Scheduling an Overloaded Multiclass Many-Server Queue with Impatient Customers

Emerging Topic: Tutorials

Emerging Topic Session

1 - Scheduling an Overloaded Multiclass Many-Server Queue with Impatient Customers

Amy R. Ward, University of Chicago, Marshall School of Business, Chicago, IL, 90089-0809, United States, Amber L. Puha

We describe a fluid model with time-varying input that approximates a multiclass many-server queue with time-varying arrivals (specifically, the multiclass G/GI/N +GI queue). We show how to use the restricted fluid model with constant input rate to approximately solve scheduling control problems for a queue with constant arrival rate. The key is to characterize the invariant states of the fluid model, because they typically provide an approximation to the mean steady-state behavior of the queue under a wide range of scheduling policies. The resulting fluid control problem motivates using a static priority scheduling policy when the objective is to minimize the long run average abandonment rate, but may motivate a different class of scheduling policies when there are also holding costs. We end by discussing several open problems.

Applications in Military Operations Research

Sponsored: Military and Security

Sponsored Session

Chair: Paul Goethals

1 - Saturation Analytics for Security Operations

Paul L. Goethals, United States Military Academy, West Point, NY, 10996, United States, paul.goethals@westpoint.edu, Natalie M. Scala, Nita Yodo

In the contemporary security environment, the role of sensor technology in both the physical domain and the realm of cyberspace is growing in necessity and popularity. One factor that relates to the ability and effectiveness of sensors is the principle of saturation - it is tied directly to the attributes of detection capability, target identification, and analytical precision. This research examines several potential methods for modeling and measuring the degree of saturation and describes its application to several different security problems.

2 - Empowering Election Judges to Secure Our Elections

Natalie M. Scala, Associate Professor and Graduate Program Director, Towson University, Dept. of e-Business and Technology Management, Towson, MD, 21252, United States, natalie.scala@gmail.com, Dehlinger Joshua

Training modules for polling place elections equipment are developed in partnership with a mid-sized Maryland county using optical scanners, and the efficacy and effectiveness of the educational modules are tested via a pre-post test and usability study. The goal of the research is to empower Election Judges to take a proactive role in back-end security and encourage widespread adoption of threat training. The more aware Election Judges are to threats that pertain to their specific role and the more knowledgeable they are to properly handle these threats, the more secure our elections can be.

3 - Implementing a Vision to Create and Deploy the Airport Risk Assessment Model (aram)

Robert T. Brigantic, Pacific Northwest National Laboratory, Richland, WA, 99352, United States, robert.brigantic@pnnl.gov

This presentation will review a vision enabled by our sponsor, U.S. Department of Homeland Security, Science and Technology Directorate (DHS S&T), and established by working closely with our partner stakeholders (e.g., TSA) for a tool that quantifies the risk from terrorist threats at U.S. airports and then optimally deploys resources to reduce this risk. This tool is called the Airport Risk Assessment Model (ARAM). This presentation will also outline the methods for quantifying key risk components, along with resource effectiveness. Finally, we will discuss the potential extensions of ARAM to other domains that are applicable to a range of military and civilian critical infrastructure systems.

4 - Hybrid Optimization for Radio Channel Assignment in Contested Environments

Paul J. Nicholas, Chief Scientist, Large-Scale Analytics Systems, Johns Hopkins University Applied Physics Laboratory, Laurel, MD, United States, Karla L. Hoffman

The ability to efficiently allocate electromagnetic channels for radio communications is heavily dependent on co-channel interference, i.e., interference between two radios using the same channel. This problem is even more challenging in contested or degraded EM environments, as may be experienced in combat or dense urban environments. We present a new hybrid method to solve this problem via local neighborhood heuristics and constraint programming techniques, and provide performance results using realistic data sets from a large U.S. Marine Corps operational scenario.

Quantum Computing Architectures & Algorithms

Sponsored: Optimization/Computational Optimization and Software

Sponsored Session

Chair: Aaron Lott, D-Wave Systems, Palo Alto, CA, 94303, United States

1 - Challenges and Opportunities for Hybrid Quantum-classical Discrete Optimization and Machine Learning

Masoud Mohseni, Google Inc, Vencie, CA, 90291, United States

We present an overview of our progress on quantum-inspired and quantum-assisted algorithms for optimization and machine learning at Quantum AI Lab at Google. We develop an end-to end quantum-inspired discrete optimization platform that uses an interplay of local and non-local thermal updates to sample from inaccessible low-energy states of spin-glass systems that encode high-quality solutions of certain hard combinatorial optimization. We introduce several new techniques for quantum circuit learning on Noisy Intermediate-Scale Quantum (NISQ) processors. We perform metalearning on parameterized quantum circuits via black-box optimization with classical recurrent neural networks. We develop layerwise learning on quantum neural networks to tackle the problem of vanishing gradients. We provide several applications of such quantum models for characterization of the dynamics of NISQ devices and classification of quantum data.

2 - Quantum-Inspired Optimization

Helmut Katzgraber, Principal Research Manager, Microsoft Quantum, Redmond, WA, United States

The advent of the first useful quantum computing devices has resulted in an arms race with classical algorithms on traditional computing hardware. While near-term quantum devices might revolutionize, e.g., optimization and quantum chemistry, tackling many applications will directly depend on either hybrid or purely classical computing techniques. Inspired by these recent exciting developments, a variety of new classical algorithms have emerged. In this talk an overview on quantum inspired methods and their applications is given.

3 - Putting Quantum Computing in your Toolbox

Aaron Lott, D-Wave Systems, Palo Alto, CA, 94303, United States

We describe relationships between statistical physics and quantum annealing to provide insight into areas where quantum computation and simulation may play a role in solving industrial problems. We present an overview of the D-Wave 2000Q quantum computer architecture and discuss several optimization and machine learning algorithms that have been designed to leverage current and future D-Wave quantum computers. We outline the suite of software tools and cloud services that are available for researchers and developers to start assessing the technology today.

4 - Quantum Algorithms for Solving Mathematical Programming Problems

Pooya Ronagh, 1QBit, Waterloo, ON, Canada

We present quantum algorithms for solving mathematical programming problems that arise frequently in machine learning applications such as structured prediction. We analyze the computational complexity of these algorithms and show that they achieve a quadratic speed-up in the size of the label space for the structured prediction task. We also show that our method attains an almost optimal convergence rate with respect to the precision of the solution. We use these theoretical results and additional numerical experiments to assess the applicability of our quantum algorithms to solving real-world problems.

Advances in Mixed Integer Nonlinear Programming

Sponsored: Optimization/Integer and Discrete Optimization

Sponsored Session

Chair: Robert Hildebrand, VIrginia Tech, Blacksburg, VA, 24061, United States

1 - New Relaxations for Composite Functions

Mohit Tawarmalani, Purdue University, West Lafayette, IN, 47907-2076, United States, Taotao He

We introduce a composite relaxations that are a tighter way to relax composite functions than factorable relaxations. The relaxation encodes inner functions structure in terms of underestimators and their bounds and uses this structure to relax the outer-function. We show that these relaxations are particularly suitable for MIP discretization. Moreover, these relaxations provide ways to improve relaxation hierarchies.

2 - Compact Disjunctive Approximations to Nonconvex Quadratically Constrained Programs

Hongbo Dong, Assistant Professor, Washington State University, Pullman, WA, 98103, United States, Yunqi Luo

We propose a new approach, namely Compact Disjunctive Approximation, to approximate nonconvex Mixed-Integer Quadratically Constrained Programs (MIQCPs) to arbitrary precision by convex MIQCPs (i.e., all quadratics are convex). The novelty of our method lies in a compact lifted mixed-integer formulation for approximating the (scalar) square function, exploiting rotational symmetry in a similar fashion as in the BenTal-Nemirovski approximation of second-order-cones. We implement (with JuMP+Julia) an adaptive refinement algorithm. Promising numerical results are reported on several classes of synthetic instances used in the literature.

3 - A Convex Integer Programming Approach for Optimal Sparse PCA

Guanyi Wang, Georgia Institute of Technology, 500 Tech Parkway, Atlanta, GA, 30332, United States, gwang93@gatech.edu

Principal component analysis (PCA) is a widely used dimensionality reduction method. To enhance additional interpretability, it is desirable to consider the sparse principal component analysis (SPCA). Unlike the PCA, the SPCA is NP-hard. Heuristics cannot give guarantees via dual bounds. The dual bounds are only available via hard-to-scale semidefinite programming (SDP) relaxations. We present a framework that involves solving convex integer programs (CIP) to produce dual bounds. We show worst-case results on the quality of the dual bound obtained by CIP. In practice, the CIP model performs better than worst-case performance, and SDP bounds on some cases with shorter running-time.

4 - On Exact Solution and Feasibility of Polynomial Optimization Problems

Daniel Bienstock, Columbia University, New York, NY, 10027, United States, derdano@gmail.com

We discuss ongoing work on solving polynomial optimization problems. A surprisingly tricky issue is the relationship between accuracy (feasibility) and correctness of solution. We discuss theoretical work and computational experiments.

Data-driven Optimization Under Uncertainty

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Hoda Bidkhori, University of Pittsburgh, Pittsburgh, PA, United States

1 - A Study of Distributionally Robust Multistage Stochastic Optimization

Yongpei Guan, University of Florida, Gainesville, FL, 32611, United States, Kezhuo Zhou, Jianqiu Huang

In this paper, we focus on a data-driven risk-averse multistage stochastic programming (RMSP) model considering distributional robustness. We optimize the RMSP over the worst-case distribution within an ambiguity set of probability distributions constructed directly from historical data samples. We reformulate it into a deterministic equivalent that contains a series of convex combination of expectation and conditional value at risk (CVaR), which can be solved by a customized stochastic dual dynamic programming (SDDP) algorithm.

2 - Tight and Tractable Bounds for Weighted Sums of Dependent Bernoulli Random Variables

Arjun Ramachandra, Singapore University of Technology and Design, Singapore, 439959, Singapore

Sums of Bernoulli random variables have been extensively studied as part of probability theory with applications in computer science, risk management, reliability systems, stochastic programming and graph theory. In this talk, we investigate tight bounds on weighted sums when the variables are dependent and the weights are any real numbers while assuming univariate and tree-type bivariate marginal information of the n variables. We develop tight bounds in these cases.

3 - Effective Scenarios in Multistage Distributionally Robust Optimization with Total Variation Distance

Guzin Bayraksan, The Ohio State University, 210 Baker Systems, 1971 Neil Avenue, Columbus, OH, 43210-1271, United States, bayraksan.1@osu.edu

Traditional multistage stochastic optimization assumes the underlying probability distribution is known. However, this distribution is often not known or cannot be accurately approximated. Distributionally robust optimization (DRO) addresses this issue by considering a set of possible probability distributions. We study multistage convex DRO with a finite set of scenarios, where the distributional ambiguity is modeled stagewise by the total variation distance on conditional probability distributions. We illustrate that not all but only some scenarios have an effect on the optimal value, and we formally define this notion. We illustrate the results on finance and energy problems.

4 - Data-driven Optimization with Distributionally Robust Stochastic Dominance Constraints

Chun Peng, PhD, HEC Montreal, Montreal, QC, Canada, chun.peng@hec.ca, Erick Delage

Optimization with stochastic dominance constraint (SDC) has been received increasing attentions on managing risk. Instead of knowing fully probabilistic description of uncertain outcome, we propose a novel optimization framework for problem with distributionally robust SDC in a data-driven context, which can be presented as a two-stage robust model under Wasserstein metric. Applying finitely adaptive policy, we derive the adaptive robust optimization formulation that motivates us to develop an iterative partition-based Branch-and-Bound method. We also propose several extended variants under different distributional settings and verify our framework for portfolio selection problem.

5 - Online Assortment Optimization with Reusable Resources

Xiao-Yue Gong, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, xygong@mit.edu, Vineet Goyal, Garud N. Iyengar, David Simchi-Levi, Rajan Harish Udwani, Shuangyu Wang

We have n capacitated substitutable reusable products. A sequence of users arrive. We offer an assortment St to each user, who selects a product based on their preference model (potentially adversarially chosen) and uses the product for some periods. The usage times of a product is i.i.d and only depends only on the product selected. We want to maximize the expected cumulative revenue. We show that a simple myopic policy achieves at least 1/2 the expected revenue of the optimal policy that knows the sequence of users and the usage time distributions with a coupling queue technique. We also show the assumption that the usage time only depends on the product is necessary for a nonzero competitive ratio.

6 - Tight and Tractable Bounds for Weighted Sums of Dependent Bernoulli Random Variables

Arjun Kodagehalli Ramachandra, Singapore University of Technology and Design, Singapore, arjun_ramachandra@mymail.sutd.edu.sg

In this talk, we investigate tight bounds on weighted sums of Bernoulli dependent variables assuming univariate and tree-type bivariate marginal information of the n variables. When only univariate information is available, we exploit the structure in the dual of an exponential size primal, suitably transforming it to a compact LP. An interesting application of split dependency among variables is presented. A special case of weights results in tight bounds for the occurrence of at least k out of n events for which we recreate an existing closed form result using order statistics. A similar concept is used to improve on best known analytical bounds with pairwise independence.

Optimization Techniques in Power System Applications under Uncertainty

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Bowen Li, University of Michigan, Lemont, IL, 48105, United States

1 - Truly Robust AC Optimal Power Flow

Line A. Roald, University of Wisconsin-Madison, Madison, WI, 87544, United States, Dongchan Lee, Konstantin Turitsyn, Daniel K. Molzahn

We consider the robust AC OPF problem, where particularly challenging aspect is to guarantee existence of a solution to the non-linear, implicit AC power flow equations for all possible realizations of the uncertain power injections. We use so-called convex restrictions, which defines a convex inner approximation to the AC feasible region in power injection space (without limiting assumptions on nodal power balance), and devise a sequential solution algorithm which provide rigorous robustness guarantees. Empirical results using a variety of test cases demonstrate the algorithm's fast convergence, scalability, and limited conservativeness.

2 - Efficient Algorithm for Stochastic Climate Adaptation Problem on Coastal Power Networks

Bowen Li, Argonne National Laboratory, 9700 Cass Avenue, Lemont, IL, 60439, United States, bowen.li@anl.gov, Russell Bent, Ruiwei Jiang, Johanna Mathieu, Harsha Nagarajan

We develop an efficient algorithm to solve a multi-period power system adaptation problem (i.e., bus hardening and expansion) that is scalable in the problem dimension and scenario size. The objective of this problem is to improve the resiliency of coastal power networks facing potential threats of sea level changes and storm surge events. The problem is difficult to solve because it contains a large number of constraints and discrete variables. To speed up the computation, we improve the problem formulation and develop a decomposition and cutting-plane based algorithm using the special ordered sets.

3 - Solving Chance-constrained Optimal Power Flow Problems via a Smooth Nonlinear Approximation

Alejandra Pena-Ordieres, Northwestern University, C210, Evanston, IL, 60208, United States, Daniel Molzahn, Line Roald, Andreas Waechter

The increasing levels of fluctuating renewable energy make managing uncertainty in power injections an important concern to power system operators. In this talk, we address this uncertainty via a chance-constrained formulation of the optimal power flow problem. We avoid making assumptions on the distribution of the uncertainty by using a sample-based approach. Our formulation is designed to satisfy all the constraints simultaneously for a pre-determined probability. We use an Sl1QP-type trust-region algorithm that has proven to perform well in practice and that scales favorably with the number of samples. We illustrate the performance of our method on the 118-bus MATPOWER network.

4 - Stochastic Defense Against Complex Grid Attacks

Mauro Escobar, Columbia University, New York, NY, 10027, United States, me2533@columbia.edu, Daniel Bienstock

We describe stochastic defense mechanisms designed to detect sophisticated grid attacks involving both physical actions (including load modification) and sensor output alteration. The initial attacks are undetectable under a full AC power flow model even assuming ubiquitous sensor placement, while hiding large line overloads. We first show that such attacks can be computed in the case of large transmission systems. The defensive techniques apply network control actions that change voltages in a random fashion, and additionally introduce (random) low-rank corrections to covariance matrices.

Optimization in Unmanned Aerial Systems (UAS) Applications

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Yanchao Liu, Detroit, MI, 48214, United States

1 - Integrated Routing and Charging Scheduling for Autonomous Electric Aerial Vehicle System

Jun Chen, San Diego State University, 5500 Campanile Drive, San Diego, CA, 92182, United States, jun.chen@sdsu.edu

Autonomous electric aerial vehicles (EAVs) are expected to bring fundamental changes to city infrastructures and daily commutes. Currently, the EAVs, including the delivery drones and the air taxi, are all under limited battery endurance and vertiport capacity, which is insufficient for long-range commutes. In this paper, we propose a joint scheduling methodology to handle the optimal routing and charging tasks for the Autonomous EAV System. By considering the unique characteristics of EAVs, the joint optimization problem can effectively utilize the energy. The problem is formulated as a mixed integer linear program and solved by a distributed algorithm based on dual decomposition method.

2 - Safety-assured Routing Automation for High-density Omnidirectional UAV Traffic

Yanchao Liu, Assistant Professor, Wayne State University, Detroit, MI, 48214, United States, yanchaoliu@wayne.edu

This paper presents a mixed integer programming (MIP) model that comprehensively characterizes all relevant aspects of the business scenario, and proposes an optimization-driven, progressive algorithm for online fleet dispatch operations. The model endogenously accounts for geometry and mobility and therefore permits dynamic input of order information with arbitrary pickup and delivery locations. The model is augmented with special constraints and an artificial objective function which effectively relay the system states between successive time horizons. The algorithm is validated through simulation case studies and is shown to meet the design objectives.

3 - Optimal Landing Algorithms for UAV Fleets

Zhenyu Zhou, Wayne State University, Detroit, MI, United States, zyzhou@wayne.edu, Yanchao Liu

Drone fleets will be increasingly used for delivery and urban air mobility. To prove airworthiness of fleet operations, it is critical to have in place a robust fleet-level failsafe mechanism. This paper investigates the problem of quickly landing a large fleet of drones as if in emergency. We consider factors such as the spatial distribution of drones, capacity of the landing depots and inter-vehicle collision avoidance. The problem is formulated as a series of optimization models, and fast and robust algorithms are proposed for near real-time solution. We furthermore integrate the algorithms in a fleet management platform and verify their practical performance in simulated and real flight tests.

4 - Path Planning for Package Delivery UAVs in Urban Environment

Fang He, City University of Hong Kong, Tat Chee Avenue, Kowloon, Hong Kong
Fang He, Shanghai Jiao Tong University, Shanghai, China, Lishuai Li, Yongbiao Lv, Lei Zhang, Gang Xiao

Using unmanned aerial vehicles (UAVs) for autonomous package delivery in urban environment is emerging. It offers a range of benefits, e.g. reduced road congestion and pollution, enabling agile services. However, a key challenge is how to scale up operations in high-density urban areas. We propose a modified Lazy Theta* grid search algorithm, coupled with a priority ordering algorithm and an iterative searching scheme, to solve the multi-path planning problem between depots considering complex urban environment. Simulation shows good performance in terms of quality and speed. The proposed method is also tested in real urban maps.

Transportation, Operations III

Contributed Session

Chair: Darweesh E Salamah, Mississippi State University, McCain, Mississippi State, MS, 39763-9542, United States

1 - Transportation Improvement for Patients at a Safety Net Family Health Center

Jia Guo, University of Texas-Austin, Austin, TX, United States, jia.guo@utexas.edu, Jonathan F. Bard, Douglas Morrice

In this work, we investigate options to improve transportation service for patients at Family Health Center (FHC) with UT Medical School in San Antonio. We first analyze data and conduct logistic regressions to find the impact of transportation factors on cancellations and late arrivals. Next, we develop a TSP to find shuttle routes within the poorest neighborhood of FHC. The solution includes number of vans in each route. In addition to regular multiple TSP constraints, the IP model includes van capacity, route time limit and shuttle inter-arrival time. The objective is to minimize weighted sum of vans fixed cost and travel cost. With FHC data, we can achieve cost reduction of more than $12,000 per month.

2 - Impact of Time Window Policies on Supply Chain Costs

Arpan Rijal, Erasmus University, Rotterdam, Netherlands, rijal@rsm.nl, Marco Bijvank, René De Koster

Sustainability driven time window policies have significant impact on secondary transportation cost for retailers. In this work, we reassess time window policies' impact more holistically. A joint approach that considers warehouse operations and transport planning can mitigate the negative financial impact of time window policies for retailers.

3 - Layout Design for the Future Container Terminals

Amir Gharehgozli, California State University Northridge, Northridge, CA, 91330, United States, Nima Zaerpour, Rene B.M. De Koster

Container terminals play an important role in transporting containerized goods in global supply chains. The number of containers handled in container terminals has increased astronomically. To accommodate and handle the increasing number of containers entering and leaving container terminals, their layout has seen several changes in the past decades. New layouts and designs require smaller footprint and ensure faster, cheaper, and more efficient transfer of containers. This paper studies the transition of layout design from traditional to automated and future container terminals.

4 - Dynamic Relocation of Vehicles and Staff for a One-Way-Car-Sharing Service

Ricardo Giesen, Pontificia Universidad Catolica de Chile, Santiago, Chile, giesen@ing.puc.cl, Diego Strobl, Mathias A. Klapp

Many Car-Sharing (CS) companies operate one-way car-sharing (OWCS) services, which pose many operational challenges. In particular, due to imbalances in demand patterns, some stations receive more departures than arrivals and others the opposite, so if cars are not relocated, some arriving customers will not find cars available at their origin station, or they might not find a place where to park at their desired destination. In this work, we formulated a dynamic optimization model to jointly relocate cars and staff, and proposed different real-time operational strategies. These strategies were tested in different scenarios and one instance with real data from the OWCS AWTO in Santiago, Chile.

5 - Multiobjective Team Orienteering Problem with Time Windows for Energizing Microgrids with Electric Vehicles and Hybrid Electric Vehicle During Natural Disaster Sabotage

Darweesh E. Salamah, PhD. Student, Mississippi State University, Mississippi State, MS, United States, darweesh.salamah@gmail.com, Mahdi Fathi, Mohammad Marufuzzaman

We study the routing and scheduling of power delivery until the arrival of relief in disaster management. And we introduce a new energizing for on-demand energy sharing locations based on EV/HEV during the disaster and post-disaster relief. We consider multiple profits from different aspects associated with each on-demand energy location (ODEL) for each EV/HEV owners. We formulate energizing microgrids with EVs/HEVs during natural disaster problem MOTOPTW to find the set of Pareto optimal solutions to support managers to make decisions. Moreover, we apply a multi-objective evolutionary algorithm based on decomposition and constraint programming (CPMOEA/D) for MOTOPTW optimization.

Embracing Non-smoothness and Non-convexity in Statistical Learning

Sponsored: Optimization/Nonlinear Programming

Sponsored Session

Chair: Yudong Chen, Cornell University, Ithaca, NY, 14853, United States

1 - Inference and Uncertainty Quantification for Noisy Matrix Completion

Yuxin Chen, Princeton University, Princeton, NJ, United States, Jianqing Fan, Cong Ma, Yuling Yan

Noisy matrix completion aims at estimating a low-rank matrix given only partial and corrupted entries. Despite substantial progress in designing efficient estimation algorithms, it remains largely unclear how to assess the uncertainty of the obtained estimates. We develop a simple procedure to compensate for the bias of the widely used convex and nonconvex estimators. The resulting de-biased estimators admit nearly precise non-asymptotic distributional characterizations, which enable optimal construction of confidence intervals for, say, the missing entries. As a byproduct, our de-biased estimators provably achieve full statistical efficiency.

2 - When Nonconvexity Meets Nonsmoothness

Ju Sun, Stanford University, Stanford, CA, United States, sunju@stanford.edu

Most applied problems we encounter can be naturally written as nonconvex optimization, which in theory is hard to solve globally. In practice, however, simple methods often work surprisingly well in finding high-quality solutions. In this talk, I will describe recent efforts in bridging the mysterious theory-practice gap. I will highlight a family of smooth nonconvex problems that can be solved to global optimality using simple methods. The discovery does not cover nonsmooth functions, which are increasingly popular in modern applications. I will introduce tools from nonsmooth analysis, and show how nonsmooth, nonconvex problems can also be analyzed and solved in a provable manner.

3 - Low-rank Matrix Recovery with Composite Optimization: Good Conditioning and Rapid Convergence

Damek Davis, Cornell University, ITHACA, NY, 14850, United States, Yudong Chen, Dmitriy Drusvyatskiy, Lijun Ding, Vasilis Charisopoulos, Mateo Diaz

The task of recovering a low-rank matrix from its noisy linear measurements plays a central role in computational science. Smooth formulations of the problem often exhibit an undesirable phenomenon: the condition number, classically defined, scales poorly with the dimension of the ambient space. In contrast, we here show that in a variety of concrete circumstances, nonsmooth penalty formulations do not suffer from the same type of ill-conditioning. Consequently, standard algorithms for nonsmooth optimization, such as subgradient and prox-linear methods, converge at a rapid dimension-independent rate when initialized within constant relative error of the solution.

4 - Large Scale Machine Learning via Gradient Sketching

Amirali Aghazadeh, Stanford University, Stanford, CA, United States, amiralia@stanford.edu

Feature selection is an important challenge in large-scale machine learning. Recently the explosion in the size and dimensionality of real-world datasets has posed a severe challenge to standard feature selection algorithms. Today, it is not uncommon for datasets to have billions of dimensions. At such scale, even storing the feature vector is impossible. In this talk, I will present MISSION, a novel framework for ultra large-scale feature selection that performs stochastic gradient descent while maintaining an efficient representation of the features in memory using a Count-Sketch data structure.

1 - Most Closeness-Central Clique Problem

Farzaneh Nasirian, UMass Boston-College of Management, Boston, MA, United States, farzaneh.nasirian001@umb.edu, Foad Mahdavi Pajouh, Balabhaskar Balasundaram

This talk addresses the most closeness-central clique problem in which we are interested in detecting the most accessible clique in a graph. We use two metrics of maximum and total distance to a clique for measuring its accessibility resulting in two variants of the most closeness-central clique problem. For each of these two problems, we address the computational complexity, develop a new mixed 0-1 integer programming formulation, and propose the first combinatorial branch-and-bound algorithm. The computational performance of these exact algorithms is studied on a test-bed of real-life instances.

2 - The Most Degree-central Clique Problem

Haonan Zhong, University of Massachusetts-Boston, Boston, MA, 02188, United States, Foad Mahdavi Pajouh, Oleg A. Prokopyev

The most degree-central clique problem is to find a clique of maximum degree centrality in a graph. We addressed the computational complexity of this problem and proposed a series of theoretical foundations to build a combinatorial branch and bound algorithm for its solution. The performance of our proposed algorithm is tested on real-life networks and random graphs.

3 - The Longest Induced Path Problem: Formulations and Extensions.

Dmytro Matsypura, University of Sydney, Sydney, Australia, dmytro.matsypura@sydney.edu.au, Alexander Veremyev, Oleg A. Prokopyev

The longest induced path problem is defined as the problem of finding a subset of vertices of the largest cardinality such that the induced subgraph is a simple path. In contrast to the polynomially computable graph diameter, this problem is NP-hard. In this talk, we focus on exact and heuristic solution approaches for the problem and its generalisations. We conduct computational experiments to evaluate the performance of the proposed solution methods.

4 - A Network Optimization Approach for Flood Risk Mitigation in Coastal Cities Facing Climate-change-induced Sea Level Rise

Donald J. Jenkins, University of Massachusetts-Boston, Boston, MA, United States, Donald.Jenkins001@umb.edu, Foad Mahdavi Pajouh, Paul Kirshen

Incomplete climate change knowledge is presenting decision-makers in coastal cities with challenges to protect their cities in a deeply uncertain situation. This research extends existing flood cost-benefit optimization research by modeling a coastal region lacking an existing flood mitigation infrastructure with an at-risk network grid to evaluate optimal cost-benefit strategies. Expected flood costs are included using a loss function that samples a range of sea level scenarios, while investment costs are for overall infrastructure development. The problem is modeled as a large-scale mathematical program that optimizes for the minimal overall expected costs.

5 - An Integer Programming Formulation of the Key Management Problem in Wireless Sensor Networks

Maciej Rysz, Miami University, Oxford, OH, 32578, United States, Guanglin Xu, Alexander Semenov

With the advent of modern communications systems, much attention has been put on developing methods for securely transferring information between constituents of wireless sensor networks. To this effect, we introduce a mathematical programming formulation for the key management problem, which broadly serves as a mechanism for encrypting communications in networks. In particular, an integer programming model of the q-Composite scheme is proposed and utilized to distribute keys among nodes of a network. Numerical experiments demonstrating the effectiveness of the proposed model are conducted.

1 - Heuristics for a Nested Cluster Ratio Cut

Victoria Ellison, Duke University, Durham, NC, 27705, United States, victoria.ellison@duke.edu

Building upon the strengths of the minimum cluster ratio cut problem and hierarchical clustering algorithms, we propose an optimization-based divisive hierarchical clustering algorithm for networks. This algorithm uses a proposed extension of the cluster ratio cut. Introducing a parametric linear programming based heuristic for this algorithm, we compare the utility of our proposed algorithm to that of the minimum nested cluster ratio cut and an iterative application of the minimum cluster ratio cut when applied to gene expression co-association networks.

2 - Finding the Length of the Longest Path in Perturbed Directed Acyclic Graph

Golshan Madraki, Assistant Professor, Clarkson University, Potsdam, NY, 13617, United States, gmadraki@clarkson.edu

This research proposes an efficient algorithm called the Improved Structural Perturbation Algorithm (ISPA) to find the length of the longest path in a structurally perturbed Directed Acyclic Graphs (DAG) where several edges are simultaneously deleted and added. ISPA can update all the length of the affected nodes through a single pass. The mathematical prove for ISPA is provided. The application of ISPA is transformative to problems which can be presented by a structurally perturbed DAG. To illustrate the application of this paper, ISPA is used in the scheduling problem.

3 - Network Optimization Model for Intermodal Empty Railcars Relocation

Juliana Arango, Clemson University, Clemson, SC, United States, arangoc@g.clemson.edu

Given unbalanced supply and demand for empty railcars in the hubs on the intermodal railroad network, the need for empty railcars repositioning is inevitable. Every week hubs request inbound and outbound empty trains for specific dates and times to manage this unbalance. Our objective is to satisfy the maximum number of these request at a minimum cost, considering traveling times between location, availability of empty railcars, and the capacity of nearby storage locations that can be used for holding empty sets. To do so, we formulated a capacitated multi-commodity network flow model.

4 - Network Interdiction with Asymmetric Cost Uncertainty

Di H. Nguyen, PhD Student, Clemson University, Clemson, SC, 29670, United States, din@clemson.edu, Cole Smith

We study a network game between a leader and a follower having opposing objectives. The follower aims to travel from source to sink incurring the least amount of cost possible. The leader's goal is to increase the expected value of the shortest-path cost. In this game, the leader will inflict attacks on some arcs in the network, incurring extra costs on a set of arcs. In this problem, the leader only knows the cost distributions, not each arc's exact value. The follower, after observing the attacks made on the network, obtains perfect information and traverses using a least cost path.

Sponsored Session

Chair: Cheng Guo, University of Toronto, Toronto, ON, M5T 1K5, Canada

1 - Logic-based Benders Decomposition and Binary Decision Diagram Based Approaches for Stochastic Distributed Operating Room Scheduling

Cheng Guo, University of Toronto, Toronto, ON, M5T 1K5, Canada, cguo@mie.utoronto.ca, Merve Bodur, Dionne Aleman, David Urbach

The distributed operating room (OR) scheduling problem aims to find an assignment of surgeries to ORs across collaborating hospitals that share their waiting lists and ORs. We propose a stochastic extension of this problem where surgery durations are considered to be uncertain. In order to solve the stochastic model, we develop an enhanced decomposition approach that utilizes logic-based Benders cuts and binary decision diagram based cuts. Our computational experiments on a real dataset illustrate that the stochastic formulation generates robust schedules, and that our algorithm improves the computational efficiency.

2 - A Logic-based Benders Decomposition Algorithm for Two-stage Stochastic Planning and Scheduling Problem

Ozgun Elci, Carnegie Mellon University, Tepper School of Business, Pittsburgh, PA, 15217, United States, oelci@andrew.cmu.edu, John Hooker

We focus on two-stage stochastic planning and scheduling problems (SPSP). We treat the scheduling decisions as recourse decisions since they are made after the uncertainty is revealed. We develop an exact logic-based Benders decomposition (LBBD) algorithm and benchmark it against an integer programming solver and the integer L-Shaped method. Our results show the effectiveness of our LBBD algorithm. We provide insight as to why the integer L-shaped method fails to perform well in solving the instances of SPSP. Our study exemplifies the importance of exploiting problem structure and the use of decomposition-based hybrid methods in solving two-stage stochastic programs with integer recourse.

3 - Stochastic Task Scheduling with Heterogeneous Agents

Carlos Henrique Cardonha, Research Staff Member, IBM Research, Sao Paulo, 04007-005, Brazil, carlos.cardonha@gmail.com, Andre Augusto Cire

We investigate a variation of the machine scheduling problem motivated by an application on an information technology service line, where tasks have release times and due dates; also, processing times are uncertain and depend on the seniority level of the assigned agents. The proposed solution strategy consists of a logic-based Benders decomposition which uses a stochastic variant of sequencing decision diagrams to minimize expected delay costs. We discuss numerical results on a real-world dataset comparing our algorithm with scheduling algorithms and policies used in practice.

4 - Adaptive Partition-based Stochastic Dual Dynamic Programming Algorithms for Multistage Stochastic Linear Programs

Murwan Siddig, Clemson University, Clemson, SC, 29634, United States, msiddig@g.clemson.edu, Yongjia Song

We extend the adaptive partition-based approach for solving two-stage stochastic programs with fixed recourse to the multistage setting. The proposed algorithm integrates the adaptive partition-based strategy with a popular approach for solving multistage stochastic programs, Stochastic Dual Dynamic Programming (SDDP), via different tree-traversal strategies in order to enhance its computational efficiency. Our numerical experiments on a hydro-thermal power generation planning problem show the effectiveness of the proposed approach.

Computational Aspects of Multistage Stochastic Programming

Sponsored: Computing

Sponsored Session

Chair: Harsha Gangammanavar, Southern Methodist University, Dallas, TX, 75275, United States

1 - Sequential Decision Making Affected by Partially Observed Exogenous Forces

Reid Bishop, PhD Candidate, Georgia Institute of Technology, Atlanta, GA, United States, rrb@gatech.edu, Chip White

We consider a class of sequential decision-making problems under uncertainty with multiple levels of effects — a partially observed, exogenous modulation process that affects the dynamics of a completely observed, controllable state process. We model this broad class of problems as a specially structured partially observed Markov decision process (POMDP) and call it the modulated POMDP or M-POMDP. The M-POMDP has many application areas, from inventory control to healthcare systems to dynamic pricing. We show that the M-POMDP inherits value function and optimal policy function structure from its completely observed MDP analog and allows for specialized approximate solution procedures.

2 - Dynamic Freight Routing for Less-than-truckload Carriers under Demand Uncertainty

Ahmad Baubaid, Georgia Institute of Technology, Atlanta, GA, United States, Natashia Boland, Martin Savelsbergh

Less-than-truckload (LTL) carriers consolidate the freight of multiple shippers by routing shipments through a number of intermediate terminals on their way from origins to destinations. Each day, carriers pick up new shipments whose origins, destinations, deadlines, and quantities are unknown beforehand. Carriers make daily routing and consolidation decisions for all on-hand shipments while taking into account the future impacts of those decisions. We formulate this problem as a Markov Decision Process and discuss the use of the computational methods of Approximate Dynamic Programming to solve large instances which are intractable using exact methods due to the curse of dimensionality.

3 - A Lagrangian Dual Decision Rule Approach to Multistage Stochastic Service System Scheduling

Merve Bodur, University of Toronto, Toronto, ON, M5S 3G8, Canada, bodur@mie.utoronto.ca, Maryam Daryalal

Multistage stochastic programs can be approximated by restricting policies to follow decision rules. In this talk, we first review the recently introduced Lagrangian dual decision rules (LDDRs) for multistage stochastic integer programs (MSSIPs). Then, we propose an MSSIP model for the integrated staffing and scheduling problem for service systems, and apply the LDDR approach to get feasible policies. We provide computational results evaluating the performance of the discussed MSSIP framework in this setting and compare our MSSIP model with an existing two-stage approximation.

4 - Stochastic Dynamic Linear Programming: A Sequential Sampling-based Multistage Stochastic Programming Algorithm

Harsha Gangammanavar, Southern Methodist University, Department of EMIS, Dallas, TX, 75275, United States, harsha@smu.edu, Suvrajeet Sen

We present a sequential sampling approach for multistage stochastic linear programming problems that we refer to as the stochastic dynamic linear programming (SDLP) algorithm. Our approach uses samples that increase in size during the course of the algorithm to construct statistical estimates of the value functions. The algorithm uses regularization at non-terminal stages and a piecewise-affine solution discovery scheme to identify incumbent solutions. The SDLP algorithm is shown to provide asymptotically convergent value functions and an optimal policy, with probability one.

Sponsored Session

Chair: Albert Berahas

1 - Trust-Region Methods for the Derivative-Free Optimization of Nonsmooth Black-Box Functions

Luis Nunes Vicente, Lehigh University, Departamento de Matematica, Bethlehem, PA, 3000, United States

We present for the first time a derivative-free trust-region method for black-box type functions, without assuming any access to (generalized) derivatives or any knowledge about the analytical origin of the nonsmoothness. We propose a trust-region model that is the sum of a max-linear term with a quadratic one so that the function nonsmoothness and possible smoothness can be properly captured. The method enjoys global convergence properties provided the vectors randomly generated for the max-linear term are asymptotically dense in the unit sphere. The numerical results reported demonstrate that our approach is both efficient and robust for nonsmooth unconstrained optimization problems.

2 - Dingo: Distributed Newton-type Method for Gradient-norm Optimization

Fred Roosta, University of Queensland, St. Lucia, 4067, Australia

For optimization of a sum of functions in distributed computing environment, we present a communication efficient Newton-type algorithm that enjoys a variety of advantages. Our algorithm, DINGO, does not impose any specific form on the underlying functions, and its application range extends beyond convexity. Also, the distribution of the data across the computing environment can be arbitrary. Further, the underlying sub-problems of DINGO are simple linear least-squares. Lastly, DINGO involves a few hyper-parameters that are easy to tune. Moreover, DINGO is not sensitive to its hyper-parameters in that a strict reduction in the gradient norm is guaranteed, regardless of the hyper-parameters.

3 - Second Order Stochastic Trust Region Algorithm

Rui Shi, Lehigh University, Lehigh University, Bethlehem, PA, United States, rus415@lehigh.edu

In this talk, we present a new second order stochastic trust region method for solving stochastic and finite-sum minimization problems. This is an extension for our previous work 'TRish' where normalized steps are taken in a controlled manner. While TRish only incorporate stochastic gradient estimate into the algorithm, the new method include stochastic hessian approximation that may help generate a better descent direction. We show that the second order stochastic trust region method has the same type of convergence result with TRish. We also present numerical results showing that the new method has excellent performance when solving convex and nonconvex machine learning test problems.

4 - Nonlinear Acceleration of Primal-Dual Methods

Raghu Bollapragada, Northwestern University, Evanston, IL, 60201, United States, raghu.bollapragada@u.northwestern.edu, Damien Scieur, Alexandre d'Aspremont

In this talk, we present convergence acceleration schemes for primal-dual methods such as Chambolle-Pock. The extrapolated solution is written as a nonlinear average of the iterates produced by the original optimization algorithm where the weights are computed via a simple linear system. Our analysis of Regularized Nonlinear Acceleration, aka Anderson acceleration, does not need the underlying fixed-point operator to be symmetric. We use Crouzeix's conjecture to show that acceleration is controlled by the solution of a Chebyshev problem on the numerical range of a non-symmetric operator. Numerical experiments are detailed on image processing and logistic regression problems.

Joint Session TSL/ITS/Practice Curated: Planning and Operations of Electric Tranportation Systems

Sponsored: Transportation Science & Logistics/Intelligent Transportation Systems (ITS)

Sponsored Session

Chair: Mertcan Yetkin, Lehigh University, Lehigh, Bethlehem, PA, United States

1 - An Optimization Framework of National Corridor Charging Infrastructure Planning Considering Heterogeneous Travelers

Fei Xie, Oak Ridge National Lab, Knoxville, TN, United States, xief@ornl.gov, Zhenhong Lin

We introduce a multi-stage optimization framework that optimizes national inter-city public charging station expansion (new location and capacity increase) along the U.S. national interstate highway corridors. The framework has capability of modeling impacts of heterogeneity (e.g., home charging availability) in travel behaviors. Trade-offs in energy and mobility measures, such as total electric vehicle miles traveled, are evaluated with different charging and vehicle technologies.

2 - Dynamic Customer Allocation and Charging Policies for Shared Autonomous Electric Vehicles

Yuxuan Dong, University of Science and Technology of China, Hefei, China, René de Koster, Debjit Roy, Yugang Yu

Multiple platforms exist for vehicle sharing in different countries. In the future, they will be unmanned, autonomous, and electrical. In such an autonomous electric vehicle sharing service systems, the platforms need to decide which vehicle should pick up which type of customer, and when vehicles should recharge based remaining battery level. We model this system as a semi-open queueing network with multiple synchronization stations and propose dynamic customer allocation and charging policies to control the vehicles.

3 - Co-optimizing the Smart Grid and Electric Public Transit System

Mertcan Yetkin, Lehigh University, Bethlehem, PA, United States, mey316@lehigh.edu, Brandon Augustino, Lawrence V. Snyder, Alberto J. Lamadrid

We consider electric public transportation buses in an urban area, which can provide ancillary services to the smart grid during off-schedule times. In particular, we consider a multiperiod optimal power flow (OPF) problem that also decides the optimal charging/discharging times and locations for each bus. In doing so, the transit authority and the ISO co-optimize the power system to minimize the total operational cost of the grid, while ensuring that the buses are fully charged before starting their routes on the next day. We demonstrate the capabilities of the model and the benefit obtained via a coordinated strategy. Our study is motivated by a project with a large transit authority in California.

4 - Dynamic Repositioning in an All-electric Carsharing System

Satya Sarvani Malladi, Postdoc, Technical University of Denmark, Copenhagen, Denmark, samal@dtu.dk, Andrea Papu Carrone, Allan Larsen, Jeppe Rich

Managing a carsharing platform with an all-electric fleet presents unique challenges. In this paper, we investigate solution methods for repositioning cars in a free floating carsharing system that uses electric vehicles. We use a novel basis for the representation of incoming and outgoing trips.

5 - Two-stage Stochastic Choice Modeling Approach for Electric Vehicle Charging Station Network Design in Urban Communities

Seyed Sajjad Fazeli, Dr., Wayne State University, Detroit, MI, United States, Saravanan Venkatachalam, Ratna Babu Chinnam, Alper E. Murat

Electric vehicles (EVs) provide a cleaner alternative that not only reduces greenhouse gas emissions but also improves air quality and reduces noise pollution. The consumer market for Electrical Vehicles is growing very rapidly. Designing a network with adequate capacity and types of public charging stations is a challenge that needs to be addressed to support the current trend in the EV market. In this research, we propose a choice modeling approach embedded in a two-stage stochastic programming model to determine the optimal layout and types of EV supply equipment for a community while considering randomness in demand and drivers' behaviors.

Chair: Changhyun Kwon, University of South Florida, Tampa, FL, 33620, United States

1 - Traffic Equilibrium Tools in the Julia Language: Trafficassignment.jl and Complementarity.jl

Changhyun Kwon, University of South Florida, Tampa, FL, 33620, United States, chkwon@usf.edu

The Julia Language is a computer language designed for computational science and engineering. In this talk, tools and packages available in the Julia Language for optimization and equilibrium problems are introduced. In particular, traffic equilibrium problems are emphasized.

2 - DTALite-virtual Cyber Tracks: Open Source Modeling Framework for Real-time Management of Large Fleets of Self-Driving Cars

Jiawei Lu, Arizona State University, Tempe, AZ, 85281, United States, jiaweil9@asu.edu, Xuesong Zhou

In today's practice, integrated modeling generally functions more like a series of independent activities. We will talk about a data hub as a systematic approach for integrating Analysis Modeling and Simulation (AMS) tools to enable the continuous flow of data which, in turn, allows users to dedicate more time to performing modeling functions such as calibration, alternatives and sensitivity analyses, and performance evaluation.

3 - Open Source Tools for Network Games

Reed Harder, Dartmouth, Hanover, NH, 03755, United States, reed.haseltine.harder.TH@dartmouth.edu

Many transportation networks involve multiple agents making many interrelated decisions in competitive environments. The design and control of such systems can benefit from analysis using tools from game theory. Recent years have seen many theoretical advances in the area of network games, but there are few open source tools for analyzing a broad range of scenarios with potentially continuous, multi-dimensional payoff functions and networked interactions. We present work aimed at filling this gap.

Transportation Procurement & Vehicle Routing

Sponsored: Transportation Science & Logistics/Freight Transportation & Logistics

Sponsored Session

Chair: Akang Wang, Carnegie Mellon University, Pittsburgh, PA, 15213, United States

1 - A Branch-and-cut Algorithm for Continuous-time Inventory Routing Problems

Akang Wang, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, akangw@andrew.cmu.edu, Xiandong Li, Chrysanthos Gounaris

The Inventory Routing Problem integrates inventory management, vehicle routing and delivery-scheduling decisions, and is thus of great importance for a multitude of industrial applications. In this talk, we focus on the Continuous-time Inventory Routing Problems (CIRP), where the inventory level is managed in continuous time. We propose a branch-and-cut approach for solving the CIRP, and we also adapt the well-known rounded capacity inequalities so as to strengthen its linear relaxation. Extensive computational studies are performed on literature benchmark instances and demonstrate the competitiveness of our proposed approach against the state-of-the-art.

2 - Dynamic Transportation Procurement with Demand Visibility

Pol Boada-Collado, Northwestern University, Evanston, IL, United States, boada.pol@u.northwestern.edu, Sunil Chopra, Karen Smilowitz

We investigate the value of short-term demand visibility in the decision process of selecting the optimal transportation procurement, a scenario motivated by industry. We show that having this demand information essentially changes contracting policies by adding more dynamism and, with seasonal demand, information is leveraged by properly coordinating with expected demand shocks (e.g. Black Friday) using tailored strategies.

3 - Inter-city Package Service Flow Planning

Adolfo Rocco, PhD Student, Georgia Institute of Technology, Atlanta, GA, United States, Alan Erera, Martin Savelsbergh

We consider an inter-city service network design problem in which packages need to be routed from their origins to their destinations. The main objective is to find a cost minimizing set of routes such that service time requirements are met and sorting capabilities at hubs are respected. The equipment at a hub implies a maximum number of destinations that the hub can sort to. Packages can be cross-docked to any destination at a hub. We propose a two phase model in which the first phase determines commodity sort paths, i.e., decides where a commodity will be sorted, and the second phase determines commodity cross-dock paths, i.e., decides how a commodity is cross-docked between two consecutive sorts.

4 - An Exact Algorithm for a Two Stage Stochastic Vehicle Routing Problem

Vincentius Cornelis Gerardus Karels, Technical University Eindhoven, Utrecht, Netherlands, Tom Van Woensel, Lucas Petrus Veelenturf

A logistics service provider services a set of customers with different service agreements. A difference here is the time period in which customers make their requests known. When customers of the first time period are planned, they require information about their driver and an early indication of the arrival time. At this time customers of the second time period are uncertain. Some estimates of this uncertainty exist. Ultimately all customers have to be planned, constrained by the information given to the customers of the first time period. The objective is to formulate a plan such that the costs in vehicles ordered and kilometers driven is minimized. For this problem an exact algorithm is presented.

5 - Estimation of Marginal Cost to Serve Individual Customers

Akang Wang, Carnegie Mellon University, 5000 Forbes Avenue, Doherty Hall, Pittsburgh, PA, 15213, United States, akangw@andrew.cmu.edu, Jeffrey E. Arbogast, Gildas Bonnier, Chrysanthos Gounaris

We focus on the quantification of the marginal distribution cost for serving new individual customers. We approach this problem via a scenario-sampling framework, where each scenario is a Vehicle Routing Problem with Intermediate Replenishment Facilities (VRPIRF). Utilizing the Hoeffding's inequality, we estimate the number of required scenarios that need to be sampled. We then solve each VRPIRF instance via a Branch-Price-and-Cut approach we have developed to this purpose. We demonstrate our approach via extensive computational studies based on classical benchmark instances from the literature.

Simulation-based Optimization for Transportation Systems

Sponsored: Transportation Science & Logistics/Urban Transportation Sponsored Session

Chair: Vadim Sokolov, George Mason University, Fairfax, VA, 22030, United States

1 - Dimensionality Reduction for Stochastic Processes

Laura Schultz, George Mason University, Fairfax, VA, 20169, United States

Simulators play a major role in analyzing multi-modal transportation networks. As their complexity increases, optimization becomes an increasingly challenging task. Current calibration procedures often rely on heuristics, rules of thumb, and sometimes on brute-force search. Alternatively, we provide a statistical method which combines a distributed, Gaussian Process Bayesian optimization method with dimensionality reduction techniques and structural improvement. We then demonstrate our framework on the problem of calibrating a multi-modal transportation network of city of Bloomington, Illinois.

2 - Formulation and Solution Approach for Calibrating Activity-based Travel Demand Model-system via Microsimulation

Siyu Chen, Massachusetts Institute of Technology, Cambridge, MA, United States, siyuc@mit.edu, A. Arun Prakash, Carlos Lima De Azevedo, Moshe Emanuel Ben-Akiva

This study formulates the activity-based model-system calibration problem as a simulation-based optimization problem and proposes a stochastic gradient-based solution procedure to solve it. We derive approximate analytical expressions for the gradient of the objective function. Also, the solution procedure relies on microsimulation on mini-batches of the population to calculate aggregate statistics of interest and gradient of the objective function. Finally, we show that the solution procedure outperforms other state-of-the-art purely simulation-based optimization approaches in terms of computational efficiency, stability, and convergence through a real-world application.

3 - A Network-specific Metamodel Approach for Real-time Demand Calibration of Traffic Simulators

Kevin Zhang, Massachusetts Institute of Technology, Cambridge, MA, 02143, United States, Carolina Osorio

We propose a simulation-based optimization algorithm for real-time demand calibration of stochastic traffic simulators. We present a metamodel-based extended Kalman filter approach that combines simulator information with a problem-specific analytical network model. With this method, we aim to identify transportation-relevant solutions with improved performance within a strict computational budget. The approach is validated on a real traffic network; results are presented.

CC- Room 619

Transportation, Rail

Contributed Session

Chair: Nikola Besinovic, Delft University of Technology, Stevinweg 1, Delft, 2600CN, Netherlands

1 - An Approach to Minimize Energy Consumption in Urban Rail Transit Systems

Wenxin Li, Southwest JiaoTong University, Chengdu, China, wenxinli@my.swjtu.edu.cn

This paper proposes an energy-saving operation model for urban railways with real-world speed profiles, to minimize the trains' energy consumption with dwell-time control. Furthermore, considering the complexity of the train energy consumption model, we use calculus to reduce the power of the train energy consumption model. Then, we have suggested an exterior point method to find an appropriate solution for an energy-saving timetable. The practical case study of the Yizhuang urban railway line in Beijing is selected to verify the effectiveness and the energy-saving performance of the proposed model.

2 - Nearly Real-time Object Detection for Railway Track Inspection via a Deep Learning Based Framework

Li Zhuang, City University of Hong Kong, Hong Kong, Hong Kong, Zijun Zhang

Regular inspection of railway components is crucial to guarantee the safety of railway system. Since fasteners, such as bolts and clippers, and tracks are main components in the railway, detection the existence of these items via a deep learning based framework is proposed in this paper. The detection performance of the proposed method has been demonstrated in the experiment.

3 - A Robust Composition Rescheduling Model

Joris Wagenaar, Assistant Professor, Tilburg University, Tilburg, Netherlands, j.c.wagenaar_1@uvt.nl

Our focus is on rescheduling the composition schedule for practical railway applications. Existing models assume the duration of a disruption given at the time of rescheduling. However, in practice the duration of a disruption is uncertain, so in case new information about the duration is available, the composition schedule must be rescheduled again. In case the disruption lasts longer, decisions taken in the past might turn out to be costly.

We propose a model that is able to reschedule the composition schedule in a robust way with respect to the duration of disruption. Even more, we are able to give a full robust or semi-robust solution. We will demonstrate that robustness comes at a price.

4 - Rail Transfer Hubs Selection in a Metropolitan Area Using Integrated Multimodal Transits

Xinmei Chen, Eindhoven University of Technology, Eindhoven, Netherlands, Tom van Woensel, Virginie Lurkin, Qiyuan Peng, Qiyuan Peng

With the development to urbanization and the passenger's increasing need for convenient travel, integrating multimodal transits (such as metro with railway) is becoming necessary. A MILP model is built for the selection of the transfer hubs in a metropolitan area by considering the fixed cost for the construction suburban railway facilities and the variable passengers' travel time cost.

5 - Excellence in Innovation and Productivity of Indian Railways: Manufacturing of Rolling Stock in ICF and MCF

Sundaravalli Narayanaswami, Associate Professor, Indian Institute of Management Ahmedabad, Ahmedabad, India, sundaravallin@iima.ac.in, Swayambhu Arya

Indian Railways (IR) has not been able to meet with the growing demands for good transport services. An aspect to highlight is dated transport infrastructure which is detrimental. A major and recent bootstrap attempt of IR has been through the two rolling stock manufacturing units: Integral Coach Factory (ICF) and Modern Coach Factory (MCF). ICF manufactured the Vande Bharat Express, a semi-high speed, low-cost, driverless train in a record 18 months. MCF is technologically advanced and they demonstrated a 100% increase in the number of units manufactured annually. We present the transformations that these units have gone through in recent years and the subsequent enhanced credibility of IR.

6 - Integrated Train and Passenger Disruption Management: Simulation-based Optimization Approach

Nikola Besinovic, Delft University of Technology, Delft, Netherlands, n.besinovic@tudelft.nl

Urban railway transit systems in big cities observe increasing occurrences of infrastructure failures which may cause severe disruptions. In this research, we propose a new integrated disruption management methodology for automatically rescheduling trains and controlling passenger flows. Our simulation-based optimization framework incorporates train management decisions with controlling stations and adjusting flows of passengers and aims to minimize total system costs. We test our approach on real-life cases of Beijing metro and discover dependencies between control measures. Our goal is developing solutions that will lead to future decision support systems for railway dispatchers.

Joint Session AAS/TSL Air: Analytics in AAS Management

Sponsored: Aviation Applications

Sponsored Session

Chair: Xiaojia Guo, University College London, London, WC1N 1AS, United Kingdom

1 - Air Passenger Demand Forecasting Using Deep Learning Methods

Nahid Jafari, Assistant Professor, SUNY, Farmingdale, New York City, NY, United States, jnahid@hotmail.com

Demand for air travel is essentially driven by economic and tourism activities. The economic recessions decreases demand for leisure and business travel, consequently, demand for air transport. Air transport demand forecasting is receiving increasing attention, especially because of intrinsic difficulties and practical applications. The forecast of the air passenger demand over time can be analyzed as time series forecasting in which it has a complex behavior due to their irregularity, high volatility and seasonality. We examine various deep learning methods to predict the air passenger demand of the U.S. domestic airlines. We implement the models with Keras, the Python deep learning library.

2 - Forecasting Airport Transfer Passenger Flow Using Real-time Data and Machine Learning

Xiaojia Guo, University College London, International Hall, Lansdowne Terrace, London, WC1N 1AS, United Kingdom, x.guo.11@ucl.ac.uk, Yael Grushka-Cockayne, Bert De Reyck

We develop a two-phased predictive system that produces forecasts of transfer passenger flows. In the first phase, the system predicts the entire distribution of passengers' connection times. In the second phase, the system samples from the distribution of individual connection times and produces distributional forecasts for the number of passengers arriving at the immigration and security areas. Theoretically, we show that point forecasts of passenger flows generated by the two-phased approach are unbiased, and that distributional forecasts can be well-calibrated when adding correlation as a tuning parameter. Our two-phased approach is shown to be more accurate when compared to benchmarks.

3 - Boost Ancillary Product Upsell Prospects by Using Airline Clickstream Data

Cheng-Lung Wu, Associate Professor, UNSW Australia, School of Aviation, Kensington, NSW 2052, Australia, Jacob Wong

We used airline clickstream data to develop a predictive model to predict ancillary product upsell opportunities for potential customers. We focused our modelling on frequent flyer members of an airline from which rich frequent flyer data could be utilised for model development. To test the model, we built a simulated airline booking website with the Python model integrated at the back-end for real-time prediction and choice experiments. Results show that it is harder to predict ticket purchase with click data alone but easier for ancillary products. The model could reasonably predict return visits to the airline website and this prediction is crucial for customer engagement in airline e-commerce.

4 - Collaborative Decision-making and the Airport Operations Centre in Europe

Floris Herrema, EUROCONTROL, Brussel, Belgium, floris.herrema@eurocontrol.int

Improving airport performance is at the heart of the SESAR's Airport Operations Centre (APOC) solution. In this study, we review APOC roles and responsibilities, identify the key APOC processes that could be enhanced by data-driven predictions and machine learning techniques, and demonstrate a case study of how shared data and advanced analytics can be used to make predictions of passengers' connection times. In the case study, a regression tree model is fitted to a large training set with 3.7 million passenger records. This predictive model is applied to generate forecasts of each passenger's connection time and the passenger flows during an eight-hour live trial.

5 - Gate Assignment Optimization with the Consideration of Airport Retailing

Tulay Flamand, Colorado School of Mines, Division of Economics and Business, Golden, CO, 80401, United States, tulayvarol@gmail.com, Heng Chen

We address a gate assignment problem by considering its impact on the revenue of airport retailers. We propose a mixed-integer programming model that assigns flights to gates in a way that optimizes several objectives, as well as the retail sales. A column generation methodology is used to solve this challenging problem and the experimental results are reported.

1 - Data-driven Dynamic Pricing and Ordering with Perishable Demand Information and Inventory

Yuexing Li, Duke University, Durham, NC, United States, yuexing.li@duke.edu, N. Bora Keskin, Jing-Sheng Jeannette Song

We study joint pricing and inventory decisions for a perishable product in a changing environment. The decision maker does not know inventory perishability rate, demand change-points, or demand parameters before and after the change. We design two data-driven policies to aid decision making for profit maximization and establish their rate optimality. Our policies achieve significantly higher profits relative to the company policy used in practice.

2 - Causal Inference via Matrix Factorization

Xiaojie Mao, Cornell University, New York, NY, United States, xm77@cornell.edu, Madeleine Udell, Nathan Kallus

Valid causal inference usually requires measuring confounders precisely. However, in practice measurements of confounders may be noisy and lead to biased causal effect estimates. We propose to reduce the bias by using matrix factorization to infer confounders from a large number of noisy and missing covariates. This flexible and principled framework accommodates diverse data types and enhances many causal inference methods. We bound the error for the induced causal effect estimator and show its consistency in a linear regression setting with Exponential Family Matrix Completion preprocessing. We demonstrate the effectiveness of the our procedure in both synthetic data and real clinical data.

3 - Dynamic Assortment Planning with Changing Contextual Information

Xi Chen, New York University, New York, NY, 10012, United States, xchen3@stern.nyu.edu, Yining Wang, Yuan Zhou

We consider the problem of dynamic assortment planning with changing feature information, and the customers' preferences are modeled by items' feature vectors together with an unknown linear model. We present a dynamic policy for simultaneous learning preference models and maximizing expected revenues, and give the near-optimal regret analysis.

4 - Online Assortment Optimization with High-dimensional Data

Mike Wei, University at Buffalo, Buffalo, NY, 14260, United States, mcwei@buffalo.edu, Xue Wang, Tao Yao

In this study, we consider the online assortment optimization problem with high-dimensional covariates. We propose an online assortment optimization algorithm that combines Lasso and random projection to handle the high-dimensional issue and show that the cumulative regret of this algorithm is upper bound by O(T^(1/2) log d), where d is the covariates dimension and T is the time length.

Co-Chair: Ashwin Venkataraman, New York University, Cambridge, MA, 02139, United States

1 - Global Convergence Guarantees for Policy Gradient Methods

Daniel Russo, Columbia University, Kellogg School of Management, New York, NY, 60208, United States

Policy gradients methods are perhaps the most widely used class of reinforcement learning algorithms. Unfortunately, even for simple control problems solvable by classical techniques, policy gradient algorithms face non-convex optimization problems and are widely understood to converge only to local minima. This work identifies structural properties — shared by finite MDPs and several classic control problems — which guarantee that policy gradient objective function has no suboptimal local-minima despite being non-convex. When these conditions are relaxed, our work shows any local minimum is near-optimal, where the error bound depends on the expressive capacity of the policy class.

2 - Applications of Stochastic Bandits for Behavior-aware Recommendations

Theja Tulabandhula, UIC, FF07 Ajanta Vihar, Yelahanka, Chicago, IL, United States, Yunjuan Wang, Priyank Agrawal

We consider two behavioral effects that modulate relevance and revenue while making recommendations sequentially: (a) the users have a latent propensity to act on a recommendation based on its position in a sequence of recommended items, and (b) the users have a latent propensity to act on a recommendation only if it has been shown to them repeatedly. In both settings, the platform wants to simultaneously learn the quality of its recommendations and the corresponding user behavior, while exploiting the information it knows so far to maximize revenue. We explore the applicability of popular bandit algorithms to these settings.

3 - Contextual Bandits with Cross-Learning

Jon Schneider, Google Research, New York, NY, 10018, United States

In the contextual bandits problem, in each round t, a learner observes some context c, chooses some action a to perform, and receives some reward ra,t(c). We study the variant of this problem where the learner also learns the values of ra,t(c') for all other contexts c'. This variant arises in several strategic settings, such as learning how to bid in non-truthful repeated auctions. The best algorithms for the classical contextual bandits problem achieve O(sqrt(CKT)) regret against all stationary policies, where C is the number of contexts, K the number of actions, and T the number of rounds. We demonstrate algorithms for our variant that remove the dependence on C and achieve improved regret bounds.

4 - A General Framework for Regularized Gradient Boosting

Ashwin Venkataraman, UT Dallas, TX, 02139, United States, Srikanth Jagabathula

Gradient boosting is a very popular ensemble learning technique to improve the performance of many machine learning tasks like classification and regression. However, boosting can suffer from overfitting, especially if the underlying set of base hypotheses is complex. We propose a general framework for regularized gradient boosting that provides a principled way to tackle the overfit issue. We show that the regularized empirical risk minimization problem can be formulated as a constrained convex program, and by leveraging the Frank-Wolfe algorithm to solve it, we recover one base hypothesis in each iteration, resulting in the structure of a standard boosting algorithm.

Online Algorithms for Matching and Assortments

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Vineet Goyal, Columbia University, New York, NY, 10027, United States

1 - Matching with Stochastic Departures

Ali Aouad, London Business School, London, NW64TG, United Kingdom, aaouad@london.edu, Omer Saritac

Dynamic matching markets are subject to a fundamental tradeoff between the latency and the quality of the matches. In this context, we study a stochastic matching optimization model, with long-lived agents whose departure times are uncertain. We present simple non-adaptive matching policies, backed by worst-case performance guarantees on a large class of graphs. By implementing these policies on real data sets, we provide insights about the cost efficiency frontier of ridesharing platforms.

2 - Assortment Auctions: A Myersonian Characterization for Markov Chain Based Choice Models

Will Ma, Columbia University, New York, NY, 02139, United States

We introduce assortment auctions, where each buyer reports a ranking preference to a platform, and is then sold a product by a truthful mechanism. We compute the revenue-optimal mechanism under Markov Chain choice models and show it is Myersonian, in that allocations are made using virtual valuations, which are assigned to each buyer based on her ranking and Markov chain. We show that this structure fails for general ranking distributions. Our result generalizes both Myerson's optimal auction and assortment optimization with Markov chain models. We apply it to online assortment problems.

3 - Online Matching with Reusable Resources: Beating 1/2

Rajan Udwani, Columbia University, New York, NY, United States, Vineet Goyal, Garud N. Iyengar

We consider the problem of online matching with reusable resources. This setting arises commonly in many applications including cloud computing, physical storage, make-to-order service and other sharing economy applications. Previously, Gong et al. (2019) showed that the greedy policy is 1/2 competitive for this problem. We give an algorithm with competitive ratio better than 1/2.

4 - On the Disclosure of Promotion Value in Platforms with Learning Sellers

Gregory Macnamara, Stanford University, Stanford, CA, United States, Yonatan Gur, Daniela Saban

We consider the problem of an online platform that hosts third-party sellers and seeks to maximize consumer surplus. The platform cannot set prices but influences a seller's pricing policy through its own promotion policy (e.g. by giving a seller a prominent position on the webpage) and through the information it communicates to sellers about the value of promotions. The platform's information design problem is complicated by the fact that sellers can learn from past sales observations and update prices dynamically. In this setting, we characterize the maximum long-run average consumer surplus, and platform information and promotion policies that achieve it.

Revenue Management Models for Pricing and System Control

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: John G Turner, University of California-Irvine, Irvine, CA, 92697-3125, United States

1 - Markov Chain Models for Controlling the Exposure Frequency Distribution of Online Advertising

Ali Hojjat, University of New Hampshire, 10 Garrison Ave., Durham, NH, 03824, United States, ali.hojjat@unh.edu, John G. Turner

Recent trends in online advertising show that explicit reach and frequencyspecifications are preferred over aggregate impression or budget goals. Wemodel a user's ad exposure as a controlled Markovian process. Then we derive a closed-form ad serving policy that can achieve a desired frequency distribution for an online ad campaign and characterize the necessary and sufficient conditions for such policy to exist. Extensions of our framework to multi-advertiser and multi-audience-segment settings are also presented.

2 - Analysis of Pricing Mechanisms in Resource Exchange Economy

Ali Hassanzadeh Kalshani, The Paul Merage School of Business, UC Irvine, 1723 Verona Place, Irvine, CA, 92617, United States, ahassan2@uci.edu, John G. Turner, Luyi Gui

In many real-world settings where resources are shared, decentralized agents (e.g., individual competing firms) maximize their profits, and in so doing, choose to use an amount of a resource. Motivated by a desire to understand the theoretical and structural underpinnings of what makes coordinating decentralized agents hard or easy, we study the effectiveness of different pricing mechanisms. In particular, we analyze nonlinear prices as well as prices obtained by Dantzig-Wolfe decomposition algorithm.

3 - Revenue Management of Observable Express Queues with Customer Choice

Jiaqi Zhou, PhD Candidate, University of Maryland, Robert H. Smith School of Business, College Park, MD, 20742, United States, emily719@math.umd.edu, Ilya O. Ryzhov

We consider a stylized model motivated by paid express lanes on highways: two parallel, observable queues, one of which has a faster service rate, but charges a fee to join. Customer choice is based on observed queue lengths at the time of arrival, subject to random shocks as in the MNL and exponomial choice models. We characterize the equilibrium of the system, show how the structure of the equilibrium changes depending on the entry fee, and demonstrate that the revenue function can be nonconcave.

4 - Asymmetric Pricing and Replenishment Controls for Substitutable Products

Oben Ceryan, City, University of London, 106 Bunhill Row, Cass Business School, London, EC1 Y. 8TZ, United Kingdom, Oben.Ceryan@city.ac.uk

We study settings in which a firm offering substitutable products may face restrictions in its ability to either replenish or adjust the prices of some of its products, resulting in asymmetries in the pricing and replenishment controls available for each product. We characterize the structure of the optimal pricing and replenishment policies under this asymmetric control setting. Through the insights gained by the optimal policy structure, we also develop an effective heuristic policy.

Joint Session PSOR/Practice Curated: Healthcare Policy Modeling

Sponsored: Public Sector OR

Sponsored Session

Chair: Yueran Zhuo, PhD, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States

Co-Chair: Gizem Nemutlu, PhD, Massachusetts General Hospital, Harvard Medical School, Boston, MA, 02114, United States

1 - Scaling Up HPV Vaccination to Reduce HPV-associated Anal Cancer Incidence: Model-based Predictions

Gizem S. Nemutlu, Postdoctoral Research Fellow, Harvard Medical School and MGH, 8 Kimball Ct Unit 914, Boston, MA, 01803, United States, gnemutlu@mgh.harvard.edu, Jagpreet Chhatwal, Ashish A. Deshmukh, Ryan Suk

Human papillomavirus (HPV)-associated anal cancer is one of the most common cancers in HIV-infected (HIV+) men who have sex with men (MSM). The incidence of HPV-associated anal cancer has continued to increase among HIV+ MSM in the US. HPV vaccination may reverse rising rates; however, vaccination uptake remains low in boys. To our knowledge, no study examined the effect of HPV vaccine on anal cancer incidence. We develop a microsimulation model to address this gap and inform policy makers by evaluating the impact of different vaccination coverage policies on HPV-associated anal cancer incidence trends.

2 - Modeling the Feasibility of Achieving the 2030 Hepatitis C Elimination Targets in the United States

Yueran Zhuo, Harvard University, East Boston, MA, 02128, United States, yzhuo1@mgh.harvard.edu, Jagpreet Chhatwal, Peter Mueller, Qiushi Chen, Tiannan Zhan, Mary Ann Ladd

Hepatitis C virus (HCV) infection is a public health threat in the United States. The availability of highly effective oral direct-acting antivirals (DAAs) has changed the HCV treatment paradigm, offering an unprecedented opportunity to eliminate HCV. We utilize a validated mathematical model to assess temporal trends in hepatitis C disease burden from 2018 to 2040. We aim to investigate if, and under what conditions, HCV elimination is feasible at the state level and in selected subpopulations including state Medicaid beneficiaries and incarcerated individuals. Our analysis also serves as important guideposts to policymakers to determine progress towards HCV elimination at the state level.

3 - Physician Staffing and Shift Scheduling at Emergency Departments with Time Varying Productivity

Alireza Sabouri, Haskayne School of Business, University of Calgary, Calgary, AB, T2N 1N4, Canada, Negar Ganjouhaghighi, Marco Bijvank

We consider the problem of physician staffing and shift scheduling for an emergency department (ED). Patients show up according to a non-homogenous random arrival process and the productivity of physicians varies over time and between physicians. The variable productivity alongside the stochastic nature of arrivals to the healthcare system, create a mismatch between demand and the number of patients that can be served by the scheduled physicians. We propose a stochastic programming formulation for the staffing and shift scheduling problem. Our numerical results based on real data from an ED suggest that our proposed schedules lead to shorter average waiting times and more balanced workload.

CC- Yakima 1

Disaster Operations Management

Sponsored: Public Sector OR

Sponsored Session

Chair: Christopher Zobel, Virginia Tech, Blacksburg, VA, 24061-0235, United States

Co-Chair: Andrew N. Arnette, University of Wyoming, Laramie, WY, 82071-2000, United States

1 - Beneficiary Appointment Scheduling for Delivering Humanitarian Aid in Conflict-affected Regions

Burcu Balcik, Ozyegin University, Industrial Engineering Department, Istanbul, 34794, Turkey, burcu.balcik@ozyegin.edu.tr, Melih Celik, Maria Battarra, Bashar Khoury

Humanitarian agencies manage multiple aid programs to meet the needs of the people in the conflict-affected regions. The final delivery of aid is made by local agencies at the relief service centers. Motivated by the needs of local humanitarian agencies that deliver aid in Syria, we develop mathematical models and heuristic algorithms to support beneficiary appointment scheduling decisions at the local service centers. We discuss our findings and insights obtained from the surveys conducted by the local agencies in the conflict-affected area and present how we incorporate the unique challenges of this setting into decision making. We illustrate our methods on a real-world network.

2 - Value Function Approximation for Last-mile Distribution in Humanitarian Relief

Robert A. Cook, Northeastern Illinois University, Chicago, IL, 60646, United States, Racook2@neiu.edu, Emmett J. Lodree

This study describes a Value Function Approximation approach for solving a Markov Decision Problem in which we distribute stochastically-arriving donations to disaster survivors. Donations accumulate over time at collection sites and are periodically transported to a relief center where the donations are distributed to beneficiaries over a finite horizon.

3 - Agent-based Model Simulations of Spontaneous Volunteer Convergence in Disaster Response

Kyle Paret, North Carolina State University, North Carolina, Raleigh, NC, 27519, United States, keparet@ncsu.edu, Maria Esther Mayorga

The use of Spontaneous Volunteers (SVs) is widespread following a disaster such as a hurricane. However, there exists a need to address the implications of the rise in spontaneous volunteering. Management plans and more structured efforts to integrate SVs are necessary for effective disaster response. We develop an Agent-Based model to simulate SV convergence in disaster response. We highlight the effects that information sharing, individual motivation, and integration have on response efforts.

4 - Risk-based Modelling Approach for Post-disaster Sheltering Problem

Duygu Pamukcu, Virginia Tech, Blackburg, VA, 24060, United States, duygu@vt.edu, Andrew N. Arnette, Christopher Zobel

Managing shelter operations during natural disasters requires good understanding of the characteristics of both the hazard event and the affected population. Although reducing the potential risk of disaster is an important concern of relocation, it is not typically regarded as an objective of shelter location-allocation decisions. This study follows a Design Science Research Methodology to provide decision support for sheltering operations and suggests a multi-objective decision-making approach that minimizes evacuation time and disaster risk for more effective management of disaster shelters.

Human Trafficking and ORMS: A Panel Discussion

Sponsored: Public Sector OR

Sponsored Session

Chair: Kayse Lee Maass, Northeastern University, Boston, MA, 02115, United States

Panelist

Kayse Lee Maass, Northeastern University, 360 Huntington Ave., 334 SN, Boston, MA, 02115, United States, k.maass@northeastern.edu

Dr. Kayse Lee Maass is an Assistant Professor of Industrial Engineering and leads the Operations Research and Social Justice lab at Northeastern University. Her research focuses on optimization models to disrupt human trafficking through prevention, interdiction, and service provision to victim-survivors. Discussion topics include her ongoing research in scaling capacity for increased victim-survivor access to shelter services, interdicting human trafficking networks, and understanding cross-border human trafficking flows, as well as lessons learned in pursuing convergence research.

Panelist

Kezban Yagci Sokat, Northwestern University, Evanston, IL, United States, kezban.yagcisokat@u.northwestern.edu

Dr. Yagci Sokat is an adjunct professor at the Industrial Engineering and Management Sciences Department at Northwestern University, where she received her PhD Dr. Yagci Sokat's research focuses on using mathematical modeling and decision analytics to alleviate human suffering. Her main research interests are human trafficking, humanitarian logistics and healthcare operations. She specializes in integrating limited information in decision making for NGOs and public officials. She pursues multiple human trafficking projects on prevention, identification, response and disruption in collaboration with a variety of groups ranging from victims to law enforcement personnel.

Panelist

Shawn Bhimani, Northeastern University, Boston, MA, 37922, United States, s.bhimani@northeastern.edu

Shawn Bhimani uses econometrics, game theory, and qualitative research to study the supply chain of human trafficking through the lenses of government intervention mechanisms and supply chain disruption. His industry background in supply chain management influences his perspective and research on human trafficking networks. He has worked in consulting, corporate supply chains, research for the U.S. Department of Energy, co-founded a private distribution company, and teaches Supply Chain Management at Northeastern University. He has developed frameworks for catastrophic supply chain disruption and applies them to attack the trafficking networks involved with forced labor.

Panelist

Anna White, University of Michigan, Ann Arbor, MI, United States, agracew@umich.edu

Anna is a second year PhD student at the University of Michigan in the Department of Industrial and Operations Engineering. She is using predictive modeling and data analytics to study human trafficking, with a particular focus on illicit massage parlors as a venue of trafficking. In this panel, she will discuss her perspective on using operations research methods to tackle the problem of human trafficking.

Panelist

Matt Kammer-Kerwick, Research Scientist, The University of Texas at Austin, Austin, TX, 78723, United States, mattkk@ic2.utexas.edu

This talk will discuss ongoing NSF-funded research (CMMI 1838039) which is exploring the use of stochastic games, reinforcement learning algorithms, and agent-based models to assess and develop disruptive interventions for illicit supply chains. Additional discussion topics will include challenges faced in the development and application of operations research models and data analytic methods toward solutions for social, environmental, and and economic justice problems, assessing the scope and prevalence of human trafficking in the State of Texas, and assessing the perceptions and prevalence of interpersonal violence at institutes of higher learning.

12:05-12:50 T-Mobile
12:50-1:35 Simio Simulation & Scheduling Software

Vendor Tutorial

1 - From Theory to Practice: Applying O.R. to Change Wireless for the Better

Orcun Molvalioglu, T-Mobile, Seattle, WA, United States

At T-Mobile, we're a vast, complex, evolving business that puts customers first - and we need creative, analytical minds to make sure we're efficient also. In this session, Orcun will illustrate some business questions that we face at T-Mobile, and how we tackle them using Operations Research techniques – for example: • pricing optimization • supply chain logistics • predicting customer churn • optimizing geographic expansion of network and retail stores • call center queueing and routing• media attribution and mix modeling • website and behavioral analytics Come learn how we apply O.R. techniques at T-Mobile, and join our analytical team!

2 - Simulation and Scheduling Software All in One!

Jason Ceresoli, Simio LLC, Lousville, KY, United States

Simio is a premier simulation and scheduling software that allows you to expand traditional benefits of simulation to improve daily operations. In this tutorial, we will demonstrate Simio's 3D rapid modeling capability to effectively solve real problems. Explore how a single tool can be used to not only optimize your system design, but also provide effective planning and scheduling. Come explore the Simio difference and see why so many professional and novice simulationists are changing to Simio.

Advancements in Spatial and Temporal Data Analytics - I

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Jian Liu, University of Arizona, Tucson, AZ, 85721, United States

Co-Chair: Shyam Ranganathan, Virginia Polytechnic Institute and State University, Blacksburg, VA, 24061, United States

1 - A Marked Point Process Spatio-temporal Model of Wildfire Ignition with a Case Study Using Oregon Data

Farshad Farkhondehmaal, Virginia Polytechnic Institute, Blacksburg, VA, 24061, United States, farshad1@vt.edu, Shyam Ranganathan

Wildfires are disastrous events endangering both people and the environment and these are increasing in number and intensity over the last few decades. Wildfire forecasting is difficult, as ignition in small fields or small timescales are rare events. At the same time, the process is not stationary over larger spatial and temporal units and hence statistical models scale badly. We introduce a a marked point process spatiotemporal model of fire ignition to forecast the ignition at a suitable spatial and temporal resolution. We predict ignition based on the climate variables in each region and ignition cause. We then consider Oregon as a case study and validate our model.

2 - Using a Spatiotemporal Model to Predict Tumor Response to Therapy

Reza Iranzad, University of Arkansas, Fayetteville, AR, 72701, United States, riranzad@email.uark.edu, Xiao Liu, Wanpracha Art Chaovalitwongse, Stephen Bowen, Daniel Hippe, Chunyan Duan, Phawis Thammasorn, Robert Miyaoka, Hubert Vesselle, Paul Kinahan, Ramesh Rengan, Jing Zeng, Shouyi Wang

The aim of this study is to predict the tumor behavior in response to treatment at early and middle stages of treatment. Quantitative assessment was performed based on the amount of F-FDG that the tumor uptakes. For this purpose, a spatiotemporal model alongside different supervised learning algorithms was used to study spatial variation and detect spatiotemporal patterns.

3 - Customers Budgeting Behavior understanding via Temporal Basis Expansion

Yifei Yuan, Google LLC, Mountain View, CA, United States, T om Ferriss

AdWords customers can set and change advertising budgets. It is important to understand budget change behavior, which leads to a more customer-friendly product. To achieve their specific goals, some customers tune their daily budget frequently, providing a rich dataset of time series. Existing temporal decomposition approaches, such as wavelets and Fourier decomposition, do not work well for all customers because of i) heterogeneity in budgeting behavior ii) customer switching between behavior patterns and iii) frequency inconsistency due to variable number of days in each month. Thus, a self-generated basis expansion approach is proposed to better understand customers' budgeting behavior.

4 - Spatiotemporal Analytics on IBM Physical Analytics Integrated Data Repository and Services (PAIRS)

Rui Zhang, PhD, IBM Research, Yorktown Heights, NY, United States, Rui.Zhang@ibm.com, Siyuan Li, Marcus Freitag, Conrad Albrecht, Xiaoyan Shao, Fernando Marianno, Ildar Khabibrakhmanov, Levente Klein

PAIRS is a platform, specifically designed for massive geospatial-temporal data analytics services. Geospatial-temporal data acquisition and preparation can be challenging as there exist vast varieties of data formats and geo-projection methods. These binary file formats are highly inefficient for spatial-temporal analysis. PAIRS has been developed to provide search-friendly ready access to a rich, diverse, and growing catalog of historical and continuously updated geospatial-temporal information. PAIRS is a multi-peta bytes data platform and ingesting multi-tera bytes of data on a daily basis. We will present several spatiotemporal analytics capabilities developed upon PAIRS.

Data Analytics for Advanced Manufacturing Systems

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Chenang Liu, Blacksburg, VA, 24060, United States

Co-Chair: Wenmeng Tian, Mississippi State University, MS, 39762, United States

1 - A Constrained Signal Decomposition Approach for Side Channel Monitoring of Additive Manufacturing Process

Wenmeng Tian, Mississippi State University, Mississippi State, MS, 39762, United States, tian@ise.msstate.edu, Chenang Liu, Chen Kan

Additive manufacturing (AM) technologies have been widely applied to a large variety of areas. However, how to achieve effective in-situ process monitoring and control for AM still remain challenging. To address this issue, this study proposes a constrained signal decomposition approach to detect unintended process changes with accurate root cause diagnosis using side channel sensing signals. The effectiveness of the proposed method is validated by both simulation and actual AM case studies.

2 - Deep Learning of Variant Geometry in Layerwise Imaging Profiles for Additive Manufacturing Quality Control

Farhad Imani, The Pennsylvania State University, Leonhard Building, State College, PA, 16802, United States, Ruimin Chen, Evan Diewald, Edward Reutzel, Hui Yang

Additive manufacturing (AM) is a new paradigm in the design-driven build of customized products. Nonetheless, mass customization and low volume production make the AM quality assurance extremely challenging. The proposed research is aimed at developing a novel machine learning approach that is focused on variant geometry in each layer of the AM build, namely region of interests, for the characterization and detection of layerwise flaws. A DNN model is designed to learn variant geometry in layerwise imaging profiles and detect fine-grained information of flaws. Experimental results show that the proposed deep learning methodology is highly effective to detect flaws in each layer.

3 - Multivariate Model Calibration in the Absence of Experimental Observations: An Application in Metal Additive Manufacturing

Bing Zhang, Texas A&M University, College Station, TX, 77843, United States, zb19911212@tamu.edu, Mohamad Mahmoudi, Alaa Elwany

Simulation models for additive manufacturing are essential to enable process planning and accelerate qualification and certification of fabricated parts. One important task involves calibrating these models to ensure that predictions are in agreement with experimental observations. In this study, we consider the calibration of a computer simulation model with multiple outputs where experimental observations for one (or more) of the output are expensive to acquire. We present a case study on calibrating an analytical simulation model for new materials development in metal additive manufacturing.

4 - Multiple Signals Monitoring for Quality Control in Additive Manufacturing

Marco Grasso, Politecnico di Milano, Milano, 20156, Italy, marcoluigi.grasso@polimi.it, Bianca Maria Colosimo

In this talk, we describe novel solutions for multi-stream signal data analysis and monitoring for inline detection of defects in powder bed fusion via electron beam melting.

Joint Session QSR/HAS: Data Analytics in Medical Decision-making

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Devashish Das, University of South Florida, Tampa, FL, 33620, United States

1 - Privacy-preserving Predictive Analysis Across Multiple EHR Databases

Ying Lin, University of Houston, Houston, TX, 77204, United States, ylin58@uh.edu

Predictive analysis across hospitals is challenging due to the concerns on patient privacy and lack of efficient data sharing framework. Contextual embedding models which encode the medical events into vector representations while preserve the contextual dependencies between events have shown promises in predictive analysis without the need to disclose original data. To promote the predictive analysis across hospitals, we developed a novel data sharing framework which integrates the contextual embedding and embedding harmonization. The harmonized embeddings are further used to perform predictive analysis which outperforms the prediction in single data source.

2 - Survfit: Doubly Sparse Rule Ensemble Learning for Survival Data

Ameer Hamza Shakur, University of Washington, Seattle, WA, United States, ahamza@uw.edu, Shuai Huang

A crucial objective in the study of high dimensional medical data is the development of inherently interpretable models which can capture sparse underlying signals while retaining a high predictive accuracy. Rule-based models have been shown to accomplish these objectives. However, conventional rule-learning approaches do not promote variable selection and sparsity among the generated rules. Here we present Survfit, a 'doubly sparse' rule extraction formulation for survival data which induces sparsity in both rules and the variables involved in the rules. We subsequently demonstrate the utility of this model via simulated experiments and a real-world data-set of sepsis.

3 - Statistical Monitoring of Queuing Networks

Yanqing Kuang, University of South Florida, Tampa, FL, 33613, United States, ykuang@mail.usf.edu, Devashish Das

Many service systems can be modeled as queueing networks with multiple service nodes, and their performance are highly influenced by the service rate. In this research, by using the likelihood ratio based cumulative sum(CUSUM) scheme, the simple CUSUM chart, general CUSUM chart and penalized CUSUM chart are proposed to monitor the change of node service rate . Furthermore, the performance of proposed CUSUM charts are compared and evaluated in terms of the average run length (ARL) for detecting the shift through numerical studies. It's demonstrated that the proposed CUSUM charts can effectively detect the shift of the service rate for any node.

4 - Quantifying the Impact of Resuscitation-team Activation in Hospital Emergency Departments

Devashish Das, University of South Florida, Tampa, FL, 33620, United States, Xiaochen Xian, Kalyan Pasupathy, Eric Boie, Mustafa Y. Sir

Hospital emergency department (ED) operations are affected when critically ill or injured patients arrive. Such events often lead to the initiation of specific protocols, referred to as Resuscitation-team Activation (RA) in the ED of a large academic medical center where this study was conducted. RA events lead to the diversion of resources from other patients in the ED to provide care to critically ill patients; therefore it has an impact on the entire ED system. This research presents a data-driven and flexible statistical learning model to quantify the impact of RA on the ED.

CC- Tahoma 1

Data-driven Approaches for Emergency Department Applications

Sponsored: Health Applications

Sponsored Session

Chair: Hyojung Kang, University of Illinois at Urbana-Champaign, Mahomet, IL, 61853, United States

Co-Chair: Kalyan Pasupathy, Mayo Clinic, Rochester, MN, 55905, United States

1 - Analysis of Emergency Department Visits by Frequent Users Using Deep Learning

Hyojung Kang, University of Illinois at Urbana-Champaign, Champaign, IL, 61853, United States, hyokang@illinois.edu, Riordan John

Patients who have recurrent emergency department (ED) visits have been identified as frequent users (FUs). Approximately 21-28% of ED visits are attributable to only 4.5-8% of ED patients. Previous studies on FUs have focused on comparing characteristics between regular ED users and FUs using a traditional statistical model. This study aims to identify patient clusters among FUs by their ED visit patterns over time using deep learning models.

2 - Flexible Designs for Off-placing Patients in Inpatient Wards

Vahid Sarhangian, University of Toronto, Toronto, ON, Canada, sarhangian@mie.utoronto.ca, Carri Chan, Yuan Zhong

A common practice in hospitals is the off-placement of admitted emergency department (ED) patients to a non-primary inpatient ward (IW) when the primary ward is at full capacity. It has been however empirically shown that this leads to an increased length of stay for the off-placed patients. We use a queueing model to study the value of off-placement and provide guidelines for design of practical flexible designs in the presence of the slow-down effect.

3 - Impact of Split-flow Models in Emergency Departments on Patient Outcomes

Juan David Gomez, University of Wisconsin-Madison, Madison, WI, United States, davidgomez@wisc.edu, Brian Patterson, Gabriel Zayas-Caban

Many interventions have been proposed to alleviate crowding in Emergency Departments (EDs). One group of interventions that has gained popularity is the creation of "split flow" models, in which a provider is stationed at patient intake and briefly sees all walk-in patients. In this project, we use observational data from a tertiary teaching hospital to evaluate the impact of the split-flow model on length of stay and other patient outcomes (e.g., ED revisits, readmissions).

4 - Should Everybody be Screen for Diabetes in the Emergency Department?

M Gabriela Sava, Assistant Professor, Clemson University, Clemson, SC, United States, msava@clemson.edu, Ronald G. Pirrallo, Jerrold H. May, Jingyuan Tian

Diabetic screening of ED patients can proactively improve health outcomes, but it is uneconomic to screen all such patients. We present a modeling approach for identifying patients who have a negligible risk of diabetes, so that available resources can be used to screen those with a non-negligible risk.

Joint Sessions HAS/MIF: Appointment Scheduling for Outpatient Care

Sponsored: Health Applications

Sponsored Session

Chair: Aleida Braaksma, University of Twente, Enschede, 7500 AE, Netherlands

Co-Chair: Miao Bai, Mayo Clinic, Rochester, MN, 55904, United States

1 - Identifying and Prioritizing Elderly People More in Need of Preventive and Patient-centered Primary Care

Jennifer Mendoza-Alonzo, University of South Florida, Tampa, FL, United States, jennifermend@mail.usf.edu, Jose L. Zayas-Castro

Primary care has a central role in the United States healthcare system given the rise in chronically ill patients. Yet the increase of elderly people and shortage of primary care physicians difficult the timely delivery of primary care. The objective of this work is to develop a decision-making model to prioritize the preferred older adults in receiving preventive and patient-centered primary care. We formulated a multi-objective optimization model and a methodology to identify the older adults that are at the highest risk of worsening their existing conditions. This will reduce the morbidity and mortality, the emergency department visits, the hospitalizations, and thus, the healthcare costs.

2 - Priority Based Templating for Outpatient Specialty Practices

Miao Bai, University of Connecticut, Storrs, CT, 55904, United States, miao.bai@uconn.edu, Bjorn Berg, Esra Sisikoglu Sir, Mustafa Y. Sir

Patient scheduling within outpatient specialties presents unique challenges. Capacity allocation policies are often multi-dimensional in their need to balance competing criteria including clinical urgency, alignment with provider expertise and case mix targets. Further, the need to schedule patients within a pre-determined time frame (timely access) provides motivation for priority-based scheduling templates. We propose a priority-based scheduling approach motivated by specialty appointment data from a large academic medical center. Formulated as a two-stage stochastic program, the problem's structure is used to guide allocating patient groups into a tiered priority scheme.

3 - Overbooked and Overlooked: Machine Learning and Racial Bias in Medical Appointment Scheduling

Shannon Harris, Virginia Commonwealth University, Richmond, VA, 43203, United States, harriss10@vcu.edu, Michele Samorani, Linda Goler Blount, Haibing Lu, Michael Santoro

Machine learning (ML) is often used in scheduling to identify patients with a high no-show risk, and to overbook them in an effort to maximize clinic performance. If those patients are in the same demographic group, they may be overbooked disproportionately more than other patients; a tactic that may result in them incurring a greater expected waiting time. Motivated by a real-world large specialty clinic, we demonstrate that combining ML with optimization causes racial disparity in terms of patient waiting time. We provide a solution to eliminate this disparity, and find that our method can reduce racial disparity by up to 87.5% at a moderate increase in cost when compared to traditional overbooking.

4 - Dynamic Advance Patient Scheduling with Short-Term Follow-Ups

Antoine Sauré, Assistant Professor, University of Ottawa, Ottawa, ON, Canada, Antoine.Saure@telfer.uottawa.ca, Vusal Babashov, Onur Ozturk, Jonathan Patrick

In many healthcare systems, patients require multiple visits to a healthcare provider. In general, the first visit is known as the consult visit and all the subsequent visits are known as the follow-up visits. The latter typically occur according to predefined booking guidelines. We develop an MDP model to efficiently allocate available capacity to consults and follow-up visits in a dynamic fashion. We solve this model using the linear programming approach to Approximate Dynamic Programming and discuss the characteristics of the approximate optimal booking policy (AOP) for a multi-class patient setting. We compare the performance of the AOP policy to that of a myopic policy through simulation.

5 - A Generic Classification System for Appointment Scheduling Literature

Aleida Braaksma, University of Twente, Faculty of EEMCS - SOR (ZI-4013), Netherlands, a.braaksma@utwente.nl, Jasper Bos, Noelle Maria van de Vrugt, Maarten Otten, Richard J. Boucherie

Scheduling appointments occurs in many application areas, such as healthcare, production, and telecommunications. Hence, the vast body of existing research is fragmented and frequently case-oriented. As such, the field of appointment scheduling is in a similar state as machine scheduling before the introduction of Graham's three-field classification. We propose a generic classification system for appointment scheduling, aiming to instigate cross-fertilization between different application areas and thus promote systematic progress of the field. Using our classification, we review and classify the online appointment scheduling literature.

Optimization in Clinical Trial Supply Chains

Sponsored: Health Applications

Sponsored Session

Chair: Nan Kong, Purdue University, Biomedical Engineering, West Lafayette, IN, 47906-2032, United States

1 - Drug Supply Chain Optimization for Adaptive Clinical Trials: A Stochastic Programming Approach

Wei-An Chen, Purdue University, Weldon School of Biomedical Engineering, West Lafayette, IN, 47907-2032, United States, Nan Kong

As adaptive clinical trials receive growing attention, they also present challenges on drug supply chain management. To facilitate drug supply decision making in response to trial adaptations, we developed a two-stage stochastic production-inventory-distribution optimization model for trials that allow size re-estimation, adaptive randomization, and arm/dosage-dropping designs. This problem addresses important trial supply aspects, including trial length, resupply schemes, drug wastage, and costs minimization. Our numerical study shows our model can deliver promising operational responses from the supply chain aspect to the trial design adaptiveness.

2 - Stochastic Modeling and Simulation in Clinical Trials

Anh Ninh, College of William and Mary, Williamsburg, VA, United States, Michael Lefew, Vladimir Anisimov

We propose a new framework for end-to-end supply management for clinical trials. Numerical results are illustrated using analytically-based simulations and show wide opportunities to analyze the impact of different effects (risk level, arms, depots, etc.) that has a great potential for applications to real studies.

3 - Improving Clinical Trial Data Management Using Blockchain Technology

Raja Jayaraman, Khalifa University of Science & Technology, Abu Dhabi, United Arab Emirates, raja.jayaraman@kustar.ac.ae, Ilhaam Aziz Omar, Khaled Salah, Mecit Can Emre Simsekler

Clinical trials (CT) data management faces severe challenges in patient recruitment, persistent monitoring, data analytics and accurate reporting. Blockchain technology guarantees the authenticity of transactions without the interference of a third party. The inherent functions including provenance, transparency, decentralized transaction validation and immutability can enable efficiency of CT. Using blockchain based approach in CTs can improve patient retention, data integrity, patient privacy and ensure the CTs comply with the regulatory policies. In this presentation, we propose a novel blockchain based solution for improved CT data management.

4 - Optimizing the Cost of Clinical Trials in Phase 3: A Two-stage Stochastic Programming Approach

Osman Ozaltin, North Carolina State University, 400 Daniels Hall, Industrial and Systems Engineering, Raleigh, NC, 27605, United States, Abdolhossein Tohidi

Phase 3 costs about 75% of the overall expenditure in a clinical trial. This phase involves strategic decisions such as site selection as well as tactical decisions such as patient recruitment and resource allocation across clinical sites. All of these critical decisions are made under uncertainty regarding the success of the drug and patient arrival. We propose a two-stage stochastic program that minimize the expected cost of running clinical trials for a portfolio of new drugs in phase 3. We present numerical experiments providing policy insights for realistic instances.

Modeling Safety, Sufficiency, and Cost in the Blood Supply

Sponsored: Health Applications

Sponsored Session

Chair: Alton Russell

1 - Modelling Rare Blood Inventory in Canada

John Blake, Dalhousie University, Halifax, NS, B3H 4R2, Canada, john.blake@dal.ca

Many countries maintain programs to provide blood for patients with complex serology. An analytic approach used to evaluate how rare a blood type must be before frozen blood is necessary. A simulation model was employed to evaluate the impact of inventory on patient access. Results suggested that insufficient donors had been identified to ensure a stable inventory. Simulation results show that some amount of frozen inventory is necessary for most phenotypes. However, holding more than two units apiece did not improve patient access. We conclude that modest amounts of frozen inventory, combined with increased door screening, provides the greatest chance of maximizing patient access.

2 - Strategic Supply Chain Design for Locating Blood Distribution Centers in Korea

Hoon Jang, Korea University (Sejong Campus), Sejong, Korea, Republic of, hoonjang@korea.ac.kr, Hyun-Jung Kim, Jun-Ho Lee

Considering that supply of blood units is limited, developing an efficient supply chain for the right amount of blood for the right number of recipients within the right time window is a particularly important issue in public health. However, in case of Korea, the overall quality of the blood supply chain currently falls far short of the ideal standard. Motivated by this reality, in this study, we propose a mathematical model which optimally allocates blood distribution centers by simultaneously considering uncertainties both in demand and supply. Experimental results using real data present the effectiveness of our approach, which may be helpful in redesigning blood supply management strategies.

3 - Robust Post-donation Blood Screening under Prevalence Rate Uncertainty

Hadi El-Amine, George Mason University, Fairfax, VA, 22030, United States, helamine@gmu.edu

Blood product safety, in terms of being free of transfusion-transmittable infections, is crucial. Under prevalence rate uncertainty, various objective functions, including minimization of a mean-variance objective and minimization of the maximum regret, were considered in order to determine a “robust” post-donation blood screening strategy that minimizes the risk of releasing an infected unit of blood into the blood supply. Efficient and exact algorithms are provided.

4 - An Interactive Hospital Model to Inform Adoption of Platelets Processed with New Technologies

Laura T. Pizzi, Professor and Director, Rutgers University, Piscataway, NJ, 08854, United States, laura.pizzi@rutgers.edu

Many US blood centers and hospitals now transfuse pathogen-reduced (PR) platelets. We describe an interactive model to enable hospital assessment of the budgetary impact for platelet types, including PR vs. conventional platelets tested with a secondary bacterial test. We incorporate acquisition, testing, wastage, and transfusion costs including adverse events. PR cost offsets are also considered due to elimination of bacterial testing and irradiation, increased shelf-life, and higher outpatient reimbursement. The model exemplifies how operations research is applied to inform hospital decision makers concerned with adoption of new blood technologies.

5 - Optimal Safety Policies for Donated Blood: Defer, Test, or Treat?

W Alton Russell, Stanford University, Stanford, CA, United States, altonr@stanford.edu

The number of interventions for managing risk of transfusion-transmitted infections in donated blood grows annually, and the epidemiological profile of donor populations varies geographically and temporally. This makes deciding which blood safety interventions to implement difficult. I present a framework for determining the optimal portfolio of blood safety measures in a given context. This flexible health-economic framework considers demand for donated blood and enables the comparison of policies that combine interventions across three classes: donor deferral, disease marker testing, and donation treatment, where a pathogen inactivation technology is used to reduce risk.

Joint Session QSR/Practice Curated: Deep Learning Applications on Multi-Channel Sensors

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Seoung Bum Kim, PhD, Korea University, Seoul, Korea, Republic of

1 - Explainable Failure Prediction for Multi-channel Sensor Data

Mingu Kwak, Korea University, Seoul, Korea, Republic of, min9kwak@korea.ac.kr, Seoung Bum Kim

Prediction of equipment failures is an important issue in various industries. Also, identifying the causes of the failures can be very helpful in determining how to deal with it. In this study, we propose an attention mechanism-based neural network model that yields high performance to predict the failures with interpretability. The model provides attention distributions of sensor-level and segment-level denoting which sensor and segment contribute to the prediction. We evaluate the performance of the proposed method through the real multi-channel sensor data collected from the vehicle engine.

2 - Predicting A 6-component Load Cell of Vehicle Using Regularized Convolutional Neural Networks

Minjung Lee, Korea University, Seoul, Korea, Republic of, leemj2520@gmail.com, Seoung Bum Kim

As technology advances, numerous sensors are attached to driving vehicles. Among them, the six-component load cell incurs significant costs for installation and measurement of their values. To address this issue, we replace those load cell values with predicting them using regularizing grouped weights convolutional neural networks. This model improves predictive performance by regularizing redundant and noisy sensors of multi-channel signal data. We demonstrate the usefulness and applicability of the proposed method through the actual multi-channel dataset of vehicles.

3 - Root Cause Failure Analysis Based on Convolutional Neural Network and Response Activation Map

Yoon Sang Cho, Korea University, Seoul, Korea, Republic of, yscho187@korea.ac.kr, Seoung Bum Kim

Identification of causes of failures is essential to maintain stable manufacturing processes. In this study, we propose a method to predict quality states and analyze causes of failures based on convolutional neural network-based response activation mapping (CNN-RAM). To demonstrate the effectiveness and applicability of the proposed approach, we conduct experiments through the multichannel sensor data that can explain various process conditions in manufacturing systems. The proposed method can successfully detect the causal processes and distinct patterns for each quality state.

4 - Online Learning in Equipment Failure Prediction for Nonstationary Multi-channel Sensor Data

Ji Yoon Lee, Korea University, Seoul, Korea, Republic of, jiyoon.lee52@gmail.com, Seoung Bum Kim

Equipment failure prediction is essential in the construction industry because the failure of vehicles directly leads to a significant loss of productivity. In general, sensors are attached to vehicles to monitor their condition. However, it is challenging to predict failures based on signals collected from sensors because they are nonstationary. To overcome this limitation, we propose an online learning framework for adaptive equipment failure prediction. We demonstrate the effectiveness and applicability of our framework through the real multi-channel sensor data collected from actual construction equipment.

5 - A Stochastic Response Control Method for Optimizing Manufacturing Processes

Jihoon Kang, Seoul, Korea, Republic of, Samsung SDS

Data-driven Model Predictive Control (D-MPC) is widely used for improving control systems in a quantitative way. In this research, we introduce a novel control method named Stochastic Response Control (SRC) which performs properly when a target variable has zero-inflated, intermittent, and time-invariant patterns. Proposed method is consist of 2 main ideas which are stochastic transformation of response variable and coefficient adjustment algorithms that can overcome the current limitations in manufacturing fields. Results of industrial case studies demonstrate the efficacy of SRC especially in the manner of robustness and usability of model based control.

Simulation Solution & Model Selection

Sponsored: Simulation

Sponsored Session

Chair: Linda Pei, Northwestern University, Evanston, IL, 60202, United States

1 - Variational Bayesian Methods for Stochastically Constrained System Design Problems

Prateek Jaiswal, Purdue University, West Lafayette, IN, United States, Harsha Honnappa

We study system design problems stated as parametrized stochastic programs with a constraint set defined using a coherent risk measure. For the problem to be a well-defined convex program, the use of coherent risk measure ensures the convexity of the feasible set, given the underlying constraint function is convex. We adopt a Bayesian approach that requires the computation of a posterior predictive integral which is usually intractable. Consequently, we propose a variational Bayes-based method to approximately compute the posterior predictive integral. We present our analysis using an M/M/c queueing model to choose the optimal number of servers c for a given coherent risk measure.

2 - Efficient Model Selection for Arrival Data

Zeyu Zheng, University of California, Berkeley, Berkeley, CA, 94720, United States, zyzheng@berkeley.edu, Peter W. Glynn

Appropriately modeling and statistically characterizing arrivals are crucial in service, logistics, and transportation systems. In this talk, we will discuss several new tools that we have developed for statistical estimation and selection for arrival models.

3 - A Simulation-based Iterated Local Search for the In-house Logistics Routing Problem

Marcelus Fabri, Universitat Pompeu Fabra, Spain, Helena Ramalhinho

The objective of this work is to optimize the internal logistics processes in the car assembling company SEAT S.A., a Volkswagen subsidiary. We focus on the In-house Logistics Routing Problem (ILRP), an extension of the VRP. In the ILRP the routes are fixed and cannot be modified; the demand is unknown; the fleet is homogeneous; there are time-window and back-orders constraints. To solve the ILRP, we propose an Integer Linear Programming (ILP) model and a Simulation-based Iterated Local Search (SimILS) algorithm. We conducted experiments based on real company's data. Results showed that the SimILS provided the best overall results overcoming both the ILP approach and the current company's solution.

4 - Sequential Risk Set Inference for Simulation Optimization under Input Uncertainty

Eunhye Song, Penn State University, University Park, PA, 16802, United States, eus358@psu.edu

This talk concerns measuring model risk in simulation optimization when the simulation input model is estimated from finite real-world data. We define the -level risk set as a set of solutions that perform better than a nominal solution by a margin greater than ≥0 with probability greater than , where the probability is taken with respect to the posterior distribution of the input model conditional on the data. Our goal is to propose an algorithm that sequentially simulate an input model-solution pair to efficiently and effectively identify the risk set. Taking a Bayesian approach, we propose two sampling criteria to minimize the estimation error of the risk set.

Sharing Rides, Durable Goods, and Solvers

Emerging Topic: Sharing Economy & Crowdsourcing

Emerging Topic Session

Chair: Gizem Korpeoglu, United Kingdom

1 - Sharing of Durable Goods: Business Models for Heavy Equipment Manufacturers

Philippe Blaettchen, INSEAD, Fontainebleau, France, philippe.blaettchen@insead.edu, Sameer Hasija, Niyazi Taneri

Technological advances enable new business models, replacing or augmenting ownership-based with access-based usage. These models not only influence sales but also impact after-sales services, an important profit driver in the heavy equipment industry. We focus on understanding the performance of different models by considering salient economic and operational factors. Using a game-theoretic approach, we capture trade-offs that arise in conjunction with after-sales services. We show that these services play an important role in shaping a firm's optimal business model choice, a point which has been overlooked in the existing literature and which deserves close attention by decision-makers.

2 - Competition Between Two-sided Platforms under Demand and Supply Congestion Effects

Fernando Bernstein, Duke University, Durham, NC, United States, fernando.bernstein@duke.edu, Gregory A. DeCroix, N. Bora Keskin

We explore the impact of competition between platforms in the sharing economy. Each platform sets a price charged to customers. A portion of that price is paid to the driver. Customers' and drivers' utilities are sensitive to prices and to congestion in the system. We consider two scenarios. One assumes that drivers work through a single platform. In the second scenario, drivers deliver service through both platforms. We study the equilibrium prices and the supply and demand outcomes that arise at equilibrium. We leverage the model to study practical questions in the ride-sharing industry: surge pricing and the increasingly common practice of drivers choosing to operate on multiple platforms.

3 - Award Structure in Collaborative Contests

James Siderius, Massachusetts Institute of Technology, Cambridge, MA, 02134, United States, Mohamed Mostagir

Society poses a research question whose solution becomes increasingly less valuable over time and can only be discovered through costly effort. The solution requires a series of breakthroughs, and the designer may offer award(s) for each breakthrough. Depending on the award structure, agents may hoard results to prevent others from catching up, which can be socially inefficient. On the other hand, if the designer offers copious awards to encourage agents to share progress, he risks investing huge sums into an intractable problem. We set up the designer's problem of optimally choosing the award structure of this collaborative contest and provide a characterization of the solution.

4 - Do Workers and Customers Benefit from Competition Among On-demand Service Platforms?

Shihong Xiao, University of Minnesota, Minneapolis, MN, United States, xiaosh@umn.edu, Xiaotang Yang, Saif Benjaafar

We study two-sided competition between two on-demand service platforms, where duopoly platforms set price and wage rate to compete for both customers and drivers. By comparing monopoly and duopoly equilibria, we investigate how competition impacts wage rate, price, and firms' profits. We find that when the labor pool size is large, the wage rate and the price in the symmetric duopoly equilibrium is lower than those in the monopoly equilibrium; and it can be the reverse when the labor pool size is moderate. However, the platforms' payoffs are always lower under competition.

Stochastic Processes and Finance

Contributed Session

Chair: Lei Zou, Rensselaer Polytechnic Institute

1 - Edgy Hermite Processes Are Not Hermite Processes

Joshua B. Levy, Senior Adjunct Professor, University of Massachusetts-Lowell, Lowell, MA, United States, joshua_levy@uml.edu

We examine two finite-variance self-similar processes defined for $t \geq 0$. Both are characterized by a positive integer $k \geq 1$ and a k-dependent pair of real numbers, (p,q), that can differ between the processes. Suppose k is fixed. If $p-q=1$ either process is a version of one of the well-known Hermite processes, and hence is self-similar and has stationary increments. If, however, p-q is "slightly different" from 1, then that process may be described as "edgy Hermite." It fails to have stationary increments, and so it cannot be a version of an Hermite process. In fact, this occurs whenever p-q is not 1. Of further interest in this case is how these two non-Hermite processes compare.

2 - A Set-valued Markov Chain Approach to Credit Default

Bin Zou, University of Connecticut, Storrs, CT, United States, bin.zou@uconn.edu, Dianfa Chen, Jun Deng, Jianfen Feng

We propose a novel credit default model that takes into account the impact of macroeconomic information and contagion effect on the defaults of obligors. We use a set-valued Markov chain to model the default process, which includes all defaulted obligors in the group. We obtain analytic characterizations for the default process, and derive pricing formulas in explicit forms for synthetic collateralized debt obligations (CDOs). Furthermore, we use market data to calibrate the model and conduct numerical studies on the tranche spreads of CDOs. We find evidence to support that systematic default risk coupled with default contagion could have the leading component of the total default risk.

3 - A Two-stage Bayesian Network Model for Corporate Bankruptcy Prediction

Jia Zhai, Lecturer in Finance and Economics, University of Salford, Salford, United Kingdom, j.zhai@salford.ac.uk, Yi Cao

We develop a two-stage Bayesian network for predicting firm bankruptcy. We select financial ratios via the Least Absolute Shrinkage and Selection Operator, establish the topology of Bayesian network and obtain coefficients for conditional probabilities. The empirical results based on 32,344 US firms in 1961-2018 show that our model outperforms 5 alternative methods. It provides an interpretation of its internal functionality by describing how conditional default probabilities are obtained from selected variables and allows sensitivity analyses with respect to changes in input variables. It represents a step towards interpretable machine learning model with strong empirical performance.

4 - Identifying Board of Director Network Influence for Firm Characteristics

Lei Zou, Rensselaer Polytechnic Institute, Troy, NY, United States, zoulei325@gmail.com, Aparna Gupta, Abena Owusu

We utilize network analysis to evaluate the relationship between firms' characteristics and board of director networks. In a sample of 20 firms, we cluster the firms by firm-level characteristics, and develop a multiplex network of the firms' board members consisting of two major layers, one for board members' direct connections and another for their indirect connections. 4 sub-layers of each major layer of the multiplex network. We observe that director networks display significant connectivity at all multiplex network layers and firms belonging to the same cluster display similar director network characteristics, specifically enhanced by appropriate weighting of director network layers.

Sponsored Session

Chair: Qianqian Liu, City University of Hong Kong, Kowloon, Hong Kong

1 - Effects of Cooperative and Competitive Gamification on Fitness Mobile App Use: A Field Experiment

Jiang Qiqi, Copenhagen Business School, Copenhagen, Denmark

Despite the rapid growth of the fitness mobile app market, fitness app companies suffer from a significant portion of poorly motivated, inactive users. In practice, gamification, especially story-based gamification, has been widely adopted as an effective approach to improve system use and reduce user churn rate. However, prior findings suggest that gamification can result in both positive and negative behavioral outcomes, and it remains unclear how to craft a gamified fitness app to maximize its effectiveness in promoting engaged use. Moreover, previous studies mainly emphasized on the designs of rewarding mechanics (e.g., points, badges, and leaderboards) and narrative mechanics (e.g. storytelling) but did not comprehensively investigated the role of social interaction mechanisms in the design of gamification. In this study, we focus on the influences of different social interaction mechanisms (competition, cooperation, and coopetition) on users' task engagement and app use. With a self-developed mobile app, Fitness Castle, we conducted a 2*2 longitudinal field experiment and examined the effectiveness of completion and cooperation among users in a gamified fitness app. Results indicate that competitive game mechanics have a significant positive influence on fitness app use. In addition, when gamified system is purely cooperative, users are not better motivated to use the app more extensively; however, when competitive and cooperative mechanisms are jointly provided, the system use significantly increases.

2 - Investigating Dynamics of Crowdfunding Policy

Keehyung Kim, Chinese University of Hong Kong, Shatin, Hong Kong

Crowdfunding platforms lower entry barriers for less-sophisticated investors to participate in an investment market. However, such inexperienced investors often lack the ability and resources to correctly examine the quality of various projects. In most cases, they heavily rely on information provided by the project managers. To alleviate such information asymmetry, crowdfunding platforms have recently started to introduce a policy requiring project managers to disclose any potential risks involved in the project. This study utilizes economics experiments to understand the role of risk disclosure policy and how it may affect the decisions of both project managers and crowd investors.

3 - Social Information Disclosure in C2C E-commerce: A Natural Experiment

Di Zhou, Institute of Economics, Tsinghua University, Beijing, China, zhoudidkc@gmail.com, Ke Rong

This paper aims to explore the influence of social information disclosure on the sales rate in the online C2C trading market, and a mediator effect of privacy and a moderator effect of trading experience are considered. The empirical results show that partial social information disclosure would decrease the sales rate while full social information disclosure would increase the sales rate. The mediator effect of privacy would increase the sales rate, but the impact is relatively small compared to the trust. The moderator effect of trading experience would only enhance the negative influence of partial social information disclosure.

4 - Digital Communication Channel Migration: A Field Experiment

Zherui Yang, PhD Candidate, Erasmus University, Rotterdam, Netherlands, yang@rsm.nl, Aaron Cheng, Ting Li

When targeting customers for digital communication channel migration, age is generally considered as a significant influencing factor. It is widely believed that younger customers are more likely to communicate digitally. By combining a field experiment with empirical testing, the authors demonstrate that age is not always an effective factor and propose two factors to better target customer in the context of digital communication, namely individual digital activeness and information seeking intensity. it is demonstrated that customers with higher individual digital activeness or lower information seeking intensity are more likely to migrate to digital communication channel.

1 - Consumers' Trust in Social Responsibility Disclosure: The Role of Supply Chain Visibility

Leon Valdes, University of Pittsburgh, Sloan School of Management, Pittsburgh, PA, 02139, United States, lvaldes@katz.pitt.edu, Tim Kraft, Yanchong Zheng

We experimentally investigate the role of supply chain visibility on consumers' trust in a firm's social responsibility (SR) communications. Specifically, we design a three-player game with the roles of Consumer, Seller, and Worker. The Worker's payment is private information, but the Seller observes a signal about this payment. The Seller can invest to improve this signal's quality, which captures the level of supply chain visibility. Finally, the Seller communicates with the Consumer about the observed signal. With this game, we study whether the level of visibility affects the Consumer's trust in the Seller's communication.

2 - Impact of Quality Bias on Platform Performance

Kyungmin (Brad) Lee, Boston University Questrom School of Business, Boston, MA, 22180, United States, kminlee@bu.edu, Nitin R. Joglekar, Marshall Van Alstyne

A two-sided platform like UBER allows only seller whose quality is above a screening threshold to join. In turn, buyers face a trade-off between ensuring high-quality sellers and guaranteeing enough sellers (or lowering wait-time). We first formally characterize the optimal screening threshold and price in equilibria under the rationality assumption. We then show that this optimality is sensitive to buyer bias in perceiving driver quality. Buyer biases are identified and estimated through controlled experiments. The results document the impact of quality control, in the presence of biases, on a platform's profitability. We provide governance implications that induce favorable behaviors.

3 - Modeling Customer Response to Service Quality Variability with Implications for Pricing

Xiaoyang Long, University of Wisconsin-Madison, Wisconsin School of Business, WI, 53706, United States, xiaoyang.long@wisc.edu, Jordan D. Tong, Gregory A. DeCroix

Given the same expected quality, customers tend to demand less when quality is more variable. How should firms price their service in light of this behavior? In a simple setting of repeat service under stationary but variable quality, we show that a simple and behaviorally robust learning-from-experience formulation - even with risk neutrality - can lead to a quality variability penalty. We study the structure of the optimal pricing policy under this relatively understudied mechanism to generate insight into pricing strategy under quality variability.

4 - Centralized or Decentralized Transfer Prices: A Behavioral Approach for Improving Supply Chain Coordination

Elena Katok, University of Texas at Dallas, Jindal School of Management (SM30), Richardson, TX, 75080, United States, ekatok@utdallas.edu, Sebastian Villa

We study transshipment decisions in a channel with one supplier and two retailers under both decentralized and centralized transfer-price settings. Analytically, the optimal transfer price should depend on the critical ratio, but results show that participants almost ignore it. However, we observe a positive relationship between transfer prices and ordering quantities. We next study the centralized transfer-price setting, with exogenous transfer price. We find that using the theoretical price does not help to increase either profits or coordination. However, by setting a behavioral transfer price, subjects place orders that lead to high supply chain profits.

5 - Agile Project Management – Improved Performance Through Scrum Sprints?

Tobias Lieberum, Technical University of Munich, Mÿnchen, Germany, tobias.lieberum@tum.de

Agile Scrum sprints are characterized by timeboxed progression and output goals for every sprint. In a 2x2 experimental design, we show that in the absence of timeboxed progression and phase-specific output goals participants spend too much time on early compared to later project phases. We refer to this effect as Progression Fallacy. Timeboxed progression mitigates this effect, but only little improves the overall exerted effort. Phase-specific output goals without timeboxed progression have an adverse effect, due to an amplification of the Progression Fallacy. Only the combination of timeboxed progression and phase-specific output goals results in an overall performance uplift.

1 - A Structural Analysis of Bitcoin Cash's Emergency Difficulty Adjustment Algorithm

Vipul Aggarwal, University of Washington, Seattle, WA, 98105, United States, aggarv@uw.edu, Yong Tan

We analyze the equilibrium behaviour of cryptocurrency miners in the wake of a major cryptocurrency fork. Miners are responsible for validating transactions and ensuring smooth functioning of the cryptocurrency platform. Specifically, we are interested in their strategic interactions with the incentives provided by the developers of the newly born minority chain to prioritize its transactions over that of the dominant parent currency. We focus our attention on the Bitcoin (BTC) fork of August 2017 that resulted in the birth of Bitcoin Cash (BCH). BCH's developers introduced emergency difficulty adjustment (EDA) algorithm to incentivize miners to process BCH's transactions over that of BTC's.

2 - Sympathy to the Seemingly Needy: Does Social Influence Alleviate Biases in Medical Crowdfunding?

Yun Young Hur, Georgia Institute of Technology, Atlanta, GA, 30312, United States, Fujie Jin, Xitong Li, Yuan Cheng, Jeffrey Hu

In this study, we conduct a large-scale randomized field experiment with a leading medical crowdfunding platform to examine whether leveraging social influence impacts users' willingness to donate and how the impact differs for cases involving male and female patients. Our results show that social influence alleviates gender bias in donations, particularly for cases lacking other strong signals such as involving patients of young age or with cancer-related conditions. On the other hand, presence of other strong case-level signals makes patient gender a redundant signal and therefore, social influence's impact on willingness to donate is likely similar across patient gender in these cases.

3 - The Value of Alternative Data in Credit Risk Prediction: Evidence from a Large Field Experiment

Tian Lu, Carnegie Mellon University, Pittsburgh, PA, United States, tianlu@andrew.cmu.edu, Yingjie Zhang, Beibei Li

This paper conducts a comprehensive evaluation of the value of alternative data on microloan platforms with a large field experiment. Our machine-learning analyses demonstrate that alternative data can significantly improve the prediction accuracy of borrowers' default behavior and increase platform profits. Moreover, we find that our framework helps financial institutions extend service to more lower-income and less-educated loan applicants from less-developed geographical areas. Our study demonstrates the tremendous potential of leveraging alternative data to alleviate such inequality in the financial service markets, while in the meantime achieving higher platform revenues.

4 - Information Asymmetry and Strategic Early Bidding in Peer-to-Peer Lending

Kai Lu, Assistant Professor of Finance, University of Science and Technology of China, International Institute of Finance, School of Management, Hefei, China, kailu666@ustc.edu.cn, Tat Y. Chan, Zaiyan Wei

We study how investors on peer-to-peer lending platforms utilize their information advantage to bid strategically. Better-informed investors face a tradeoff between the probability of successful funding and the expected return when deciding the timing of bidding. Using a unique dataset from Prosper.com, we document the phenomenon of early bidding (or "squatting") behaviors. We show that "good" loans attract more early bids than "bad" loans. Most importantly, "good" loans with a low ex-ante probability of funding success attract more early bids from better-informed investors. Those early bids would benefit not only the borrowers but also uninformed investors.

1 - Prospective Dynamic Fraud Control for Optimal Profitability in E-commerce

Anand Oka, Microsoft, Redmond, WA, United States, John Beaver, Yung-Wen Liu

Many merchants conduct their businesses through e-commerce. One major challenge in tackling e-commerce fraud results from dynamic fraud patterns, which can degrade the detection power of risk models and can lead to them failing to detect fraud that has emerging unrecognized patterns. The problem is further exacerbated by the conventional decision frameworks that ignore the follow-up decisions made by other associated parties (e.g., payment-instrument issuing banks and manual review agents). Microsoft developed a new fraud management system (FMS) that effectively tackles these two challenges. It keeps features used by the machine learning (ML) risk models up to date by using real-time archiving, dynamic risk tables, and graph theory. The FMS uses customized long-term and short-term sequential ML models to detect both historical and emerging fraud patterns. It also makes rapid real-time optimal decisions using a dynamic programming approach to optimize the long-term profit by taking into account the aforementioned multi-party decisions. After implementing these innovations over a two-year period (2016 to 2018), Microsoft reduced its fraud loss by 0.52%, thus generating $75 million in additional savings, reduced the incorrect fraud rejection rate by 1.38%, and improved its bank authorization rate by 7.7%. The result was many millions of dollars in additional revenue. These innovations simultaneously prevent fraud and increase bank acceptance. In April 2019, Microsoft launched Microsoft Dynamics 365 Fraud Protection, a cloud-based service available for all e-commerce merchants.

2 - Bus Routing Optimization Helps Boston Public Schools Design Better Policies

Arthur J. Delarue, MIT, Cambridge, MA, 02139, United States, Sebastien Martin

Spreading start times allows school districts to reduce transportation costs by reusing buses between schools. However, assigning each school a time involves both estimating the impact on transportation costs and reconciling additional competing objectives. These challenges force many school districts to make myopic decisions, leading to an expensive and inequitable status quo. For instance, most American teenagers start school before 8:00 AM, despite evidence of significant associated health issues. We propose an algorithm to jointly solve the school bus routing and bell time selection problems. Our application in Boston led to $5 million in yearly savings (maintaining service quality despite a 50-bus fleet reduction) and to the unanimous approval of the first school start time reform in 30 years.

3 - Vattenfall Gets Hundreds of Millions in Gains Through the Application of Operations Research for Offshore Wind Farm Design

David Pisinger, Technical University of Denmark and Vattenfall, Lyngby, Denmark, Martina Fischetti, Jesper Runge Kristoffersen, Thomas Hjort, Michele Monaci

Vattenfall Gets Hundreds of Millions in Gains Through the Application of Operations Research for Offshore Wind Farm DesignMartina Fischetti, Jesper Runge Kristoffersen, Thomas Hjort, Michele Monaci, David PisingerWind energy is a fast-evolving field that has attracted a lot of attention and investments over the past decades. The development into a more mature and competitive market makes reduction of costs and maximisation of power production imperative already in the design phase of new wind farms. Vattenfall is one of the largest producers of electricity and heat in Northern Europe, having the ambition to enable a fossil free living within one generation. To reach this goal Vattenfall developed OR methods to identify the optimal location of wind turbines in a given site, and the corresponding routing for offshore electrical cables. In this way Vattenfall is able to maximize the power output and reduce building costs.The tools developed in our project are now fully deployed in the company and used to design all Vattenfall s offshore wind farms. They allowed for savings the order of 150M€for the complete pipeline of sites under construction (so far).

Flash Session III

Flash Session

Chair: Raymond Fan, University of Houston, Cypress, TX, 77429, United States

1 - Clustering Algorithms for Scheduled Ride Sharing

Muhammad Naiman Jalil, Lahore University of Management Sciences, Lahore Cantt., Pakistan, muhammad.jalil@lums.edu.pk

We focus on clustering of customer ride requests in scheduled ride sharing setting. A typical practical problem in scheduled ride sharing often involves thousands of pickup and delivery customers that are candidates for pooled rides. Hence, clustering techniques may be utilized to reduce problem size while identifying requests that are preferable candidates for pooled rides. The problem is unique since each customer request involves pickup, delivery and n-intermediate vertices. In this talk, we discuss the suitability of clustering techniques in data mining for this problem.

2 - Crew Recovery for Airline Operations: Case of Transavia

Evrim Ursavas, Associate Professor in Energy and Logistics, University of Groningen, Groningen, Netherlands, e.ursavas@rug.nl, Albert Schrotenboer, Stuart Zhu

Disruption management in airline operations is becoming increasingly important. We study an airline crew recovery problem where a schedule is repaired in a cost-efficient and a flexible way to cope with additional future disruptions. We evaluate the expected shortfall of reserve crew and propose a set-covering formulation which encapsulates flexibility for reserve crew usage. A tailored branch-and-price algorithm is developed where the pricing problems are solved by a pulse algorithm. Experiments at a Dutch carrier show that the approach delivers more stable schedules, which leads to less last-minute crew alterations (and subsequent delays) and cancellations.

3 - Differentiating Interhospital Transfer Types: Varied Impacts and Diverging Destination Choice Strategies

Raymond Fan, University of Houston, Cypress, TX, United States, raymondfan@bauer.uh.edu, Ming Zhao, David Xiaosong Peng

This study first develops a method to empirically separate clinical interhospital transfers (IHTs) from non-clinical IHTs. Next, we evaluate their impacts on care outcomes and find: (1) clinical IHTs are associated with better outcomes than non-clinical IHTs; (2) for non-clinical IHTs, transfers within the same healthcare system are associated with better outcomes than those out of the system, whereas for clinical IHTs, destinations out of the system are better than those in the system. We use Heckman selection model and propensity score matching to address potential sample selection bias. The results provide managerial insights on IHT destination choice strategies.

4 - Digital Transformation in Retail Banking and the Role of Digital Service Development

Ting Cao, York University, Toronto, ON, Canada, tingc0109@gmail.com, Murat Kristal, Larry Menor

We empirically examine the impact of digital transformation on digital service performance in retail banking. A multi-dimensional construct, digital service development, is developed to capture banks' efforts in generating digital service options through the integration of digital technologies into the operational system. A two-stage approach is used for new multi-item scale development. A global based survey "Innovation in Digital Services" is conducted to collect data. The results offer not only "know-what" of digitalization but also the "know-how" of developing digital services by appropriately managing relevant perspectives to achieve higher digital service performance.

5 - Evaluating Demand-driven Material Resource Planning for an Assembly Line Using Discrete-event Simulation

Kentaro Kuwahara, Chuo University, Tokyo, Japan, a15.xdc5@g.chuo-u.ac.jp, Wenhe Yang, Soemon Takakuwa

Nowadays, manufacturers are required to cope with uncertainties due to product-wide customization and demand uncertainty. Demand-driven MRP (DDMRP) is regarded as an effective approach for managing the multi-echelon demand and replenishment planning for enhancing traditional MRP and other management methods. For evaluating DDMRP, in this study, a discrete-event simulation model for an assembly line of bicycles is constructed to compare performance measures with MRP under the several specified scenarios.

6 - Current Challenges in Development of a Survival Analysis Data Mining Study

Hamidreza Ahady Dolatsara, Clark University, Worcester, MA, United States, hamid@auburn.edu, Fadel Mounir Megahed, Chen Ying-Ju Tessa

This study highlights the issues and challenges that are associated with the development of a data mining (DM) study in the transplantation field. The UNOS dataset was investigated for the development of a data mining study to predict survival of patients within one year after heart transplantation surgery. CRISP-DM (CRoss Industry Standard Process for Data Mining) was adopted as the outline of the DM based survival analysis.

7 - Dominant Strategy Implementation Without Quasilinearity

Brian Baisa, Amherst College, Amherst, MA, United States, bbaisa@amherst.edu

I study the problem of a mechanism designer who wants to implement a social choice function. Agents have non-quasilinear preferences and private values. My main result illustrates a duality between non-quasilinear private value mechanism design settings and quasilinear interdependent value mechanism design settings. In particular, a social choice function is dominant strategy implementable in the non-quasilinear setting if and only if it is ex post implementable in a corresponding interdependent value setting. I apply this result to show that it is impossible to implement non-trivial social choice functions in certain private value settings when agents have multi-dimensional types.

8 - Detecting Anomalous Online Reviewers: A Novel Hierarchical Machine Learning Approach

Naveen Kumar, University of Washington, Bothell, Bothell, WA, United States, Deepak Venugopal, Liangfei Qiu, Subodha Kumar

Online reviews and discussions play a significant role in influencing decisions made by users in day-to-day life. However, the presence of reviewers who deliberately post fake or deceptive reviews for financial or other gains negatively impacts both users and businesses. Unfortunately, automatically detecting such reviewers is well known to be a challenging problem, particularly since fake reviews do not seem out-of-context as compared to genuine reviews. In this paper, we propose a novel machine learning approach for this task. Our approach is highly generalizable, allows us to seamlessly combine both univariate and multivariate distributions into a unified anomaly detection system.

1 - Multi-process Production Scheduling with Onsite Renewable Energy Integration and Demand Response

Jose Luis Ruiz Duarte, University of Arizona, Tucson, AZ, United States, jlruizduarte@email.arizona.edu, Neng Fan

International efforts to reduce greenhouse gases emissions require industrial sector, one of the major energy consumers, to be involved in its solution. Integrating renewable energy sources to power manufacturing operations is one approach to achieve greenhouse gases reduction targets. In this presentation, the development of an mathematical programming model to obtain the optimal production scheduling of a manufacturing facility with onsite energy storage systems and renewable energy sources with uncertain power output and operating under demand-side management policies is shown. A sensitivity analysis is performed under different production scenarios and policies.

2 - Safety Control in the Online Take-out Food Platform

Xinping Wang, Nanjing Agricultural University, Nanjing, China, wangxp@njau.edu.cn, Shengnan Sun, Lindu Zhao

While the online take-out food platform benefits these food stores, it brings more risk to food safety. This paper investigates how the food safety outcome is affected by the government regulations and platform safety policies. We analyze the effectiveness of these regulations and policies and explore their impact on operational decisions of both platform and food stores.

3 - Sharing Economy in the Cloud: Pricing Schemes of the Peer-to-peer Storage Platforms

YoungJae Jang, KAIST, Seoul, Korea, Republic of, jyj0902@kaist.ac.kr, Jaeung Sim, Kun Soo Park, Daegon Cho

Peer-to-peer (P2P) cloud storage platforms, which allow people to share their unused storage resources to others, have emerged as a solution of the unprecedented surge in data storage demands. In this paper, we analyze a P2P storage platform that aims to maximize its consumer surplus and profit simultaneously.

4 - Cooperation and Competition in the Joint Sales Platform

Hakjin Chung, Assistant Professor, Korea Advanced Institute of Science and Technology (KAIST), Seoul, Korea, Republic of, hakjin.chung@kaist.ac.kr

The joint sales platform provides the seller to earn greater exposure of their products and to reach outside of their usual markets at the shared cost of marketing. At the same time, it spurs competition among partners. We consider a seller's problem of determining whether to participate in the joint sales platform and setting the optimal prices. We also compare a number of different platform settings such as pricing by platform, revenue sharing, and negotiation level.

5 - Hunger Game for a Competitive Supply Chain Simulation

Ju Myung (JM) Song, San Jose State University, San Jose, CA, United States, jumyung.song@sjsu.edu

We invented an online game for OM class, called "Hunger game", which group of students will compete with each others under a supply short by playing. We will discuss how it works and the effectiveness of it to understand Newsvendor model, supply shortage, information's role, and a fair sharing's concept.

Scheduling III

Contributed Session

Chair: Mario Gnägi, University of Bern

1 - Maintenance Scheduling of Fiber-optics Network

Ramesh Bollapragada, San Francisco State University, San Francisco, CA, United States, rameshb@sfsu.edu, Saravanan Kuppusamy, Uday Rao, Sridhar Seshadri

We present a mathematical optimization model for a novel, practically-motivated maintenance scheduling problem that schedules activities on a fiber-optics network. The objective is to minimize the sum of network outage costs and penalties for not scheduling activities. We solve the problem for a host of instances that differ in number of activities, outage duration, planning horizon, precedence relationships between activities and we identify harder instances that take longer to solve. We note that the solution run time is not monotone in the planning horizon; certain precedence relationships we study and longer outage durations make the instances harder.

2 - Intra-project Learning in Resource-constrained Project Scheduling

Jordan Ticktin, California Polytechnic State University, San Luis Obispo, CA, United States, jticktin@calpoly.edu, Alessandro Hill

It's commonly assumed that experience leads to efficiency, yet this is largely unaccounted for in resource-constrained project scheduling. We consider the case that selected activities can be completed within reduced time when scheduled after activities that result in learning of relevant skills. Using constraint programming, we computationally explore this intra-project learning effect on optimal makespan and problem difficulty across hundreds of thousands of scenarios. We evaluate the impact of multiple parameters such as project size, learning frequency, and learning intensity. We compare different model formulations and lower bounding techniques with respect to their efficiencies.

3 - Multi-mode Resource Constrained Project Scheduling for Pharmaceutical R & D

Hua Wang, Carnegie Mellon University, Pittsburgh, PA, United States, huaw@andrew.cmu.edu, Shekhar K. Viswanath, Steve V. Guntz, John Dieringer, Shankarraman Vaidyaraman, Salvador Garcia-Munoz, Chrysanthos E. Gounaris

The R&D management of a major pharmaceutical company constantly faces a complicated activity scheduling and resource allocation problem. We model this setting as a generalized resource constrained project scheduling problem under various business-driven objectives, and we demonstrate its tractability to address portfolio-wide instances, while we deploy a decision support tool for the systematic and largely automated derivation of optimal solutions. By instantiating the tool with different inputs in the context of automated workflows, we can also use our tool to conduct various analyses to assess the system's ability to cope with sudden changes or react to shifting management strategies.

4 - A Variable Neighborhood Search Based Matheuristic for Resource Constrained Project Scheduling Problem with Learning Considerations

Ying Liu, Nanjing Univeristy, Nanjing, China, liuyingsme@smail.nju.edu.cn, Qian Hu

We study the resource constrained project scheduling problem with learning considerations, including autonomous learning (learning by doing) and induced learning (learning by review). In our problem, the real processing time of an activity becomes variable and depends on the sequencing relation between two activities and review times of other activities in a project. We develop a variable neighborhood search based matheuristic, which fully exploits the mathematical solver CPLEX and VNS framework, in which a set of neighborhoods are iteratively searched by CPLEX within a given time limit.

5 - A Novel Continuous-time Mixed-binary Linear Programming Formulation for the Multi-site Resource-constrained Project Scheduling Problem

Mario Gnägi, University of Bern, Bern, Switzerland, mario.gnaegi@pqm.unibe.ch, Norbert Trautmann

In the multi-site resource-constrained project scheduling problem, some precedence-related project activities which require some scare resources for their execution, and the sites at which these activities can be performed, are given. Sought are a start time and a site for each activity such that the project duration is minimized, and all precedence relationships, resource capacities, and transportation times between the sites are respected. We present a novel continuous-time mixed-binary linear programming formulation and report computational results for test instances from the literature.

Data Envelopment Analysis I

Contributed Session

Chair: Xu Wang, Waseda University, 3-4-1 Okubo, Shinjuku-ku, Tokyo 169-8555, Jap, Tokyo, Japan

1 - A Data Envelopment Analysis Approach for Ranking Climate Change Adaptation Technologies

Daiki Min, Associate Professor, Ewha Womans University, Seoul, Korea, Republic of, dmin@ewha.ac.kr

This paper is motivated by observations on the problem for ranking climate change adaptation technologies in Korea. To overcome the drawbacks of using conventional multi-criteria decision analysis, this paper formulate the decision process as a DEA-like model. The decision process involves heavy subjective judgements, which results in data uncertainty. We propose a Monte-Carlo simulation based method to provide robust analysis against the data uncertainty. This paper used the proposed method for a case study in which 11 technologies for climate change adaptation are evaluated.

2 - Analysis of the Operational Efficiency of Public Regional Art Centers in Korea

Sung-min Park, Doctor's course, Kyungpook National University, Deagu, Korea, Republic of, Chae-Bogk Kim

Because of the interest on arts and performance frequency of concerts, the supporting budget for public regional art centers in Korea is increasing. Even though the importance of the operational efficiency of public art centers in each region has been emphasized, there are not many researches on the operations of public art centers. The purpose of this paper is to analyze the operational efficiency of public regional art centers through both DEA and AHP techniques based on the survey data provided by government and to propose various recommendations to inefficient regional public art centers.

3 - Time Series Analysis of Community Banks Using a Combination of Slack Based Efficiency Measure and Social Network Model

Yaoyao Wei, Northwestern Polytechnical University, Xi'An, China, weiyaoyao@mail.nwpu.edu.cn, Haibo Wang, Yang Wang

This paper presents the time series analysis on the performance of 1550 community banks in the US from 1993 to 2006. We use the slack-based efficiency measure on the variables provided by FDIC and a social network model to identify the best-practice frontiers in the community bank system. We choose the size of bank and type of business loan for cross-sectional analysis on the efficiency measure. We perform the same analysis procedure on 1260 non-community banks from the same period for comparison.

4 - Data Envelopment Analysis as a Tool for Process Improvement Based on Agents Efficiencies

Ricardo A. Cassel, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, cassel@producao.ufrgs.br, Vinicius E. Simionato, Daniel P. Lacerda

Studies on efficiency and productivity improvements have been getting more and more attention, both in academic and professional publications. Furthermore, process modelling and improvement are fundamental for companies development. Despite the wide bibliography in these two areas, studies are scarce in their intersection. Hence, this study proposes the application of the Data Envelopment Analysis to evaluate the efficiency of the process agents and its impact on the next stages of the process. A theoretical framework was proposed and a case study was conducted in a financial institution.

5 - DEA Based Bankruptcy Assessment Approach

Xu Wang, Waseda University, Tokyo, Japan, xu.wang@aoni.waseda.jp, Takashi Hasuike

In this research, we propose to use Data Envelopment Analysis (DEA) as an easy-and-quick tool for bankruptcy assessment and prediction. An important feature of DEA is that it is a non-parametric approach which measures the weight estimates of a functional form for classifying observations into two groups: efficient and inefficient DMUs. Moreover, the uniqueness of DEA lies in that it can provide ``what to do" information (improvement goals and plans) for those inefficient DMUs (default firms). Thus, using DEA for bankruptcy assessment give an early warning of the firm's financial performance and provide an improvement goal or plan for the default firm.

Disruption Management and Humanitarian Logistics

Contributed Session

Chair: Shubhra Paul, North Carolina A&T State University, Greensboro, NC, 27405, United States

1 - Consumer Side View of Market Disruptions

Hisanaga Amikura, Sophia University, Tokyo, Japan, h-amikur@sophia.ac.jp, Masahiro Ishii

The purpose of this study is to find decisive factors of disruptive innovation. Whereas many studies suggested that a disruptive innovation arises from product di erentiation, not every di erentiated good leads to disruption of a market. Based on the Japanese Digital Still Camera (DSC) market case, the authors discuss why customer changed their evaluation towards novel products. Combining analyses on 1) hedonic pricing analyses of POS records, 2) contents analyses of press release wordings, and 3) correspondence analyses of hardware specifications, we found that Japanese customers highly evaluate certain product attributes in one time, but their concern went to other factors in short period.

2 - A Reinforcement Learning Approach for Measuring Delivery Variability under Disruption in Emergency Routing

Zohreh Raziei, Southern Methodist University, Dallas, TX, United States, zraziei@smu.edu, Eli Olinick, Khaled Abdelghany

We model the distribution of relief supplies after a natural disaster as a vehicle routing problem with infrastructure distribution and demand uncertainty. In the model, routing decisions are made both to meet estimated demand and to obtain information about actual demand and travel conditions on the road network. We propose a machine learning approach with sequential sampling to address the dynamic nature of the problem.

3 - A Stochastic Programming Model for Dynamic Emergency Supply Planning Considering Transportation Network Development and Traffic Congestion

Qingyi Wang, Sichuan University, Chengdu, China, qingyiwang@scu.edu.cn, Xiaofeng Nie

Some emergency supply planning challenges, like dynamic post-disaster environments and traffic congestion, are seldom addressed in the literature. We propose a stochastic programming model, which integrates pre-disaster supplies pre-positioning and transportation network development decisions with post-disaster transportation decisions. We solve the formulated mixed-integer nonconvex nonlinear program with a generalized Benders decomposition algorithm. Moreover, some case study results are presented.

4 - Fleet Sizing Across Different Humanitarian Organizations

Laura Turrini, European Business School, Oestrich Winkel, Germany, laura.turrini@ebs.edu, Nathan Kunz, Maria Besiou, Luk N. Van Wassenhove

We focus on fleet management and empirically estimate what drives the fleet size of multiple humanitarian organizations in different countries. The analyzed elements include organization size, number of target beneficiaries and country vulnerability. We derive additional insights by comparing our results across the case organizations.

Joint Session TIME/Practice Curated: Management of Product, Service and Data Integration

Sponsored: Technology, Innovation Management & Entrepreneurship

Sponsored Session

Chair: Juliana Hsuan, Copenhagen Business School, Frederiksberg, DK-2000, Denmark

1 - On the Evolution of Knowledge in Online Communities

Nitin V. Mayande, Portland State University, Engineering and Technology Management, Portland, OR, 97207, United States, Charles M. Weber

A study of a diverse set of Twitter conversations over a prolonged period of time provides insights into how knowledge evolves in online communities.

2 - From Likes to Liability: Investigating the Dark Side of Social Media for Entrepreneurs

John N. Angelis, Elizabethtown College, Elizabethtown, PA, 17554, United States, Dmitriy Krichevskiy, Joseph Miller

Entrepreneurs benefit from social media in terms of promotion, networking, education, and many other opportunities. However, recent research and scandals have uncovered the dark side of social media, such as bullying, privacy violations, and addiction. We survey 200 entrepreneurs and 200 business personnel to verify if there are significant differences in social media usage. Our focus is on whether entrepreneurs are more likely to have negative experiences on social media, or to report personal misuse of social media.

3 - The Impact of Ontological Semantic Patent Searches on New Product Development

Charles M. Weber, Portland State University, Engineering and Technology Management, Po Box 751, Portland, OR, 97207, United States, Farshad Madani

A patent search method, which is based on ontologies and semantic analysis, identifies pertinent patents for new product development. The approach, which focuses on the body text of patents, is demonstrably superior to the current state of the art.

4 - Pricing Services Using Transaction Data

Eric Bentzen, Copenhagen Business School, Frederiksberg, Denmark, eb.om@cbs.dk, Juliana Hsuan

Many of the attributes with respect to pricing services are implied by economic theory that can be modeled and investigated by using relevant data from a company. In this paper, we investigate effects that a large service provider use in the pricing of services. From a company we have access to customer transaction data. The dataset has been collected during a period of one year. With the use of transaction data, we expand the microeconomic model and decompose the loyalty parameter into single customers and this opens up for several new microeconomic considerations and new challenges.

Shale Energy Optimization

Sponsored: Energy, Natural Res & the Environment/Natural Resources Petrochemicals

Sponsored Session

Chair: John Eason, EQT Production Company, Pittsburgh, PA, 15222, United States

1 - Optimal Artificial Lift Infrastructure Plan for Shale Gas Horizontal Wells under Endogenous and Exogenous Uncertainties

Zuo Zeng, Auburn University, Auburn, AL, United States, zzz0057@tigermail.auburn.edu, Selen Cremaschi

Artificial lift methods (ALMs) are used in horizontal shale-gas wells to lift the accumulated fluids in the well and to help sustain well performance. We present a multistage stochastic programming (MSSP) model for artificial lift infrastructure planning (ALIP) of shale gas horizontal wells. The model incorporates both endogenous, ALM-dependent well production, and exogenous, shale gas price, uncertainties. The objective is to maximize the expected net present value. Finally, we apply MSSP model for a horizontal well located in Woodford shale.

2 - Strategic Planning of Reservoir Development through Adaptive Mixed Integer Optimization under Endogenous Uncertainty

Zukui Li, University of Alberta, Chemical and Materials Engr, Edmonton, AB, T6G 1H9, Canada

During the lifecycle of an oilfield project, development is the most critical phase due to intensive investments required for capital and operating costs. Determining whether it is economic to develop an oilfield or not and finding the best schedule for field development are the main concerns in this field of study. This work presents an optimization method for strategic planning of reservoir development under endogenous reservoir uncertainty. Multistage adaptive optimization is applied to solve the problem where the integer decisions are adjustable. The novelty of the work is the combination of lifting based adaptive binary decision rule and the consideration of endogenous uncertainty.

4 - Shale Gas Development Planning under Uncertainty

John Eason, EQT Production Company, Pittsburgh, PA, 15222, United States, Can Li, Markus G. Drouven, Ignacio E. Grossman

In this paper, we study shale gas pad development under natural gas price uncertainty. We optimize the sequence of operations, gas curtailment and storage on a single pad to maximize the net present value (NPV). The optimization problem is formulated as an mixed-integer linear programming (MILP) model, which is similar to the one proposed by Ondeck et al. [1]. We investigate how natural gas price uncertainty affects the operation strategy in the pad development. Both two-stage and multi-stage stochastic programming are used as the mathematical framework to hedge against uncertainty. Our case study shows that there is value of using stochastic programming when the price variance is high. However, when the variance of the price is low, solving the stochastic programming problems does not create additional value compared with solving the deterministic problem.

Food Waste

Sponsored: Energy, Natural Res & the Environment/Environment & Sustainability

Sponsored Session

Chair: Arzum E. Akkas, Boston University, Cambridge, MA, 02142, United States

1 - Strategies for Reducing Food Waste in Retailing: a Multi-stakeholder Perspective

Christina Holweg, WU Vienna University of Economics and Business, Vienna, Austria, Christina.Holweg@wu.ac.at, Christoph Teller, Herbert Kotzab, gerald Reiner

Food waste has become an increasing issue for retailers in industrialized nations. The research investigates the causes of food waste across product categories and different retail store formats. In a mixed methods approach face-to-face interviews with store managers serve as the key source of information, complemented by expert interviews. Results reveal that the occurrence of food waste is impacted by various stakeholders and factors as e.g., the retail parent organization, employees, consumer’s shopping behavior, or regulatory constraints. We propose measures of prevention and reduction which also illustrate opportunities behind the issue of food waste.

2 - A Predictive-prescriptive Model for Food Allocation

Debjit Roy, Indian Institute of Management Ahmedabad, Ahmedabad, India, debjit@iima.ac.in, Elena Belavina, Nathan Kallus, Karan Girotra

We study the food allocation problem for government-run schools. We first identify the factors that can explain the demand variance among the schools and then develop a predictive-prescriptive model for optimal allocation of food to different schools. Our methods lead to significantly more children being fed with the same resources; our analysis can be generalized to other allocation problems in resource-constrained environments.

3 - Combating Consumer Food Waste

Ekaterina Astashkina, University of Michigan, Ross School of Business, Ann Arbor, MI, United States, astash@umich.edu, Elena Belavina

We build an analytical model to compare the efficacy of different instruments that combat consumer food waste. We compare (i) taxes and subsidies on groceries, food waste & transportation as a part of the comparison within the fiscal instruments group; (ii) the development of an online grocery outlet against increased store density as a part of the comparison of zoning laws, and (iii) distinct consumer education campaigns. We find that the efficacy of these instruments depends on the market type and its characteristics. The numerical calibration of the model with the demographic data reveals that, in realistic settings, certain instruments are always dominated by others.

4 - Impact of Strategic Farmers on Mechanization Investment in Rainfed Agriculture

Ying (Maggie) Zhang, Clemson University, Clemson, SC, United States, Ying6@clemson.edu, Jayashankar M. Swaminathan

In this paper, we study the optimal investment of farming machinery and seeds for a single crop when farmers could be strategic about commodity pricing. In the computational study, utilizing filed weather data and simulated yield data, we explore the impact of strategic and naive pricing decisions on the optimal investment portfolio.

Policy-Enabling Models for the Power Sector II

Sponsored: Energy, Natural Res & the Environment/Electricity

Sponsored Session

Chair: Afzal Siddiqui, University College London, London, WC1E 6BT, United Kingdom

1 - Investment under Uncertainty and Risk in Competitive Electricity Markets

Golbon Zakeri, University of Auckland, Dept. of Eng Science, Auckland, New Zealand, g.zakeri@auckland.ac.nz, Andrew Philpott, Corey Kok

We will discuss an investment model in electricity generation when the generating agents are competitive yet risk averse. We will discover interesting manifestations of the so called ‘theorem of second best’ when agents are risk averse and the market for risk is not complete. We will also present a numerical study comparing effectiveness of various risk trade instruments and the extent to which they complete the risk market.

2 - A Closed-loop Model of Imperfect Competition in Natural Gas Supply Contracts for Electric Power Generation

Francisco David Munoz, Universidad Adolfo Ibáñez, Santiago, Chile, Mauricio Fernández, Rodrigo Moreno

We develop an open-loop equilibrium model to evaluate if generation firms have incentives to contract or import the socially-optimal volumes of natural gas to generate electricity and illustrate an application of our model using a network reduction of the electric power system in Chile. Our results indicate that strategic firms that own a portfolio of different technologies could have incentives to sign natural gas contracts for volumes that are much lower than the socially-optimal ones. This effect is rather sensitive to the price of natural gas. A high price almost eliminates the incentives of generation firms to exercise market power through natural gas contracts.

3 - Analyzing Time Period Aggregation Methods for Power System Investment and Operation Models with Renewables and Storage

Sonja Wogrin, Comillas Pontifical University, C/ Santa Cruz de Marcenado 26, Madrid, 28015, Spain, sonja.wogrin@comillas.edu, Diego Tejada-Arango, Salvador Pineda, Juan Morales

The transition of the power system from its current state to the power system of the future is heavily influenced by the growing penetration of renewables combined with the increasing importance of storage technologies. We present and compare two different time-period aggregation methods (enhanced representative periods; and, chronological time-period clustering) that allow for the adequate representation of both renewables and storage technologies in power system models. And we assess the quality of both aggregation methods in terms of accurately predicting investment and operating decisions.

4 - Power Based Generation Expansion Planning for Flexibility Requirements

Sonja Wogrin, Universidad Pontificia Comillas, IIT, C/ Santa Cruz de Marcenado 26, Madrid, 28015, Spain, sonja.wogrin@gmail.com, Diego A. Tejada-Arango, Efraim Centeno, German Morales-Espana

Flexibility requirements are becoming more relevant in power system planning. In order to consider these requirements GEP models have recently incorporated Unit Commitment (UC) constraints, using traditional energy-based formulations. However, recent studies have shown that energy-based UC formulations overestimate the actual flexibility of the system. Instead, power-based UC models overcome these problems by correctly modeling ramping constraints and operating reserves. This presentation proposes a power-based GEP-UC model that improves the existing models by including real-time flexibility requirements and the flexibility provided by energy storage.

Flow Relaxations for Energy Models

Sponsored: Energy, Natural Res & the Environment/Energy Sponsored Session

Chair: Antonio J. Conejo, The Ohio State University, Columbus, OH, 43210, United States

Co-Chair: Chen Chen, The Ohio State University, Columbus, OH, 43201, United States

1 - Gas-Aware Unit Commitment

Pascal Van Hentenryck, Georgia Institute of Technology, Atlanta, GA, 30332, United States, Geunyeong Byeon

The increase in Gas-Fueled Power Plants (GFPP), have created significant interdependencies between the electrical power and natural gas transmission systems. This may lead to significant economic and reliability risks as revealed by the 2014 polar vortex event. To mitigate these risks, while preserving the current structure of the markets, this presentation explores the idea of introducing gas network awareness into the standard unit commitment model. The approach is validated on a case study that can reproduce the gas and electricity price spikes experienced in 2014. The results demonstrate that gas awareness in unit commitment is instrumental in avoiding the peaks in electricity prices.

2 - Using Coordinate Transformations to Strengthen QC Relaxations of Optimal Power Flow Problems

Daniel K. Molzahn, Assistant Professor, Georgia Institute of Technology, Atlanta, GA, 60605, United States, molzahn@gatech.edu, Mohammad R. Narimani, Mariesa L. Crow

Recent convex relaxation techniques provide new insights regarding the global optimality of optimal power flow (OPF) solutions. The QC relaxation is a promising approach that convexifies nonconvex terms (i.e., trigonometric and product terms) by enclosing them in convex envelopes. The accuracy of the QC relaxation strongly depends on the tightness of these envelopes. We present several improvements which strengthen QC relaxations of OPF problems via coordinate transformations of the power flow equations. These transformations facilitate the development of tighter envelopes for these equations, resulting in higher quality solutions to the QC relaxation.

3 - A Convex Model for Joint Topology Identification and State Estimation of Power Networks

Ramtin Madani, PhD, The University of Texas at Arlington, Arlington, TX, 76019, United States, ramtin.madani@uta.edu, Tuncay Altun, Ali Davoudi

In this talk, we introduce a convex method for joint topology identification and state estimation of power networks based solely on nodal measurements. We show that the binary and continuous variables accounting for the connectivity and the operating condition of any power network can be determined by minimizing a novel nuclear norm-based objective function. The ability of the proposed approach in offering real-time situational awareness is demonstrated through hardware-in-the-loop simulations for both direct-current microgrids and alternating-current transmission networks.

Flexibility Markets in Energy Systems

Sponsored: Energy, Natural Res & the Environment/Energy Sponsored Session

Chair: Asgeir Tomasgard, Norwegian University of Science and Technology, Trondheim, Norway

Co-Chair: Guray Kara, Norwegian University of Science and Technology, Trondheim, Norway

1 - A Linear Programming Approach to Analyze Cost Saving Responses to Capacity Based Grid Tariffs for Energy Flexible Neighborhoods

Stian Backe, PhD Candidate, Norwegian University of Science and Technology, Trondheim, Norway, stian.backe@ntnu.no, Guray Kara, Asgeir Tomasgard

We propose a linear program to analyze operation of flexible electricity assets to minimize costs under a capacity based power grid tariff. We compare two consumers being billed based on individual load vs. their combined load, and investigate the frequency of adjusting the subscribed capacity level (weekly vs. annually). We find that peak load shaving is triggered when the subscribed level is adjusted over the year. Incentives for load reduction during low demand periods lead to a welfare loss by penalizing utilization of idle grid capacity. Depending on where the bottleneck in the grid is located, the price signal should be based on the combined load of several customers rather than individual loads.

2 - Market Design Considerations for Scarcity Pricing: A Stochastic Equilibrium Framework

Anthony Papavasiliou, CORE, UCLouvain, Voie du Roman Pays 34, L1.03.01, Office b.114, Louvain la Neuve, 1348, Belgium, anthony.papavasiliou@uclouvain.be

The implementation of scarcity pricing is underway in a number of US markets, including Texas and PJM, and is also currently under consideration in Belgium. As the mechanism was originally conceived in the context of a US-style two-settlement system, its implementation in a European setting poses a number of interesting market design dilemmas. These market design choices can affect the back-propagation of scarcity prices to forward day-ahead markets for energy and reserve capacity. We propose a modeling framework for analyzing these market design choices based on stochastic equilibrium.

3 - Adaptive Trading in the Continuous Intraday Market

Gilles Bertrand, FNRS/UCLouvain, Belgium, bertrandgi@outlook.com, Anthony Papavasiliou

The continuous intraday electricity market has become increasingly important in recent years in Europe. Trading in this market is challenging due to the multistage nature of the problem, its high uncertainty, and the fact that decisions need to be made rapidly in order to lock in profitable trades. In this work, we model the problem using Markov Decision Processes, and solve it using policy function approximation. We compare our policy against rolling intrinsic, which is a method that is commonly used in industry, in the German continuous intraday market. We demonstrate an increase in profits of 12.1% relative to rolling intrinsic.

4 - Optimal Scheduling and Bidding of Flexibility for a Portfolio of Power System Assets in a Multi-market Setting

Guray Kara, Norwegian University of Science and Technology, Gloshaugen, Trondheim, 7491, Norway, guray.kara@ntnu.no, Asgeir Tomasgard, Hossein Farahmand

Flexibility is an important concept to cope with uncertainty in energy systems. In this paper, we consider the problem of an actor that manages a set of assets that can provide flexibility based services. We present a stochastic programming model for the dynamic scheduling of a portfolio of assess for which energy and flexibility products can be delivered into multiple markets, like day-ahead, intraday, balancing markets, and flexibility markets. Some of these services and products are locations specific, while others can be delivered system-wide or even cross-border. The purpose in the short-term is to remove bottlenecks, inefficiencies, and ensure security of supply at the minimum cost.

Manufacturing for Materials

Emerging Topic: Advanced Manufacturing

Emerging Topic Session

Chair: Asif S. Iquebal, Texas A&M University, College Station, TX, 77843, United States

1 - Online Monitoring, Detection and Mitigation of Defects in a Self-repairing Hybrid Manufacturing System

Marco Grasso, Politecnico di Milano, Milan, Italy, marcoluigi.grasso@polimi.it, Bianca Maria Colosimo

This talk presents the first Laser Powder Bed Fusion (LPBF) system that is able to detect the onset of a defect and remove it during the process, to achieve first-time-right production capability. The main idea consists of combining a multi-sensor in-situ monitoring system, aimed at detecting defect onsets in a robust and automated way, with a novel in-line defect removal system that "deletes" the defective layers by means of a surface grinding operation integrated into the LPBF system.

2 - Materials Characterization with Acoustic Emission Signatures

Xinyu Zhao, Arizona State University, Tempe, AZ, United States, xzhao119@asu.edu, Hao Yan, Asif S. Iquebal

In this paper, we develop a novel approach to discern certain intrinsic properties, especially of nonequilibrium and rarely occurring material phases. More specifically, we build up a hidden markov model to capture the transition among different materials based on the acoustic signals. We test the prediction accuracy in a Ti-6Al4V fabricated using electron-beam melting (EBM) followed by fine-abrasive finishing processes where the acoustic emission signals generated during this process is able to characterize the hidden material properties.

3 - A Machine Learning Approach for Characterizing Material Microstructure and its Impact on Machinability of Natural Fiber Reinforced Plastic Composites

Zimo Wang, Texas A&M University, College Station, TX, United States

Natural Fiber reinforced Plastic (NFRP) composites offer tremendous ecological advantages for sustainable manufacturing because of their degradability and recyclability. However, the heterogeneity of the NFRP leads to variations of material removal mechanisms over time which adversely impacts the surface finish. We present a machine learning approach for characterizations of machining Natural Fiber Reinforced Plastic (NFRP) materials. The presented model allows accurate estimation of the localized fiber packing density (FPD) and resultant surface integrity using extracted features from sensor signals.

4 - Real-Time Control for Large Scale Additive Manufacturing Using Thermal Images

Feifan Wang, Arizona State University, Tempe, AZ, 85281, United States, feifan.wang@asu.edu, Feng Ju, Kyle Rowe, Nils Hofmann

Large scale additive manufacturing has great application potentials in a variety of industries. To guarantee a good product quality, printing process is subject to constraints on print surface temperature. In this study, thin wall test components are printed, and thermal images are used to monitor print surface temperature. A regression model is built to predict surface temperature accurately. Based on the temperature prediction model, a layer time control method is proposed, which reduces the total build time by about 30%.

5 - An Active Learning Approach to Microstructure Prediction

Ashif S. Iquebal, Texas A. & M. University, College Station, TX, 77840, United States, Bhaskar Botcha, David Shoukr, Raymundo Arroyave, Satish Bukkapatnam

Acceleration of materials discovery and design is contingent on designing optimal experimental design that minimizes the cost of experimentation while reducing the prediction uncertainty. In this work, we present an approach to predict the response surface of the microstructure of an additively manufactured stainless steel with minimum experimental cost and uncertainty. We use a measure of prediction deviation as a metric for actively querying the subsequent experimental runs to guarantee a consistent reduction in the model uncertainty. Results show a significant reduction in the uncertainty via the present approach as compared to randomly selecting the sample points in the design space.

Joint Session I-SIM/TSL: Simulation Optimization and Applications in Maritime Logistics

Sponsored: Simulation

Sponsored Session

Chair: Jie Xu, George Mason University, Fairfax, VA, 22030, United States

1 - Using Simulation-optimization in Dynamic Resilience Estimation for Container Ports

Weiwen Zhou, George Mason University, Fairfax, VA, United States, Elise Miller-Hooks, Chun-Hung Chen, Loo Hay Lee, Haobin Li

We present a simulation-optimization based approach for dynamic resilience estimation in the context of container ports faced with the risk of disruption from multiple sources. The solution methodology makes use of a port digital twin and techniques from stochastic optimization. The methodology is illustrated on an example application.

2 - Rate-optimal Contextual Ranking and Selection

Jianzhong Du, City University of Hong Kong, Kowloon, Hong Kong, jianzhodu2-c@my.cityu.edu.hk, Siyang Gao, Chun-Hung Chen

We consider R&S in the presence of context, where the context corresponds to some input information to the simulation model and can influence the system performance. This is a new and emerging problem in simulation for personalized decision making. The goal is to determine the best allocation of the simulation budget among various contexts and designs so as to efficiently identify the best design for all the contexts that might possibly appear. We call it contextual ranking and selection. We utilize the OCBA approach in R&S, and solve the problem by developing appropriate objective measures, identifying the rate-optimal budget allocation rule and analyzing the convergence of the selection algorithm.

3 - Maritime Industry Digital Twin Utilizing O2Des.net Standard

Haobin Li, National University of Singapore, Singapore, 117576, Singapore, li_haobin@nus.edu.sg, Muhammad Riza Marhaban, Loo Hay Lee, Ek Peng Chew

For a smarter maritime industry, the digital twin shall be developed in all the four dimensions as follows. Firstly, the Connectivity indicates the level of communication with its physical counterpart; then, the Visibility indicates the ease of perception for human beings; in addition, the Granularity that indicates the detail level of the model; and more importantly, the Analyzability that enables a digital twin with the smartness to support decision making. This talk will give an overview of how the O²DES (object-oriented discrete-event simulation) framework built with the latest .NET Standard complies with the development of the smart digital twin on these four dimensions.

4 - Simulation-optimization Approach for Capacity Planning of Battery-powered Automated Guided Vehicle System

Si Zhang, Associate Professor, Shanghai University, Chenhao Zhou, National University of Singapore, Singapore, Si Zhang, Jie Xu, Loo Hay Lee, Ek Peng Chew

With the development of battery and automated guided vehicle (AGV) technology in maritime industry, the deployment of battery-powered AGV (B-AGV) in major container terminals is getting popular. However, designing and optimizing the mage complex system is not easy in manual way, especially for the system which may cost billions of dollar. In order to minimize the setup cost while maintaining high throughput, a simulation-optimization approach is proposed to find the best configuration in terms of the number of charging stations and their locations, the number of AGVs and quay cranes in a given layout.

Health Care, Strategy and Policy I

Contributed Session

Chair: Salar Ghamat, Wilfrid Laurier University, Waterloo, ON, N2L 3C5, Canada

1 - Understanding and Modeling Preterm Birth in the U.S. Using Systems Approach

Alireza Ebrahimvandi, Virginia Tech, Blacksburg, VA, United States, alvandi@vt.edu, Niyousha Hosseinichimeh

Preterm birth rate (PBR) stands out as a major public health concern in the U.S. However, effective policies for mitigating the problem is largely unknown. The complexities of the problem raise critical questions: Why is PBR increasing despite the massive investment for reducing it? What policies can decrease it? To address these questions, we develop a causal loop diagram to investigate mechanisms underlying high preterm rate. Then, we build a simulation model, calibrate it, and apply structural tests and check goodness of fit. This study proposes and tests a theory about why increasing expenditure on medical interventions has not improved health outcomes.

2 - Using Panels Design Strategies to Improve Accessing to the Healthcare Services

Hao-Wei Chen, Assistant Professor, University of Toledo, Toledo, OH, United States, haowei.chen@utoledo.edu

The presentation is to provide managerial insights on how to improve the operational efficiency of healthcare systems through better physician capacity allocation strategies. Specifically, we focus on how a clinic should design its physician panels for a pool of heterogeneous patients to determine whether specialization (e.g., one provider has all high-frequent patients, and the other has all low-frequent patients) or equal assignment (e.g., two providers have identical patient composition) is better by formulating the problem as mathematical models and perform stochastic ordering analysis.

3 - Data Driven Incentive-based Reimbursement Programs Design for Reducing Readmission and Healthcare Expenditure Using Game Theory When Patient Care is Co-produced.

Hasan Symum, University of South Florida, Tampa, FL, United States

To reduce healthcare expenditure and preventable readmission rate, many healthcare organizations are fully or partially transitioning from traditional fee for service (FFS) to other reimbursement policies such as Medicare shared savings program (MSSP), bundled payment (BP), and Pay for performances (P4P). This research examines the impact of the four reimbursement policies on cost reduction and readmission rate in health co-produced game model where patient admission and readmission can be both controlled by the efforts exerted by both patient and hospitals. This analysis enables a healthcare organization to compare the equilibrium outcomes associated with the policies.

4 - Home is Where the Heart Is: An Ecological Systems View of Process Outcomes in Heart Disease

Eric Xu, University of Minnesota, Minneapolis, MN, United States, xuxx1064@umn.edu, Kevin Linderman

The Center for Medicaid and Medicare Services has implemented a Hospital Readmissions Reduction Program to streamline processes and ensure quality outcomes. However, this program has varied success in terms of patient outcomes. This study examines the patient context in greater depth to better explain the varied outcomes for patients with heart disease. The analysis uses patient data from the state of New York to understand how built environment contextual variables can impact treatment process outcomes.

5 - Design of Specialist Response Policies in Emergency Departments: A Data-driven Approach

Cheng Zhu, Assistant Professor, Texas State University, San Marcos, TX, United States, cheng.zhu@mail.mcgill.ca, Beste Kucukyazici, Zhankun Sun

We build a queueing model with a non-homogeneous arrival rate to model the time-dependent demand of specialist consultations in Emergency Departments (EDs), and then figure out the best timing for specialists to fulfill the demands with a controlled waiting time for patients and commuting frequency for specialist. We also recommend different timing policies for all sorts of specialists and the strategy to integrate the policies into the ED patient flow management.

6 - Influencing Primary Care Antibiotic Prescription Behavior: Insights from a Game Theory Approach

Salar Ghamat, Assistant Professor, Wilfrid Laurier University, Waterloo, ON, Canada, sghamat@wlu.ca, Lauren Cipriano, Michael Silverman

Unnecessary antibiotics prescription is a major public health concern and despite guidelines, antibiotics continue to be prescribed at high rates for non-bacterial acute upper respiratory infections. We consider a system that consists of a payer, a healthcare provider, and a sequence of patient experiencing symptoms which could be due to either a viral or bacterial infection. We explore the existence and features of payer-provider contracts designed to reduce antibiotic prescriptions for viral infections and maximize social welfare.

Robust Methods in Finance

Sponsored: Finance

Sponsored Session

Chair: Stathis Tompaidis

Co-Chair: Daniel Mitchell

1 - Systemic Risk and Central Clearing Counterparty Design

Hamed Amini, Georgia State University, Atlanta, GA, United States, hamini@gsu.edu

We examine the effects on a financial network of multilateral clearing via a central clearing counterparty (CCP) from an ex ante and ex post perspective. The CCP is capitalized with equity and a guarantee fund. We propose a CCP design which improves aggregate surplus, increases the utility of the banks and of the CCP and reduces the expected shortfall losses on the endusers. We determine the CCP's equity and guarantee fund policies as a Nash bargaining solution. A simulation study based on aggregate market data shows that under our proposed design with hybrid guarantees there exists a unique Pareto optimal equity and guarantee fund policy of the CCP, which reduces systemic risk.

2 - Optimal Scenario Generation for Stress Test

Rohit Arora, University of Texas at Austin, Austin, TX, United States, Rui Gao, Stathis Tompaidis

We consider the regulator's problem of assessing the riskiness of financial institutions using a stress testing procedure. To measure risk, the regulator designs plausible but extreme scenarios, and evaluates the riskiness of financial institutions using the profit and loss values corresponding to these scenarios. We appeal to the optimal experimental design to generate scenarios for stress testing, so that the variance of the riskiness estimator (such as conditional value-at-risk) is minimized.

3 - Robust Portfolio Variance Minimization with Bootstrapping and Factor Model

P.A. Nguyen, University of Minnnesota, Minneapolis, MN, United States

We study a robust portfolio variance minimization problem using bootstrapping. In this approach, we bootstrap the training data to obtain various variance estimations of the portfolio returns. We solve for the portfolio weights that minimize the average variance over k worst-case variances, where k is no more than the number of the bootstrapped samples. The robust portfolio variance minimization problem is derived as a knapsack problem and reformulated into a quadratically constrained linear program problem. We then extend the robust problem to a factor model and show that the robust factor model can result in a better optimal solution than the robust non-factor robust model.

Logistics I

Contributed Session

Chair: Teun van Gils, UHasselt, Agoralaan Building D, Diepenbeek, 3590, Belgium

1 - Risk Assessment of Dangerous Cargos in Multimodal Transportation Based on Improved WBS-RBS Method

Jingni Guo, Southwest Jiaotong University, Sichuan, China, 947082371@qq.com, He Zhenggang

In order to effectively assess the security risks in multimodal transport networks, a security risk assessment method based on WBS-RBS and Pythagorean Fuzzy Weighted Average (PFWA) operator is proposed. The risk matrix 0-1 assignment of WBS-RBS is replaced by the Pythagorean Fuzzy Number (PFLN) scored by experts. The security risk ranking values of multimodal transport network are calculated from two processes of whole-stage and phased, respectively, and the safety risk assessment results are obtained. Finally, an example of railway-roadway-waterway intermodal transportation process of dangerous phosphoric acid is given to verify the validity of the method.

2 - Nucleolus Based Cost Allocation Methods for Collaborative Truckload Transportation Procurement

Gultekin Kuyzu, MIT-Zaragoza International Logistics Program, Zaragoza, Spain, Nihat Oner

In truckload transportation procurement networks, identifying the minimum cost collaborative solution and sharing the costs in fair manner are two interrelated and critical tasks for the success of such networks. In this paper, we take a cooperative game theory approach and study the resulting constrained lane covering game. We first show the set of conditions which must be satisfied for the game to have a non-empty core. We propose nucleolus based cost allocation methods. We compare our proposed cost allocation models with alternative cost allocation methods and each other using a set of core stability metrics through computational experiments on randomly generated instances from the literature.

3 - Strategic Design of Highly Responsive Urban Distribution Networks

André Snoeck, Massachusetts Institute of Technology, Cambridge, MA, United States, asnoeck@mit.edu, Matthias Winkenbach

To meet the rising customer expectations in e-commerce, companies promise increasingly short lead-times. The additional required responsiveness puts tremendous stress on the last-mile distribution network. The strategic design of such networks is a major driver of the overall distribution efficiency. We propose an efficient simulation-based optimization approach that captures the non-linear and non-convex characteristics of the strategic network design problem. Leveraging this, we provide insights into key drivers of the performance of highly responsive urban distribution networks.

4 - Integrated Student to School Assignment and School Bus Routing Problem

Azadeh Ansari, West Virginia University, Morgantown, WV, United States, aansari@mix.wvu.edu, Leily Farrokhvar, Behrooz Kamali

In this paper, we propose an integrated mathematical model for student to school assignment and school bus routing problems considering special needs students. The model is linearized and validated for small instances. A heuristic solution approach based on capacitated K-means clustering algorithm is developed that is capable of generating high quality solutions within a reasonable amount of time. We implement our proposed methodology on several randomly generated test instances and a real-world data set. The results suggest that our developed heuristic method outperforms previously developed methodologies.

5 - Improving Network Connectivity of Compromised Digital Logistics Network via Online Optimization

Kam-Fung Cheung, The University of Sydney, Sydney, Australia, kf.cheung@sydney.edu.au, Michael Geoffrey Bell, Man-Chung Yue

A high-level adversary can compromise the digital logistics network and launch attacks inside an organization to deteriorate the network connectivity. In contrast, the defender aims to maximize the network connectivity given that the network is under attack. An online optimization model is proposed to model the arms race between the adversary and the defender. The solution to this model is a defense strategy to allocate resources to improve the network connectivity of the compromised network.

6 - Increasing the Practical Applicability of Models Planning Order Picking Operations

Teun van Gils, Postdoctoral Researcher, UHasselt, Hasselt, Belgium, teun.vangils@uhasselt.be, Sarah Vanheusden, Kris Braekers, Katrien Ramaekers, An Caris

Warehouses are challenged with fulfilling the ever increasing customer requirements, differentiating from competitors, and facing the rising costs of resources. Although literature optimizing order picking operations is comprehensive, managers often do not implement findings from academic research and researchers rarely integrate real-life features when developing planning models. These real-life features could comprise workload equity issues and safety regulations with respect to stock-keeping-units. This study deals with the integration of such real-life features in order picking planning models.

Incentives in Healthcare

Sponsored: Manufacturing & Service Oper. Mgmt/Healthcare Operations

Sponsored Session

Chair: Sasa Zorc, University of Virginia, Darden School of Business, Charlottesville, VA, 22903, United States

1 - From Gray to Black: Markets for Counterfeit Pharmaceutical Products

Sasa Zorc, Assistant Professor, University of Virginia, Darden School of Business, 100 Darden Blvd, Charlottesville, VA, 22903, United States

We model the supply chain for Malaria medication in developing countries where one of the key challenges are counterfeiters which often hold significant market share (even >50%). Our work aims to provide prescriptive recommendations to humanitarian organizations which are looking to improve access to medication in those markets. We show that retail subsidies - the currently most prolific subsidy scheme - result in counterfeiters (rather than the patients) being the primary beneficiaries. We identify the optimal mechanism for distributing the subsidies, and study how it varies dependent on market characteristics.

2 - Clinical Ambiguity and Conflicts of Interest in Interventional Cardiology Decision-making

Tinglong Dai, Johns Hopkins University, Baltimore, MD, 21202, United States, dai@jhu.edu, Xiaofang Wang, Chao-Wei Wang

Coronary heart disease leads to one out of every six deaths in the United States, more than any other cause of death. However, decision-making in a cardiac catheterization laboratory— an indispensable segment of cardiology patient care—has not been well understood. We develop a novel analytical model to capture both clinical ambiguity and conflicts of interest in interventional cardiology decision-making. Our analysis highlights the central importance of the endogeneity of advanced testing decisions.

3 - Heteroskedasticity and Bias in Hospital Readmissions Reduction Program and Their Implications

Cem Aydin, London Business School, London, United Kingdom, caydin@london.edu, Nicos Savva, Tolga Tezcan

Yardstick competition is used across Medicare's outcome based reimbursement programs to incentivise quality improvement effort in hospitals. We study the Hospital Readmission Reduction Program (HRRP), which penalizes hospitals up to 3% of their total Medicare reimbursement based on a yardstick competition on their risk adjusted readmission rates. We analyze the methodology used in HRRP to risk adjust readmission rates. We examine the implications of heteroskedasticity and bias in measured performance on quality improvement incentives using a model of HRRP's yardstick competition.

4 - Can Big Data Cure Risk Selection in Healthcare Capitation Programs?

Zhaowei She, Georgia Institute of Technology, Atlanta, GA, 30067, United States, zhaowei@gatech.edu, Turgay Ayer, Daniel Montanera

We analyze the risk selection problem in Medicare Advantage (MA), the largest capitation payment program in the U.S. healthcare market. In practice and current literature, the observed risk selection in MA is primarily attributed to data limitations and low explanatory power (e.g. low R^2) of the current risk adjustment design. However, our study shows that MA cannot eliminate risk selection even if its risk adjustment design becomes informationally perfect (e.g. R^2 =1) in the age of big data. To address risk selection in capitation programs, payers should not solely rely on big data and advanced ML algorithms, and and need to consider mechanisms other than pure statistical risk adjustment designs.

Robust Optimization in Healthcare

Sponsored: Manufacturing & Service Oper. Mgmt/Healthcare Operations

Sponsored Session

Chair: Chaithanya Bandi, 1987, Evanston, IL, 60208, United States

1 - Robust Analytics in Radiation Therapy

Omid Nohadani, Northwestern University, Technological Institute M233, Evanston, IL, 60208-3119, United States, nohadani@northwestern.edu, Dimitris Bertsimas

In radiation therapy and many other applications, statistical estimators serve to derive conclusions from data. However, the conclusions are dependent on uncertainties in the data. We use robust optimization principles to provide robust maximum likelihood estimators that are protected against data errors. We provide efficient algorithms to compute the robust estimators. The performance is demonstrated on simulated data and on a large set of clinical radiation therapy data, where robust estimators offer more reliable decisions. This approach is general and applicable to a broad range of problems.

2 - Robust Optimal Recommendations for Risk-aware Customers

Yam Huo Ow, Northwestern university, Evanston, IL, United States

We consider optimal recommendations problem for risk-aware customers with possibly uncertain risk preferences, where an online insurance platform has to offer the best insurance plan that matches the customers' risk preferences. We present a novel approach to model the uncertainty in risk preferences using robust optimization; and discuss tractable approaches for passive estimation and active learning to construct the uncertainty set of risk preferences from historical and interaction data, respectively. Lastly, we examine Linear Programming formulations which allow for tractable optimization with insightful solutions.

3 - Robust Queueing Inference Engine

Alexej Proskynitopoulos, Student, Northwestern University, Evanston, IL, 60208, United States, alexej.proskynitopoulos@kellogg.northwestern.edu, Chaithanya Bandi

We consider the statistical study of partially observed queueing systems arising in application areas such as hospital networks, data centers and cloud computing systems. We propose an analytically tractable framework based on robust optimization for studying such inference problems . We report results from an implementation of our framework at one of the biggest hospitals in India, where we estimate the service times at various locations throughout the hospital using partial patient flow data. Our methodology achieves significant computational tractability and provides accurate approximations for primitives of the service process relative to simulations.

Sustainable Operations

Sponsored: Minority Issues

Sponsored Session

Chair: Mikhail Gordon, University of Pittsburgh, Pittsburgh, PA, 15224, United States

1 - Target Setting and Sharing Rule in Crowdfunding Platforms

Joyaditya Laik, University of Pittsburgh, Katz Business School, University of Pittsburgh, Pittsburgh, PA, 15260, United States, jol76@pitt.edu

Crowdfunding platforms ‘recommend’ campaigns that surpass their Goal within few days after launch. A quickly achieved target earns the campaign a slot in the recommended section and gives greater visibility. This creates perverse incentives for the creator to set targets even below start-up costs that increase their chance of delinquency. We build conditions under which a creator would set a target that is lower than their setup cost. Furthermore, we show that the information rent, extracted by the platform when setup cost is uncertain, increases with uncertainty about the setup cost.

2 - Learning by Doing: Service Firm with Delay Sensitive Customers

Jing Luo, University of Pittsburgh, Roberto Clemente Drive, Pittsburgh, PA, 15260, United States, JIL204@pitt.edu

Smart city is trying to build a more sustainable society. Our project under Pitt Smart Living aims to reduce the waste, imrpove the efficency of local businesses and smooth the traffic. We analyze the forecasting and planning strategy for service firm with the delay sensitive customers before and after traffic congestion.

3 - Political Ideology and the Use of Autonomous Vehicles

Brian Park, Georgia State University, Atlanta, GA, United States, bpark@gsu.edu, Eunhee Sohn, David Dubois, Yusen Xia

Although political ideology has been extensively studied in relation to consumption behavior and operation management, researchers have paid little attention to how it influences the willingness of consumers to adopt or purchase an autonomous vehicle (AV), which has become one of the most popular technologies in the contemporary age. To fill this void, we explored how individual characteristics—particularly the political ideologies to which people subscribe—affect customers’ inclination to adopt and use automated cars. By using two datasets, we show that Democrats are more willing and likely to adopt an autonomous vehicle than are Republicans.

4 - Direct and Indirect Sustainable Investment in a Competitive Environment

Mike Gordon, University of Pittsburgh, Pittsburgh, PA, 15224, United States, m.gordon@pitt.edu

This research focuses on how consumers react to a company introducing a green product and investing in Corporate Social Responsibility (CSR) in a competitive environment. Though these are both positive investments in the eyes of consumers, green product innovation and CSR investment are analyzed as separate investments.

5 - Conventional Crops or Hops? Optimal Crop Planning Policies with Yield Learning and Forward Contract

Heng Chen, University of Nebraska-Lincoln, HLH 511F, Lincoln, NE, 68588, United States, heng@unl.edu, Jennifer Ryan

With soaring demand for craft beer, hops can offer farmers higher profits than conventional crops, but at the cost of increased demand and yield uncertainty. We formulate a dynamic programming model with yield learning to determine the optimal crop allocation and contract allotment level with the objective of maximizing farm income.

Service Design in Platform Economy

Sponsored: Service Science

Sponsored Session

Chair: Kejia Hu, Vanderbilt University, Nashville, TN, 37215, United States

1 - Promotional Design for Small Businesses: The Operational Value of Online Deals

Simin Li, Kellogg School of Management, Northwestern University, Evanston, IL, 60208, United States, simin.li@kellogg.northwestern.edu, Kejia Hu, Martin Lariviere

We empirically study how service providers use advance sales period (T) and discount of the online deal, tailoring to operating margin and demand fluctuations, to smooth demand swings and reduce capacity costs. Such operational roles of the online deal are carried out via not only the classic lever discount but also the understudied timing of deal launch in service industries. We conduct counterfactual analyses to show that the optimally designed T mitigates the extreme discounts observed in any “instantaneous” price promotions, and moreover achieves an average profit boost of 23.6%. Compared to discount sensitivity, it is more effective to sway customers’ sensitivity to T for further profit boost.

2 - Intertemporal Segmentation via Flexible-Duration Group Buying

Jingchen Liu, Nanjing University, Nanjing, China, liujingchen32@gmail.com, Ming Hu, Xin Zhai

We study a special form of group buying: it succeeds only if the number of sign-ups reaches a preset threshold, with no duration constraint. Customers with heterogeneous valuations arrive sequentially and decide between signing up for the group buying or purchasing a regular product. We study the product line design with the group-buying sign-up behavior of customers characterized by the rational expectations equilibrium. We show that group buying with flexible duration can result in intertemporal customer segmentation, as different segments might be admitted at different times in the dynamic sign-up process, which is a natural discrimination scheme and has non-trivial implications.

3 - Designing Online Platforms for Offline Services

Leon Chu, USC Marshall School of Business, University Park Campus, Bridge Hall 401T, Los Angeles, CA, 90089, United States, leonyzhu@usc.edu, Xun Wu

Online platforms enable service providers to offer customized services that consumers have increasingly desired. Despite its tremendous value-creation potential, offering customized services encourages greater opportunism from the service providers. We propose a novel platform design where, from its inception, the platform deliberately limits the number of service providers below a certain threshold, even if they are homogenous. Without imposing this threshold, the competition among the service providers may lead to a unique equilibrium under which all the service providers shirk. In contrast, by imposing the threshold, the platform may induce a welfare-enhancing equilibrium.

4 - Supplier Selection Criteria in the Online B2B

Kejia Hu, Vanderbilt University, Nashville, TN, 37215, United States, Yixin Iris Wang

We study the supplier selection criteria and importance of 27 attributes that measures suppliers’ performance in price competitiveness, quality of product, service offerings and delivery.

1 - Inventory Management in an Autologous Cell Therapy Production Facility

Junxuan Li, Georgia Institute of Technology, Atlanta, GA, United States, junxuan.li@gatech.edu, Chelsea C. White

Autologous cell therapy (AuCT) is an emerging therapeutic product that has been proved to be effective for a variety of diseases. We discuss the uniquenesses of AuCT production system, e.g. customer-as-a-supplier, patient-related production capacity process and strict regulatory requirements. Reagent inventory management is critical and challenging in such novel systems. We introduce two dynamic inventory control models for the cases where the bioreactor processes are exogenous or endogenous. We conclude the talk with challenges and outlooks in AuCT supply chain design and operations management.

2 - Modeling and Simulation Efforts for the Pharmaceutical Supply Chain

Safwan Altarazi, Associate professor, German Jordanian University, Amman, Jordan, safwan.altarazi@gju.edu.jo

This presentation highlights adopting integer programming, discrete event simulation, and dynamic simulation to model the pharmaceutical supply chain network. Several network scenarios characterized by considering different number/types of echelons, drugs, decision variables, constraints; different logistics activities, and different goals; are presented. The implementation of the proposed models verified their applicability.

3 - Discussion of Inefficiencies of Liver Transplantation Supply Chain: Study Case Brazil

Daniel de Oliveira Mota, University of Sao Paulo, São Paulo, 04026090, Brazil, João Paulo Monteleone

The present study relies on concepts of healthcare logistics investigating the supply chain of Brazilian liver transplantation system. The identification of wastes along the information management provides insights to propose improvements in public policies based on operations research techniques. It was used integer programming in location problems to identify optimal solutions for positioning the Organ Procurement Organizations (OPO), responsible for guaranteeing the feasibility of the initial stages of the transplantation effort. By the application of the proposed algorithm identify a better use of the number of OPO, optimizing hospital resources allocation.

4 - Supply Chain Performance Analysis of Pharmaceutical Industry

Sangdo Choi, Assistant Professor, Christopher Newport University, Newport News, VA, United States, knowhow.schoi@gmail.com, Jeonghoon Choi

This study explores and expands the theoretical foundations of the strategic group concepts through investigations on the relationship between inventory performance including both total inventory and its discrete inventory, and financial performance in pharmaceutical manufacturing companies. We use the so-called DuPont analysis with earns (or profitability) and inventory turns (or operational excellence) to classify the strategic groups in the pharmaceutical industry. We found that most pharmaceutical companies pursue profitability, moving from the low-right to the top-left section in the Earns-Turns matrix.

5 - Economies of Scope in Community Pharmacy Operations Incorporating Medication Therapy Management into Prescription Workflow

Yucheng Chen, University of Connecticut, Storrs, CT, United States, yucheng.chen@business.uconn.edu, Manuel A. Nunez, Stephanie A. Gernant, Charles Upton

Medication Therapy Management (MTM) is a new type of service provided by community pharmacies and aims to optimize drug therapy and improve therapeutic outcomes of medication-controlled conditions in patients through a direct counselling and follow-up from pharmacists. We formulate queuing and simulation models of a pharmacy's workflow to optimize delivery of MTM services. Using our models, we determine when economies of scope are achieved, redesign workflows, and improve capacity management.

Tuesday Poster Competition

Competition Poster Session

1 - Pre-Planned Tour for Delivery with Stochastic Demands

Fatemeh Navidi, University of Michigan, Ann Arbor, MI, United States, navidi@umich.edu

We consider the a priori traveling repairman problem, which is a stochastic version of the traveling repairman problem (TRP). Given a metric (V,d) and a root r, the TRP involves finding a tour originating from r that minimizes the sum of arrival-times at all vertices. In its a priori version, we are also given independent probabilities of each vertex being active. We want to find a master tour T originating from r and visiting all vertices. The objective is to minimize the expected sum of arrival-times at all active vertices, when T is shortcut over the inactive vertices. We obtain the first constant-factor approximation algorithm for a priori TRP under non-uniform probabilities.

2 - Optimizing the Assignment of Policemen in Ecuador

Fernanda Salazar, Full time Professor, Escuela Politécnica Nacional, QUITO, Ecuador, fernanda.salazar@epn.edu.ec, Sandra Gutiérrez, Diego Recalde, Ramiro Torres, Polo Vaca, Andrés Vinueza, Estéfano Viteri

The Ecuadorian Police must find an assignment of its human resources so that the security needs of the population are covered as efficiently as possible in every basic geographical area. We design an integer programming model that not only considers the offer and demand of police services but also legal and technical constraints as well as the social dynamics of every area. Then, we compute how to distribute police officers all over the country; suggesting, in addition, what activities they must perform accordingly to their particular qualifications.

3 - The Contract Design Problem for the Aggregator in the Electricity Demand Response Market

Daeho Kim, Pohang University of Science and Technology (POSTECH), Pohang, Gyeongbuk, Korea, Republic of, Dong Gu Choi

In a demand response program, an aggregator and customers make an incentive-sharing contract. When they make the contract, customers have two private information like demand response potential and disutility level. We investigate a contract design problem under asymmetric information. In addition, we find the effect of each private information.

4 - Two Stage Stochastic Choice Modeling Approach for Electric Vehicle Charging Station Network Design in Urban Communities

Seyed Sajjad Fazeli, Wayne State University, Detroit, MI, United States, sajjad.fazeli@wayne.edu, Saravanan Venkatachalam, Ratna Babu Chinnam, Alper E. Murat

In this research, we propose a choice modeling approach embedded in a two-stage stochastic programming model to determine the optimal layout and types of EV supply equipment for a community while considering randomness in demand and drivers' behaviors. Some of the key random data parameters are: EV's dwell time at parking station, battery's state of charge, charging price, distance from home, willingness to walk, drivers' arrival patterns. We propose an outer approximation decomposition algorithm and conduct extensive computational experiments to quantify the efficacy of the proposed approach.

5 - Study of Influencing Factors of Trust Formation in B2C E-Commerce

Cong Cao, Tutor, University of Wollongong, Wollongong, Australia, cong.cao@outlook.com, Jun Yan, Mengxiang Li

This study integrates trust in e-commerce with consumers' attitudes, intention and behaviours as well as external structural guarantees and provides a new perspective for research on e-commerce and related issues. And, the trust model presented in this study integrates the main factors that influence trust online synthesised from different perspectives and levels and discusses their interactions comprehensively and systematically. Moreover, the findings of this study indicate that the perceived channels of information on online reviews and the perceived presentation type of Trusted Third Party and their services are independent factors that influence consumers' trust in online shopping.

6 - Modeling the Role of Efficiency for the Equitable and Effective Distribution of Donated Food

Md Hafizul Islam, North Carolina State University, Raleigh, NC, United States, mislam5@ncsu.edu, Julie Simmons Ivy

Food banks operate intending to serve as many of the food insecure people in the United States as possible with the limited supply available to them. This paper presents a mixed-integer programming model to identify the efficient assignment of demand zones (county) to distribution centers (branches) and equitable allocation of donated food to the demand zones. Data from Food Bank of Central and Eastern North Carolina is used to characterize the model parameters and perform numerical studies. Sensitivity analysis between the user-specified maximum inequity cap and effectiveness shows that significant improvement can be achieved in terms of effectiveness with a marginal sacrifice in equity.

7 - Railroad Track Irregularities Position Accuracy Assessments Using Low Cost Sensors

Bhavana Bhardwaj, Graduate Research Assistent, North Dakota State University, Fargo, ND, United States, bhavana.bhardwaj@ndsu.edu

Deviations from the designed track geometry result in poor ride quality and possible derailments. Thus, regular maintenance of the railroad is very important. This research investigates the potential use of low-cost sensors aboard the hi-rail vehicle to monitor automatically and continuously for inertial events caused by irregular track geometry. Due to the GPS receivers position error, this study introduces a signal processing and statistical method to estimate the position of peak inertial events from multiple traversals and validates its accuracy by comparing the estimated positions of detected irregularities with the actual positions of irregularities recorded by railroad inspector.

8 - Modeling and Prediction for IoT Systems: Methodologies and Practical Implications

Bing Zhang, Texas A&M University, College Station, TX, United States, bing.zhang@tamu.edu, Alaa Elwany, Mohammed Shafae, Shubhi Asthana, Aly Megahed

In IoT systems, not all sensor signals can be monitored at high frequencies due to costly monitoring resources. We develop a modeling framework for predicting IoT signals monitored at low frequencies via estimating the correlation of such signals with ones measured at high frequencies. We also show promising numerical results.

9 - Robust Multi-product Newsvendor Model with Substitution under Cardinality-constrained Uncertainty Set

Jie Zhang, Virginia Tech, Blacksburg, VA, United States, jiezhang@vt.edu, Weijun Xie

This paper studies Robust Multi-product Newsvendor Model with Substitution (R-MNMS), where the demand and the substitution rate are stochastic and is subject to cardinality-constrained uncertainty set. We first show that for given order quantities, computing the worst-case total profit in general is NP-hard. we formulate it as a mixed integer linear program with an exponential number of constraints, and develop a branch and cut algorithm to solve it. For large-scale problem instances, we further propose a conservative approximation of R-MNMS and prove that under some certain conditions, this conservative approximation yields an exact optimal solution to R-MNMS.

10 - Optimizing Diabetes Screening Frequency for At-risk Groups

Chou-Chun Wu, University of Southern California, Los Angeles, CA, United States, chouchuw@usc.edu, Sze-chuan Suen

BMI is a key risk factor for type 2 diabetes, but current guidelines do not provide BMI-category-specific screening frequency recommendations by age and prior testing history. We aim to determine the optimal policy with the above factors using a POMDP. We assume the physician has an estimate of the patient's health state (non-diabetic, prediabetic, or diabetic) at each period, and updates his beliefs about the patient's health given progression trends and observed test results. We show that our model has a threshold policy structure and find that the current recommended screening policy is suboptimal. High-risk individuals should be screened earlier and more frequently.

11 - The Waiting Game - How Public and Private Hospitals Should Work Together to Reduce Waiting Lists

Jorge A. Acuña, PhD Student, University of South Florida, Tampa, FL, United States, jorge@mail.usf.edu, Jose L. Zayas-Castro, Felipe A. Feijoo, Sriram Sankaranarayanan, Rodrigo Martinez, Diego A. Martinez

In this talk, we formulate and solve a bi-level game to mimic market dynamics in two-tier health systems with explicit guarantees of access and waiting time. We discuss how better coordination among public hospitals and governing institutions at a local and regional level can reduce waiting times. At the same time, we show through a bi-objective model the potential role that private hospitals can play as a backup system when the public hospitals struggle to meet demand. We conclude with insights as to how public and private hospitals can cooperate to achieve better results than each hospital acting by itself.

12 - Personal Fitness Monitoring App Data to Assess Community Recovery at Scale: Case Study on Post-hurricane Harvey Recovery of Harris County, Texas

Pariyakorn Maneekul, Department of Industrial & Systems Engineering, University of Washington, Seattle, WA, United States, parim@uw.edu, Zhanlin Liu, Scott Miles, Nicole Errett, Youngjun Choe

Near real-time data of the fitness activity level throughout a community can be a valuable source for assessing community recovery and for building capacity for community resilience. This exploratory study used cycling and running activity records from a personal fitness monitoring app as a proxy for community health and wellbeing. This near real-time, large-scale data enabled us to assess the post-Hurricane Harvey recovery of the fitness activity level throughout Harris County, Texas. The data revealed geospatial patterns of fitness activity level recovery, including how long it took for an affected region's fitness activity level to return to the pre-Harvey level.

13 - Preferred Post-acute Provider Network: An Approach to Improve Care Coordination in Healthcare Continuum

Ineen Sultana, PhD Candidate, Graduate Research Assistant, Texas A&M University, College Station, TX, United States, ineensultana@tamu.edu

Post-acute care (PAC) provides treatment for critical patients following hospital discharge to further improve patient outcomes. To ensure availability of PAC, an effective care coordination from acute care facilities (ACF) to PAC facilities is a long due necessity. Building a Preferred Post-Acute Network (PPN), which involves a contract agreement between ACF and PAC, can strengthen this care coordination. The aim of this work is to develop strategic agreement decisions and resource adjustment planning to form a PPN. In this work, a two-stage stochastic mixed integer model is proposed to optimize the decision features of PPN formation considering uncertainty in resources and patient demand.

14 - Risk Averse Parking Space Optimization in the Era of Autonomous Vehicles and Shared Mobility

QING YE, Virginia Tech, Blacksburg, VA, United States, yqing1@vt.edu

In the era of Autonomous Vehicles (AVs), the different deployment forms of automated vehicles, especially the privately-owned AVs (PAVs) and the shared AVs (SAVs), are envisioned to have dramatically different impacts on modern transportation systems, including parking spaces utilization rates, vehicle ownership, and traffic condition, etc. This work provides a deeper understanding of the parking space requirement and traffic conditions in the era of PAVs and SAVs. A mathematical optimization model, which optimizes the parking space requirement given that the parking demand and the percentages of different deployment forms of AVs as well as the conventional vehicles are stochastic, is built.

15 - Optimal and Fair Decision Trees for Non-discriminative Decision-making

sina Aghaei, USC, Los Angeles, CA, United States

Recently, automated data-driven decision-support tools are increasingly being used in socially sensitive settings. Yet, they may result in discriminative decisions in that they may treat individuals from a specific group unfairly, resulting in disparate treatment and/or impact and violating moral or ethical standards. In this paper, we unify unfairness definitions across classification and regression and propose a mixed integer optimization framework for learning optimal and fair decision trees to prevent disparity. We conduct extensive computational studies that show that our framework yields non-discriminative decisions at lower cost to overall accuracy than other approaches.

16 - The Effects of Organizational Miscommunication on Complex System Performance

John Meluso, PhD Candidate, University of Michigan, Ann Arbor, MI, United States, jmeluso@umich.edu

"Communication Problems" frequently cause failures in complex engineered systems. "Miscommunication" occurs when communication results in a "deficiency" or "problem" that hinders parties from fulfilling their individual or collective values. In three studies, this dissertation demonstrates that organizational miscommunication may substantively affect complex engineered system performance. Semi-structured interviews with practitioners revealed miscommunication about what constitutes a parameter "estimate". Agent-based modeling found that organizational miscommunication about estimate definitions may affect system performance with widespread repercussions.

17 - Rapid Detection of Hot-spot by Tensor Decomposition on Space and Circular Time with Application to Weekly Gonorrhea Data

Yujie Zhao, Georgia Institute of Technology, Atlanta, GA, United States, yzhao471@gatech.edu, Hao Yan, Sarah Holte, Yajun Mei

In many bio-surveillance and healthcare applications, data sources are measured from many spatial locations repeatedly over time. In these applications, we are typically interested in detecting hot-spots, which are defined as structured outliers that are sparse over spatial domain but persistent over time. In this paper, we propose a tensor decomposition method to detect and localize the hot-spots, which is efficient from both statistical and computational viewpoint. We represent raw data as a three-dimensional tensor, and then decompose it by tensor product. A combination of LASSO and fused LASSO is used to estimate parameters, and CUSUM procedure is applied to detect and localize hot-spots.

18 - Unsupervised Anomaly Detection Using Graph Regularized Autoencoders

Imtiaz Ahmed, Texas A. & M. University, College Station, TX, United States, imtiazavi@tamu.edu

In this work, we attempt to solve the problem of anomaly detection when high dimensional data lies near low dimensional manifold. Autoencoders enables us to extract the low dimensional features necessary for anomaly detection. However, the possibility of manifold structure and required local distance preservation is not considered. We use minimum spanning tree, a graph algorithm to approximate the intrinsic distance in presence of manifold structure. We incorporate the MST guided local structure inside the Autoencoder framework as a new regularizer. Hence, it maintains the local invariance property and provide better detection capability compared to Euclidean distance based regularizer.

19 - Minimum Cost Set-Cover Blocker Problem

Luca G. Wrabetz, State University of New York-Buffalo, Buffalo, NY, United States, lucawrab@buffalo.edu

Given a set U of n elements and a collection S of m sets whose union equals U, the set-covering problem is to identify the smallest sub-collection of S whose union contains all the elements in U. Given a cost vector c associated with blocking the selection of the subsets in S, we solve the problem of minimizing the cost of blocking some subsets of S so that the size of the optimal set cover in the resulting problem is at least a given value r. We develop a general formulation for this problem and study the convex hull of feasible solutions. We ran computational experiments over instances staged on graphs, and described applications in the context of drone surveillance.

Tuesday Poster Session

Poster Session

1 - Left Atrium Segmentation Using Gaussian Mixture Models and Network Flow Optimization

Amirhossein Koneshloo, TexasTech University, Lubbock, TX, United States, amir.koneshloo@ttu.edu

Left atrium segmentation from magnetic resonance imaging (MRI) images provides useful information about the 3D atrial structure and can be further utilized in atrial fibrillation (AF) diagnosis and treatment design. Left atrium segmentation is a challenging task due to uncertainties the MRI images. These uncertainties can be caused by patient heterogeneity, low contract ratio between atrial wall and its neighbor region, and small left atrium size in comparison with large image background. This study aims to estimate a shape prior to produce a robust estimation regarding atrial shape variations via Gaussian mixture modeling, and then apply network flow optimization for accurate segmentation.

2 - Image-guided Additive Manufacturing: From In-situ Sensing to Process Control

Farhad Imani, The Pennsylvania State University, State College, PA, United States, fxi1@psu.edu, Hui Yang, Bing Yao, Ruimin Chen

Quality assurance is one of the key obstacles preventing additive manufacturing (AM) from further proliferation in the manufacturing market. Advanced sensing provides an unprecedented opportunity to increase information visibility, cope with the product complexity, and enable on-the-fly quality control in AM. This paper develops a novel optimal control policy for AM parts whose layerwise defect states can be monitored using advanced sensing systems. We take into account the stochastic uncertainty in the variations of layerwise defects and aim at mitigating the defects before they reach the nonrecoverable stage.

3 - Promoting AI Products in Mothers' Online Social Groups: An Emotional Manipulation Approach

Huigang Liang, University of Memphis, Memphis, TN, 28590, United States, huigang.liang@gmail.com, Yajiong Xue, Yanqi He

Artificial Intelligence (AI) products offer benefits in children's intellectual development, yet have potential privacy concerns. This study investigates how to promote AI products to parents. We conducted an experiment with 400 mothers of toddlers. Using social contagion strategies, we created positive and negative environments in two social media groups. We found that the interplay of mothers' emotional characteristics and environments has an important impact on their AI product acceptance.

4 - Cost-effective Construction of Convolutional Neural Network for Wafer Map Pattern Classification

Jaewoong Shim, Seoul National University, Seoul, Korea, Republic of, shimjw@dm.snu.ac.kr, Seokho Kang, Sungzoon Cho

Wafer maps provide important information for detecting root causes of failure in a semiconductor manufacturing process. A convolutional neural network (CNN) has yielded state-of-the-art performance in wafer map pattern classification. But it is costly to annotate a lot of wafer maps manually to construct labeled training data. We propose a cost-effective wafer map pattern classification scheme based on the active learning of a CNN. The proposed scheme consists of uncertainty estimation, query wafer selection, labeling, and model update. With the repetition of these steps, the performance is effectively increased. The proposed scheme was verified with real-world data.

5 - Artificial Intelligence and the Future of Work: Challenges and a Path Forward

Jinsoo Yeo, Emory University, Atlanta, GA, United States, jinsoo.yeo@emory.edu

This study focuses on AI enabled transformation and the future of work, by assessing extant studies and providing unified answer. First, regression with additional attributes from O*NET suggests that AI amenability is multifaceted and narrow focus on specific aspects may have created discrepancy. Second, this study combines predictions from extant studies and trains a black box machine learning model for unified prediction. Third, this study applies Decision Tree model to the overfitted prediction generated from the black box mode for interpretation. Conclusion highlights the multifacetedness and complex nature of AI amenability.

6 - Draw A Deep Pattern – Temporal Convolution Neural Network Based Novelty Detection for Smartphone User Authentication from Drawing Patterns

Junhong Kim, Korea University / DSBA Lab, Seoul, Korea, Republic of, junhongkim@korea.ac.kr, Hyungseok Kim, Pilsung Kang

We propose DRAW-A-DEEP-PATTERN (DDP), which is deep learning based end-to-end smartphone user authentication method based on during the process of drawing a character or freestyle pattern. We involved 40 participants and they drew the pattern after they had recognized shape, direction and the number of strokes of each pattern. Based on real-world situation, proposed Temporal convolution network (TCN) based model produced excellent performance which average of AUROC, FAR and FRR are 0.99, 1.41% and 1.23% respectively. Also, we confirmed that proposed TCN model not only produced excellent performance and computational efficiency, but also could prevent threat scenario than RNN based model.

7 - Data Analytical Models of Human Trafficking and Interactional Illicit Supply Networks

Laura Devine, PhD Student, University at Buffalo, SUNY, Buffalo, NY, United States, Nafisa Mahbub, Jun Zhuang

Successful disruptions of illicit supply networks require an interrelated understanding of organizational strategy, network structure, and the flow of illicit commodities. This study aims to examine the interactional nature of human trafficking and other multiple illicit trade networks such as drug trafficking to advance this understanding. Using publicly available databases we investigate the dynamics of illicit trade networks through spatial and temporal analysis of crime profiles and socio-economic factors in various geographic locations. The data analysis will provide the vulnerability measures in order to outline the interdiction strategies in a more informative and justified way.

8 - To Hide or Show: An Empirical Examination of Identity Disclosures and Contributions in Online Charity-based Crowdfunding

Lei Ye, Peking University, Beijing, China

Providing services both for borrowers and lenders, lending platforms are widely regarded as intermediaries, where information provided either from lenders or borrowers is of great importance. However, lenders may tend to be anonymous due to their concerns, peer pressure, and social norm, etc. We identify the relationships between lenders' anonymous choices and their lending contributions, and also the influence of others' anonymity on the followers' behavior, through the empirical analysis of one of the largest lending platforms worldwide, Kiva. Drawing on theories of social psychology and economics, we also deep explore the influence mechanism and provide practical suggestions.

9 - Improving Logistic Regression on Imbalanced Data by a Novel Penalized Log-likelihood Function

Lili Zhang, Kennesaw State University, Kennesaw, GA, United States, lzhang18@students.kennesaw.edu, Herman Ray

Penalized log-likelihood functions have been used to improve logistic regression on imbalanced data. However, existing solutions determine penalty weights for observation misclassifications based on either hard hyperparameter (i.e. population proportion) estimation or computational expensive kernel. We propose to include penalty weights for observations in the minority class as decision variables in the log-likelihood function and learn them from data along with model coefficients. Our experimental results show that both discrimination ability and computation efficiency of logistic regression models are improved.

10 - A Group Recommendation Approach Using Group Dynamics Theory

Lu Yang, Hefei University of Technology, Hefei, China, luyang0516@gmail.com

The paper proposes a dynamic group recommendation approach, in a way that allows for improving both the predictive performance and recommendation diversity. The approach is based on group dynamics theory, which suggests the people's consumption behavior is influenced by their affiliated groups, and this group influence varies with time. Besides, the people's susceptibility to group influence is different. The authors develop a group recommendation approach by combining the traditional collaborative filtering methods and the attention mechanism of deep learning.

11 - Securing Gates and Sensor Location Problem Challenges in a Protected Area

Mahdi Fathi, Mississippi State University, Starkville, MS, United States, fathi@ise.msstate.edu, Mohammad Marufuzzaman

Please check the mobile app for this abstract.

12 - Sentiment Analysis of HCAHPS Inpatient Surveys Using Text Mining Methodologies

Sahar Khamsehi, PhD Student, SUN Y. Binghamton, Binghamton, NY, United States, skhamse1@binghamton.edu, Mohammad T. Khasawneh, Mohan Lal Tarun

Deriving actionable insights from unstructured patient satisfaction surveys' data through text mining is one of the untapped potentialities in modern health care. In this study, the data is obtained in form of unstructured texts driven from actual HCAHPS, mail, and phone surveys. The framework is developed to apply unsupervised text mining approaches using Sentiment Analysis and Topic Modeling to obtain insights and knowledge to improve the quality of patient care and operations. Early findings indicate significant correlation between the text tone, survey domain, and satisfaction rate.

13 - Health Monitoring and Anomaly Detection of a Power Plant Boiler Using Unsupervised Autoencoder

Seong-joon Kim, Assistant Professor, Chosun University, Gwangju, Korea, Republic of, seongjoon.kim@chosun.ac.kr, HyoJung Kim

In this study, we propose a data-driven health monitoring methodology to detect an abnormal condition of boiler water-steam system in a coal-fired power plant. The abnormal condition is defined as when the valve position of the desuperheater in the final-reheater is 1% or more, which reduces the boiler thermal efficiency. Based on the boiler big data including coal history and sensor data, preprocessing and feature extraction were performed. Several supervised models and a deep-learning-based autoencoder, which is an unsupervised model, are adopted to develop the anomaly detection model. (This research was supported by Korea Electric Power Corporation. Grant number: R18XA06–46)

14 - Scaling Statewide GPS Trajectories to Match Point Detector Data

Seth Miller, PhD Student, University of Utah, Salt Lake City, UT, United States, Yinhu Wang, Zachary Vander Laan, Nikola Markovic

We consider the problem of inferring statewide traffic patterns by scaling GPS trajectory data that capture 2% of the overall traffic in Utah. We apply a least-square model to scale trajectories such that resulting data best fit vehicle counts measured by traffic sensors. To enhance performance of the model, we propose a new map segmentation approach to optimally partition the region of interest. The scaled trajectories are used to compute statewide performance measures that are of interest to Utah Department of Transportation.

15 - Intrusion Detection Based on Sequential Information Preserving Log Embedding Methods and Anomaly Detection Algorithms

Seung Wan Seo, Korea University, Seoul, Korea, Republic of, zach0206@korea.ac.kr, Donghwa Kim, Pilsung Kang

The defense mechanism should have to comprehend unusual phenomenons or behaviors to successfully handles advanced threats. To achieve this, anomaly detection algorithms are capable of reducing efforts of security experts and securing labeled dataset through post-analysis. It is further possible to distinguish abnormal behaviors more precisely by training classification models if sufficient amounts of labeled dataset is obtained through post-analysis of anomaly detection results. In this study, we proposed an end-to-end abnormal behavior detection method based on sequential information preserving log embedding algorithms and machine learning-based anomaly detection algorithms.

16 - Predicting Airline Sales via Online Customer Reviews

Xiahua Wei, University of Washington, Bothell, WA, United States, Aaron Jacobson, Mark Yo, Thuy Phan

This study investigates if online customer reviews can predict the sales of airlines. Analyzing data of nine major U.S. airlines from 2015 to 2018, we find that the number of reviews (volume), rather than the average rating (valence), is important in predicting both airline revenue and the number of passengers.

17 - An Ongoing Cat-and-mouse Game: The Effect of VPN Block on Social Media Usage in China

Xiaoying Tu, Carnegie Mellon University, Pittsburgh, PA, United States, xiaoying@cmu.edu

In January 2017, China started a 14-month "cleanup" operation that bans any unauthorized use of virtual private networks (VPN), a popular tool among Chinese netizens to access censored information and services such as Instagram and Twitter. We are interested in finding out if blocking VPN is an effective way of cutting back access to censored contents online. By analyzing weekly volume trends of posts in China, Hong Kong and Taiwan around the time of VPN block using DID models, we find that Instagram posts in China increased by 25% more than control regions after VPN block, whereas Twitter posts in China remained as before. In neither case, clamping down VPN cut back access to these censored services.

18 - The Impact of Pre-release Online Activities on Digital Album Sales: A Hidden Markov Model Approach

Xiaoying Tu, Carnegie Mellon University, Pittsburgh, PA, United States, xiaoying@cmu.edu

Internet and digitization present both opportunities and challenges for music industry to maintain and grow digital music sales. Artists rely on social media to promote contents. Pre-release piracy leaks are a threat to revenue. We develop a measure of promotional efforts for a new album based on Twitter intensities and use it as an input to explicitly model the consumers' decision process of purchasing digital albums using hidden Markov model. We find that consumers of different albums respond similarly to social media as well as word-of-mouth. We also find that consumers have an average of 32% possibility to listen to pre-release piracy leaks, which can be quite harmful for legal album sales.

19 - Text Analysis on the Stock Market Thorough "Fake" News Generated by GPT-2

Yoshihiro Nishi, Keio University, Yokohama, Japan, nishi_yoshihiro@keio.jp, Aiko Suge, Hiroshi Takahashi

News has great impacts on asset prices in the financial markets. Many attempts have been reported to ascertain how news influences stock prices. However, the limitations in the number and quality of available data sets usually become the hurdle for the model accuracy. In this study, Reuter's news texts are classified based on each return through LSTM models. "Fake" news generated by GPT-2 was used with original news, and the model accuracy was examined. The results showed that "fake" news data are influential over the prediction of stock price fluctuation.

20 - Measuring the Waterway Congestion Using AIS Data: A Case Study of Houston Ship Channel

Sepideh Zohoori, Lamar University, Beaumont, TX, 77396, United States, Masood Jafarikang, Maryam Hamidi

Waterway congestion is a big problem in Marine transportation, causing many issues such as long waiting time, higher transportation cost, safety, and environmental concerns. The first step in waterway congestion management is quantifying the congestion. To do so, some measures need to be extracted and using the existing data and information, they should be quantified. In this paper, we first introduce some important congestion measures including traversal time, average travel speed, traffic flow, traffic density, and then the way to compute them is discussed. Then, we perform the proposed measures for the Houston Ship Channel (HSC) as a case study. Using AIS data, all the measures are computed, and the results are analyzed. The results indicate the congestion points, congestion time, and the reasons which make congestion in HSC. This study can be applied by the managers and decision-makers to make better decisions to come up with the congestion problem in waterways.

21 - Co-creation in Apps World: Technology as an Operant vs. an Operand

Amrita George, Marquette University, Milwaukee, WI, United States

With the high penetration of mobile technologies globally, it is only natural for firms to leverage these technologies for idea generation and innovation whenever and wherever they occur. Firms can now integrate customer feedback into the development or enhancement of their products/services through the co-creation process. Prior research suggests that IT plays the role of an operand (static) and an operant (dynamic) resource during the co-creation process. Our research seeks to identify the stages and activities of co-creation on mobile platforms as well as various actors involved in the process, and how the nature of the relationship between the actors' change based on the role of technology.

22 - Assessing ISA Tree Risk Assessment Approach Using Econometrics Analysis

Elnaz Kabir, University of Michigan, Ann Arbor, MI, United States, ekabir@umich.edu, Seth Guikema

Tree failure could pose many risks to society. Using the evidence from evaluating characteristics of trees and assessing failure risk on 560 trees based on the above-mentioned qualitative approach, we first evaluate the performance of the ISA tree failure risk assessment approach and compare it with statistical models for formulating tree failing probability. Second, we study the associations between tree conditions and its failure risk. We also evaluate the relationship between different tree trimming practices and the risk of tree failure using econometric models.

23 - Privacy Preserving Methods for Sharing Cyber Risk Exposures

Fransisca Susan, Massachusetts Institute of Technology, Cambridge, MA, United States, fsusan@mit.edu, Andrew W. Lo, Leo de Castro, Nicolas Zhang, Vinod Vaikuntanathan, Taylor Reynolds

Worried about the potential loss of business, companies often fail to report cyberattacks or discuss their risk exposure. We develop methods for sharing and aggregating risk exposures that protect the privacy of all parties involved, and without a trusted third party. We use a homomorphic encryption scheme for floating-point arithmetic based on the ring learning with errors problem. Using this efficient protocol, multiple parties can compute joint functions — average, standard deviation, and logistic regression on aggregated data — without revealing their inputs.

24 - Application of Multivariate Analysis in Prediction of Absenteeism at Work

Motahareh Tavakolikashi, Student, Suny at Binghamton, Binghamton, NY, United States, mtavako1@binghamton.edu, Nasim Khan, Yuqiao Cen, Shuxia Susan Lu

In the highly competitive market, the urge to produce more with utilizing less resources, puts lots of pressure on employees and causes absenteeism at work. In this paper, first different feature selection methods are implemented to identify the most important attributes. Then, different of machine learning algorithms (Decision Tree, Naïve Bayes, Logistic Regression and Linear Discriminant Analysis) have been implemented to achieve an accurate predictive model for absenteeism. The performance of these algorithms is evaluated by several metrics including accuracy, sensitivity, specificity, and AUC of the ROC curve. The results show that the DT algorithm outperforms other algorithms.

25 - Employment Analysis Based on Panel Data in the Background of Industry 4.0

Rongyan Zhou, CentraleSupelec, Université Paris-Saclay, Gif-sur-Yvette, France, rongyan.zhou@centralesupelec.fr, Julie Stal-Le Cardinal

Although Industry 4.0 will bring a great of convenience to our lives, the unemployment brought by new technologies is concerned by the public. Whether the new jobs created by the industry 4.0 can make up for the losses caused by technical unemployment; what is the difference in the new job opportunities created by investment of industry 4.0 in different regions is focused in this paper. The panel data is applied in the study, and the study found that the EU faced the most serious unemployment problem brought by the industry 4.0 technologies, followed by NAFTA, then SAARC and East Asia. Furthermore, the study describes the possible reasons of the difference and proposes future research directions.

26 - Meal Specific Consumption Cycles on Choice Behavior: in Case of Japanese Meal

Hiroki Takahashi, The University of Tokyo, Tokyo, Japan, takahashi@css.t.u-tokyo.ac.jp, Nariaki Nishino

This research analyzed meal specific consumption cycles on consumers' selecting behavior in case of Japanese meals. Particularly, it seems that there is a difference between meals, those you periodically choose like once in a week, and those you are into just for a while and you totally do not eat anymore. However, there are not sufficient researches which are considering these characteristics. In our research, we used data of employees selecting meal at a Japanese restaurant franchise company in order to analyze meal specific consumption cycles and show the importance of clarifying these cycles.

27 - A Modified DEA-based Approach for Selecting Preferred Benchmarks in Social Networks

Sheng Ang, University of Science and Technology of China, Hefei, China, shengang@ustc.edu.cn, Rui Zheng, Fangqing Wei, Feng Yang

We propose a combined method of data envelopment analysis and social network analysis to select preferred benchmarks. The proposed method can identify efficient units that obtain little endorsement from inefficient units and inefficient units that could be good benchmarks. Examples are used to illustrate the practicability and superiority of our proposed method.

28 - Evaluation of a Two-year Addiction Recovery Policing Initiative

Veronica M. White, University of Wisconsin-Madison, Madison, WI, United States, vmwhite@wisc.edu, Meghan Meredith, Laura Albert

The Madison Addiction Recovery Initiative (MARI) is a Smart Policing Initiative in Dane County, Wisconsin, that seeks to offer persons stopped for low-level offenses an alternative to criminal charges via medication-assisted and behavioral drug treatment. Using individual-level data, collected over a two-year period, hypothesis testing is used to demonstrate the impact of the program on health and criminal justice outcomes. The analysis sheds light on the impact of the MARI program on police operations and community health. We also present a framework for policy analysis and evaluation for policing programming.

29 - The Hidden Constraints on Career Mobility: How Skills Determine a Worker's Next Move

Morgan R. Frank, Massachusetts Institute of Technology, Cambridge, MA, United States, mrfrank@mit.edu

Instead of abstract low- and high-skill descriptions of labor, specific skill requirements determine a worker's employability and mobility between labor markets. Here, we employ the O*NET skill database to create a job network that encapsulates information about workers' career mobility and spatial mobility between cities. Our unsupervised analysis reveals a new description for US job polarization and enables new investigations into how changing skill demand may contribute.

30 - The Optimal Bidding Strategy of a Virtual Power Plant with Consideration of Uncertainties

Hyungkyu Cheon, Pohang University of Science and Technology (POSTECH), Pohang, Gyeongbuk, Korea, Republic of, hkyucheon@gmail.com, Yedam Lee, Daeho Kim, Dong Gu Choi, Seongbin Im, Ilhan Ham

Recently, the need for a new energy distribution system has emerged due to the development of energy storage system technology and the increase of small distributed resources. Therefore, in this study, we developed an algorithm to determine the optimal bidding considering uncertainty for virtual power plant.In this study, a prediction model was developed based on data from solar power generation and electricity demand of facilities with energy storage system. In addition, uncertainties regarding forecast errors were quantified through scenario generation. Finally, the optimal bidding profile was derived by the stochastic dynamic programming method .

31 - Reliability-Based Spare Parts Provisioning

Alejandro Najera-Acosta, New Mexico State University, Las Cruces, NM, United States, a_najera@nmsu.edu, Delia J. Valles-Rosales

In industrial practice, the availability of production equipment is influenced by the time of its repair. The latter is also influenced by the time needed to obtain a spare component or replacement. Spare parts inventories are established in order to allow rapid replacement of failed parts and ensure continuity of the operations. However, provisioning of spare parts is a significant challenge because these components have characteristics that differentiate them from other products. For the current work, it is proposed a reliability-based approach, to estimate the failure risk of an equipment when it is subjected to its working conditions.

32 - The Decisions on Assembly with 3D Printing and Their Impact on Subassembly Inventory

Jeonghan Ko, Professor, University of Michigan, Ann Arbor, MI, United States, jko@ajou.ac.kr, Ajou University, Suwon, Korea, Republic of, jko@ajou.ac.kr

This research presents decision models on assembly structure with 3D printing thorough multi-stage assembly, and investigates the impact of this hybrid structure on the product variety and the safety inventory of subassemblies. We develops mathematical models to incorporate 3D printing substitution to conventional component assemblies for the products by combinatorial part assemblies. We show how the model can be used to evaluate the total subassembly inventory levels on the condition of little component commonality. In particular, we show that different product structure and 3D printing selection will lead to different levels of subassembly inventory.

33 - Using Control Charts to Monitor Manufacturing Processes

Vahid Azizi, Iowa State University, Ames, IA, United States, Guiping Hu, Cameron MacKenzie

Statistical process control chart (SPC) is a method to monitor, control, and improve a process through statistical analysis. One of the most important SPC tools is the control chart. Common challenges for control chart applications in manufacturing systems are the identification of the best statistical method, the selection of type of control chart, and the identification of special causes when a change is signaled. Another challenge is to determine which data to monitor in a real-time environment especially when data is collected every second. This study aims to design and present control charts to monitor manufacturing processes in a real-time environment for a manufacturing company in Iowa.

34 - Strategic Production and Sourcing Study under Emissions Trading Scheme

Xin Ma, Monash University, Melbourne, Australia, xin.ma@monash.edu

Shareholders have paid attention to the environmental issues in practice, particularly for the manufacturing industry under environmental regulations. A multi-stage game model is proposed to study the impact of emissions trading scheme on the production and sourcing decisions. Sourcing the materials with lower emissions rate is not a strictly dominate strategy for the manufacturer. The manufacturer can gain more profit with a lower production quantity by using the performance-based sourcing contract in the chain-to-chain competition. The analytical outcomes could provide useful guidance for the manufacturing industry practice in sustainable sourcing and production.

35 - A Two-stage Distribution System Model with Committed Home-delivery-time-dependent Demand

Yue Wang, Texas A&M University, College Station, TX, United States, yuewang92@tamu.edu, Joseph Geunes, Xiaofeng Nie

We consider a two-stage distribution system in which the demand level depends on a committed home delivery order fulfillment lead time. The model assumes periodic and uncertain but bounded demand in each period over a finite horizon. Both the maximum and the expected period demand depend on the committed delivery time. The model's objective is to determine the committed delivery time and inventory stock placement decisions that maximize expected system profit. This model serves as a building block for solving large-scale distribution system planning problems with committed delivery times.

36 - Opaque Pricing Strategy in Healthcare Management

Yuqiong Jiang, Tianjin university, Tianjin, China, junejiang@tju.edu.cn, Zhaofang Mao, Xinghao Yan

In reality, the service quality of the doctor at a hospital with a higher ranking is perceived to be higher. Therefore, the patients would have more incentive to visit the doctors at the hospital with a higher ranking. The patients' asymmetric incentives for doctors at different hospitals can result in serious congestion problem. However, the doctors' real service quality may not be that different. So, we propose a mechanism of opaque pricing applied to healthcare which gives patients more incentive to switch. And comparing with the traditional model and opaque mechanism, we can make some suggestions for pricing decision-making of medical services.

37 - Buyer Power Implications in Contract Farming - An Analysis

Sreehari Karnam, Indian Institute of Management, Indore, India, f15sreeharik@iimidr.ac.in, Hasmukh Gajjar, Bhavin J. Shah

Contract farming has been a growing practice in developing countries especially for the export oriented agricultural crop. However, the food processors, by exerting their bower power, are always at advantage and thus gaining more supply chain profits. Hence, in order to extract more profits, farmers, by considering the buyer power aspect, need to see under what conditions the direct contract with the processors is more beneficial and under what conditions a cooperative structure which in turn contracts with the processor is beneficial. A further analysis with a model considering the aspect of buyer power and channel structure gives a mathematical solution for the farmers to increase their profits.

38 - Sensor Driven Spare Part Management Using Adaptive Stochastic Mixed Integer Programming

Jiachen Shi, Georgia Tech, Atlanta, GA, United States, Murat Yildirim, Nagi Gebraeel

Advances in sensor technology and data mining unlocked accurate methods for predicting life distribution of engineering assets. The visibility attained through these predictions are reshaping many large-scale systems. In this study, we propose a unified framework that utilizes equipment condition monitoring data to jointly optimize condition-based maintenance and inventory decisions. We formulate our problem as a stochastic mixed integer program that accounts for the interplay between maintenance, spare parts inventory, and asset reliability. We present extensive computational experiment the demonstrate the benefits of our proposed approach in terms of cost and reliability.

39 - Manufacturers' Assortment Planning and Pricing in a Two-Tier Supply Chain

Juan Xu, University of Illinois Urbana Champaign, Urbana, IL, United States, juanxu2@illinois.edu, Xin Chen, Qiong Wang

We consider assortment competition in a two-tier supply chain with multiple manufacturers and one wholesaler. Manufacturers choose assortments (and wholesale prices) for the wholesaler, and the latter sets market prices. We characterize a manufacturer's assortment (and pricing) response to other manufacturers' decisions, and establish the existence of an equilibrium.

40 - The Empirical Research on the Impact of Venture Capital on the Cross-border M&A Premium of Chinese Listed Firms

Yingzi Xiong, Associated Professor, Xiamen University, Xiamen, China, Panpan Wu

Based on the M&A events of listed companies in China in 2003-2018, this paper explores the impact of venture capital institutions on the cross-border M&A premium. The study found that listed companies with a background in venture capital have a significantly lower cross-border M&A premium. Based on the results of this study, the author believes that the supervisory function and resource advantages of venture capital institutions play a positive role in the M&A activities in the listed companies.

41 - Interaction Strategies Between Public and Private Sectors in Concession Length of Infrastructure Projects

Zhouyang Lyu, Hohai University, Nanjing, China, lzyseu@hhu.edu.cn

This work studies the intention of private sector investment under tenuous rules of law (Incomplete Information) and associated with concession period length. First, a static game model was created to analyze the tactical concession length, indicating 60% of the legal maximum length. Then, to analyze private investment promotion, another model was created to investigate the influences of the investment ratio. Results from the models show: 1) "zero concession" is negated; 2) only under extreme risk the private sector's motivation will be influenced, but with limitation.

42 - Optimal Payment Policies and Resource-Constrained Project Scheduling with Discounted Cash Flows: The Contractor's Perspective

Michael T. Williams, California Polytechnic State University, San Luis Obispo, CA, United States, mwill143@calpoly.edu, Alessandro Hill, Parth Thakker

We consider new variants of the resource-constrained project scheduling problem with discounted cash flows that are relevant from the contractor's perspective. We use constraint programming to optimize models that foresee different payment policies such as pay per milestone, job, and batch, and study the obtained revenue spectrum for PSPlib instances.

43 - Activating underutilized Resource: Experience in Developing Innovation Service Platform Based on S&T Resources for Beijing-Tianjin-Hebei, China

Ning Xiang, Beijing Science and technology information research institute, Beijing, China, xiangning_xn@163.com

Demand-oriented for the collaborative innovation and industrial development, the Innovation Service Platform based on Science and Technology(S&T) Resources for Beijing-Tianjin-Hebei in China integrates information of nine major types of S&T resources and adopts a three-integration mode, i.e. "S&T resource + digital map, internet + S&T service, expertise wisdom + intelligence forecasting" to provide big-data information service and consulting service. Based on Web GIS framework, the platform formulates data standards and constructes a "3+12" cooperation network in the region.

44 - Earned Value Measurement in Project Buffers Management

Pawel Blaszczyk, University of Silesia, Katowice, Poland, pawel.blaszczyk@us.edu.pl, Tomasz Blaszczyk

The aim of this research was the trial of modelling and optimizing the time-cost trade-offs in project planning problem. The base of the problem description contains both safe and reasonable amounts of time and cost estima-tions and the influence factors matrix. We assumed also the pricing opportunity of performance improving. Finally we try to combine that method with Earned Value Analysis (EVA) method - one of the most popular project audit method.

45 - Multiple Objective Optimization of a Small-scale Renewable Energy System

Eduardo Castillo Fatule, University of Texas-El Paso, El Paso, TX, United States, jecastillofatule@miners.utep.edu, Jose F. Espiritu

Energy use and production in the United States has shifted greatly since the industrial revolution. Today, most of the electricity produced is generated through the burning of fossil fuels. This, however, releases massive amounts of carbon dioxide and other gasses into the atmosphere, which results in increased global temperatures as global warming effects worsen. One of our main objectives in this study is to demonstrate the viability of a renewable energy grid as a reliable, sustainable source of energy. Stochastic analysis is used to evaluate the alternatives, and a metaheuristic process will be used for design optimization.

46 - Optimal Consignment Stocking Policy under Uncertainty

Md Shahriar J. Hossain, Northwestern State University, Natchitoches, LA, United States, msjhossain1@gmail.com, Bhaba R. Sarker

Consignment stocking is an effective approach to bring a product next to the door of a consumer. This supply chain system often encounters both demand and lead-time uncertainty, as well as space and shelf life constraints. In this paper, a joint total cost model is developed and solved to determine the optimum order quantity and reorder point for a single-vendor, single-retailer consignment stocking system. The solution procedure varies depending on the distribution of demand and lead time. For uniformly distributed demand and lead time a gradient method is applied with an iterative search procedure. In case of normal distribution, an exhaustive search procedure is followed within certain domains.

47 - D-Optimal Design for Network A/B Testing

Victoria Pokhilko, Virginia Commonwealth University, Henrico, VA, 23294, United States, Qiong Zhang, Lulu Kang, D'Arcy Mays

A/B testing refers to the statistical procedure of conducting an experiment to compare two treatments, A and B, applied to different testing subjects. It is widely used by technology companies such as Facebook, LinkedIn, and Netflix, to compare different algorithms, web-designs, and other online products and services. The subjects participating in these online A/B testing experiments are users who are connected in different scales of social networks. Two connected subjects are similar in terms of their social behaviors, education and financial background, and other demographic aspects. Hence, it is only natural to assume that their reactions to online products and services are related to their network adjacency. In our research, we propose to use the conditional auto-regressive model to present the network structure and include the network effects in the estimation and inference of the treatment effect. A D-optimal design criterion is developed based on the proposed model. Mixed integer programming formulations are developed to obtain the D-optimal designs. The effectiveness of the proposed method is shown through numerical results with synthetic networks and real social networks.

48 - The Lexicographic Winner Determination Problem (WDP) for Real World Combinatorial Auctions

William K. Schwartz, Co-founder, Illinois Institute of Technology, Chicago, IL, United States, wkschwartz@gmail.com, Ingraham and Schwartz Auction Advisers, LLC, Arlington, VA, United States, wkschwartz@gmail.com

WDP asks which combination of indivisible bids for discrete goods maximizes revenue. Textbooks present it as an integer program (IP) constrained by goods' supplies. IP can be cumbersome to use for national radio spectrum auctions, which have tie breaking rules and side constraints, and often require repeated solving of related WDPs. We introduce a more realistic formalism, and a warm-startable dynamic programming algorithm for solving it, generic enough for real auctions and with a simple data interface. A custom radix tree accelerates memoization. Work on fathoming and relaxation is ongoing.

49 - Service Network Design for Regional Multi-modal Rail Transit System

Yihan Wang, Master candidate, Southwest Jiaotong University, Chengdu, China, johnw@my.swjtu.edu.cn, Lan Liu, Weike Lu, Jiannan Mao, Yalong Lao

Focusing on making full use of transport capacities and transfer passengers during the rush hour by allocating the components of the multi-modal rail transit system, this paper formulated the MINLP model which minimized the generalized travel cost of the passenger and considered the multiple services departing interval. Furthermore, a MILP model was reformulated by modifying the nonlinear constraints according to the change of notation. This new model was tested by a numerical example and solved by Cplex solver. The results showed that the reconstruction modal was valid to the real problem and illustrated the superiority in the computation.

50 - Operational Constroperational Constraints for Real-world VRP

Heather Moe, ESRI, Redlands, CA, United States, Yuzhe Yan

Solving a standard VRP to optimality is a difficult challenge. However, the optimal solution is often unrealistic and infeasible in the real world. Additional constraints must be added to the model to make it operationalizable. In this analysis, we examine qualitative constraints such as how best to cluster a solution; balancing workloads but still being reasonably efficient; sequencing orders on a "Neighborhood" basis to facilitate repeat attempts; and prioritizing high revenue orders but visiting nearby lower priority ones. We will look at the multitude of ways these can be defined quantitatively to fit a company's business rules, and the implications of the different interpretations.

51 - Failure Detection for K-out-of-N Systems

Tonguc Unluyurt, Sabanci University, Istanbul, Turkey, tonguc@sabanciuniv.edu

We consider a k -out-of- n system that has just failed. There is an associated cost of testing each component. In addition, we have apriori information regarding the probabilities that a certain set of components is the reason for the failure. The goal is to identify the subset of components that have caused the failure with the minimum expected cost. In this work, we provide exact and approximate policies that detect components' states in a failed k -out-of- n system. We propose two integer programming (IP) formulations, two novel Markov decision process (MDP) based approaches, and two heuristic algorithms.

52 - Routing of Platform Supply Vessels in Offshore Oil and Gas Logistics

Victor Silva, PETROBRAS, Rio de Janeiro, Brazil, vasilva@andrew.cmu.edu, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil, Carnegie Mellon University, Pittsburgh, PA, United States, vasilva@andrew.cmu.edu, Chrysanthos E. Gounaris, Akang Wang

This work introduces a novel feature-rich maritime routing problem, which models cargo transport activities performed by Platform Supply Vessels in offshore oil and gas logistics. We present a mathematical formulation and results inspired by real operator data.

53 - Comparison of Linear and Nonlinear Analysis for Train Routing and Scheduling Problem

Yuan Xu, Lecturer, Rensselaer Polytechnic Institute, Troy, NY, United States

This paper presents a comparison of a novel mixed integer linear program and a traditional nonlinear program on solving a train routing problem combined with a train scheduling problem in a railway network including both single and multi-track sections. The proposed models consider several important elements and issues besides train route selection, such as headway, trip time, side capacity, conflict at common stations, and overtaking between trains. A numerical study is applied to perform the comparison analysis.

54 - Strengthened SOCP Relaxation and Efficient Hybrid Bounds Tightening of ACOPF

Yuanxun Shao, Georgia Institute of Technology, Atlanta, GA, United States, yuanxun@gatech.edu, Dillard Robertson, Joseph Scott

ACOPF problem is fundamentally important for power grid operations at all scales. The key challenge for global methods is that tens of thousands of optimization variables making exhaustive branching procedures impractical. To address these challenges, this talk presents a strengthened SOCP relaxation based on McCormick envelopes, cycle basis relaxations, and reverse cone cuts that are added dynamically. We also first identify a minimal subset of the variables for optimization-based bounds tightening. Next, we utilize simple bound updates based on interval arithmetic. The advantages of our proposed method will be demonstrated through extensive tests on NESTA benchmarks.

55 - Modeling Framework and Decomposition Scheme for On Demand Mobility Services with Ridesharing and Transfer

Sepide Lotfi, Southern Methodist University, Dallas, TX, United States

A modeling framework for the operations of on demand mobility services (ODMS) in urban areas is presented which provides the capabilities to analyze ODMS operations while representing emerging services such as ridesharing and transfer. The problem is formulated as a mixed integer program and an efficient decomposition based methodology is developed for its solution. The results of a set of experiments show that increasing the number of passengers willing to rideshare and/or transfer improves the overall performance of ODMS as it increases number of served passengers and associated profit and reduces the number of used vehicles.

56 - Optimizing Power System Resilience Using Conditional Value-at-Risk Within a Markov Decision Process Framework

Thanh To, Clemson University, Clemson, SC, United States, tto@clemson.edu

We propose a model that incorporates the Conditional Value-at-Risk measure into the Markov Decision Process framework. We then apply this framework to optimize the power system resilience.

57 - Coordination of a Multi-supplier and Single-manufacturer Supply Chain in Presence of New Technology Investment under a Stochastic Demand

Cesar Rodriguez, Concordia University, Montreal, QC, Canada, Qingguo Bai, Mingyuan Chen

This work explores the impact of technology investment on supply chain coordination. To be specific, we investigate the optimal pricing and technology investment decisions in a system consisting of multiple complementary suppliers and a single manufacturer. We compare both the decentralized and centralized settings, and show that if the supply chain members decide to cooperate and coordinate the system, they could increase the overall expected profit by at least 1/3. We then find that the cost-revenue sharing contract is capable of coordinating the supply chain. Moreover, we establish the conditions at which this contract offers a win-win profit scenario to all parties of the negotiation.

58 - A Novel Feature Selection Algorithm for Continuous Response Prediction with Interacting Variables

Maryam Nikouei Mehr, Iowa state university, Ames, IA, United States, Sigurdur Olafsson

This paper concerns a new feature selection method for multiple linear regression models. While common feature selection methods focus on the removal of redundant or irrelevant features, we show that such features may be important. We establish a computational framework for selecting a subset of features that have significant interactions with the response and a subset of features that may have little interactions with the response, but when combined with others, they can be strongly predictive of the response. Removal of these features can thus result in poor predictions. A mixed integer linear programming model is implemented to recognize feature interactions and their exact combinations.

59 - Pricing Problem for a Product with Network Effects and Multiple Demand Segments

Fatemeh Nosrat, Univeristy of Minnesota-Twin Cities, Minneapolis, MN, United States, nosra002@umn.edu

We consider a pricing problem for a product that experiences network effects. We assume that there are multiple segments of buyers, and individuals' intrinsic values for the product and sensitivities to the network effect vary across segments. Demand is described by the Mixed Multinomial Logit model, modified to incorporate network effects. We formulate and analyze an optimization problem that aims to find the seller's revenue-maximizing price. In settings with an arbitrary number of demand segments, we present a simple, effective heuristic solution approach. In settings with two segments, we obtain a solution method that outputs near-optimal prices.

60 - Adaptive Cluster Sampling-based Approximation for Two-stage Stochastic Programs

Siavash Tabrizian, Southern Methodist University, Dallas, TX, United States, stabrizian@smu.edu

We present an adaptive clustering based sampling technique for two-stage stochastic programs, and we discuss its performance for estimating the recourse function. We also present a decomposition algorithm design for solving two-stage stochastic programs and demonstrate its efficiency through numerical experiments on classical test instances.

61- Deep Inverse Optimization

Yingcong Tan, PhD Candidate, Concordia University, Montreal, QC, Canada, Andrew Delong, Daria Terekhov

We propose a framework for inverse optimization based on deep learning by treating an interior point solver as a deep differentiable computational process. Given a set of observations from an unknown linear optimization process, we can learn LP model parameters consistent with those observations, facilitating prediction of optimizing agent behavior.

62 - Conditional Supervalid Inequalities for Graph Interdiction Problems

Ningji Wei, University at Buffalo, SUNY, Buffalo, NY, United States, ningjiwe@buffalo.edu, Jose Luis Walteros

We focus on attacker-defender network interdiction problems in which: (1) the objective minimizes the attacker's cost of achieving a certain disruption level over the defender's problem; (2) the defender's problem is to select an optimal graph structure (e.g., a shortest path, a spanning tree) over the residual graph; (3) the attacker strategies are defined over the same ground set of the defender's graph structures. We develop a cut-generating framework that produces a general class of supervalid inequalities that remove non-trivial suboptimal solutions. We show how to adapt the proposed framework to tackle a wide variety of theses problems.

63 - A Patient No-show Predictive Model with Limited Data and Information for Outpatient Appointments

Fangzheng Yuan, North Dakota State University, Fargo, ND, United States, Fangzheng.yuan@ndsu.edu, UGPTI, Fargo, ND, United States, Fangzheng.yuan@ndsu.edu, Joseph Szmerekovsky, Vera Tilson

No-shows is one of the most common and challenging issues for appointment scheduling. However, it is not always able to obtain the data and information wanted in order to predict patients' no-shows due to some business, privacy, and ethical reasons. In this study, we developed a decision tree model for predicting the no-show probability of outpatient appointments for a medical center and compared it with few commonly used models in related topic. This study demonstrates an alternative way to predict patient's no-show probability based on limited data and information and has been proved to be effective with a high R-square value.

64 - Knowledge Discovery From Patient Experience Surveys through Text Mining

Mohammadsadegh Mikaeili, Binghamton University, Binghamton, NY, United States, mmikaei1@binghamton.edu, Sarah S. Lam, Joshua Bosire, Jady Yao

Unstructured data in healthcare can be utilized to develop intelligent models to improve operations. One source of such data is the unprocessed textual data in form of surveys completed by patients after they receive their care. The mechanism for collecting unstructured feedback from patients has become commonplace, however, analysis techniques have not been frequently applied to examine this data source. This research utilizes text mining on free-text feedback to evaluate patients' perception of service quality and to use this insight to identify inefficiencies. The proposed methodology explores the analysis of textual commentary using an unsupervised learning (topic modeling) procedure.

65 - Precipitation Prediction Based on Historical Data Using the K- Nearest Neighbor Method

Sean C. Guidry Stanteen, Research Assistant, University of Texas at Arlington, Arlington, TX, United States

Weather, particularly precipitation, is an environmental condition on which agriculture is wholly dependent. As such, prediction on precipitation and other weather factors is essential to proper farming management. A data science method, K-Nearest Neighbor (KNN), is utilized to matches up historical patterns for short term prediction, and preliminary data testing shows the validity of the methodology. This work is in collaboration with Dr. Xunchang John Zhang, Dr. David Brown, Dr. Jianzhong Su, and USDA-ARS Grazinglands Research Laboratory, El Reno, Oklahoma.

66 - Adaptive Spaces and Real-time Emotive Prediction Using Unobtrusive Wearable Devices for Personalized Healthcare.

Mona Ghandi, Washington State University, Pullman, WA, United States, mona.ghandi@wsu.edu, Marcus Blaisdell

Personal automatic emotional classification analytics can offer a new diagnostic tool that allows personalized medical care and helps researchers to find patient-specific information that would be difficult to spot with traditional research methods and often times more quickly and cost effectively. We have developed a method that can provide automatic real-time emotional state determinations out of the laboratory. The use of wearable sensors in conjunction with mobile connectivity combined with machine learning techniques allow us to move this technology out of the laboratory and into real-world applications in smart adaptive environments to improve users' mental health and well-being.

67 - A Hierarchical Model of the Federal Funds Market

Saurav Chakraborty, Doctoral Candidate, University of South Florida, Tampa, FL, United States, sauravc@mail.usf.edu, Don Berndt, David Boogers

The Great Recession (2007-2009) had profound impact on the US Federal Reserve (FR) system. In response to the crisis, the FR took unprecedented action. In particular, the Fed responded by lowering the target Federal funds rate, granting credit to financial firms, and eventually engaging in a series of large scale asset purchase programs comprising quantitative easing (QE). As the FR seeks to unwind its positions, the impacts of monetary policy normalization (MPR) are uncertain. We propose a framework using agent-based modeling and simulation to better understand and evaluate policy alternatives. In particular, a hierarchy of coarse-grained and fine-grained models are used to simulate MPR.

68 - Implementing KIER's Basic RND Project Assessment Based on Technology Readiness Level for Managing RND Projects Efficiently

Seongkon Lee, Principal Researcher, Former Head, Korea Institute of Energy Research, Daejeon, Korea, Republic of, sklee@kier.re.kr

Korea Institute of Energy Research(KIER) has been carrying out strategic energy RnD projects for addressing the national energy agenda. KIER receives basic RnD funds from the Government annually and budget in 2019 accounts for 146 million USD. This research changes the previous basic RnD assessment method focused on the achievement of technical targets to Technology readiness level(TRL) assessment approach classifying each level's technical target clearly. In addition, technical status table, including TRL and current status of the global leading research institute or company, is added in proposal. This research will enhance the management of KIER's basic RnD funds more efficiently.

69 - Optimum Design of Blood Pressure Telemonitoring Systems for Hypertensive Patients

Sulki Park, Texas A&M University, College Station, TX, United States, sulkipark828@tamu.edu, Hye-Chung Kum, Mark Lawley

Blood pressure (BP) telemonitoring offers hypertensive patients the opportunity to obtain early clinical intervention and cost-effective care. Using a telemonitoring company data, we analyzed the number of non-clinical staffs, who followed up with patients to get daily BP readings, and clinical staffs, who followed up with abnormal BP readings, as well as time consumed for the supports, to provide scheduling insights of telemonitoring support services. Through these results, we can help to develop an optimal program of telemonitoring support system, including the optimal number of clinical and non-clinical staffs, and the effect of procedure length on patients' health outcomes.

70 - Hedge Modelling for Solar Power Business Using Multiple Non-parametric Regression Methods

Takuji Matsumoto, PhD candidate, University of Tsukuba, Tokyo, Japan, s1745014@s.tsukuba.ac.jp, Yuji Yamada

The large-scale introduction of natural energy being promoted worldwide in recent years leads to an increased impact of weather fluctuations on wholesale electricity prices. Under such circumstances, hedging needs for revenue fluctuations in the solar power business have been expanding. Therefore, this work proposes hedging strategies for the power companies, using a portfolio of derivatives with fuel price, solar radiation and temperature as underlying assets. We specifically propose a hedging method that applies multiple non-parametric regression methods such as tensor product spline and ANOVA decomposition and demonstrate the hedge effect using empirical data from the Japanese market.

71 - A Time Series Clustering Based Customer Segmentation Framework for Predicting Account Behaviors

Xingwei Yang, PhD student, Queen's University, Kingston, ON, Canada, xingwei.yang@queensu.ca, Matthew Thompson, Akram Khaleghei Ghosheh Balagh, Mikhail Nediak

For many applications, banks need to classify customers into groups of individuals with shared characteristics. Traditional customer segmentation intuitively segments the customer using sets of predefined information such as age, gender, geographic information and etc. We present the design of a customer segmentation framework based on time series clustering from the account balance activities of customers through time. We demonstrate how the clustering of account behaviors can improve the prediction of the expected lifetime of each dollar deposited to the bank and monitor the expected duration and the total amounts of the investments the bank can fund.

72 - Optimizing the Biorefinery Supply Chain: Impact of Feedstock Quality on Logistics Design

Yingqian Lin, Postdoctoral Researcher, Idaho National Laboratory, Idaho Falls, ID, United States, yingqian.lin@inl.gov, Pralhad Burli, Damon Hartley, Roni Mohammad, Mike Griffel, David N. Thompson

Biomass is known to be a raw material as it can be used in a variety of applications for the production of bioenergy and bioproducts. We propose a novel mixed-integer linear programming (MILP) model to find the maximum number of biorefining facilities that could be supported based on estimates of available crop residue and dedicated energy crops.

73 - Eco-efficiency Assessment of U.S. Tourism Industry Using the EIOLCA and DEA Framework

Yong Shin Park, St.Edward's University, Austin, TX, United States, Myungwoo Lee, Hyelin Kim

This study proposes an EIO-LCA and DEA based eco-efficiency assessment for the U.S tourism sector considering direct and indirect impacts. Results indicated that other amusement and recreation industries and bowling centers were found to have the most significant shares in environmental impact. Based on supply chain decomposition analysis, there was a high environmental impact across the supply chain for each tourism industries. Based on DEA analysis results, the average eco-efficiency score of U.S tourism industry is found to be 0.47 meaning that inefficient U.S tourism industries need to reach an average reduction of 53% on the environmental impact to reach 100% eco-efficiency frontier.

74 - A Joint Ordering and Markdown Policy for Perishable Products with Fixed Lifetime

Zheng Wang, Southeast University, Nanjing, China, wangz@seu.edu.cn, Xue Qiao

For perishable products with fixed lifetime, we study the joint ordering and markdown problem based on the two-shelf (i.e., fresh product shelf and less fresh product shelf) management rule, in the situation that demand depends on price and freshness and unsatisfied demand is lost. Firstly, for the single-period case, we consider the inventory levels for products at different shelf-ages and obtain the optimal analytic solution by using the KKT-condition. Secondly, we extend the one-period decision to a myopic policy and apply it to the multi-period case. Numerical experiments show that the proposed joint ordering and markdown policy performs better than the traditional one-shelf management rule.

75 - Designing a Data-driven National Research and Development Budget Allocation Model

Hoon Jang, Korea University (Sejong Campus), Sejong, Korea, Republic of, hoonjang@korea.ac.kr

Since research and development (R&D) has been proven to be a key driver of economic growth, the volume of R&D budgets has been growing in many countries. This requires decision makers to determine the right number of R&D projects and optimally allocate budgets. Motivated by this, in this study, we propose an integrated model which assists decision makers to select and distribute R&D budget effectively. Specifically, we offer a way of allocating R&D budgets in order to maximize the total expected outputs from R&D projects. Experimental results confirm that our approach can help improve the entire of R&D budget allocation process.

76 - Tuning Deep Flooding Risk with Adaptive Strategy: An Application for NYC

Kairui Feng, PhD Student, Princeton University, Princeton, NJ, United States, kairuif@princeton.edu, Ning Lin

The impact of the storms worsens in the coming decades due to the rapid development of the coastal zone in conjunction with sea-level rise and possibly increased storm activity due to climate change. We develop a reinforcement-learning-based strategy of adaptive seawall design, to cope with the deep uncertainty in climate change effects by continuous observation and modeling. We apply this method to New York City and estimate its optimal adaptive seawall design. We show that the total lifetime cost is significantly reduced (by 20% to 40%; ~1 billion) when the dynamic, reinforced learning strategy is applied, compared to traditional design methods.

77 - Welfare Impacts of Optimal Virtual Bidding in A Multi-settlement Electricity Market with Transmission Line Congestion

Hyungkwan Kim, Lawrence Berkeley National Laboratory, Berkeley, CA, United States, hyungkwankim@lbl.gov, Paul V. Preckel, Douglas Gotham, Andrew Lu Liu

The objective of this research is to understand the effect of virtual transactions on electricity market efficiency using a model that explicitly includes the network as well as relationships that reflect the physical properties of electricity flows through a network (i.e. loop flow). The core research question is; what impact does network congestion have on the welfare shifts caused by the participation of financial virtual traders? Results indicate that optimal virtual bidding tends to decrease consumer welfare when the expected spot price is equal to the cleared forward price, and congested lines in the network can magnify the welfare changes while virtual traders essentially always benefit.

78 - Power Grid Resilience Planning for Extreme Weather Recovery

Priyadharshini Kumaravelan, Masters in EE, Texas State University, San Marcos, TX, United States, p_k41@txstate.edu

The traditional N-1 power grid system is inadequate as it cannot withstand extreme weather events like hurricane, flooding, earthquake etc. Extreme event analysis reports by NERC, BPU, ERCOT state that failure of outdoor grid components like transmission lines, transformers and generators lead to majority of the power outages where millions of customers get affected. This paper addresses the problem of power grid resilience post an extreme weather event and how the grid recovery can be planned. We propose a repair and recovery model for transmission lines for the case of Hurricane Harvey. We also present a Vehicle-to-Grid based resilience model for a manufacturing facility during an extreme event.

79 - Distribution Electricity Pricing under Uncertainty

Robert Mieth, NYU / TU Berlin, Brooklyn, NY, United States, robert.mieth@nyu.edu, Yury Dvorkin

Distribution locational marginal prices (DLMPs) facilitate the efficient operation of low-voltage distribution systems. We propose an approach to internalize the stochasticity of renewable resources and risk tolerance of the distribution system operator in DLMP computations. This is achieved by means of applying conic duality to a chance-constrained AC optimal power flow. We show that the resulting DLMPs consist of the terms that allow to itemize the prices for the power production, balancing regulation, and voltage support provided. Finally, we prove the proposed DLMP constitute a competitive equilibrium, which can be leveraged for designing a distribution electricity market.

80 - Regulatory Innovation and the Convergence of Electric Utility Policies: New Business Models and Electricity Market Design

Joseph Nyangon, Postdoctoral Research Scholar, University of Delaware, Newark, DE, United States, jnyangon@udel.edu

Several disruptive trends are driving energy transformation and forcing electric utilities to change their business models. The challenge for utilities is how to transition to "Utility 2.0" concepts: microgrid development, automated, distributed solar, electric market design innovations, smart grid systems, and big data and analytics. Using a multidimensional framework and case studies from United States (i.e., New York's REV, Illinois's NextGrid and California's Energy Savings and Performance Incentive), the U.K.'s RIIO, Germany's Energiewende, and Australia's Electricity Network Transformation Roadmap, this study examines electricity market design and flexibility innovations.

81- Development of Customer DNA Database in a Gas Company

Noriko Furuta, Tokyo Gas Co Ltd, Minato-ku, Japan, noriko.furuta@tokyo-gas.co.jp

Personalized customer experience has become more important in Japanese energy retailers. In this study, we constructed models to estimate customer attributes, lifestyles, and values from our data by machine learning, and developed "customer DNA" database. By using this database, we can improve response rate of marketing actions by 16-23%.

82 - Online Readiness in undergraduate Students

Sara Hooshangi, The George Washington University, Washington, DC, United States

The purpose of this study is to examine the online readiness characteristics of undergraduate students majoring in an information technology program. Computer, internet, online communication self-efficacy, self-directed learning, and learner control were measured. The result showed that students' level of self-efficacy in using online tools was very high. The learner control was low and self-directed learning was moderate among these students. Comparison between gender and different age groups showed no significant differences in online readiness factors among these groups.

83 - Normalization Strategies and Development for Improved NCAA Basketball Tournament Predictions

Jessica M. Rudd, PhD Candidate, Kennesaw State University, Kennesaw, GA, United States, jess@irudd.com

The study utilizes various normalization techniques for NCAA basketball tournament prediction. Baseline models using tournament seeds, several popular sports ranking methods, regular season game statistics, and tournament results, dating back to 1985 where available, are compared with results using several normalization strategies, including approaches not known to be tested on this problem as well as a novel season rank-based approach. Baseline models predicted previous tournament wins with accuracy as high as 76%. Normalized model brackets performed as high as 97% accuracy in the 2019 tournament.

84 - Staffing Level in Optimization Service Systems

Mohammad Maydanchi, Graduate Research Assistant, Auburn University, Auburn, AL, United States, Samira Shirzaei

Waiting time is one of the important factors in queuing theory. To have a less waiting time, more staffs are needed, however, extra staffs can be expensive. Thus, managers prefer to have an optimal balance between these two elements. We developed a user friendly GUI tool in Excel using VBA. This tool aims to simulate the queuing system to achieve the optimal number of required staffs.

85 - Gradient Based Criteria for Sequential Experiment Design

Bruce Ankenman, Northwestern University, Evanston, IL, United States, ankenman@northwestern.edu, Collin Erickson, Matthew Plumlee, Susan Sanchez

Computer simulation experiments are commonly used as an inexpensive alternative to real-world experiments to form a metamodel that approximates the input-output relationship of the real-world experiment. While users may want to understand the entire response surface, they may also want to focus on interesting regions of the design space, such as where the gradient is large. We present a batch sequential algorithm that adaptively runs a simulation experiment that focuses on finding areas of the response surface with large gradient while also gathering an understanding of the entire surface. The design points within each batch can be run simultaneously.

86 - Latent Variable Model with Embedding Structure

Xiexin Liu, Tippie College of Business, Iowa City, IA, United States, xiexin-liu@uiowa.edu

Finite mixture model assumes observed instances are from a mixture of K component distributions. It is often of applied researchers' interest to understand the practical meaning of the mixture components, e.g., topics in Latent Dirichlet Allocation. However, like most statistical models, finite mixture model assumes independency among variables, which is not the case in most real-world problems and could identify false components following this assumption. To this end, we extend finite mixture models to incorporate an embedding structure, where we consider variable interaction when identifying the underlying mixture components. We use variational inference to solve for the proposed model.

87 - Simulating the Impact of Multiple-region Listing and Information Sharing on Kidney Transplant Outcomes and Discard Rates

Zahra Gharibi, State University Of New York at Plattsburgh, Plattsburgh, NY, United States, zghar001@plattsburgh.edu

New kidney allocation system and modern IT solutions are developed to improve kidney assignment. We develop a simulation model that considers the effect of several important factors for organ transplantation affecting kidney utilization. We investigate how the optimal individual-level acceptance decisions are affected by the difference in supply in different transplantation regions. We also focus on a macro-level aspect of transplantation, namely the contribution of information sharing on the social welfare and discard rates.

88 - Deterrence As Target Shifting in Layered Cyber Defense: A Behavioral Analog Game

Sarah Kusumastuti, Center for Risk and Economic Analysis of Terrorism Events (CREATE), Los Angeles, CA, United States, kusumast@usc.edu, Jim Blythe, Heather Rosoff, Richard S. John

This study examines how exploiting biases in probability judgment can enhance deterrence using a fixed allocation of defensive resources. We designed and conducted a behavioral experiment functioning as an analog cyber-attack with multiple targets requiring three stages of attack to successfully acquire a target. Participants play as cyber attackers choosing between target types with different resource allocations but approximately equal overall success rate for all targets. We collected data from a total of 1600 separate target selections from 80 players. The findings are consistent with both anchoring and ambiguity biases and an interpretation of failed attacks as near misses.

89 - Theoretical Constructs for Assessing the Long-term Effectiveness of Airport Infrastructure Interventions

Bortiorkor Nii Tsui Alabi, Purdue University, West Lafayette, IN, United States, Julius Keller, Samuel Labi

Airport infrastructure maintenance intervention effectiveness can be measured in terms of infrastructure longevity, cost-efficiency, profitability, safety, and mobility. With regard to these performance criteria, this study presents theoretical constructs that utilize their respective performance functions to measure intervention effectiveness. These measurements will assist airport managers assess the success of physical or operational interventions, and thus help them monitor airport infrastructure performance.

90 - Hotspots: Real-time Driver Navigation Guidance via Reinforcement Learning

Hao Yi Ong, Lyft, San Francisco, CA, United States, hong@lyft.com

While experienced drivers can rely on their knowledge of historical demand to guide their driving, newer drivers suffer from relative inexperience. Hotspots are the Lyft driver's real-time navigational aid for where to drive to maximize long-term driver earnings subject to uncertainty in the supply and demand distributions. The algorithm generates a value heatmap with suggested peaks unique to each driver, and is based on learning offline estimates of the value of driving at specific times and places and fusing it with online estimated travel times and demand and supply forecasts to produce real-time value estimates.

91 - Research on Coordinated Development of Inland Port and Seaports under the Background of the Belt and Road

Jingying Yang, National United Engineering Laboratory of Integrated and Intelligent Transportation, Chengdu, China, 1457146422@qq.com, Southwest Jiaotong University, Chengdu, China, 1457146422@qq.com, Yinying Tang

With the promotion of the Belt and Road strategy, the problems arising from the coordinated development of inland ports and seaports have gradually become prominent. Based on the idea of system dynamics, this paper constructs a dynamic model of collaborative development between inland port and seaports, and simulates the system dynamics by changing some factors in the system. The simulation results show that the investment in the port of the sea has the most obvious effect on the development of the system. Improving the port's ability to pass and strengthening the smoothness of the interconnection channels within the system have some promotion on synergistic development.

92 - Optimization of High-speed Railway Network Based on Accessibility of Stations

Jinqu Chen, Southwest Jiaotong University, Chengdu Sichuan, China, Chenjinqu@my.swjtu.edu.cn, Yong Yin

The optimization of High-Speed Railway (HSR) network is studied. Based on the stations' degree, stations' clustering coefficient and other indicators, the topology characteristics of China's HSR network in 2030 are analyzed. The LeaderRank algorithm is used to identify the key stations of HSR network. Then the optimization model is established and solved with the goal of optimal accessibility of global network. The result shows that Changsha is the most important station in China's HSR network in 2030. Considering the investment restrictions of railway construction, constructing HSR links in Northeast and North of China can maximize the global accessibility of China's HSR network in 2030.

93 - Research on Collection and Distribution Optimization of Chengdu International Railway Port Based on Genetic Algorithms

LuLu Liu, Southwest Jiaotong University, Chengdu, China, 990972547@qq.com, National United Engineering Laboratory of Integrated and Intelligent Transportation, Chengdu, China, 990972547@qq.com, YinYing Tang, Si Chen

Taking the transportation cost of the whole network as the objective function and the time requirement of the shipper, the capacity limitation of nodes and edges as the conditions, the model is constructed to meet the minimum transportation cost of the whole network. The priority-based piecewise encoding inverse method is used for encoding, and the elite strategy is used to solve the model. Finally, the model is used to collect and disperse Chengdu International Railway Port.

94 - The Value of Halal in the U.S. Market Implications for the Logistics Industry

Neeraj Dhingra, North Dakota State University, Fargo, ND, United States

Halal is adherence to Islamic Sharia dietary laws mostly practiced by Muslim communities. Demand for halal meat is growing rapidly in the US primarily because of the rapidly growing Muslim population which is expected to increase to 8.1 million by 2050, and availability of agricultural and livestock resources. The objective of the study is to examine the determinants that could influence customer willingness to pay for halal logistics services. Consumer Willingness to pay analysis for halal food logistics is an essential attribute for understanding customer response to halal supply and determining the corresponding change in the logistics industry.

95 - Recognition of Critical Nodes in Emergency Transportation Network Considering Random Node Failure of Natural Disasters

Si Chen, Southwest Jiaotong University, ChengDu, China, chensi@swjtu.edu.cn, National United Engineering Laboratory of Integrated and Intelligent Transportation, Chengdu, China, Xiaozhen Deng, Yinying Tang

Combining PageRank and Warshall to establish the algorithm identifies key nodes in different stages under random failure of nodes to identify key nodes and isolated key nodes in transportation network under natural disasters. Based on the premise of maximum natural disasters and greedy strategy, this paper takes the critical transportation network of Wenchuan earthquake as an example, the results of key transportation network nodes are accurate. The algorithm can detect the key nodes of transportation network dynamically in real time, and provide theoretical basis for material transportation and personnel evacuation in the rescue process.

96- Potential Transfer Station Selection Using Integrated Development of Rail Transit Nodes and the City in a Metropolitan Area

Siyu Tao, Southwest Jiaotong University, Chengdu, 610031, China, National United Engineering Laboratory of Integrated and Intelligent Transportation, Chengdu, China, Xinmei Chen, Tao Feng, Qiyuan Peng

Integrated development of transit nodes and the city (ITCD) is a new concept based on the Transit-Oriented Development (TOD). Reasonable integrated planning the transport facilities with the city is also significant in improving the interaction between transit and the surrounding development. Therefore, we propose a methodology to quantitatively measure the ITCD degree of the exist rail transit nodes. The value of the ITCD degree indicates the current level of the stations, which will help find out the specific characteristics or functions should be improved for a better integrated development of stations and the city.

97 - Logistics Network Layout Design for E-commerce Demand in Remote Mountainous Areas- A Case Study of Aba Prefecture

Zhaoyi Xie, Southwest Jiaotong University, Chengdu, China, 346072525@qq.com, National United Engineering Laboratory of Integrated and Intelligent Transportation, Chengdu, China, Si Chen, Yinying Tang

According to the characteristics of E-commerce in remote mountainous areas, this paper carries out factor analysis and cluster analysis on logistics nodes to select first-level nodes and second-level alternative nodes.Taking the minimum annual total cost as an objective function,the optimization model of location selection of logistics network nodes in remote mountainous areas is constructed.Finally this paper takes 13 counties and municipalities of Aba Prefecture as the object of study,and obtains the three-level logistics network which provides theoretical basis for the development of e-commerce logistics in Aba Prefecture.

98 - Street-level Travel Time Estimation Using Data from Uber Movement and OpenStreetMap

Kelsey Maass, University of Washington, Seattle, WA, United States, Pacific Northwest National Laboratory, Richland, WA, United States, Arif Khan, Arun Sathanur

Data-driven transportation modeling forms an important part of modern urban planning. We propose a method for estimating street-level travel times from data aggregated over traffic analysis zones. Using data for the Los Angeles region from Uber Movement and OpenStreetMap, we present a workflow for 1) obtaining and preprocessing data, 2) estimating street-level travel times using a combination of graphical models and optimization methods, and 3) validating results using a variety of metrics.

99 - Adjusting Departure Time for Reducing Power Consumption of MRT Railways

Kyung Min Kim, MyongJi University, Yongin-si, Korea, Republic of, kmkim@mju.ac.kr

As regenerative power produced when train braked can be used by other accelerating trains within a specific range of the power supply system, it is possible to reduce power consumption. This paper considers the problem of adjusting train departure time to reduce power consumption of mass rapid transit (MRT) railways. We formulated the problem as mixed integer program and developed genetic algorithm (GA) to solve the problem. To validate the suggested GA, a computational experiment was conducted using data generated by a simulator. Applied to the current daily timetable of the Gwangju Line 1, we could find a practical solution, which is an about 4% improvement over the current timetable.

100 - A Heuristic Approach for Improving Utilization in Micro-Mobility Systems with Crowd-Sourced Resupply

Lacy Greening, Georgia Institute of Technology, Atlanta, GA, United States, Alan Erera

The rapid growth of shared micro-mobility systems has resulted in idle bikes and scooters overcrowding sidewalks across the United States. We present simulation-based heuristic approaches for distributing vehicles in an effort to improve the utilization of a shared, free-floating, electric micro-mobility fleet that relies on daily crowd-sourced charging and relocating. An integer programming model of the system is used to identify trends in distribution plans and determine a good sample-average upper bound on the expected number of trips served by a given fleet size. This upper bound is then used to assess the quality of distribution plans determined by different variants of the core heuristic.

101 - Exploring Time Variants for Short-term Metro Passenger Flow Based on EEMD with Data Characteristic Analysis

Lan Liu, Southwest Jiaotong University, Chengdu, China, jianan_l@home.swjtu.edu.cn, Hao Huang, Jiannan Mao

To explore time variants of short-term metro passenger flow, the ensemble empirical mode decomposition (EEMD) with data-characteristic-driven reconstruction is proposed in this paper. Firstly, the EEMD is employed to decompose the original data into several intrinsic mode functions (IMFs) and a residue. Besides, a data-characteristic-driven method is introduced to reconstruct the IMFs into meaningful components. Finally, the proposed model is tested on the real short-term passenger flow data in Chengdu, China. The results show that the proposed model is a promising method to analyze time variants for metro passenger flow because it can extract the inherent pattern of the passenger flow.

102 - Electric Vehicle Charging Station Daily Load Analysis with a Randomized Algorithm

Martin Trouilloud, Brown University, Providence, RI, United States, martin_trouilloud@brown.edu

The load on the power grid from electric vehicles (EVs) is continuously increasing. Applying queueing theory and the Monte Carlo method, we built a randomized algorithm to investigate the power output of an EV charging station. Combining stochastic (e.g. traffic rate) and non-stochastic (commuter data) phenomena, this interactive simulation allows for more accurate analysis of their impact on the grid.

103 - On the Application of Matrix Factorization for NYC Traffic Pattern Recognition

Marzieh Abolhelm, University of Illinois at Urbana Champaign, Champaign, IL, United States, abolhel2@illinois.edu

Please check the mobile app for this abstract.

104 - New Data Visualizations Support Analysis of Vehicle Traffic at DFW Airport

Michael R. Hilliard, Oak Ridge National Laboratory, Oak Ridge, TN, United States, Hilliardmr@Ornl.Gov

We look at a collection of data visualizations as analytical tools to complement statistical and machine learning approaches. Integrating the visualizations into dashboards using Tableau software provides an interactive tool for exploration an discovery within a 20 million record data set of vehicle entry and exits at the Dallas Fort Worth Airport. The visualizations highlight seasonal, weekly, and daily temporal patterns for various types of traffic—parking, drop-off, employees, etc.. The poster is an opportunity to provide feedback to the researchers on the effectiveness of the visualizations.

105 - Text Mining Railroad Accident Narratives for Identifying Contributors to Railroad Accidents and to Extend the Sustainability of Fixed Field Data.

Neeraj Dhingra, North Dakota State University, Fargo, ND, United States

Identifying and evaluating the factors that contribute to rail accidents would help in developing prevention strategies. The FRA maintains historical data of railway accidents, including text description explaining the reasons for causing accidents in detail. Hence, understanding and evaluating the text would help in finding out responsible factors and extend the explanatory power of fixed field data. To achieve this goal, the author is applying advanced data mining techniques and association mining rules for evaluating the series of factors that contributes to accidents and financial losses.

106 - Vehicle Minimum Occupancy Standards for TNCs To Encouraging Ride Pooling

Paul Leiby, Oak Ridge National Laboratory, Oak Ridge, TN, United States, pleiby@gmail.com, Jonathan Rubin

Ride pooling (shared rides) and increased vehicle occupancy are key for achieving the full benefits of new mobility systems, including transportation network companies (TNCs) and automated vehicles. Incentives for ride pooling can limit congestion, energy use, and emissions by discouraging single or zero-passenger travel (deadheading). We evaluate flexible Minimum Occupancy STandards (MOSTs) to encourage higher vehicle occupancy (ride pooling). We utilize available data on TNC travel, analysis of ride pooling potential, and economic behavioral assumptions to benchmark a numerical model, and develop initial insights on the efficiency of pooling standards.

107 - Simulation on Signal Priority of Modern Tram Based on Anylogic —Case Study of Rong No.2 in Chengdu

Qi Liu, National United Engineering Laboratory of Integrated and Intelligent Transportation, Chengdu, China, yinyong@home.swjtu.edu.cn
Qi Liu, Southwest Jiaotong University, Chengdu, China, yinyong@home.swjtu.edu.cn, National Engineering Laboratory for Integrated Transportation Big Data Application Technology, Chengdu, China, Yong Yin

Modern tram follows a uniform signal at the intersection when it runs on urban roads. Its operation in semi-independent right of way affects the normal running of social vehicles to a certain extent. In order to research the time delay on other vehicles when modern tram is in semi-independent right of way, the intersection of Xiyuan Avenue and Piwen Road in Modern tram line (Rong NO.2) in Chengdu is simulated by Anylogic software. The simulation experiments are carried out on three kinds of control strategies. They are fixed signal timing, absolute signal priority and relative signal priority, respectively.

108 - Research on Diffusion Characteristics and Influencing Factors of Trucks in China Based on Freight Big Data

Qiujun Qian, Southwest Jiaotong University, Chengdu, China, 1006045506@qq.com, Mi Gan, Yuling Deng, Dandan Li

Mastering the characteristics of trucks diffusion and the main factors affecting the diffusion provide a preliminary basis fo China's highway capacity forecasting and freight regulation.Based on the data provided by the OFEX,we found (1) the empirical distribution of trucks transport distance basically presents a Normal distribution,(2)most drivers working only in a small area. (3) The number of unique provinces visited by more than 80% of trucks less than 10. A province can only attract up to 234 unique trucks. (4) The diffusion range of trucks was basically stable after about 4 weeks. (5) Possibility of each truck transfer is strongly influenced by the province's freight volume and GDP.

109 - How to Allocate Lanes on Urban Roads in the New Era of Mixed Traffic with Autonomous Electric Vehicles and Human-driven Vehicles?

Rui Ma, Assistant Professor, The University of Alabama in Huntsville, Huntsville, AL, United States, Rui.Ma@uah.edu, Jingjing Liang, Michael Zhang, Xiaoning Zhang

We investigate the lanes allocation problem in mixed traffic of human-driven vehicles and Autonomous electric vehicles(AEVs) with the aim of jointly minimizing the total travel time and the total life-cycle greenhouse gases emissions, then identify critical links that are really necessary to build dedicated lanes in the long run by analyzing the optimal solutions under different levels of market penetration of AEVs. A bi-objective programming model with equilibrium constraints is proposed for describing the lanes allocation problem. A solving algorithm is also developed and computational results are provided.

110 - Strategic Decision of Determining Air Taxi Network Infrastructure Locations Using an Iterative Constrained Clustering Approach

Suchithra Rajendran, Assistant Professor, University of Missouri, Columbia, MO, United States, Joshua Zack

This study is one of the first to estimate the demand for air taxi aviation services and provide recommendations on the potential infrastructure locations to support the network operations. We adopt a two-phase approach: first phase estimates the demand for this market by taking a subset of the regular taxi customers based on several parameters, and second phase proposes a constrained clustering approach, with multimodal warm start technique, to identify potential infrastructure sites based on the estimated demand from the first phase. We test the feasibility of the proposed approach using the millions of real-life New York City taxi records.

111 - Bike-sharing Operations

Qiuzhuang Sun, National University of Singapore, Singapore, Singapore, q_strong@163.com

Applications of Data Mining in Supply Chain Management

Sponsored: Data Mining

Sponsored Session

Chair: Phillip Howard

1 - Reinforcement Learning Versus Optimization

Seho Kee, Arizona State University, Tempe, AZ, 85044, United States, skee4@asu.edu, Ghazal Shams, Jan Buchmann, Mani Janakiram, Sangbum Lee, Jonathan Tan, Mark A. Wilkinson, George Runger

Reinforcement learning has earned huge interest recently due to its successful applications in many domains. However, investigation on its performance has gained less research interest. In this presentation, we evaluate the effectiveness of reinforcement learning and compare with optimization solutions.

2 - Applications of Machine Learning to Supply Chain Forecasting & Inventory Management

Phillip Howard, Intel Corporation, Chandler, AZ, United States, Joshua Quine Hale

While methods for forecasting and inventory management in supply chains are well-established, many of these traditional approaches can be improved upon through application of machine learning techniques. In this presentation, we will discuss how methods such as cross validation and ensembles can improve upon the performance of time series models commonly used for forecasting. Additionally, we will show how traditional approaches which treat forecasting and inventory management as separate modeling tasks are sub-optimal. Methods for integrating forecasting & inventory management in order to improve the overall performance of the business process will be explored.

3 - Forecasting Customer Returns

Aysegul Demirtas, Intel, Chandler, AZ, 85281, United States, Aysegul.Demirtas@asu.edu, Zhenying Zhao, Vivian Zheng, Shamin Shirodkar

Intel has a high ranking among the most complex supply chains around the globe. In this project, our goal is to increase the forecast accuracy of returns at depots from different continents. We present the detail descriptive analytics on customer returns and predictive models that we built to increase accuracy.

4 - Hunting for Phantom Inventories

Sergio A. Caballero Caballero, Massachusetts Institute of Technology (MIT), Cambridge, MA, United States

In this paper we use machine learning techniques to detect phantom inventories at customers' retail stores for a major CPG manufacturer. We leverage daily point-of-sales, inventory on-hand, and audit data at a SKU-level in more than 400 stores. Our approach provides timely and more accurate predictions compared to existing solutions.

5 - Assessing and Mitigating Supply Request/Response Variability Using Advanced Data Analysis

Sean Cunningham, Supply Chain Professional, Intel Corporation, Santa Clara, CA, United States, sean.p.cunningham@intel.com, Alison Friday

Intel plans and procures components manufactured by a vast world-wide network of original design manufacturers (ODMs). These ODMs perform work in serial manufacturing stages, including fabrication, assembly, product test, etc. We present analytics for assessing the within-cycle and cycle-over-cycle variability of Intel's supply planning build request to these ODMs. We review findings from multiple ODM manufacturing stages, and we determine root causes for supply chain build request variability. We review Intel's work to reduce this variability, and to show improvement in the overall performance in ODM accept rate for Intel's build requests.

1 - The Power of Analytics - Improve Nuclear Power Plant Operations and Maintenance

Charlotte (Pu) Wang, Lead Data Scientist, Duke Energy, Charlotte, NC, United States

Power plants have huge amount of data stored in their control and monitoring systems. In this paper, we showcase a recent analytics practice which turns data into actionable information, hence greatly improves plant O&M. The challenge is to identify failed seal in the Reactor Coolant Pump (RCP) in a nuclear generation unit. The traditional diagnose process is manual and tedious, accuracy is also questionable. A regression-based model is developed to provide timely and accurate diagnose. With a conveniently designed web-based application, model tuning and data analysis is automated, interactions are directly between nuclear engineers, with no intervene required from data scientists.

2 - Integrating Graph-based Structure and Time-series in Demand Forecasting

Bo Zhang, PhD, Alibaba Group, Bellevue, WA, United States, Zhongjun Zhang

Due to the availability and expense, the amount of data is not always sufficient for deep learning based forecasting. Furthermore, since there exists a demand of interpretability, a linear closed-form is the first choice in many situations. However, this is incompatible with data volatility and accuracy requirement. In this talk, we propose a graph-based approach for demand forecasting. First, metrics are defined based on demand characteristics, then embedding methods are applied to represent the graph structure. In addition to commonly used error metrics, we also consider inventory features. The effectiveness of this method is demonstrated on the demand forecasting of Alibaba's IoT Products.

3 - Simulation Framework and Algorithms for Route Tickets Assignment in Fulfillment Center

Guang Yang, Jet.com/Walmart Labs, Hoboken, NJ, 07030, United States, guang@jet.com

In e-commerce business, customers online orders will be batched into route tickets, and then associates will hold a cart to pick items scattered in the fulfillment center for these orders. It is desired to batch these orders in a way that associates overall travel distance is minimized given the limited cart space and required completion time. This is a complicated problem that involves bin packing, vehicle routing, and job scheduling problem. In this study, we built a simulation framework and algorithms for this route tickets assignment problem. We show that a greedy approach based on additive route path can drive down the travel distance by 27%-35%, comparing to the chronological assignment baseline.

Joint Session DM/Practice Curated: Data Mining and Advanced Analytics Applications in Supply Chain

Sponsored: Data Mining

Sponsored Session

Chair: Manjeet Singh

1 - Solving Slotting and Order Batching Problem Using Data Mining and Heuristics

Siqiang Guo, Senior Solutions Design Analyst, DHL Supply Chain, 570 Polaris Pkwy, Westerville, OH, 43082, United States, siqianggeorgeguo@gmail.com

Picking is the most labor intensive activity in order fulfillment warehouses. A powerful and flexible order batching algorithm plays a key role in meeting customers' high service level requirements with low labor costs. However, intelligent batching of orders could be compromised by a sub-optimal slotting strategy . That's why an efficient slotting method is an indispensable part of a comprehensive solution to improve the picking efficiency.This research solves a real example which demonstrates the efficacy of the proposed hybrid approach, based on data mining and constructive heuristics, in solving the slotting and order batching problem.

2 - Continuous Cost Oriented Carton Optimization for eCommerce Operations

Bocheng Yu, DHL Supply Chain, Westerville, OH, 43082, United States, max.yu@dhl.com

Nowadays, eCommerce orders are delivered in cartons. Due to dimensional weight charge, the size of carton plays significant role in shipping cost. Although make-to-order packaging machine can reduce shipping cost, it has limits such as space requirement and complexity. Thus, most warehouses stock different sizes of pre-made cartons. However, the sizes of eCommerce orders are infinite, leading to the question, i.e. which carton sizes and how many should a warehouse store to minimize shipping cost. This research shows application of machine learning and meta-heuristic to (a) find out near optimal array of cartons and (b) monitor and update carton sizes based on changing order profiles.

3 - Network Mode Optimization for DHL Supply Chain

Yibo Dang, Ohio State University, Columbus, OH, United States

DHL Supply Chain North America moves more than twenty million packages each year. As one of the largest third-party logistic providers, DHL Supply Chain perform routing and cost deduction tasks for many large-scaled business projects. The objective is to diagnose heterogeneous dedicated fleets and common carrier opportunities out of a half-million scheduled shipments, so that the overall transportation network costs are optimized. Unlike the ordinary Vehicle Routing Problems, the network optimization for DHL may require a power to solve this complex combinatorial problem fast. We formulate our problem with MILP, evaluated its tightness, provided an approximate decomposition-based procedure, and developed a so-called "Red-Black Ant Colony Meta-Heuristic" to solve the problem.

4 - Dynamic Decision Transportation Optimization

Manjeet Singh, DHL Supply Chain, Columbus, OH, 43230-9893, United States, manjeet.singhin@dhl.com, Jon Cox

Dynamic transportation optimization includes three optimization routines - Mode Selection Optimization, Pool Point Optimization and Round Trip Optimization. This session will explore the connection between freight savings and data analysis, weigh the business benefits of dedicated and private fleets, and show how applying freight optimization can lead to lower rates in both the truckload and LTL arenas.

5 - Solving the Uniform Case Pallet Loading Problem - A Case Study

Manjeet Singh, DHL Supply Chain, Columbus, OH, 43230-9893, United States, manjeet.singhin@dhl.com, Gan Du

The pallet loading problem (PLP) is generally tackled by attempting to maximize the number of boxes that can be loaded orthogonally on a pallet. Several methods have been proposed in the literature that focus on maximizing the volume utilization and stability of the pallet. In this research, a two-phase algorithm is proposed to solve a 3-dimensional PLP while considering humidity, and storage time. In the first phase, the boxes should fit completely within the pallet without any overhang. In the second phase, the number of horizontal layers per pallet is calculated based on pallet maximum height, max weight, and dynamic compressive strength of boxes.

Joint Session DM/Practice Curated: Data Mining & Analytics in Emerging Marketing Ecosystem – A

Sponsored: Data Mining

Sponsored Session

Chair: Ankur Jain

1 - Evaluating and Optimizing Campaign Strategy to Drive Brand Growth Through Lens of Multi-Touch Attribution

Diane Ma, Kantar, Lisle, IL, United States, diane.ma@kantar.com

Brand equity is critical in driving business outcomes. Campaigns effectiveness measurement needs to capture impact on both short-term sales and brand building, a multiplier on lower funnel business outcomes. While some attribution modeling approaches helps understand how channels and campaign strategies contribute to brand equity, multi-touch attribution approach (MTA), provides more granular insights on channel performance and efficiency of media strategy/tactics in driving incremental brand KPIs, and yield optimization opportunities of consumer targeting, frequency of exposures, and creative executions for future campaigns.

2 - Learning and Comparative Advertising: Evidence from Pharmaceutical Drug Detailing

Xiaojing Dong, Santa Clara University, Santa Clara, CA, United States, xdong1@scu.edu, Ying Xie, Pradeep Chintagunta

In this paper, we evaluate the impact of comparative messages on new product adoption, by developing a learning model with three distinctive features compared to the standard Bayesian learning framework, using data from a pharmaceutical category. First, we allow the information efficiency associated with the detailing visits to differ across message formats and brands. Second, we allow the comparative message from competing brands to jam the signals and disturb doctors' learning of the drugs' true qualities. Finally, we allow the doctors to forget the quality belief they've learned so far, due to the time elapsed since the last prescription.

3 - Campaign Identification Process for Marketing Mixed Model

Sepideh Pourazarm, Data Scientist, Nielsen, Needham, MA, United States, sepideh.pourazarm@nielsen.com, Mariappan Subramanian, Shweta B. Shah

Marketing Mix Modeling (MMM) aims at using statistical modeling to estimate effectiveness of media campaigns, based on historical sales and media data. Media data available for MMM is very granular and highly sparse making it un-fit to be used directly in modeling. Identifying the proper level of aggregation of media data is crucial for both model performance and stability. However, the process involves considerable manual intervention and analysis. In this paper, we propose a novel heuristic to automate finding effective definitions of marketing campaigns to enter the model that uses entropy-based approach for ranking media dimensions and a correlation analysis algorithm for collapsing them.

4 - Improving Survey Measurement Quality Through Geotargeting

Susruthi Vasudevan, Gartner, New York City, NY, United States, susruthi.143@gmail.com

Location is as valuable in the digital world as it is in the real world. Businesses are identifying customers and targeting them precisely when they enter storefronts. Given this sophistication for advertising, it's imperative to have the same knowledge incorporated into surveys to get better feedback and increased responsiveness. In this study, we explore a novel method to implement geo-targeting by identifying consumers when they are at locations where their time can be conveniently purposed towards a survey making the value proposition more attractive - motivating a more willing participation for a survey, and in turn, less straightlining and better quality of data.

Urban Traffic Management and Computing for the Era of Automated Transportation System

Sponsored: Data Mining

Sponsored Session

Chair: Pengfei(Taylor) Li, The University of Texas at Arlington

Co-Chair: Xianfeng (Terry) Yang, University of Utah, Salt Lake City, UT, 84112, United States

1 - Estimation of Queue Lengths and Traffic Volumes Using Probe Vehicle Trajectory Data

Yan Zhao, University of Michigan, Ann Arbor, MI, 48104, United States, zhaoyann@umich.edu, Jianfeng Zheng, Wai Wong, Henry Liu

The emergence of connected vehicle technologies and ride-hailing services has enabled the collection of probe vehicle trajectory data in large scale. The vast amount of trajectory data could become a substitute for the widely used fixed-location sensors in terms of the performance measures of transportation networks. This study proposes a series of novel methods for the estimation of queue lengths and traffic volumes at signalized intersections using the probe vehicle data. Validation results have shown that the proposed methods would be accurate enough for real-world applications.

2 - Signal Control and Autonomous Vehicle Trajectory Optimization for Enhancing Mobility

Lily Elefteriadou, Professor of Civil Eng., Director of UFTI, University of Florida, Gainesville, FL, 32611, United States

The presentation will discuss on-going work to develop optimization algorithms, simulation tools, and sensor capabilities for enhancing traffic signal control operations with connected vehicles, autonomous vehicles, and conventional vehicles. Early versions of the optimization were deployed and tested at the Traffic Engineering and Research Laboratory (TERL), a Florida Department of Transportation closed-course facility. The results from the field test confirmed the feasibility of the concept and are now used to enhance it for future testing and ultimately for field deployment. The research, led by UF, is funded by NSF and FDOT, and involves two industry partners: ISS and Econolite.

3 - Distributed Feedback Control of Traffic Flow Over Networks

Ketan Savla, University of Southern California, Los Angeles, CA, 90089, United States, ksavla@usc.edu

We discuss distributed properties of optimal feedback control for traffic flow over networks. For freeway networks, we consider the Cell Transmission Model, and identify sufficient conditions on network parameters and performance metrics under which the optimal control actions (variable speed limit, ramp metering, routing) are spatially distributed. We also provide adaptations of well-known distributed scheduling algorithms from stochastic networks that are maximally stabilizing for signalized arterial networks under interrupted traffic flow model.

4 - Data-Driven Digital Twin to Test Connected Infrastructure Environmental Applications: A Case Study of North Avenue Smart Corridor

Michael Hunter, Professor, Georgia Institute of Technology, Atlanta, GA, 30332-0355, United States, Angshuman Guin, Abhilasha Saroj, Somdut Roy, Randall Guensler

Leveraging real-time information and communication technologies the Atlanta Smart City North Avenue Smart Corridor data-driven digital twin provides a platform to test connected infrastructure environmental applications. A dynamic optimized connection between the real-time data and the simulation network objects is established using the simulation model's COM interface and python's Flask web framework. This interface is capable of injecting real-time signal phase, volume, and turn movement percentage data into the simulated network. The digital twin may be used to evaluate and visualize network performance indices, providing dynamic operational feedback in a real world environment.

5 - Coordinated Traffic Control Across Multiple Intersections: An Integer Programming Formulation and Lagrangian Decomposition with Subproblem Approximation

Pengfei (Taylor) Li, Assistant Professor, University of Texas Arlington, Arlington, TX, 39759, United States

A multi-intersection traffic control model is presented for safe vehicle movements across tightly connected intersections. All the intersections are viewed as one "super intersection" within which vehicles move according to their given paths. A Mixed integer linear programming formulation is presented for joint optimization of vehicle trajectories and traffic control. A scalable optimization frame for real-world traffic control optimization is designed, namely "Lagrangian decomposition with subproblem approximation" in which the dynamic network loading based lower bound estimator is constructed to relax constraints. Two examples are presented.

Analytics for Good

Sponsored: Data Mining

Sponsored Session

Chair: Joseph Cazier, Ph.D, Appalachian State University, Boone, NC, United States

Co-Chair: Ryan C LaBrie, Seattle Pacific University, Seattle, WA, 98119-1950, United States

Co-Chair: Gerhard Steinke, Ph.D, Seattle Pacific University, Seattle, WA, United States

1 - Evaluating AI Algorithms for Good with Ethical Audits

Ryan C. LaBrie, Ph.D, Seattle Pacific University, Seattle, WA, United States, ryanl@spu.edu, Gerhard H. Steinke

In recent years there has been much talk about the advancements in artificial intelligence (AI). AI technologies, and the ways we use them, are having positive as well as negative impacts on the world. We examine various visions of the future, from where analytics is used as a force for freedom, self-actualization, development and potential maximization, to where analytics is used as a tool of suppression, manipulation and exploitation. We investigate the premise that AI algorithms have flaws and may be biased. We suggest that AI algorithms go through an ethical algorithm audit and discuss a framework in which to institute these audits in order to not only "do no harm" but ideally produce "good for all".

2 - Juried Evidence: How an Automatic Evidentiary Rating System Can Lead to Better Decision Making and Help Build a Better Society

Edgar Hassler, Assistant Professor, Appalachian State University, Boone, NC, United States, hassleree@appstate.edu

Not all evidence is created equal. Common types of evidence include peer reviewed journal articles, expert opinion, observational evidence and data distilled from sensors. Many times this evidence can be contradictory or only apply in certain circumstances. Aggregating all of this evidence in one place and grading it for different situations can help decision makers make better decisions by harmonizing the evidence. This has many benefits for society as we can use the best knowledge we have to make better decision for health, business, policies and the environment. This presentation focuses on what such a system might look like and how it can be part of using analytics for good to build a better society.

3 - A Better Society Through Better Decisions - How Blockchain Technology Can Help to Make the Right Choices

Joseph Cazier, Center for Analytics Research and Education, Boone, NC, United States, cazierja@appstate.edu, Max A. Rünzel

Our values and convictions guide our actions. When it comes to purchasing decisions, we are willing to spend considerable price premiums if a product reflects what we stand and strive for. But how can we verify that our purchase decisions are in line with our values and norms? Distributed ledger technology as the blockchain offers the opportunity to document the origin and trace the pathway of products, and services in an intrinsically verifiable manner. This presentation develops conceptually how blockchain-enabled analytics can help to build a society that is more congruent with its values by facilitating decision making driven by transparency, integrity and accountability.

4 - Life Coach: Using Big Data and Analytics to Facilitate the Attainment of Life Goals

Joseph A. Cazier, Executive Director, Professor, Appalachian State University, Boone, NC, 28607, United States, cazierja@appstate.edu

Most of Big Data and Analytics work is focused on getting people to do what other people want them to do. What if it could be turned it around? What if all the data collected on or about individuals could instead be used to help individuals in ways they want to be helped? What if the data could help individuals achieve their life goals and dreams, and coach them through the process of life? If these individuals benefited from such a service and begin living happier, balanced, and fulfilled lives they will also become more beneficial employees to organizations.

Service Operations Analytics

Sponsored: Data Mining

Sponsored Session

Chair: Subodha Kumar

1 - The Effects of Social Media Content Created by Human Brands on Engagement

Rakesh Reddy Mallipeddi, Tulane University, Mays Business School, Dept of Info. & Operations, New Orleans, LA, 77843-4217, United States, Subodha Kumar, Ramkumar Janakiraman

In this study, we propose an econometric model to examine the drivers of human brand's social media engagement. Set in the context of national elections, we examine the effects of the tone of content created by human brands. To meet our objectives, we assemble a novel candidate-level data of social media engagement.

2 - Effect of Health Information Exchange Usage on Lab Test Orders

Aditya Jain, Baruch College, Zicklin School of Business, New York, NY, 10010, United States, aditya.jain@baruch.cuny.edu, Emre M. Demirezen, Subodha Kumar

We investigate how a physician use of HIE (Health Information Exchange) affects her test ordering behavior. We should this effect is negative and is moderated by patient's history of care and her clinical condition.

3 - The Behavioral Consequences of Shipping Policy Changes

Vamsi K. Kanuri, University of Notre Dame, Notre Dame, IN, 46556, United States, vkanuri@nd.edu, Andrew Crecelius, Subodha Kumar

Shifting consumer preferences are forcing retailers to leverage the value of multichannel behavior. Yet actionable evidence of strategies to inculcate multichannel behavior across the retailer's existing channels is lacking. This research addresses this gap by investigating the behavioral effects of an online shipping policy change at a large US retailer. Counterintuitively, we find that a generous shipping policy change shifts customers away from the online channel towards the offline, with a net positive effect on overall sales. The authors explain these findings through additional analyses and conclude with timely implications for multichannel management.

4 - The Impact of Brand Mentions in News Headlines on Social Media Engagement

Debashish Ghose, Temple University, Philadelphia, PA, 19144, United States, dghose@temple.edu, Subodha Kumar, Susan Mudambi

News publishers strive to create consumer buzz around their stories and generate web traffic on social media. To increase engagement, publishers create catchy headlines that often mention known brands. We empirically quantify the impact of human and product brand mentions on engagement. Our results indicate human brand mentions have a positive effect on retweets and this positive impact is greater for satirical news than for traditional news. Results implying the great potential of satirical political news vis-à-vis traditional political news help publishers better understand retweet behavior on social media.

5 - Tell Me What I Want: A Study of Assortment Planning for Learning Consumers

Yulia Vorotyntseva, Temple University, Philadelphia, PA, 19102, United States, yulia.v@temple.edu, Canan Ulu, Dorothee Honhon

We develop a model that incorporates consumer learning into a firm's assortment problem. Consumer's prior beliefs affects their choice of a product from a given category, and the subsequent experience, in turn, affects their beliefs and future choices. We analyze the firm's optimal assortment policy in this setting.

Artificial Intelligence for Cybersecurity

Sponsored: Artificial Intelligence

Sponsored Session

Chair: Tung Cu, Bloomsburg University of Pennsylvania, Bloomsburg, PA, 17815, United States

1 - Artificial Intelligence for Cybersecurity

Tung Cu, Northeastern Illinois University, Chicago, IL, 17815, United States

The next generation of Artificial Intelligence (AI) and Machine Learning (ML) are increasingly incorporated in cybersecurity solutions. Experts predict that, over time, companies will incorporate AI into every cybersecurity product portfolio. While AI and ML increase the defenders' capability to detect and prevent abnormal behavior patterns, attackers are also using AI and ML to learn about a target's vulnerabilities and launch attacks. In this study, we solicit high-quality original research papers, both theoretical and empirical, that address the issues of AI aid, misuse and threat in cybersecurity in different contexts such as business, healthcare, education, politics, and economics.

2 - Exploring Deviant Hacker Networks on Social Media Platforms

Nitin Agarwal, University of Arkansas-Little Rock, Little Rock, AR, 72204, United States, nxagarwal@ualr.edu, Samer Al-khateeb

The initial use of social media for benign purposes has now transitioned to include malicious activities. These nefarious uses of social networks pose a significant threat to society, and thus requires research attention. In this work, we study activities of hacker groups on social media, which we term Deviant Hacker Networks (DHNs). We investigated the connection between different DHNs on Twitter. In our work, we also attempted to bridge the gap between the empirical study of social networks, machine learning, and cyber forensics, as the growth of OSNs is now bringing these domains together, due to OSNs continuously generating vast amounts of evidentiary data.

3 - Leveraging Virtual, Augmented and Mixed Reality to Facilitate Intelligence

Michael W. David, Professor, National Intelligence University, Bethesda, MD, 20301, United States, Michael.David2@dodiis.mil, Margarita Baez

The Internet of Things and the imminence of wide 5G deployment in the public arena points to an avalanche of data that will leave businesses struggling to finds ways to address the profusion of new content created every year. Machine learning and artificial intelligence—on their own or in combination—have emerged as methods to control this tide, but where does this leave the cyber intelligence analyst? This research explores the possible applications of Virtual Reality, Augmented Reality, and Mixed Reality technologies to assist the Digital Network Analyst's ability to produce digital network intelligence. The goal is to help manage the high volumes and velocity of data available to the analyst.

4 - Security, Privacy, and Ethical Concerns on Human Radio-frequency Identification (RFID) Implants

Zhanel D. Tucker, Hampton University, Hampton, VA, 23669, United States, zhanel.tucker@gmail.com, Chutima Boonthum-Denecke

This report discusses the security, privacy, and ethical concerns on human RFID-implants. Emerging technologies are being developed to help with convenience for everyday people, but these conveniences can pose security and privacy threats. The uses of technology being implanted in humans without the proper assessment could cause a new wave of security flaws. This study will review how human RFID microchip implants will impact and effect security, privacy, and ethical concerns associated with the new initiative for RFID implants to be used on human beings.

5 - Patterns of Conflict in Human Computer Teaming

Amy Magnus, Research Assistant Professor, Air Force Institute of Technology, Wright-Patterson AFB, OH, 45387, United States, Amy.Magnus@afit.edu

Narrative analysis reveals patterns of work over the arc of a document. These patterns unearth the ways we engage a topic. We generalize by extracting workflows from documents then synthesize and transfer amended flows to addition topics. When we examine the corpi of teams, patterns of conflict emerge. Some conflicts are easy to resolve. Others prove difficult and contribute to insider threats. Computation can simultaneously frustrate and facilitate agency among team players. Thus computation contributes to team discord. To address sources of conflict, we consider the role of artificial intelligence in system regulation and examine its potential in managing the expectations of team membership.

6 - Time Anomaly Detection with AI

Tudor Morosan, AVP Data Science, NASDAQ, Residence, Boston, MA, M2J2K5, United States, tudor.morosan@yahoo.com

This abstract is introducing an anomaly detector capable to identify subtle deviation from normal in time series, using recurrent neural networks and auto-encoders.

Network Analytics and Predictive Models

Sponsored: Artificial Intelligence

Sponsored Session

Chair: John Rios, University of Iowa, Iowa City, IA, 52242, United States

1 - Predicting Stock Price Movements via Multi-relational Inter-firm Networks

John Rios, University of Iowa, Tippie College of Business, Iowa City, IA, 52242, United States, john-riosrodriguez@uiowa.edu, Kang Zhao, Nick Street

Predicting stock movements is challenging, but has attracted tremendous amount of attention from both practitioners and researchers. Meanwhile, firms are connected with each other in a multi-relational network and these diverse connections could provide helpful signals for the prediction of a firm's performance. Using real-world supply and competition networks among almost three thousand firms, this research predicts a firm's stock movements by leveraging performance of different types of network peers of a focal firm. We show that graph predictive models and features based on a firm's peers can improve the prediction of the firm's future stock price movements.

2 - Data-driven Sales Forecasting with Heterogeneous Promotion Effects

Stefan Feuerriegel, ETH Zürich, Weinbergstr., Zürich, 8092, Switzerland, sfeuerriegel@ethz.ch, Christopher Stoll, Klaus Möller

This paper studies a data-driven model for sales forecasting that is explicitly designed so that it estimates causal effects of promotions on sales. Formally, we adapt generalized random forests to this research setting: responses to treatments (i.e., promotions) are modeled conditional on covariates that characterize the between-store heterogeneity in order to infer conditional average treatment effects. We demonstrate our approach to causal sales forecasting based on 844,391 sales records from 292 stores. Our findings characterize the nature of the treatment effect across stores in foresight, thereby supporting future decision-making.

3 - Virtual Item Recommender Engine: A Heterogeneous Network Embedding Perspective

Vidit Mehta, University of Maryland, College Park, College Park, MD, United States, vidit@rhsmith.umd.edu, Kunpeng Zhang

Recommender systems are a core tool for businesses to showcase their products and services. We make the observation that many a time, consumers simultaneously interact with businesses, product categories and products (for instance during Thanksgiving sales). We can think about such dynamic interactions as a part of a huge network with multiple types of nodes. We propose a novel network-embedding model for making recommendations to users in social networks. We find that our proposed model consistently outperforms other state-of-the-art recommender systems, thereby highlighting the importance of making recommendations based on meaningful relationships amongst various nodes in network space.

4 - Course Recommendation Based on Collaborative Filtering

Camilo Franco, Universidad de los Andes, Bogotá, Colombia, c.franco31@uniandes.edu.co, Nicolás Hernández, Haydemar Nuñez, Felipe Montes

Recommender systems are a popular tool that can be used to identify relevant items for interested users. Examining collaborative filtering as a basic social recommender system, as it builds recommendations from similar user rating behavior, it allows making use of other sources of information that may enhance its performance by accomplishing sparse models with higher degrees of accuracy. This proposal addresses social collaborative filtering for course recommendation, exploring a hybrid/social recommendation systems approach to academical communities for aiding students in the planning of their curriculum and the consequent enrollment in courses.

5 - Ebook Adoption Behaviors Through an Online Sharing Platform: A Multirelational Network Perspective

Xi Wang, Central University of Finance and Economics, School of Information, Central University of Finance and Economics, Beijing, 100080, China, xiwang@cufe.edu.cn

The aim of this study was to construct a multi-relational network for an online sharing platform in the age of the sharing economy, to identify the factors impacting users' product adoption behavior, and to predict consumers' purchases of user-generated products on the platform. We conducted multi-relational network analyses of 5 different sub-networks in identifying influential factors for E-book adoption. Meanwhile, the study adopted machine learning methods with different classification algorithms and feature sets to predict users' purchasing behaviors.

Joint Session SMA/Practice Curated: Word of Mouth and Online Customer Review Analytics

Sponsored: Social Media Analytics

Sponsored Session

Chair: Ali Hojjat, University of New Hampshire, Durham, NH, 03824, United States

1 - How Should Incumbent React to Disruption? A Hybrid Analytics Approach Leveraging Machine Learning and Quasi-experiments

Wei Chen, University of Arizona, Tucson, AZ, 85718, United States, weichen@email.arizona.edu, Karen Xie, Jianwei Liu, Yong Liu

The disruption of sharing economy to incumbent organizations is clear. However, the literature is silent on whether incumbent organizations should react to the sharing economy disruption, and if so, how. In this research, we fill the void by tracing the quality change of hotels after the entry of home sharing and identifying quality improvement opportunities taken notes by hotel managers in online reviews that explain the change. Our hybrid methods combine casual inference and machine learning and add new perspectives to the emerging literature on sharing economy.

2 - Impact of Social Media Recommendations on Media Performance

Sameer Borwankar, Purdue University, West Lafayette, IN, 47906, United States, sborwank@purdue.edu

This talk focuses on how the recommendations shared on social media influence the media (movies, song, etc) performance.

3 - Toward a Better Online Platform Review: Should Customers be Compensated for Providing Reviews?

Peng LI, Rutgers Business School, Highland Park, NJ, 08904, United States, Soohyun Cho, Arim Park, Yao Zhao

In recent years, online review platforms have emerged as indispensable research and business tools for consumers and businesses alike. To amplify their business profiles on online review platforms, some small businesses have begun compensating customers for platform reviews. In this paper, we seek to learn how compensated reviews affect customers, (small) businesses, and online review platforms.

4 - Detecting Anomalous Online Reviewers: A Novel Hierarchical Machine Learning Approach

Naveen Kumar, University of Washington, Bothell, WA, 98012, United States, Deepak Venugopal, Liangfei Qiu, Subodha Kumar

Online reviews and discussions play a significant role in influencing decisions made by users in day-to-day life. However, the presence of reviewers who deliberately post fake or deceptive reviews for financial or other gains negatively impacts both users and businesses. Unfortunately, automatically detecting such reviewers is well known to be a challenging problem, particularly since fake reviews do not seem out-of-context as compared to genuine reviews. In this paper, we propose a novel machine learning approach for this task. Our approach is highly generalizable, allows us to seamlessly combine both univariate and multivariate distributions into a unified anomaly detection system.

5 - Using Text Modeling and Latent Dirichlet Allocation to Study Customer Complaints

Shih-Hsien Tseng, Chung Yuan Christian University, Taoyuan City, Taiwan

Many organizations collect complaint information using Twitter. Clustering such complaints can help with prioritizing issues and diagnosing the problems. We show innovative visualizations and analysis methods to transform clustering outputs into useful improvement insights. Real data from a Taiwanese company illustrates the approaches.

Stochastic Systems

Sponsored: Applied Probability

Sponsored Session

Chair: Mark S. Squillante, IBM Thomas J. Watson Research Center, Yorktown Heights, NY, 10598, United States

1 - Confidence Regions in Wasserstein Distributionally Robust Estimators

Nian Si, Stanford University, Stanford, CA, United States, Jose Blanchet, Karthyek Murthy

Wasserstein distributionally robust optimization (DRO) estimators are obtained as the solution of a min-max problem in which the statistician selects a parameter minimizing the worst-case loss among all probability models within a certain distance from the underlying empirical measure. In addition to producing estimators endowed with enhanced robustness properties, Wasserstein DRO estimators recover as a particular case a wide range of regularized estimators, including LASSO and support vector machines. This paper studies the asymptotic normality of underlying DRO estimators as well as the properties of an optimal confidence region induced by the Wasserstein DRO formulation.

2 - Extremal Queues with Given Mean Absolute Deviation

Johan van Leeuwaarden, TU Eindhoven and Tilburg University, Eindhoven, Netherlands, Dick den Hertog

A notorious problem in queueing theory is to identify the worst possible performance of the GI/G/1 queue under mean-dispersion constraints for the interarrival and service time distributions. We address this extremal queue problem by measuring dispersion in terms of Mean Absolute Deviation instead of variance and using Distributionally Robust Optimization. We obtain the extremal interarrival time and service time distributions, and hence the sharpest possible bounds, on all moments of the waiting time.

3 - Subexponential Rate of Convergence of a Class of Levy-driven Stochastic Differential Equations for Parallel Server Networks

Guodong Pang, Penn State University, Industrial and Manufacturing Engineering, University Park, PA, 16802, United States, Ari Arapostathis, Nikola Sandric, Hassan Hmedi

We study the ergodic properties of a class of controlled Levy-driven SDEs. They include the scaling limits arising from parallel-server networks in the Halfin-Whitt regime. We identify conditions on the parameters in the drift, the Levy measure and/or covariance function which result in (uniform) subexponential and/or exponential ergodicity. For the stochastic network models, we show that the rate of convergence is polynomial and provide a sharp quantitative characterization of the rate via matching upper and lower bounds.

4 - Optimal Control of Fluid Models of Switched Networks

Mark S. Squillante, IBM Thomas J. Watson Research Center, Yorktown Heights, NY, 10598, United States, mss@us.ibm.com, Yingdong Lu, Tonghoon Suk

We consider issues related to optimal scheduling in fluid models of input-queued switches, the latter being widely used in modern computer and communication networks. We derive the corresponding optimal control policy and establish structural properties for the optimal solution.

Sponsored Session

Chair: Zeyu Zheng, University of California-Berkeley, Berkeley, CA, 94720, United States

1 - A Finite Time Analysis of Temporal Difference Learning

Jalaj Bhandari, Columbia University, New York, NY, United States, Daniel Russo

Temporal difference learning (TD) is a simple iterative algorithm used to estimate the value function corresponding to a given policy in a Markov decision process. Although TD is one of the most widely used algorithms in reinforcement learning, its theoretical analysis has proved challenging and few guarantees on its statistical efficiency are available. In this work, we provide a simple and explicit finite time analysis of temporal difference learning with linear function approximation. Except for a few key insights, our analysis mirrors standard techniques for analyzing stochastic gradient descent algorithms, and therefore inherits the simplicity and elegance of that literature.

2 - On Efficient Optimal Transport: An Analysis of Greedy and Accelerated Mirror Descent Algorithms

Tianyi Lin, University of California, Berkeley, Berkeley, CA, 94706, United States, Nhat Ho, Michael Jordan

We provide theoretical analyses for two algorithms that solve the regularized optimal transport (OT) between two discrete probability measures with at most n atoms. We show that a greedy variant of the Sinkhorn algorithm can be improved to O(n^2/eps^2), outperforming the best known complexity bound of O(n^2/eps^3). This matches the best known complexity bound for the Sinkhorn algorithm and explains why the Greenkhorn algorithm outperforms the Sinkhorn algorithm in practice. We also develop a class of algorithms that we refer to as APDAMD algorithms with the solid guarantee. Experimental results on synthetic and real datasets demonstrate the favorable performance of our algorithms in practice.

3 - Adaptive Stratified Sampling with Infinite Stratums

Teng Zhang, Stanford University, Menlo Park, CA, 94025, United States, Jose Blanchet, Peter Glynn, Zeyu Zheng

Stratified sampling, serving as an important tool for variance reduction, gives rise naturally to an infinite number of stratums (sub-groups) in applications such as Multi-level Monte Carlo (MLMC). Moreover, the optimal allocation of sampling resources depends on stratum variance which is usually unknown a priori, such that adaptive online sampling schemes are in need. We analyze the problem of stratified sampling with infinitely many stratums and unknown optimal allocation. We show that the canonical $O(n^{-1/2})$ convergence rate can be achieved as well as the asymptotic optimal efficiency.

4 - Dynamic Pricing with Inventory Constraints and External Information

Zeyu Zheng, University of California, Berkeley, Berkeley, CA, 94720, United States, zyzheng@berkeley.edu, Xiaocheng Li

We consider scenarios when the price of a product is dynamically chosen by a decision maker to maximize the profit over many time periods. Specifically in this setting, external covariates information which can impact the product demand are available and a limited overall inventory can be imposed. We first provide a new online learning algorithm to achieve a square root T upper bound, and then develop new tools to establish lower bound on the same order.

Sponsored Session

Chair: Jing Dong, Columbia University, New York, NY, 60208, United States

Co-Chair: Jamol Pender, Cornell University, Ithaca, NY, 14850, United States

1 - Ride-hailing Technologies, Powered by Mapping

Dawn Woodard, Director of Data Science, Maps, Uber, School of OR & IE, San Francisco, CA, 14850, United States

Extensive literature exists on methods for pricing and matching in ride-hailing platforms (such as Uber and Lyft), but less attention has been paid to the mapping inputs required. For example, carpool matching requires predictions of travel time between any two locations in the road network. We survey such methods for mapping. First, we show how one can perform robust decision-making by measuring and accounting for uncertainty in the travel time predictions. Next, we propose a machine learning architecture for travel time prediction that captures the detailed dynamics of traffic patterns in a road network. Finally, we discuss how to handle uncertainty, and fix errors, in the road network data itself.

Information Design in Revenue Management

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Shouqiang Wang, The University of Texas at Dallas, Richardson, TX, 75080, United States

Co-Chair: Can Kucukgul, 1989, Richardson, TX, 75080, United States

1 - Bayesian Persuasion with Communication

Kimon Drakopoulos, University of Southern California, 2928 West 78th Place, Los Angeles, CA, 90305, United States

In this paper we consider the problem of Information Design where agents can exchange information about the received signals. In particular we consider a firm that is ex-post informed about the quality of a product and customers who are deciding on their purchasing decisions. Customers, upon receiving signal from the firm regarding the unknown quality of the product exchange their information with probability p. We show that the optimal signaling mechanisms have very different structure for different values of p underlining that communication an important disadvantage of private signaling mechanisms.

2 - Persuasion in Online Retail: Efficacy of Public Signals

Krishnamurthy Iyer, University of Minnesota, Minneapolis, MN, 14850, United States, kriyer@umn.edu, David Lingenbrink

We study an online retail setting, where strategic customers seek to purchase an item with a finite inventory in one of two time periods. Only the firm knows the inventory and demand, and seeks to persuade strategic customers to buy in the first time period, when the price is higher. We analyze both public and private persuasion mechanisms, and find that, with homogeneous customers, it is optimal to signal publicly: the firm cannot raise its revenue by sending different private signals to different customers. When customers are heterogeneous, we numerically investigate the performance of various public and private persuasion mechanisms.

3 - Persuasion in Networks: Large Networks

Ozan Candogan, University of Chicago, Booth School of Business, Chicago, IL, 27708, United States, ozan.candogan@chicagobooth.edu

Agents in a social network take binary actions that exhibit local strategic complementarities. Agents are a priori uninformed about a payoff-relevant state. An information designer chooses a public signaling mechanism that sends an informative signal about the underlying state to maximize the total number of agents who take action 1. We investigate how to design mechanisms when only partial information about the network structure is available. We show that using only the degree distribution and an asymptotic characterization of cores in large random networks, it is possible to construct asymptotically optimal signaling mechanisms.

4 - Engineering Social Learning: Information Design of Time Locked Sales Campaigns for Online Platforms

Can Kucukgul, The University of Texas at Dallas, Richardson, TX, 75080, United States, cxk151030@utdallas.edu, Ozalp Ozer, Shouqiang Wang

Many online retailing platforms nowadays offer time-locked sales campaigns as an innovative selling mechanism, whereby third-party sellers sell their products at a typically discounted price for a fixed time horizon of pre-specified length. To incentivize purchases, platforms provide some information on up-to-date sales as campaigns progress, in the hope of influencing an upcoming consumer's valuation of products. We propose an easy-to-implement and near optimal information provision strategy for such a time-locked sales campaign. Our policy has important managerial implications, and yields significant profit improvement upon some naïve policies currently implemented in practice.

Machine Learning for Online Platforms

Sponsored: Manufacturing & Service Oper. Mgmt/Service Operations

Sponsored Session

Chair: Negin Golrezaei, Google Inc., Cambridge, MA, 02142, United States

Co-Chair: Adel Javanmard, University of Southern California, Los Angeles, CA, 90089, United States

1 - Dynamic Incentive-aware Learning: Robust Pricing in Contextual Auctions

Adel Javanmard, University of Southern California, Los Angeles, CA, 90089, United States, Negin Golrezaei, Vahab Mirrokni

We consider the problem of robust learning of reserve prices against strategic buyers, in repeated contextual second-price auctions. Buyers' valuations for an item depend on the context that describes the item. However, the seller a priori is not aware of the relationship between the context and buyers' valuations. The seller's goal is to design a learning policy to set reserve prices using the past sales data, and her objective is to maximize her total revenue. On the other side, utility-maximizing buyers have the incentive to bid untruthfully to manipulate the seller's learning policy. We propose learning policies that are robust to strategic buyers and quantify their performance analytically.

2 - Dynamic Learning in the Stochastic Assignment Problem

Assaf Zeevi, Columbia University, New York, NY, 10027, United States

We consider a sequential stochastic assignment problem that involves objects of random "quality" that need to be "assigned correctly" to generate maximal rewards. The original version of the problem was first introduced close to 50 years ago, and considered the assignment of workers to tasks. It has since served as an important modeling paradigm for various other OR/MS problems, though in all this line of literature, the underlying stochastic model is assumed to be known a priori. In this talk we relax this assumption and propose online learning algorithms that estimate this on the fly while concurrently optimizing the assignment objective.

3 - Contextual Pricing via Intrinsic Volumes

Jon Schneider, Google Research, New York, NY, 10018, United States

We present a new algorithm for the dynamic pricing problem (which can be realized as a special case of the contextual search problem) that achieves Od(loglogT) total loss, improving on the previous best known upper bounds of Od(logT) and matching the known lower bounds (up to a polynomial dependence on d). To do this, we introduce the problem of contextual search, a multidimensional generalization of binary search that captures many problems in contextual decision-making. Both algorithms make significant use of ideas from the field of integral geometry, most notably the notion of intrinsic volumes of a convex set.

4 - Learning from the Crowd

Nika Haghtalab, Cornell University, Ithaca, NY, 15213, United States

Crowdsourcing has become the method of choice for gathering labeled training data for learning algorithms. Standard approaches to crowdsourcing view the process of acquiring labeled data separately from the process of learning a classifier from that data. This can give rise to computational and statistical challenges —- as in most cases there are no computationally efficient learning algorithms that tolerates the high levels of noise in crowdsourced datasets, and efforts to eliminate noise through voting require a large number of queries. We show how by interleaving the process of labeling and learning, we can attain computational efficiency with much less overhead in the labeling cost.

Special Topics in Revenue Management

Sponsored: Manufacturing & Service Oper. Mgmt/Service Operations

Sponsored Session

Chair: Gustavo J. Vulcano, Universidad Torcuato di Tella, Buenos Aires, 1428, Argentina

Co-Chair: Victor Araman

1 - Dynamic Analysis of Real-time Nonlinear Pricing for Services Offered To The Strategic Customers in A Heterogeneous Market

Roozbeh Yousefi, Queen's University, Kingston, ON, K7K7M3, Canada, r.yousefi@queensu.ca, Jue Wang, Yuri Levin, Mikhail Nediak

We study optimal dynamic pricing for services offered to heterogeneous customers with different strategic behavior, under either unlimited usage subscriptions or per-usage purchase. We modeled a discrete choice problem for the customers in a dynamic market in aggregate level and used that to formulate the firm's profit maximization in terms of optimal control. We derived the optimality conditions and investigated the turnpike property of the solution, studied the dynamic aspects, optimize the length of the contract and demonstrate how subscription helps firm to exploit strategic behavior.

2 - Pricing in a Mixed Logit Demand Model with Network Effects

William L. Cooper, University of Minnesota, Minneapolis, MN, United States, Fatemeh Nosrat, Zizhuo Wang

A product displays network effects if each individual customer's valuation for the product increases in its overall sales. In this talk, we consider a pricing problem for a product that exhibits network effects. The primary objective in the pricing problem is to find a revenue-maximizing price for the seller of the product. We will focus on a setting in which demand and sales are built on a variation of the mixed multinomial logit (MMNL) choice model. We will discuss approaches for solving the seller's price optimization problem, and discuss insights from a numerical study.

3 - Two-stage Assortment Optimization with Recommendation

Venus Lo, Cornell University, Ithaca, NY, United States, vhl8@cornell.edu, Huseyin Topaloglu

In the first stage, a customer arrives and has an initial product which she wishes to buy, following the independent demand model. If her desired product is in the assortment, she purchases it and leaves. Otherwise, we move onto the second stage, where the customer's type is revealed based on the initial product. Her type reveals her preferences for the products. The retailer recommends a subset of his assortment based on her type, and she either chooses a product in the recommended subset according to MNL, or leaves without a purchase. The assortment optimization problem is NP-hard. We present a FPTAS when the number of customer types, is fixed, and present an inapproximability result.

4 - Supply Positioning for Marketplace Balance at Lyft

David Crapis, Lyft Inc., Berkeley, CA, 94709, United States

Lyft supply positioning system powers a suite of products that allow Lyft drivers to reposition themselves where they are most needed. Our system selects a combination of demand signals and monetary incentives with the goal of improving service levels and ultimately increase earnings for drivers. At the core of the system there is an optimization algorithm that relies on demand and supply forecasts. We will discuss the key aspects of the supply positioning problem and we will describe some of the challenges in solving this problem in the real world.

Supply Chain Management

Sponsored: Manufacturing & Service Oper. Mgmt/Supply Chain

Sponsored Session

Chair: C Gizem Korpeoglu, University College London, London, WC1E 6BT, United Kingdom

1 - Demand Pooling in Omnichannel Operations

Xiaolin Xu, Nanjing University, School of Business, Nanjing, 210093, China, xuxl@nju.edu.cn, Ming Hu, Weili Xue, Yi Yang

Many traditional retailers and e-tailers like Walmart and Amazon have been implementing omnichannel strategies, such as buy-online pickup-at-store (BOPS), buy-online ship-to-store (BOSS), and buy-online ship-from-store (BOFS). We build a stylized model to investigate the impacts of these omnichannel strategies on store operations from an inventory perspective.

2 - Improving Yield of Small Holder Farmers: Welfare Analysis

Utku Serhatli, INSEAD, Constance de le Boulevard, Fontainebleau, 77590, France, utku.serhatli@insead.edu, Guillaume Roels

To help secure supply in agricultural-intensive economies, manufacturers often help smallholder farmers improve their yields through training and certification programs. However, and perhaps paradoxically, some farmers feel that these programs can decrease commodity prices, which in turn can affect their profits negatively. We formulate this problem as a Stackelberg game where in the first stage, the manufacturer decides which farmers to help, and in the second stage, farmers engage in a Cournot competition in the face of yield uncertainty. We investigate the implications of such practices on the manufacturer's and farmers' profits, considering both total welfare and social inequality.

3 - A Two-Sided Budget Neutral Incentive Program for Coordinating an Influenza Vaccine Supply Chain with Endogenous Supply and Demand under Uncertainty

Kenan Arifoglu, UCL, London, United Kingdom, k.arifoglu@ucl.ac.uk, Christopher S. Tang

This paper considers a decentralized flu vaccine supply chain consisting of rational individuals and a profit-maximizing manufacturer with uncertain yield. We develop a two-sided incentive program to counteract 'demand-side inefficiency' caused by individuals' rational behavior and 'supply-side inefficiency' caused by the manufacturer's uncertain yield, and thereby coordinate the flu vaccine supply chain. On the demand side, we propose tax/subsidy payments between the social planner and vaccinated individuals, that depend on the realized yield. On the supply side,we propose a transfer payment between the social planner and manufacturer, which is also contingent on the realized yield.

4 - Reshoring or Offshoring? Impacts of Markets, Tariffs, and Premiums of Domestic Manufacturing

Xin Wang, Hong Kong University of Science and Technology, Kowloon, Hong Kong, xinwang@ust.hk, Kanglin Chen, Ying-Ju Chen, Baozhuang Niu

We analyze the reshoring decision of a global manufacturer that is based in a developed country and sells its product in both domestic and overseas markets. The manufacturer can offshore productions overseas to serve both markets, or reshore production back to the developed country and serves two markets separately. We find that when the domestic market size is large, reshoring might not be optimal. In addition, raising tariffs might cause less reshoring. Finally, reshoring may hurt consumers surplus even though consumers value domestically manufactured goods more.

Coping with Uncertainties in Supply Chain

Sponsored: Manufacturing & Service Oper. Mgmt/Supply Chain

Sponsored Session

Chair: Jun Ru, Pomona, CA, 91768, United States

1 - Association Between Diversification Strategies and Inventory Performance

Zhuang Qian, Assistant Professor, Pennsylvania State University Scranton, Dunmore, PA, United States, zuq35@psu.edu, Charles X. Wang

We conduct an empirical study to examine the associations between the firm's diversification strategies and inventory performance. Based upon a large sample of U.S. publicly traded firms, we find that (1) firms that are more diversified into related product segments hold more inventory; (2) firms that are more diversified into unrelated product segments hold less inventory; and (3) firms that are more internationally diversified hold more inventory. Based upon our empirical results, we offer important insights on achieving the strategic fits between diversification strategies and inventory decisions.

2 - Component Procurement for an Assembly Supply Chain with Random Capacities and Random Demand

Xiang Fang, University of Wisconsin-Milwaukee, Milwaukee, WI, 53211, United States, fangx@uwm.edu, Xinyan Cao

We consider a decentralized assembly supply chain with n suppliers and an assembler. Each supplier faces an uncertain production capacity. We formulate the problem as a two-stage Stackelberg game. We analytically characterize the equilibrium of this game, based on which we obtain several managerial insights. Particularly, we show that a reduction in one supplier's production cost or capacity uncertainty, or an increase in the component salvage value, might sometimes hurt this particular supplier's profitability. Furthermore, we demonstrate that when the suppliers' capacities become more positively correlated, the assembler is always better off, but the suppliers might be better or worse off.

3 - Retailer- vs. Vendor-managed Inventory: Manufacturer Margin, Product Substitution, Consumers' Store Loyalty

Jun Ru, California State Polytechnic University, Pomona, College of Business Administration, Pomona, CA, 91768, United States, jru@cpp.edu

The extant literature that studies the impacts of vendor-managed inventory (VMI) on the supply chain focuses only on a single-product setting, but in practice a retailer carries multiple products that are partially substitutable and supplied from different vendors. Therefore, this paper considers a supply chain consisting of two manufacturers and one retailer. Each manufacturer supplies a product to the retailer and both products are partially substitutable. We aim to shed light on how VMI affects the performance of each supply chain member as opposed to retailer-managed inventory (RMI) in a two-product setting.

4 - Product Quality Strategy in the Presence of Consumer Heterogeneity of Technology Platform

Xiuli He, UNC-Charlotte, Sugar Land, TX, 77479, United States, Yong Zha, Subodha Kumar

We study a smartphone device manufacturer's quality and price decisions when consumers differ in their willingness to pay for device quality. We first study the case where the manufacturer faces an exogenous OS quality (no customization). We find that the optimal device quality is not monotonic in OS quality.

CC- Room 309

Inventory Management Facing Financial and Risk Concerns

Sponsored: Manufacturing & Service Oper. Mgmt/iFORM

Sponsored Session

Chair: Rong Li

1 - Inventory Management under Corporate Income Tax

Yixuan Xiao, Washington State University, Pullman, WA, United States, Zhan Pang

Corporate income tax (CIT) is a major financial cost in most business operations and after-tax profit is one of the most important financial performance indicators of a firm. We incorporate CIT into inventory models to analyze how CIT impacts inventory decisions under both accrual accounting and cash accounting methods. We formulate the inventory control problem under CIT as a cyclic stochastic dynamic program with multiple accounting periods each of which consists of multiple ordering periods and characterize the structures of optimal policy under different accounting methods.

2 - Supply Contracting under Changing Conditions

Long Gao, School of Business, UC Riverside, Riverside, CA, United States, long.gao@ucr.edu

We study how changing supply conditions affect the optimal procurement contract under information asymmetry. We characterize the structure of the optimal contract, and refine several results from the static framework. Finally, we provide guidelines for managing long-term procurement under changing supply conditions.

3 - Market Frictions and Advance Payment Mechanisms in Pre-shipment Financing

Fasheng Xu, Washington University in St. Louis, Campus, Saint Louis, MO, 63130, United States, fasheng.xu@wustl.edu, Panos Kouvelis, Wenhui Zhao

Most of the innovation and initiatives around early payment, like different types of trade credit, revolve around post-shipment approved invoice financing. But, if waiting to get funded until the invoice was approved, many SME suppliers would have cash flow challenges and difficulty financing production activities upfront. To fill this gap, we study a pull-structure supply chain with a large retailer and a cash-constrained SME supplier who needs the bank financing from the bank.

4 - Inventory Management Facing Multiple Risk Behavior Biases

Rong Li, Syracuse University, Syracuse, NY, United States, rli138@syr.edu, Shuxiao Sun

The behavioral OM literature have demonstrated experimentally the existence of the newsvendor decision bias—-order too few of high-profit products and too many of low-profit products—-and explained theoretically by a single risk behavior bias. Since the risk behavior bias indeed arise from two dimensions: risk perception and risk propensity, this paper attempts to explain the decision bias theoretically by two biases: overprecision (a risk perception) and risk aversion (a risk propensity) which are commonly observed. Interestingly this paper finds that when a manager possesses a certain degree of both types of biases, he may behave as an unbiased decision-maker.

Sponsored Session

Chair: Saed Alizamir, Yale University, New Haven, CT, 06520, United States

Co-Chair: Safak Yucel, Georgetown University, Washington, DC, 20057, United States

1 - Investment in Wind Energy: The Role of Subsidy Policies

Foad Iravani, University of Washington, Foster School of Business, ISOM Department, Seattle, WA, 98195-3226, United States, firavani@uw.edu

Wind energy investment in the U.S. has significantly increased over time. Because wind energy provides electricity without carbon emissions, the government has been promoting wind energy investment through subsidy programs. We analyze the role of generation subsidy and investment subsidy on potential investors and examine the effects of investor characteristics on the optimal subsidy mechanisms. We also study the benefits of implementing the subsidy programs regionally, as opposed to federal implementation.

2 - Demand Response in Wholesale Electricity Markets

Asligul Serasu Duran, Assistant Professor, University of Calgary, Calgary, AB, Canada, serasu.duran@haskayne.ucalgary.ca, Baris Ata, Ozge Islegen

We explore the participation and the compensation of demand response (DR) providers in wholesale electricity markets over the long term, motivated by the Federal Energy Regulatory Commission's order that authorized DR resources to receive the same market clearing prices that generating resources receive. We model the equilibria in wholesale energy and capacity markets under various scenarios of DR participation, and investigate the impact of different DR compensation and penalization policies.

3 - A Reduce-to-threshold Approach to Direct Load Control Contracts with Monthly Constraints

Ali Fattahi, Johns Hopkins University, Anderson School of Management, Baltimore, MD, 90095, United States, ali.fattahi@jhu.edu, Foad Iravani, Sriram Dasu, Reza Ahmadi

Demand response programs are among strategies that utilities use to reduce electricity consumption during peak hours. Direct Load Control Contracts are a class of incentive-based demand response programs that allow utilities to directly “call” consumers through remote control devices and reduce their usage. We formulate an optimization model for executing DLCCs that minimizes cost subject to monthly and annual constraints on the number of times and hours customers can be called. We develop a hierarchical approximation scheme that solves the problem effectively. Our experiments with real data from the California system operator show that our approximation scheme performs remarkably well.

4 - A Structural Analysis of Consumer Electricity Demand Response to Dynamic Pricing

Bhavani Shanker Uppari, Singapore Management University, Singapore, 178899, Singapore, bhavaniu@smu.edu.sg, Kashish Arora

A large proportion of world’s electricity demand is going to be met by renewable sources in the next decade. This poses a huge operational challenge: balancing the highly variable renewable electricity supply and the (relatively more) static demand. Using data from a large scale experiment in London, we examine the effect of dynamic prices (pushed through smart meters) on the response of consumers’ demand. We build a consumer-level structural model of pricing and electricity consumption. Using the resultant estimates, we evaluate the efficacy of various policies (e.g., different tariff schemes and capacity allocations across different power sources) in terms of matching supply with demand.

5 - Electricity Consumption for Rationally Inattentive Households

Michael R. Blair, Yale University, New Haven, CT, United States, michael.blair@yale.edu, Saed Alizamir, Shouqiang Wang

We examine the electricity consumption decision for households who are rationally inattentive in a dynamic setting. That is, households pay a cognitive cost for processing information about an underlying stochastic process. As a result, households update their information and consumption infrequently. We characterize the household’s optimal consumption and information processing decisions over an infinite horizon, and show that this policy involves periodic inspections. Furthermore, our preliminary empirical analysis validates our findings.

Healthcare Decision Analysis

Sponsored: Decision Analysis

Sponsored Session

Chair: L. Robin Keller, University of California, Irvine, CA, 92697-3125, United States

Co-Chair: Cristina del Campo, University of California, Irvine, Universidad Complutense de Madrid, Irvine, CA, 28223, United States

1 - Challenges in Modelling Time Dependent Transitions in Cost-effectiveness Analysis

Jiaru Bai, Wake Forest University, Binghamton University, School of Management, Winston Salem, NC, 13902, United States, baij@wfu.edu, Cristina del Campo, L. Robin Keller

We propose challenges in estimating Markov model parameters with limited clinical data. With limited data from registration trials, we developed a way to estimate time-dependent transition probabilities in a Markov model for cancer progression. The method is applied to cervical cancer data in a clinical study.

2 - Enhancing understanding of Probability Updating with Bayes’ Rule

Alexander Robinson, University of California at Irvine, California, Irvine, CA, 92617, United States, arobins3@uci.edu, L. Robin Keller, Cristina del Campo

The process of calculating updated probabilities via Bayes’ theorem and interpreting them should be improved to avoid errors and enhance understanding. Updating probabilities given new evidence is a technique that has applications in a number of fields, in particular healthcare. Stating probabilities as numbers of people out of a total number will help health care providers, care givers and patients better understand and retain the information.

3 - A Two-Step Markov Processes Approach for Parameterization of Cancer State-Transition Models for Low- and Middle-Income Countries

Chaitra Gopalappa, University of Massachusetts Amherst, Belchertown, MA, United States, chaitrag@umass.edu, Guo Jiachen, Jeremy Lauer, Andre Ilbawi, Carel Pretorius

In low- and middle-income countries (LMICs), screening and early diagnosis programs are generally unavailable, and most cancers are diagnosed in late stages when survival is very low. As part of the Sustainable Development Goals, countries aim to reduce premature mortality from cancers and are in preparation of an ‘investment case’, economic analysis to identify prioritized interventions. However, mathematical models of natural disease progression, needed to conduct the economic analyses, are mostly based on high-income countries because the longitudinal data required for parameterization are unavailable in LMICs. We present a mathematical methodology specific for LMICs.

4 - Analytics-Based Advances in Organ Assessment and the Transplantation Decision-Making Implications

Ran Jin, Virginia Tech, Blacksburg, VA, United States, jran5@vt.edu, Qing Lan, Christian Wernz, John Robertson

Many viable organs were discarded due to ineffective assessment and conservative standards in transplantation. In addition, current assessment methods, biopsy and visual inspection, are subjective. This study is to create objective and non-invasive viability assessment methods for transplantation, leading to effective organ matching decisions. Therefore, we propose to use infrared images and spatio-temporal data analysis to predict viability and identify suspected regions for future biopsy. We validate the method by using porcine livers and kidneys. Our proposed methods can potentially secure discarded organs for transplantation to benefit more end-stage patients with organ failure.

Behavioral Decision Analysis II

Sponsored: Decision Analysis

Sponsored Session

Chair: Gilberto Montibeller, Loughborough University, Loughborough, LE11 3TU, United Kingdom

1 - Evaluation of Visual Analytics in Group Decision Support Systems

Hugo Tsugunobu Yoshida Yoshizaki, University of Sao Paulo, R. Paulo F. Costa Aguiar 1600 Ap 161 G, Vila Yara, Osasco, 06026-090, Brazil, hugo@usp.br, Filippe A. Santos, Gilberto Montibeller, Matthias Winkenbach

Location decisions are complex with multiple and conflicting objectives and a spatial dimension which made this kind of problem particularly attractive to use visual analytics. We developed a group decision support system to study how effective decision makers are to explore the decision space through visual interaction. To answer to which extent the GDSS provides effective decision support, we present how we are testing the system using behavioral role-playing simulations.

2 - Using Signal Detection Theory to Characterize Trade-offs Between Deterrence and Vulnerability Reduction in Security Screening

Richard S. John, Professor, University of Southern California, Dept. of Psychology MC 1061, Los Angeles, CA, 90089-1061, United States, richardj@usc.edu, Nicholas Scurich, William Burns

Signal Detection Theory (SDT) provides a framework for partitioning people entering security screening based on an individual risk assessment from available information. Depending on the base-rate of adversaries and relative error penalties, SDT prescribes an optimal threshold score for classifying individuals as “high-risk” or “low-risk” for purposes of screening. One deviation from the SDT fixed threshold approach is to use a randomization method that increases the likelihood of a “high-risk” screening with increased risk assessment. Such randomization approaches are useful only if the decreased threat from deterrence is greater than the increase in vulnerability.

3 - Making Decisions and Gaining Buy-in in Polarized Times

Patrick Leach, Adjunct Professor / Independent Consultant, Colorado School of Mines, Denver, CO, 80202, United States, leach.sullivan@gmail.com

People naturally seek out and believe evidence that supports their current beliefs and deny evidence that contradicts those beliefs. Liberals, conservatives, and libertarians weight and interpret basic human values differently. When people with similar views discuss a subject in a group, the group’s views become more extreme than the most extreme individual’s view prior to the discussion. Social media exacerbates this problem. How is one to make decisions, let alone gain buy-in from diverse groups in today’s polarized world? Evidence alone doesn’t change minds; there must also be an emotional appeal. This talk will discuss these problems and conclude with possible approaches to mitigating them.

4 - Which Biases Matter in Decision and Risk Analysis?

Gilberto Montibeller, Loughborough University, School of Business & Economics, Loughborough, LE11 3TU, United Kingdom, g.montibeller@lboro.ac.uk, Detlof von Winterfeldt

Behavioral decision research has identified a plethora of cognitive biases that affect judgments of experts and decision makers. Biased judgments may cause detrimental impacts on the quality of decision and risk analysis models, distorting results and invalidating recommendations. But do all these biases really matter for decision and risk analyses? We argue that some biases are more relevant than others and suggest a list of criteria that identify whether a bias is relevant. This framework may help decision analysts in identifying existing biases that are more relevant, detecting if new found biases might be relevant, and guiding efforts to debias those ones that are indeed the most relevant ones.

Co-Chair: I-Lin Wang, National Cheng Kung University, Industrial Information Management, Tainan, 70101, Taiwan

1 - An Efficient Framework Conditional-Expectation-based Simulation Optimization

Kuo-Hao Chang, National Tsing Hua University, Industrial Engineering, Hsinchu, 30013, Taiwan, Hsing-Yu Lin

Conditional value at risk (CVaR) is a widely used risk measure commonly applied by financial engineers. This paper generalizes CVaR research by developing a simulation optimization framework capable of efficiently calculating and optimizing the conditional expectation without requiring gradient information or convexity assumptions. An extensive numerical and empirical studies are conducted to demonstrate the efficiency and efficacy of our proposed method.

2 - The Integrated Bus Driver Scheduling and Rostering Problem

Dung-Ying Lin, National Tsing Hua University, Transportation Management, Tainan City, Taiwan, Chieh-Ju Juan

In the public bus transportation industry, crew management is typically decomposed into two phases: crew scheduling and crew rostering, due to the complexity when considering both procedures simultaneously. In the research, we formulate the two problems into an integrated model and propose a Branch-and-Price-and-Cut (BPC) algorithm to solve the compound problem. To validate the effectiveness and evaluate the efficiency of the proposed solution frameworks. In the numerical results, we test six groups data with different number of working tasks. The results show that the BPC algorithm performs well and can solve problems of realistic size within reasonable computational time.

3 - Search Path Planning for a Randomly Distributed Immobile Target using Fleet of UAVs with Battery Swapping Stations

I-Lin Wang, National Cheng Kung University, Industrial Information Management, 1 University Road, Tainan, 70101, Taiwan, Yen-Wei Chen

Conventional optimal searcher path problem seeks an immobile target on a network, where each arc is associated with a probability for that target. The searchers need to travel all arcs with constant speed aiming at a minimal expected time of finding the target. In our research, we use a fleet of UAVs together with pre-installed battery swapping stations to do the search job. UAVs have two travel modes: a search mode and a fly mode with different speeds and power consumption. Math programming models and solution methods will be discussed.

4 - A Network Flow Model for Scheduling Advance Reservations of Shared Parking

Chung-Cheng Lu, Professor, National Chiao Tung University, Chung-Hsiao West Road, National Chiao Tung University,, Taipei, 100, Taiwan, jasoncclu@gmail.com, Yun-Chu Hung

Shared parking is a type of parking management that aims to efficiently utilize parking spaces in urban areas. Through shard parking, private parking owners can rent out their parking space at times they don't use it. This allows drivers to park their car at parking spaces that are so far not accessible for them, and hence may help drivers to avoid the long search and the circling around to find an empty parking space. This paper addresses the scheduling problem of advance reservations for shared parking systems. We formulate the scheduling problem as a mixed integer linear program (MILP) based on an innovative parking space-flow network.

5 - Healthcare Scheduling Policies in Taiwan: Squeezing Physicians' Utilization from a Sequence-number based Appointment System

I-Hsuan Hong, National Taiwan University, Industrial Engineering, Taipei, 106, Taiwan, Pei-Sheng Cheng

The hospitals or clinics in Taiwan adopt the sequence-number based appointment system, where the physician's office provides each outpatient a specific number with a suggested arrival time on a first-call, first-appointment basis. This study investigates two appointment scheduling patterns and three late arrival policies with the consideration of outpatients' behaviors on the basis of expectation and past experience. The results indicate that a plateau-dome scheduling pattern and a three-queue late arrival policy significantly reduce waiting time compared with a uniform scheduling pattern and other used late arrival policies.

Service Analytics and Applications

General Session

Chair: Srinivasa Prasanna, IIIT-Bangalore, 26/C, Hosur Road, Electronics City, Opposite Infosys Technologies, Bangalore, 560100, India

Co-Chair: Abhilasha Aswal, International Institute of Information Technology, 26/C Electronics City, Hosur Road, Bangalore, 560100, India

Co-Chair: Anushka Chandrababu, International Institute of Information Technology, Bangalore, India

1 - Analytics and Edge Computing for Public Safety

Vidya Sagar, Spectronn, Holmdel, NJ, United States

Public safety concerns have heightened in the recent decades. Additionally, the agencies dealing with it have to adopt technologies like AI, Edge computing and IoT. At Spectronn, we help federal and state public safety agencies in this transition. This talk shares our experiences and discusses the challenges faced.

2 - Analytics for Financial Services

Ravi Venktaratna, Infosys Limited, Bangalore, India

We illustrate the issues involved in Financial Services. Mainly the issues in controlling access, maintaining database sanity, and providing high performant simple and complex services to 50 to 100 million customers. The talk will focus on general aspects in the most part, but specific examples from industry will be included.

3 - Challenges and Solutions for Problems in a Large National Railway System

Srinivasa Prasanna, IIIT-Bangalore, 26/C, Hosur Road, Electronics City, Opposite Infosys Technologies, Bangalore, 560100, India, Abhilasha Aswal

Indian Railways is the world's largest rail network, if complexity is taken into account. The system operates 20,000 passenger trains per day, and the complexity is one to two orders of magnitude larger than some of the largest Airlines in the world. The system provides both unreserved and reserved tickets, and given its scale, is fairly efficient. In this talk, we will illustrate the issues involved in serving a billion+ people, as the nation's main transportation lifeline. Issues are challenging from reservations of tickets, all the way to rolling stock and cargo logistics.

4 - Service Analytics for Airline Scheduling

Ganesh Perumal, Sabre, Bangalore, India

In this talk we illustrate issues in service delivery for airline scheduling. We illustrate the scale and stringent quality requirements, in the presence of uncertainties in aircraft arrival/departure, congestion at airports etc. We shall illustrate some generic algorithmic issues with at least one real life to scale example.

5 - Issues and Challenges in Service Analytics in a Nutshell

Anushka Chandrababu, International Institute of Information Technology, 26/C, Electronic City, Bangalore, India

In this talk we will present a sum-up of the session and comment on the recent advances in Service Analytics along with the current challenges.

Portfolio Analysis & Politics/Voting

Contributed Session

Chair: Shilpi Mukherjee, Clemson University, Clemson, SC, 29631, United States

1 - Construction of Smart Beta Index under a Non-normal Return Distribution

Rei Yamamoto, Keio University, Kohoku-ku, Japan, Naoya Kawadai

We focus on the "Rachev ratio" proposed by Biglova et al. (2004) and propose a new smart beta index using it. This ratio has demonstrated its effectiveness as a performance measure; however, it is difficult to consider it to be a portfolio tool, particularly due to its nonconvexity. Therefore, we propose a simple weighting method to construct a portfolio, transforming it into a new smart beta index. Moreover, we compare its performance with other smart beta indices in the global stock markets. Hence, we conclude that this smart beta is a new effective index that can be used in global stock markets.

2 - Statistical Assessment of Momentum-based Scenarios for Stock Index Returns and Levels

Xiaoshi Guo, Iowa State University, Ames, IA, United States, xsguo@iastate.edu, Sarah M. Ryan

We investigate how well stock index observations are represented by scenario time series generated according to a variant of geometric Brownian motion that incorporates return momentum and changing volatility. Multiple scenarios of index returns and levels are generated on a rolling basis by Monte Carlo simulation for use in stochastic optimization. In historical backtesting, uniformity of a mass transportation rank histogram is used to test a null hypothesis that the generated scenarios are indistinguishable from observed data. The hypothesis is not rejected for plausible combinations of future time horizons covered by the scenarios and past time horizons used for estimating parameters.

3 - Generating Natural Parson-Trip Data by Using Markov Model with Open Statistical Data

Reimi Shimizu, Waseda University, Tokyo, Japan, Takashi Hasuike

In japan, it is a serious problem that the number of people who has no public transport access is becoming to be large because of the aging society and depopulation, especially in the suburbs. To improve this situation, we have to develop the sustainable public transport access and before that, we need to understand the traffic demand. While the person-trip survey which investigates human movements is one of the most valuable data to consider, much less investigates has been done in the suburbs. In this paper, we propose the way of generating the natural parson-trip data by using the open statistical data which is easy to get and include no privacy data.

4 - Understanding Political Polarization Through Twitter Data

Shilpi Mukherjee, Graduate Research Assistant, Clemson University, Clemson, SC, United States, shilpim@clemson.edu, Patrick Warren

We have tried to look at political polarization between Democrats and Republicans in United States of America, by analyzing their tweets. There is an extensive literature suggesting that political polarization has increased since the Cold War. We employ a number of natural language processing techniques to understand this effect.

Learning in Online Markets and Platforms

Sponsored: Auction and Market Design

Sponsored Session

Chair: Vijay Kamble

1 - Meta Dynamic Pricing: Learning Across Experiments

Ruihao Zhu, MIT, Cambridge, MA, 02139, United States, David Simchi-Levi, Hamsa Sridhar Bastani

We study the problem of learning shared structure across a sequence of dynamic pricing experiments for related products. We consider a practical formulation where the unknown demand parameters for each product come from an unknown distribution (prior) that is shared across products. We then propose a meta dynamic pricing algorithm that learns this prior online while solving a sequence of Thompson sampling pricing experiments (each with horizon T) for N different products.

2 - Integrated Online Learning and Adaptive Control in Queueing Systems with Uncertain Payoffs

Jiaming Xu, Duke University, Durham, NC, United States, jiaming.xu868@duke.edu, Wei-Kang Hsu, Xiaojun Lin, Mark Bell

We study task assignment in online service platforms where unlabeled clients arrive stochastically and each client brings a random number of tasks. As tasks are assigned to servers, they produce client/server-dependent random payoffs. The goal is to maximize the expected payoff subject to the servers' capacity constraints. However, both the statistics of the client population and the client-specific payoff vectors are unknown. We propose a new algorithm that seamlessly integrates online learning (of the clients' payoff vectors) with adaptive control (of the queueing system). Our analysis characterizes the payoff gap of our proposed algorithm in a finite time horizon compared to an oracle.

3 - Nonparametric Contextual Bandits in an Unknown Metric Space

Christina Lee Yu, Cornell University, Ithaca, NY, United States, cleeyu@cornell.edu, Nirandika Wanigasekara

Consider a nonparametric contextual multi-arm bandit problem where each arm is associated to a nonparametric reward function mapping from contexts to the expected reward. Suppose that there is a large set of arms, yet there is a simple but unknown structure amongst the arm reward functions, e.g. finite types or smooth with respect to an unknown metric space. We present a novel algorithm which learns data-driven similarities amongst the arms, in order to implement adaptive partitioning of the context-arm space for more efficient learning. We provide regret bounds along with simulations that highlight the algorithm's dependence on the local geometry of the reward functions.

4 - Semi-Parametric Dynamic Contextual Pricing

Virag Shah, Stanford University, Management Science and Engineering, Stanford, CA, 94305, United States, virag@stanford.edu, Jose Blanchet, Ramesh Johari

We consider the problem of revenue-maximization in a setting where the seller can leverage contextual information describing the customer's history and the product's type to predict her valuation of the product. However, her true valuation is unobservable to the seller, only binary outcome in the form of success-failure of a transaction is observed. Unlike in usual contextual bandit settings, the optimal price/arm given a covariate in our setting is sensitive to the detailed characteristics of the residual uncertainty distribution. We develop a semi-parametric model in which the residual distribution is non-parametric and provide the first learning algorithm with \tilde{O}(\sqrt{n}) regret.

5 - Data-adaptive Model Selection in Online Learning

Vidya Muthukumar, University of California, Berkeley, Berkeley, CA, United States, Mitas Ray, Niladri Chatterji, Anant Sahai, Peter L. Bartlett

We consider sequential learning with full information and bandit (limited-information) feedback, models used in platforms for online advertisement placement, repeated auctions, wireless channel allocation and mobile healthcare. Theoretical guarantees are traditionally obtained in the form of (worst-case) regret with respect to a fixed offline benchmark. However, to maximize overall reward the choice of offline benchmark matters as much as the choice of regret minimizing algorithm. We motivate that this choice should be adapted in an online fashion according to the data itself, and provide algorithmic approaches to do this in contextual prediction with both full-information and bandit feedback. We obtain regret/reward bounds that are almost as good as an optimal algorithm which has oracle knowledge of the existence of stochasticity *and* the right generative model for the data. Our techniques involve adversarially robust adaptations of statistical tools — structural risk minimization, validation and hypothesis testing — to the sequential setting.

Modeling and Optimization

Contributed Session

Chair: Robert Koo, DoD, 99-793 Holoai St, Aiea, HI, 96701, United States

1 - Feature Extraction on Motor and Non-motor Assessments for Parkinson's Disease: Using Transformed Features to Characterize and Correlate Subtypes

Robert Koo, DoD; University of Hawaii, Honolulu, HI, United States, r.koo@hotmail.com, Suzanne Tsukenjo

Parkinson's Disease (PD) is a progressive neurodegenerative disorder that is defined by both motor and non-motor symptoms. Clinicians use a broad range of motor/non-motor assessments to characterize the subtype and severity of PD. Using big data from the Parkinson's Progression Markers Initiative (PPMI), this study focuses on the extraction of latent features from motor/non-motor assessments in order to establish meaningful characterization of PD subtypes and how transformed features correlate with baseline biospecimen data. Clinical assessment and biospecimen data from over 600 PD and Healthy Control subjects are analyzed through classical and modern machine learning techniques.

2 - A MCDM Method for Experts Assessment of Hospitals Quality

Diogo Ferreira, Universidade de Lisboa, Lisbon, Portugal, diogo.cunha.ferreira@tecnico.ulisboa.pt, José Rui Figueira, Salvatore Greco, Rui Marques

The object of this study consists of the performance assessment of some reference hospitals based on several experts and their judgments about the quality of these hospitals. From such qualitative assessments, we infer a preference model of the experts, which can be used for assessment of the quality of the non-reference hospitals. This is a multicriteria machine learning based tool, which proposes an overall value for each hospital. The expert judgments are provided for each criterion as well as each sub-criterion. Judgements are usually expressed through ordinal scales.

3 - Evaluation of Fiscal Policies for Electric Vehicles - A Multicriteria Sorting Approach

Maria Isabel Clímaco, ISCAC - Coimbra Business School, Coimbra, Portugal

The growing share of electric vehicles will make a decisive contribution to the decarbonization of the economy. The importance of road transportation in economic, environmental and energy dimensions requires the assessment of the impact of existing and prospective fiscal policies on the promotion of electric mobility. The evaluation of a set of fiscal policies is performed as a sorting problem, i.e. the assignment of policies to predefined categories of merit according to multiple criteria, using the ELECTRE TRI method based on an outranking relation allowing non-compensation effects.

4 - Using JSON and NoSQL Databases to Deliver Data for Deploying Optimization Models through REST API Service on the Cloud

Bjarni Kristjansson, Maximal Software Inc., Arlington, VA, 22201, United States

When preparing optimization models for deployment, it is often not the formulation of the model or the solving that is the most difficult part, but rather how to organize and deliver the data efficiently to the model. Using modeling languages, this problem can be alleviated by importing data directly from SQL databases and spreadsheets, but this is still not easy enough. In this presentation, we will demonstrate how using the JSON data format can be particularly well suited for organizing optimization data. Furthermore, using NoSQL databases such as MongoDB and DynamoDB, which are very efficient at storing dynamic data, give the model developer new opportunities for deploying optimization on the cloud.

Tutorial: The Use of Data Science for Supply Chain Transportation Management

Emerging Topic: Tutorials

Emerging Topic Session

1 - Tutorial - The Use of Data Science for Supply Chain Transportation Management

Samuel K. Eldersveld, Amazon.com, Seattle, WA, 98112, United States, Elcin Cetinkaya

Recent developments have motivated data science targeting improvements in supply-chain execution. We present techniques for three large-scale transportation problems with the goal of providing exceptional customer service and hitting targets on cost, flexibility, and speed. 1. Models for containerization used in a hub-and-spoke supply-chain network which generate pre-sorting splits for a class of distinct containers destined for fulfillment centers. 2. Efficient forecasts of package demand using multi-model inference targeting both middle-mile and last-mile transportation systems. 3. Risk prediction using large-scale machine learning models to account for weather anomalies.

Advances in Cybersecurity Analytics and Data Science

Sponsored: Military and Security

Sponsored Session

Chair: Nathaniel D. Bastian, PhD, Army Cyber Institute, U.S. Military Academy, West Point, NY, 10918, United States

Co-Chair: Andrew Oscar Hall, United States Military Academy, West Point, NY, 10996, United States

1 - Adversarial Machine Learning in the Network Intrusion Detection Setting

Elie Alhajjar, Cyber Mathematics Fellow, Army Cyber Institute, U.S. Military Academy, 68 Corbin Hill Road, West Point, NY, 10922, United States, eliealhajjar@gmail.com, Nathaniel D. Bastian, Paul Maxwell, Robert Thomson, Malcolm Haynes

In the past couple of years, it has become common knowledge that neural networks are vulnerable to any type of perturbation. This issue is hindering the application of machine learning techniques in mission-critical situations. In this talk, we investigate this phenomenon in the network intrusion detection setting. We highlight the similarities and the differences with image recognition through real data sets experiments. We focus on generating adequate perturbations to the data in hand and how this process impacts classification of network flows. Time permitting, we discuss a Generative Adversarial Network (GAN) approach to the problem of identifying benign packets.

2 - Intelligent Feature Engineering for High-Performance Computing Enabled Machine Learning in Cybersecurity

Paul Maxwell, PhD, Army Cyber Institute, U.S. Military Academy, West Point, NY, United States, Elie Alhajjar, Nathaniel Bastian

Feature engineering and selection is a critical step for any machine learning system. In application areas like cybersecurity intrusion detection, this task is made more complicated by the diverse data types and ranges. Previous efforts in this area naively apply techniques for feature engineering that were successful in image recognition. We use network packet data from the Defense Research and Engineering Network and the Engineer Research and Development Center's high performance computing systems to analyze methods of feature engineering and selection. The results are compared to previous machine learning studies on intrusion detection to provide insight on the suitability of the features.

3 - Robust Goal Programming to Optimize Army Cyber Branch Readiness and Manning under Uncertainty

Brian J. Lunday, Associate Professor, Air Force Institute of Technology, Department of Operational Sciences, WPAFB, OH, 45433, United States, brian.lunday@afit.edu, Nathaniel D. Bastian, Chris Fisher, Andrew Oscar Hall

We proffer the Robust Cyber Force Manning Model (R-CFMM), an advanced analytics framework that uses a robust goal programming approach to enable the modeling, experimentation and optimization necessary to help solve the Army's Cyber Workforce Planning Problem. Particularly, the R-CFMM helps optimize the readiness of the Army's Cyber Branch by effectively projecting the optimal number of personnel needed to meet the demands of the current force structure under conditions of uncertainty in personnel retention.

4 - A Quantitative Risk Analysis of Nation State Supported Computational Propaganda

Travis Trammell, Stanford University, Stanford, CA, 94305, United States

Strategically using information to affect the views of a population is certainly nothing new and dates all the way back to the earliest development of political systems. The rapid distribution of fake news can cause contagion, manipulate markets, spark conflict, or fracture strategic relations. Probabilistic Risk Analysis(PRA) can be leveraged to quantitatively describe the risk associated with fake news by examining all relevant factors. Additionally, optimization of the methods to execute computational propaganda, ranging from embedding bots into online social echo chambers to selecting the most polarizing content,represents a new frontier in the information warfare arena.

5 - A Machine Learning Approach to Robust Malware Classification under Adversarial Conditions

Nathaniel D. Bastian, Operations Research Scientist, Army Cyber Institute, U.S. Military Academy, 34 Booth Road, West Point, NY, 10918, United States, nathaniel.bastian@westpoint.edu, Sean M. Devine

In an environment characterized by widespread accessibility and big data, the feasibility of malware classification without the use of artificial intelligence-based techniques has been diminished exponentially. The threat of adversarial machine learning also poses challenges, as adversaries are looking to target the underlying data and/or algorithm responsible for the functionality of malware classification to map its behavior or corrupt its functionality. The ends of such adversaries are bypassing the cyber security measures and increasing malware effectiveness. This work employs a machine learning approach to accurately, robustly classify malware under adversarial conditions.

1 - STADIA: A Machine Learning Based Tool for Analyzing Dynamic Instability of Microtubules

Shant M. Mahserejian, Research Scientist, Pacific Northwest National Laboratory, Richland, WA, United States, shant.mahserejian@pnnl.gov, Jared Scripture, Ava J. Mauro, Erin M. Jonasson, Jun Li, Mark S. Alber, Holly V. Goodson

Microtubules (MTs) are cytoplasmic bio-polymers with a well-known behavior, dynamic instability (DI), characterized by switches between growth and shortening via transitions called catastrophe and rescue. We present the Statistical Tool for Automated Dynamic Instability Analysis (STADIA) to more accurately measure DI parameters, classify phases, and analyze patterns in high-resolution data sourced from either experiment or simulation. Through unsupervised machine learning, STADIA revealed “stutters”, a transient phase prevalent during catastrophes, which could help explain the structural mechanisms behind DI phase transitions.

2 - Applications of Machine Learning Methods to Maize Genetics and Plant Breeding

Emre Cimen, Institute for Genomic Diversity, Cornell University, Ithaca, NY, United States, ec796@cornell.edu
Emre Cimen, Computational Intelligence and Optimization Laboratory, Eskisehir Technical University, Eskisehir, Turkey, ec796@cornell.edu, Joseph Gage, Sarah E. Jensen, Maria Katherine Mejia-Guerra, Jacob Washburn, Edward S. Buckler

Nowadays, machine learning based methods are applied to almost all science and technology fields, and they help us to make better predictions and to discover hidden information. In this study, specific applications of machine learning methods to maize genetics and plant breeding are examined. Optimal growth temperature prediction, genotype and environment (G×E) based yield prediction, transcription factor (TF) prediction, and field effect prediction applications are defined as classification, regression, and feature selection problems. Opportunities and barriers of these applications are discussed.

3 - New Algorithms for Detecting Multi Effects and Multi Ways Epistatic Interactions

Javad Ansarifar, Iowa State University, Ames, IA, United States, ansarifar.javad@gmail.com, Lizhi Wang

Detection of epistasis, which is the phenomenon of genetic interactions, is extremely challenging problem due to the combinatorial nature of the problem. We propose three new algorithms for multi-effect and multi-way epistases detection, with one guaranteeing global optimality and the other two being local optimization oriented heuristics. The comparison of computational performance of the proposed heuristic algorithm with several state-of-the-art methods revealed the proposed heuristic algorithm was much more effective and efficient than others at finding a close-to-optimal solution.

4 - RFE-SVR Prediction Modeling for Microarray Gene Expression Analysis

Sharmin Nahar Mithy, Graduate Assistant, University of South Florida, Tampa, FL, United States, sharminmithy@mail.usf.edu, Grisselle Centeno, Susana Lai-Yuen

In the treatment of cancer patients, radiation therapy is most often applied before or after or pre-surgery to improve the local control of the disease and the survival rate of the patients. In this study, we explore the genomic information of patients in relation to the response of radiation therapy. We have developed a prediction model that is able to analyze the genomic expression data and predict SF2, which is a measure of the radiation response. For our research, we used RFE-SVR combination to first reduce the dimension of the features and then develop the model. The result has shown significant improvement in comparison with other explored statistical analysis published in the literature.

5 - Nephrotoxic Drug-Associated Acute Kidney Injury in Hospital Patients

Arsenios N. Tsokas, University of Florida, Gainesville, FL, United States, artsokas@ufl.edu, Panayote (Panos) M. Pardalos, Tezcan Ozrazgat-Baslanti, Azra Bihorac

Timely detection of Acute Kidney Injury (AKI) in hospital patients could avoid further injurious practices. In particular, if the probability of development of AKI is known to be high, administration of nephrotoxic drugs can be adjusted to prevent further complications. In this study, we evaluate the impact of nephrotoxic drugs on kidney condition. In a cohort of UF Health patients, daily status was classified with respect to AKI for each patient. Nested machine learning models are built and evaluated to investigate the association between use of nephrotoxic drugs and occurrence of Acute Kidney Injury the following day adjusting for demographic and operative data.

SCIP Optimization Suite: Recent Advances and Applications

Sponsored: Optimization/Computational Optimization and Software

Sponsored Session

Chair: Ambros Gleixner, Berlin, Germany

Co-Chair: Jakob Witzig, Berlin, Germany

Co-Chair: Gerald Gamrath, Zuse-Institut Berlin

1 - Using HiGHS as an LP Solver within SCIP

Julian Hall, University of Edinburgh, Peter Guthrie Tait Road, Edinburgh, EH9 3FD, United Kingdom, jajhall@ed.ac.uk

HiGHS is a growing open-source repository of high-performance software for linear optimization based on award-winning computational techniques for the dual simplex method. The use of HiGHS as an LP solver within SCIP is attractive since it out-performs Soplex on benchmark LP problems and is available via the MIT license. This talk will describe the challenges of achieving efficient performance via the standard SCIP interface, and analyse the performance of SCIP with HiGHS and Soplex as LP subproblem solvers.

2 - Reformulation Linearization Technique Cuts for Explicit and Implicit Bilinear Constraints

Ksenia Bestuzheva, Zuse Institute Berlin, Berlin, Germany, bestuzheva@zib.de, Tobias Achterberg, Ambros Gleixner

We present a method which applies the Reformulation-Linearization Technique to bilinear constraints, including those encoded within MILPs. These implicit bilinear relations are detected by finding linear constraints with a special structure. One drawback of RLT is the large number of cuts it produces, many of which are redundant. This is addressed in our algorithm by identifying early the combinations of problem rows and multipliers that will not produce violated cuts and thus can be ignored. The method is tested on both linear and nonlinear mixed-integer programming problems.

3 - Decomposing MINLPS and General Enhancement Techniques: Updates to the Benders' Decomposition Framework in SCIP

Steve Maher, University of Exeter, Exeter, United Kingdom

Benders' decomposition is a popular mathematical programming technique for solving large scale optimisation problems. While historically viewed as a problem specific algorithm, general frameworks provide an ideal platform to investigate general decomposition and algorithmic enhancement techniques. This talk will provide an update on the current developments for the Benders' decomposition framework available with SCIP and GCG. In particular, the extension of the methods to handle the decomposition of MINLPs and current work on general enhancement techniques will be discussed.

4 - Branching Improvements in SCIP

Gerald Gamrath, Zuse-Institut Berlin, Berlin, Germany

Branching is an essential component of state-of-the-art mixed-integer programming solvers. It splits the current problem into sub-problems for later evaluation; how this is done has an enormous impact on the solver performance. We report on our recent research on branching rules, including lookahead branching (multi-level strong branching) and the consideration of dual degeneracy in branching. All methods have been implemented in the academic MIP solver SCIP and evaluated by extensive computational experiments.

Chair: Leif Meier, HS Bremerhaven, Bremerhaven, Germany

1 - A Comparison of Constraint Programming and Mix Integer Programming in Solving Routing Problems

Tengkuo Zhu, The University of Texas at Austin, Austin, TX, United States, zhutengkuo@utexas.edu, Stephen D. Boyles

Constraint Programming (CP) has been applied to a variety of combinatorial optimization problems, most notably in scheduling applications. In other problems CP has also established itself as a competitor to state-of-art Mix Integer Programming (MIP) solvers. This work represents the comparison between these two approaches of their performance in solving routing problems, such as TSP, VRP and other variants of them. The paper explores the converging time and solution optimality of both approaches based on the test of numerous instances selected from the open-source TSPLIB and VRPLIB dataset.

2 - Optimizing Steel Manufacturing Process

Ali Esmail, Graduate Student, California State University of Fullerton, Anaheim, CA, United States, ali.esmail@csu.fullerton.edu, Hakob Avetisyan, Niranjan Mahamuni, Peter Jacoy, Zachary Chao

This research demonstrates the application of optimization theories can create feasible and practical solutions to achieve optimal production of steel, profits, and limit pollution in a steel manufacturing process. Procurement, inventory, production, administrative overhead, and low carbon footprint are the main factors to consider in order maintaining organizational stability in the construction industry. The results of this research indicate benefits for both large and small companies to increase profit and efficiency in the industry, and this model may assist companies to create a systematic approach by utilizing optimization theories and mathematical modeling.

3 - Managing Randomization in the Multi-block Alternating Direction Method of Multipliers for Quadratic Optimization

Mingxi Zhu, Stanford University, Stanford, CA, United States, mingxiz@stanford.edu, Kresimir Mihic, Yinyu Ye

The Alternating Direction Method of Multipliers (ADMM) has gained a lot of attention for solving large-scale constrained optimization. Enforcing a multi-block structure leads to computational efficiency. In this paper, we add randomness into the multi-block ADMM by developing a randomly assembled cyclic ADMM (RAC-ADMM) where the decision variables in each block are randomly assembled. We discuss the theoretical properties of RAC-ADMM and show when random assembling helps and when it hurts. Using the theoretical guidance on RAC-ADMM, we conduct multiple numerical tests. Our numerical tests show that RAC-ADMM could significantly improve the computation efficiency.

4 - Integrated Truck and Workforce Scheduling in Cross-Docks

Pascal Wolff, Technische Universität Darmstadt, Darmstadt, Germany, wolff@scnm.tu-darmstadt.de, Jiazhen Huo, Hans-Christian Pfohl

Besides its increasing practical relevance, cross-docking also received a lot of academic attention in the last two decades. A vast number of publications dealt with the determination of optimal truck schedules. However, most of the proposed models are detached from industry practice since they do not consider available workforce. In this paper, we address this research gap and propose novel model formulations which integrate the planning of truck and workforce schedules in a cross-dock. Furthermore, we present exact and heuristic solution approaches to tackle the problems.

5 - Reducing Forklift Congestion in an LTL Cross-docking Terminal

Vahid Ghomi, Penn State University at Mont Alto, Mont Alto, PA, United States, vahid.ghomi@gmail.com, Mina Ghofrani Esfahani

Tabu-search (TS) is used to solve a cross-docking quadratic assignment problem (CDAP). The model concerns to minimize the total weighted traveled distance (WTD) and congestion cost (WCC). Taguchi robust parameters settings is employed to achieve the best combination of the six signal factors while removing the effect of noise factors. Using the Taguchi method, we assume the smaller-the-better signal-to-noise ratio and TS's diversification methods are considered as noise factors. The result suggests that the best way to improve TS output quality is to start it from the best initial solution. Testing 45 instances, TS outperforms the hill-climbing and CPLEX solution.

6 - The Yard is the Heart - Analysing Yard Strategies to Match Container Terminal Business Strategies

Leif Meier, University of Applied Sciences Bremerhaven, Bremerhaven, Germany, lmeier@hs-bremerhaven.de

The yard strategy defines procedures and a methodology for a terminal to assign containers to a specific yard position. Yard management has been identified as a key competency of a container terminal to ensure an efficient container flow and customer requirements resulting in minimum handling costs and it must be aligned with the berthing strategy to minimize distances on the yard. We defined realistic yard filter sets and simulate resulting receival and delivery pattern to be matched against multiple criteria from business target functions.

1 - Intersecting Restrictions in Clutters

Gerard P. Cornuejols, Carnegie Mellon University, Tepper School of Business, Pittsburgh, PA, 15213-3890, United States, gc0v@andrew.cmu.edu

A clutter is intersecting if the members do not have a common element yet every two members intersect. It has been conjectured that for clutters without an intersecting minor, total primal integrality and total dual integrality of the corresponding set covering linear system must be equivalent. In this talk, we provide a polynomial characterization of clutters without an intersecting minor. This is joint work with Ahmad Abdi and Dabeen Lee.

2 - Minimum Spanning Trees on Infinite Graphs

Christopher Ryan, University of Chicago, Chicago, IL, 60637, United States

We discuss the problem of finding minimum spanning trees (MSTs) on graphs with countably many nodes and arcs. We find the naive extensions of greedy algorithms, familiar in the finite setting, do not necessarily converge to minimum spanning trees. We propose a non-greedy algorithm, that finds MSTs on finite subgraphs in each iteration, converge (possibly along a subsequence) to a spanning tree. This result, however, only holds for graphs that has no infinite length cycles.

3 - Semidefinite Programming Relaxations of the Traveling Salesman Problem

Samuel C. Gutekunst, Cornell University, Ithaca, NY, 06883, United States, scg94@cornell.edu, David P. Williamson

The traveling salesman problem (TSP) is a fundamental problem in combinatorial optimization. Several semidefinite programming (SDP) relaxations have been proposed recently that perform strongly in small computational tests; these experiments motivate theoretical interest in the SDPs. We characterize the worst-case performance of these relaxations by showing that several major TSP SDP relaxations have an unbounded integrality gap. To do so, we provide a family of simplicial TSP instances that form a litmus test for future SDP relaxations.

4 - Parallel Hypergraph Matching

Oussama Hanguir, Student, Columbia University, New York, NY, 10025, United States, oh2204@columbia.edu, Clifford Stein

As massive graphs become ubiquitous, the need for scalable algorithms that solve graph problems grows as well. We are interested in the Maximum Hypergaph Matching Problem in the massively parallel computation (MPC) model that is a common abstraction of MapReduce-style computation. This problem arises in many applications where we need to partition elements under strong constraints, including scheduling airline flight crews to airplanes or finding the optimal coalition in cooperative games. We present the first three algorithms for Hypergraph Matching in the MPC model, and we analyze them in terms of resources such as memory usage, rounds of communication needed, and approximation ratio.

Nonconvex Optimization in Machine Learning

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Ethan Xingyuan Fang, Pennsylvania State University, University Park, PA, 16802, United States

1 - Towards understanding the Importance of Noise in Training Neural Networks

Tuo Zhao, Georgia Tech, NW, Atlanta, GA, 30332, United States, tourzhao@gatech.edu, Mo Zhou, Tianyi Liu, Yan Li, Dachao Lin, Enlu Zhou

Stochastic Gradient Descent-type (SGD) algorithms have been widely applied to many nonconvex problems in machine learning. In this talk, we propose to analyze the behavior of the SGD-type algorithms through a simple but nontrivial nonconvex problem - Training Nonoverlapping Two-layer Convolutional Neural Networks. Specifically, we show that in conjunction with noise annealing, perturbed-GD attains sublinear convergence to the global optimum with high probability. Our theory not only helps better understand SGD, but also provides new insights on more complicated nonconvex problems in machine learning.

2 - On the Global Convergence of Policy Optimization in Deep Reinforcement Learning

Zhaoran Wang, Northwestern University, Evanston, IL, United States, zhaoran.wang@northwestern.edu

Policy optimization (with neural networks as actor and critic) is the workhorse behind the success of deep reinforcement learning. However, its global convergence remains less understood, even in classical settings with linear function approximators. In this talk, I will show that coupled with neural networks, a variant of proximal/trust-region policy optimization (PPO/TRPO) globally converges to the optimal policy. In particular, I will illustrate how neural networks enable us to establish much stronger guarantees. (Joint work with Qi Cai, Boyi Liu, Zhuoran Yang)

3 - Variational Transport: A Convergent Particle-Based Algorithm for Distributional Optimization

Zhuoran Yang, Princeton University, Sherrerd Hall, Department of ORFE, Princeton, NJ, 08544, United States

We consider the problem of minimizing a functional defined over a family of probability distributions, where the functional is assumed to have a variational form. For this problem, we propose the variational transport algorithm, which approximately performs functional gradient descent over the manifold of probability distributions via iteratively pushing a set of particles. By characterizing both the statistical error of estimating the functional gradient and the computational error of optimization algorithm, we show that the proposed algorithm enjoys global convergence with high probability. This is based on a joint work with Zhaoran Wang and Yongxin Chen.

4 - Combinatorial Inference in Large-Scale Graphs

Junwei Lu, Harvard University, Cambridge, MA, United States

We present computationally efficient algorithms to test various combinatorial struc- tures of large-scale graphical models. In order to test the hypotheses on their topological structures, we propose two adjacency matrix sketching frameworks: neighborhood sketching and subgraph sketching. The neighborhood sketching algorithm is proposed to test the connectivity of graphical models. This algorithm randomly subsamples vertices and conducts neighborhood regression and screening. The global sketching algorithm is proposed to test the topological properties requir- ing exponential computation complexity, especially testing the chromatic number and the maximum clique. This algorithm infers the corresponding property based on the sampled subgraph. Our algorithms are shown to substantially accelerate the computation of existing methods. We validate our theory and method through both synthetic simulations and a real application in neuroscience.

Recent Advances in Stochastic Integer Programming

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Rui Chen, University of Wisconsin, Madison, WI, United States

1 - On Solving Nonconvex Two-stage Stochastic Programs with Generalized Benders Decomposition

Can Li, Carnegie Mellon University, Pittsburgh, PA, United States, canl1@andrew.cmu.edu, Ignacio E. Grossmann

In this paper, we propose a generalized Benders decomposition-based branch and cut algorithm for solving two stage stochastic mixed-integer nonlinear programs (SMINLPs) with mixed binary first and second stage variables. At a high level, the proposed decomposition algorithm performs spatial branch and bound search on the first stage variables. Each node in the branch and bound search is solved with a Benders-like decomposition algorithm where both Lagrangean cuts and Benders cuts are included in the Benders master problem. The performance of the proposed algorithm is compared with a Lagrangean decomposition-based branch and bound algorithm.

2 - Value of Multistage Stochastic Programming in the Rolling-horizon Procedure: A Computational Study

Yongjia Song, Clemson University, Clemson, SC, United States, yongjis@clemson.edu, Murwan Siddig

In this talk, we will present an adaptive stochastic look-ahead algorithmic framework for sequential decision making under forecast ambiguity. We aim to investigate the value of multi-stage stochastic programming as a look-ahead policy within the rolling-horizon procedure. To facilitate such understanding, we employ a variety of computational tools within this framework to effectively balance various sources of errors and uncertainty that come from the underlying stochastic processes, the Monte Carlo samples generated to solve the SP models, and model approximations and aggregations. Preliminary results will be presented.

3 - Two-stage Stochastic Conic Mixed Integer Programs

Manish Bansal, Virginia Tech, Blacksburg, VA, United States, bansal@vt.edu

In this talk, we present our recent advances on solving two-stage stochastic conic mixed integer programs.

4 - A New Cutting Plane Approach for Approximately Calculating the Lagrangian Dual of a Stochastic Integer Program

Rui Chen, University of Wisconsin-Madison, Madison, WI, United States, rchen234@wisc.edu, James Luedtke

We propose a new cutting plane approach for approximately calculating the nonanticipative Lagrangian dual bound of a two-stage stochastic integer program. We develop a family of cuts for the Benders master problem that can be generated by solving single scenario integer programs. We show that optimizing the Benders master problem with all of these cuts added yields the Lagrangian dual bound. Judicious use of these cuts within a branch-and-cut framework could lead to faster convergence. Preliminary computational results demonstrate the strength of the proposed approach in comparison with some existing decomposable methods.

Risk-Averse Stochastic Programming: Theory and Applications

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Weijun Xie, Virginia Tech, Blacksburg, VA, 24061, United States

1 - Risk Aversion to Parameter Uncertainty in Markov Decision Processes

Merve Merakli, Northwestern University, Evanston, IL, United States, merakli@northwestern.edu, Simge Kucukyavuz

In classical Markov Decision Processes (MDPs), action costs and transition probabilities are assumed to be known, although an accurate estimation of these parameters is often not possible in practice. This study addresses MDPs under cost and transition probability uncertainty and aims to provide a mathematical framework to obtain policies minimizing the risk of high long-term losses due to not knowing the true system parameters. To this end, we utilize the risk measure value-at-risk associated with the expected performance of an MDP model with respect to parameter uncertainty. We provide mixed-integer linear and nonlinear programming formulations and heuristic algorithms for such risk-averse MDPs under a finite distribution of the uncertain parameters. Our proposed models and solution methods are illustrated on an inventory management problem for humanitarian relief operations during a slow-onset disaster.

2 - Zeroth-order Algorithms for Risk-averse Optimization

Dionysios S. Kalogerias, Princeton University, Charlton Street, Princeton, NJ, 08544, United States, dkalogerias@princeton.edu, Warren B. Powell

We present Free-MESSAGEp, the first zeroth-order algorithm for optimizing convex mean-semideviation risk functions, which is also the first zeroth-order compositional stochastic optimization algorithm, whatsoever. Using a non-trivial extension of Nesterov's results on Gaussian smoothing, we develop the Free-MESSAGEp algorithm on a smoothed version of our problem, and we explicitly relate it to the original problem. We then present a complete analysis of the Free-MESSAGEp algorithm, which shows convergence in a tunable neighborhood of the optimal solutions of the original problem, essentially striking a certain balance between problem dimensionality and algorithmic implementation.

3 - Finding Minimum Volume Ellipsoids Using Copositive Programming with an Application to Risk-averse Stochastic Programming

Grani Adiwena Hanasusanto, The University of Texas at Austin, Austin, TX, 78712, United States, Areesh Mittal

We study the problem of finding an ellipsoid of minimum volume that contains a given convex set. We reformulate the problem as a copositive program and use that reformulation to derive tight, tractable semidefinite approximations. We prove that our method never provides an ellipsoid of higher volume than the one obtained by scaling the maximum volume inscribed ellipsoid. We empirically demonstrate that our method generates high-quality solutions faster than solving the problem to optimality and outperforms the existing schemes in terms of solution time and quality. We present an application in the design of improved decision rule approximations for two-stage problems with random recourse.

4 - A Geometric Branch and Bound Method for Concave Robust Optimization with Functional Form Uncertainty

Sanjay Mehrotra, Northwestern University, Evanston, IL, 60208-3119, United States, mehrotra@iems.northwestern.edu, Fengqiao Luo

We study the minmax optimization problem where the inner problem is defined over a set of concave functions. These problems are significantly harder than the models where the inner problem is defined over a set of convex functions. For the case where the functions specifying the inner problem are piecewise linear, we give a mix-integer formulation of the model. We then present a novel geometric branch-and-bound method that systematically explores the feasible solutions. This method is extended to the case of more general concave functions. Computational results show that the proposed B&B method performs significantly better than the MIP formulations of the problem for the piecewise linear case.

Joint Session RAS/Practice Curated: Railroad Maintenance

Sponsored: Railway Applications

Sponsored Session

Chair: Qing He, University at Buffalo, SUNY, Buffalo, NY, 14260, United States

1 - Rail Service Failure Analysis: A Data-drive Approach

Faeze Ghofrani, University at Buffalo, Buffalo, NY, 14228, United States, Seyedsina Yousefianmoghadam, Qing He, Andreas Stavridis

In maintenance planning of rail track, it is essential to assess the potential of service failures. In the present study a new method is proposed to study the factors affecting the risk of rail service failures. The method is applied to the prediction of service failures for a US Class I Railroad. The outcome of this study, along with necessary future developments to broaden the scope of applicability of the method, will benefit railroad existing practice in capital and maintenance planning.

2 - Joint Optimization of Track Maintenance and Renewal Planning

Reza Mohammadi, University at Buffalo, Amherst, NY, 14228, United States, rm245@buffalo.edu, Qing He

We propose a data-driven robust optimization approach for joint planning of track maintenance and renewal activities. The optimization problem is formulated as a mixed integer programming model that maximizes the quality index of the track. This approach captures the uncertainty of the maintenance effects using a data-driven method and builds a robust mathematical model based on that uncertainty. Numerical results demonstrate clear trade-offs between maintenance and renewal activities to achieve the optimal track quality index.

3 - Using Smartphones to Assess Vehicle Running Quality and Track Conditions of Urban Rail Transit

Qing He, University at Buffalo, SUNY, Buffalo, NY, 14260, United States, qinghe@buffalo.edu, Jianli Cong

This paper uses smartphones as an inspection device in urban rail transit to evaluate the vehicle running quality and track conditions. Also, this paper proposes a data-cleaning method and a coordinate alignment method for processing smartphone collected data. The location of placing the smartphone in the car has been examined.

4 - Machine Learning for Predictive Maintenance of Positive Train Control (PTC) System

Clark Cheng, Chief Data Scientist, Norfolk Southern Corporation, Atlanta, GA, 23510, United States, Clark.Cheng@nscorp.com, Mabby Amouie, Ilya Lavrik

To ensure safe operations, freight railroads in North American have adopted positive train control (PTC) which is an advanced system designed to automatically stop a train before an accident occurs. Norfolk Southern has spent over $1.7 billion implementing PTC on about 8,000 miles of rail network. Given the importance and complexity of PTC, we developed a machine learning approach to predicting potential failures. In this presentation, we'll describe the methodology and results.

5 - Optimizing Conditioned-Based Maintenance and Investment in Shared Freight and Passenger Corridors

John F. Betak, Managing Member, Collaborative Solutions LLC, 726-23 Tramway Vista Dr NE, Albuquerque, NM, 87122, United States, john@collaborativesolutionsllc.com, Trefor P. Williams

In the US, most intercity passenger service track is in shared use corridors. This paper combines four methodological approaches to optimize condition-based track maintenance and investment in this environment; 1) automated text analysis; 2) calculated conditional probabilities in network-level scheduling problems; 3) integrating track inspection optimization models with ERM optimization models; 4) advanced data visualization techniques for decision support systems.

Sponsored Session

Chair: Sven Leyffer

Chair: Mohan Krishnamoorthy

Chair: Sara Shashaani, North Carolina State University, Raleigh, NC, 48105, United States

1 - Bi-level Optimization for Design of Experiments

Mohan Krishnamoorthy, Argonne National Laboratory, Lemont, IL, 60439, United States, mkrishnamoorthy@anl.gov

We propose a bi-level optimization approach where in the upper level, we solve an optimization problem that chooses the experimental parameters using DFO. In the lower level, we solve an inverse problem to match observations to a model whose gradients are not available. Instead of relying on data generated through Monte-Carlo (MC) simulations, we propose an approach that approximates the parameters of the model as a pole-free rational function, which is obtained through an optimization formulation with structural constraints. Results show significant improvement in quality of tunes and the rational approximation are of high quality while being significantly more efficient than MC simulations.

2 - Decomposition in Simulation-based Optimization

Kaiwen Ma, Carnegie Mellon University, Pittsburgh, PA, United States, Nikolaos Sahinidis, Sreekanth Rajagopalan, Satyajith Amaran, Scott Bury

We propose a novel decomposition framework for simulation-based optimization. Our framework significantly extends the scope of current simulation-based solvers to larger-scale problems. We address several key questions, including how to select variables for each subproblem, and how to determine sub-problem dimension and sub-problem function evaluation limits. A practical implementation is developed and exemplified with the global model-based solver Stable Noisy Optimization by Branch and Fit (SNOBFIT). Significant improvements in the quality of solutions obtained under a 2500 function evaluation limit are observed for a large fraction of the test problems.

3 - Multi-Objective Two-Stage Stochastic Programming with Probabilistic Branch and Bound and Monte-Carlo Simulation

Hao Huang, Assistant Professor, Yuan Ze University, Taoyuan, Taiwan, haohuang@saturn.yzu.edu.tw

The main objective is to develop a multiple objective algorithm for two-stage resource allocation problems with statistical distribution uncertainty, simultaneously considering cost and risk assessment, by combining simulation optimization, Monte-Carlo simulation and mixed integer linear programming techniques. Specifically, a constrained version of Multiple Objective Probabilistic Branch and Bound with mixed-integer variables is introduced and applied to the first stage search, where the evaluation of second stage is performed with Monte-Carlo simulation.

4 - Autotune: A Derivative-free Optimization Framework for Hyperparameter Tuning

Yan Xu, SAS Institute, Inc., 1075 Upchurch Farm Lane, Cary, NC, 27519, United States, Yan.Xu@sas.com

Machine learning applications often require hyperparameter tuning. The hyperparameters usually drive both the efficiency of the model training process and the resulting model quality. For hyperparameter tuning, machine learning algorithms are complex black-boxes. This creates a class of challenging optimization problems, whose objective functions tend to be nonsmooth, discontinuous, unpredictably varying in computational expense. We present an automated parallel derivative-free optimization framework called Autotune, which combines a few specialized sampling and search methods that are very effective in tuning machine learning models despite these challenges.

5 - Efficiency of the Adaptive Sampling Trust-Region Optimization Derivative-Free (ASTRO-DF)

Sara Shashaani, North Carolina State University, 1221 Island Dr Apt 104, Raleigh, NC, 48105, United States, sshasha2@ncsu.edu, Raghu Pasupathy

ASTRO-DF is a class of adaptive sampling algorithms for solving simulation optimization problems that are derivative-free in the sense that they do not rely on direct observations of the function derivatives. The salient feature is adapting the computation effort to the algorithm trajectory to ensure efficiency. ASTRO-DF has been demonstrated to generate iterates that globally converge to a first-order critical point with probability one. We now identify the time complexity in two aspects: iterations and total work. We compare these complexities to those obtained from methods that use traditional random or fixed sampling rules.

Optimization Problems in Social Networks

Sponsored: Optimization/Network Optimization

Sponsored Session

Chair: Chrysafis Vogiatzis, North Carolina A&T State University, Greensboro, NC, 27411, United States

1 - On Polyhedra of Two Influence Maximization Problems in Social Networks

Cheng-Lung Chen, University of Central Florida, Orlando, FL, 32816, United States, chenglung@knights.ucf.edu, Vladimir Boginski, Qipeng Phil Zheng, Eduardo Pasiliao

Influence maximization problem in social networks has attracted more attention recently because of the rise of online social media platforms. Various studies have been focused on the improvement of approximation algorithm to find the optimal seed location so as to maximize total number of activated nodes. In this study, we investigate the polyhedral structure of the maximum active set formulation and its extension. We derive valid inequalities for both single and dual bound threshold on nodes and demonstrate the validity and strength of the proposed inequalities.

2 - Identifying Outlier Groups Using Combinatorial Optimization

Chrysafis Vogiatzis, North Carolina A&T State University, Greensboro, NC, 27411, United States, cvogiatzis@ncat.edu

In this talk, we present a variant of the graph bipartitioning problem, in which structural requirements are imposed. In addition to the homogeneity criterion of traditional graph bipartitioning, we also impose that one of the subgraphs satisfies a predefined structural property, i.e., the subgraph induces a given motif. This extension has applications in identifying fringe, outlier groups in online social networks. We derive the complexity of the problems, provide mathematical formulations for the problem, and present techniques to solve them exactly and heuristically. We conclude the talk with our computational results in both real-life and randomly generated networks.

3 - Presenter

Sean Suehr, North Carolina Agricultural and Technical State University, Greensboro, NC, 27411, United States, ssuehr@aggies.ncat.edu, Chrysafis Vogiatzis

Criminal networks are complex due to the limited and imperfect data available. In addition, entities participating in a criminal network tend to misrepresent themselves to entities outside the network. In this talk, we propose formulations to identify groups of entities that are prone to misrepresent themselves by enforcing a minimum distance between different neighbors of the group. We use newly developed formulations for k-clubs and we also extend the problem to other clique relaxations such as k-plexes and k-cores. We also propose valid inequalities and compare their performance to commercial solvers. Finally, we present computational results on a series of real-life and synthetic networks.

Modeling and Optimizing the Resilience of Networked Systems

Sponsored: Optimization/Network Optimization

Sponsored Session

Chair: Andres David Gonzalez, University of Oklahoma, Norman, OK, 73019, United States

Co-Chair: Camilo H Gomez, Universidad de los Andes, Bogota, Colombia

1 - Community Resilience Planning Decision Support via a Two-stage Stochastic Programming Model Integrating Critical Path Method and Flow Based Modeling

Kenneth W. Harrison, NIST, Gaithersburg, MD, United States, kenneth.harrison@nist.gov

NIST's Community Resilience program provides guidance for reducing hazard impacts — 2017 Hurricanes alone were estimated to cost $265 billion (FEMA) and displaced many. NIST's ARC model, a two-stage stochastic integer linear programming model, aids in the identification of effective mitigation actions (1st stage) while recognizing the costs and other challenges of recovery (2nd stage). Here, the recovery modeling is described, which includes critical path method-like calculations for a flow-based network that captures complex interdependencies among the involved physical (e.g., infrastructure) and social systems (e.g., housing). Results from a flood-based case study are presented.

2 - Auction-based Resource Allocation in Decentralized Decision Making for Interdependent Networks

Hesam Talebiyan, PhD Student, Rice University, Houston, TX, United States, Hesam.talebiyan@rice.edu, Leonardo Duenas-Osorio

The desired performance of decentralized decision makers is highly influenced by the number of available resources, and in turn, the mechanism used to allocate resources among them. In this talk, we propose that decision makers may engage in an "auction" to bid for resources and capture field-observed post-disaster decision processes. We explore different auction types and bidders' valuations, and compare them regarding computational burden and the ability to approach optimal resource allocations. We apply our approach to idealistic and real-world interdependent networks, and show that first- and second- price auctions significantly reduces the sub-optimality of decentralized plans.

3 - Modeling Infrastructure Operation Through Public-private-Partnerships - An Optimization-based Approach Combining Technical and Institutional Aspects

Camilo Gomez, Universidad de los Andes, Bogota, Colombia, gomez.ch@uniandes.edu.co, Camilo Daza, Jorge-Mario Lozano, Diego Castiblanco, Andres David Gonzalez

The operation and management of critical infrastructure systems depend on intensive logistical planning as well as on the institutional and regulatory context. Public-Private-Partnerships (PPPs) are a compelling means to carry out infrastructure projects. However, PPPs are prone to the 'agency problem', which states that one party (i.e., the private one) does not necessarily act in the best interest of the other (i.e., the public one). We propose a Mixed Integer Programming model to understand and address potential conflicts of interest in PPPs in the context of infrastructure maintenance problems (e.g., a contractor failing to comply with safety requirements in order to increase profits).

4 - Optimizing Supply Chain Network Restoration with Fair Distribution

Andres David Gonzalez, University of Oklahoma, Norman, OK, 73019, United States, Mastoor Abushaega

Supply chain networks are constantly under hazards associated with natural disasters and targetted attacks. Thus, being able to restore then quickly is imperative. In this paper, we propose a mathematical model that focuses on minimizing the unmet demands and restoration costs associated with a supply chain network, while guaranteeing that the distribution of commodities is done fairly. We show that by enforcing the fair distribution of commodities, the service levels are kept at high levels across the supply chain network.

5 - Network Resilience: How Firms Can Survive Economic Shocks

Toby Li, Texas A&M University, College Station, TX, United States, Taoufik Zormati, Andres David Gonzalez

Economic shocks cause businesses to fail, which can further exacerbate the resulting subsequent industry downturns. We ask whether a firm can strategically structure its network of partners - specifically the types of partners and the relationships with those partners - to make it more or less resilient to these economic shocks. We introduce this idea of "corporate network resilience" and offer unique features common for firms successfully building such a network. Our context is drillers and their network of client operators in the oil-gas industry during oil price shocks over the past three decades.

1 - Geometric Properties and Solution Methods for Inverse Mixed Integer Optimization

Ian Yihang Zhu, University of Toronto, 5 King's College Road, Toronto, ON, M5S3G8, Canada, i.zhu@mail.utoronto.ca, Merve Bodur, Timothy Chan

Inverse optimization (IO) broadly defines the set of problems in which we use a set of solutions of a "forward" optimization problem to infer unknown parameters of the forward problem. In this talk, we focus on the inverse mixed integer optimization problem, which denotes the problem of inferring the objective function of a mixed integer programming problem by observing a solution to that problem. We present new insights into the geometric properties of these problems, and propose a set of enhancements to be used in conjunction with existing cutting-plane approaches that lead to substantial computational gains in MIPLIB benchmark instances.

2 - A Simulated Annealing Based Approach for the Directed Steiner Tree Problem

Matias Siebert, Georgia Tech, Atlanta, GA, United States, msiebert6@gatech.edu

A new approach for the directed Steiner tree problem has been recently proposed, which consists in solving a set of integer programs (IP). Each IP finds an optimal directed Steiner tree with a specific structure, and can be solved in polynomial time. But, the number of IPs to solve grows exponentially with the number of terminal nodes. We propose a Simulated Annealing based approach to address the latter issue. We present an algorithm to solve each subproblem efficiently, and a complete characterization of the neighborhood of each tree structure.

3 - On the Depth of Cutting Planes

Laurent Poirrier, University of Waterloo, Combinatorics and Optimization, Waterloo, ON, N2L 3G1, Canada, James Yu

Cut selection has become a major question in Integer Programming. We can now compute many cuts, but we cannot add them all, and it is not clear how we should be selecting the "best" ones. To that end, we propose a concept of "depth" that applies to individual cutting planes as well as entire families. It has a natural definition and nice properties that make it easy to work with theoretically, and we argue that it is a good proxy for the practical strength of cuts. In particular, we give parametric upper bounds on the depth of two prominent types of cutting planes, which nicely line up with computational observations. Finally, we show how to efficiently compute the depth of an individual cut.

4 - Online Optimization for Ride-sharing

Ezgi Karabulut, Rensselaer Polytechnic Institute, Troy, NY, 12180-2406, United States, karabe@rpi.edu, Jennifer A. Pazour

A ride-sharing problem can be formulated as a bilevel optimization problem, where the leader is the platform, maximizing the platform's utility, and the followers are the set of drivers, maximizing their individual utilities. This problem can also be interpreted as an online optimization problem, where the ride-sharing problem needs to be solved repetitively for multiple iterations with changing data at every iteration, and where the followers' data is not directly accessible by the leader. Our goal is to continuously learn the followers' information throughout the iterations to improve the performance of the leader's bilevel optimization problem.

Chair: Wei Wang, University of Pittsburgh, Pittsburgh, PA, United States

1 - Quantifying a Game-theoretic Model of Pre-disaster Relocation from Two Coastal Cities

Yuqun Zhou, University of Wisconsin, Dept of Ind Eng Mechanical Eng Bldg, Madison, WI, 53706, United States, yzhou364@wisc.edu

In the face of sea-level rise, encouraging pre-flood retreat can be an effective way to reduce disaster damage, especially for vulnerable coastal cities. We apply our previous game-theoretic model to major U.S. coastal cities, using realistic estimates of future sea-level rise, realistic housing prices, and realistic government and resident discount rates. Results make it possible to assess the efficacy of "nudge" policies (i.e., government incentives encouraging voluntary relocation) as a function of flood probability, house elevation, property value, and resident/government discount rates.

2 - Interdependent Water & Electricity Distribution in the Virgin Islands

Daniel A. Eisenberg, Research Assistant Professor, Naval Postgraduate School, 1 University Circle, Monterey, CA, 93943, United States, daniel.eisenberg@nps.edu

In September 2017, Hurricanes Irma and Maria made landfall in the US Virgin Islands (USVI) Territory causing significant damage to local infrastructure. Since this event, recovery efforts for water and power infrastructure on St. Croix have been hampered by interdependent losses across both systems. This work presents interdependent operator models for water and electricity infrastructure systems and identifies operations and system designs that improve their resilience. Specifically, we develop a simulation optimization that uses couples the both systems models together and locates decision variable values that maximize (best-case) or minimize (worst-case) performance.

3 - A New Defender-attacker-defender Model for System Protection

Wei Wang, University of Pittsburgh, Pittsburgh, PA, 15261, United States, w.wei@pitt.edu, Bo Zeng

Traditional defender-attacker-defender (DAD) game, seeking optimal defense or hardening strategies against physical attacks, is widely used in many infrastructure protection applications. However, it ignores the possible restrictions that can be placed by the defender in the decision-making process of the attacker. In this study, we formulate a new DAD game model to fully utilize this advantage of the defender. Novel reformulation and decomposition techniques are developed for solving the resulting complex problem. Computational experiments on typical power grids will be presented to illustrate the advantages of our new model and the solution method.

4 - Strategic Interdiction of Network Flows

Mathieu Dahan, Georgia Institute of Technology, Atlanta, GA, United States, mdahan@mit.edu, Saurabh Amin, Patrick Jaillet

In this talk, we consider a generic network security game on flow networks. In this game, a routing entity sends its flow through the network while facing transportation costs, and an interdictor simultaneously interdicts multiple edges while facing interdiction costs. By proving the existence of a probability distribution on a partially ordered set that satisfies a set of constraints, we show that the equilibrium properties of the game can be described using primal and dual solutions of a minimum-cost circulation problem. Our analysis provides a new characterization of the critical network components in strategic flow interdiction problems.

Chair: Albert Berahas

1 - Analysis of the BFGS Method with Errors

Yuchen Xie, Northwestern University, Evanston, IL, 60201, United States, ycxie@u.northwestern.edu, Richard Byrd, Jorge Nocedal

The classical theory for BFGS method assumes that the function and gradients employed at each iteration are exact. In this study, we consider the case when there are (bounded) errors in the function and gradients computations, and establish conditions under which a slight modification of the BFGS algorithm with the standard Armijo-Wolfe line search converges to a neighborhood of the solution that is determined by the size of the errors. We present both theoretical analyses and numerical results illustrating the performance of the new BFGS method in the presence of noise.

2 - Limited-Memory BFGS with Displacement Aggregation

Baoyu Zhou, Lehigh University, Bethlehem, PA, United States, baoyu.zhou@lehigh.edu, Albert S. Berahas, Frank E. Curtis

We present a displacement aggregation strategy for the curvature pairs stored in a limited-memory BFGS method such that the resulting (inverse) Hessian approximations are equal to those derived from a full-memory BFGS method. Using said strategy, an algorithm employing the limited-memory method can achieve the same convergence properties as when full-memory Hessian approximations are employed. We illustrate the performance of an LBFGS algorithm that employs the aggregation strategy.

3 - Behavior of L-BFGS on Nonsmooth Problems in Theory and in Practice

Azam Asl, NYU, 251 Mercer st., New York, NY, 10012, United States, Michael Overton

When applied to minimize nonsmooth functions, the “full” BFGS method works remarkably well, typically converging linearly to Clarke stationary values, with no counterexamples to this behavior known in the convex case, though its theoretical behavior is not yet well understood. In contrast, limited-memory BFGS may converge to non-stationary values, even on a simple convex function, but this seems to be rare. We summarize our experience with L-BFGS in both theory and practice.

4 - A Log-barrier Newton-CG Method for Bound Constrained Optimization with Complexity Guarantees

Michael O’Neill, University of Wisconsin-Madison, Madison, WI, United States, mjoneill2@wisc.edu, Stephen J. Wright

We describe an algorithm based on a logarithmic barrier function, Newton’s method, and linear conjugate gradients, that obtains an approximate minimizer of a smooth function over the nonnegative orthant. We develop a bound on the complexity of the approach, stated in terms of the required accuracy and the cost of a single gradient evaluation of the objective function and/or a matrix-vector multiplication involving the Hessian of the objective. The approach can be implemented without explicit calculation or storage of the Hessian.

Transportation Network Resilience and Planning for Emergency Response

Sponsored: Transportation Science & Logistics/Intelligent Transportation Systems (ITS)

Sponsored Session

Chair: Nasrin Mohabbati Kalejahi, Auburn University, Auburn, AL, 36832, United States

1 - A Data-driven Resilience-based Approach for understanding the Operation of Transportation System

Farnaz Khaghani, Virginia tech, Blacksburg, VA, United States, farnazk@vt.edu

Traffic congestion has negative impacts on the general operation of urban communities. We propose using the concept of resilience, which usually has been used for extreme events and disturbance to the transportation system, for high-probability low impact events to quantify and assess traffic congestion and study the performance behavior of roadways. We determine the potential causes and drivers of the bottlenecks and look at the infrastructure options to improve the performance of the system through a data-driven multi-dimensional approach. Knowing the potential causes can lead to automotive and more efficient mitigation strategies to move towards sustainable and resilient mobility.

2 - Robust Optimization Model for Hazardous Materials Closed-loop Supply Chain Network Design with Locating Emergency Response Teams

Nasrin Mohabbati Kalejahi, Assistant Professor, California State University, San Bernardino, CA, United States, nasrin@auburn.edu, Alexander Vinel

In this study, we investigated the hazmat closed-loop supply chain network design problem and proposed a bi-objective stochastic robust mathematical formulation with the aim of minimizing the strategic, tactical and operational costs as well as the risk exposure on the road network. The proposed model provides a set of Pareto optimal solutions for locating the hazmat facilities such as production, distribution, collection, recovery and disposal centers, their corresponding capacities, the quantity of shipments across the network, and hazmat route planning. The emergency response team location decisions are made simultaneously with forward and reverse logistics design.

3 - Cyber-vulnerability Analysis for Connected Vehicle Based Traffic Signal Control Systems

Shihong Huang, University of Michigan, Ann Arbor, MI, United States, edhuang@umich.edu, Wai Wong, Yiheng Feng, Alfred Chen, Morley Mao, Henry Liu

Connected vehicle (CV) technology has great potentials in improving traffic signal control systems (TSCSs). On the other hand, the connectivity might open a new door for cyber attacks, if the vulnerabilities of the control systems can be identified and utilized by attackers. In order to effectively defend CV-TSCSs against cyber attacks, vulnerability analysis is the premise step. In this study, we propose a generic analysis approach for identifying the cyber-vulnerabilities of CV-TSCSs. A surrogate model is used to learn signal control logic and a feature selection method is applied to identify vulnerable traffic features. A comprehensive case study shows that the proposed approach is effective.

4 - Using Connected Vehicle Technology to Improve Emergency Response Vehicle Travel in an Urban Transportation Network

Thidapat Chantem, Virginia Tech, Blacksburg, VA, United States, Gaby Joe Hannoun, Pamela Murray-Tuite, Kevin Heaslip

A system using the connected vehicle technology is proposed to assist an emergency response vehicle’s (ERV) travel. The core of the system is an integer linear program that generates, as the ERV is travelling towards its destination, the optimal ERV intra-link movement as well as instruction messages for downstream vehicles, requesting them to stop at specific locations they can reach comfortably. The system is adapted to urban transportation networks with signalized intersections and with partial market penetrations of connected vehicles. The system reduces the ERV’s travel time and vehicular interactions while limiting the effect on downstream traffic.

5 - Ambulance Location and Relocation Problem for Nagoya in Japan

Keisuke Inakawa, Doctor of Business Administration, Akita Prefectural University, Akita, Japan, inakawa@akita-pu.ac.jp

Recently, the number of calls for ambulances tends to increase in Japan, and the mean response time is also increasing. In these contexts, Nagoya City is considering a plan for adding two more ambulances. In this research, we decide the optimal locations of additional two ambulances, and we evaluate the effect of additional two ambulances by the mean response time which is computed by a Markov chains simulation model. In addition, the relocation plan is also solved by the simple Median problem, and we compare these ambulance locations by the mean response time.

1 - An Order-first Split-second Approach to an Application of the Multiple Traveling Salesman Problem

Norbert Trautmann, University of Bern, FM Quantitative Methoden, Bern, 3012, Switzerland, norbert.trautmann@pqm.unibe.ch, Chantal Schöni, Philipp Baumann

We consider a service operations management problem of a real-estate valuation company; it consists in routing on-site visits of properties such that the total operating costs are minimized subject to various constraints including a lower bound on the number of visits in each route. We propose an order-first split-second approach which first, applies the Concorde solver to determine an optimal TSP solution for the set of all visits, and second, splits this TSP solution into sequences of visits by solving a BLP. Our results for various-sized instances indicate that our approach requires less CPU time than a recent matheuristic to devise feasible solutions with comparable total costs.

2 - Generalizing the Covering Path Problem on a Grid

Liwei Zeng, Northwestern University, Evanston, IL, United States, Karen Smilowitz, Sunil Chopra

This paper generalizes the covering path problem on a grid which finds the cost-minimizing path connecting a subset of points such that each point is within a predetermined distance of a point from the chosen subset. We leverage the geometric properties of the grid to introduce simple construction techniques to provide path cost bounds within a constant factor.

3 - Consistent Routing with Simultaneous Pickups and Deliveries

Mohsen Emadikhiav, University of Connecticut, Storrs, CT, 06066, United States, Mohsen.emadikhiav@uconn.edu, David Bergman, Robert Day

We consider a new class of vehicle-routing problems with simultaneous pickups and deliveries where consistency of site visits is desired. Our problem is motivated by the operations of an instrument-calibration company, where items need to be transferred among different laboratories around the country, with multi-day processing at each facility. We develop a mixed-integer programming model and propose branch-and-check and branch-and-price implementations, with an analysis of the instance characteristics for which each of these algorithms outperforms the other.

4 - Strategic Learning in Routing Games with Private Information

Manxi Wu, Massachusetts Institute of Technology, Cambridge, MA, United States, manxiwu@mit.edu, Saurabh Amin

We study a learning dynamics in which traveler populations repeatedly route on a transportation network with an uncertain state. In each stage, travelers choose routes according to Bayesian Wardrop equilibrium based on the initially acquired private information, and the repeatedly updated public belief of the state. An information system updates the belief based on noisy stage outcomes according to Bayes' rule. We show that the belief and edge load converge almost surely to a rest point, where travelers have no incentive to deviate and the estimated costs on taken edges are accurate. We highlight some conditions under which the learning is complete in that travelers route as if they know the true state.

5 - Column Selection by Machine Learning in Exact Branch-and-price Algorithms

Mouad Morabit, Polytechnique Montreal & Gerad, Montreal, QC, Canada, mouad.morabit@gerad.ca, Guy Desaulniers, Andrea Lodi

Column generation (CG) is a well-known method for solving large-scale linear problems. In this presentation, we propose to integrate a machine learning technique in the context of CG to reduce computation time. More precisely, a classification algorithm is proposed to select promising columns at each CG iteration when solving a problem that is subject to degeneracy in the master problem. Applications to the vehicle and crew scheduling problem and the vehicle routing problem with time windows will be presented.

Chair: Sung Hoon Chung, Binghamton University, Binghamton, NY, 13902, United States

Co-Chair: Jinkun Lee, East Carolina University, Greenville, NC, 27858-4353, United States

1 - Simulation of Drone Truck Combined Operation

Jinkun Lee, East Carolina University, Engineering Dept., 1000 E. 5th St. East Carolina University, Greenville, NC, 27858-4353, United States, leejin18@ecu.edu, Sung Hoon Chung

We propose an improved drone-truck combined operation routing solution by adopting the concept of drone operation sortie and introducing a pseudo node to minimize waiting time either from drone and truck. However, an optimal solution found need to be adjusted for real world situation since there exist several constraints such as truck's extended stay time at nodes, drone's takeoff/landing time, and so on. We consider such minor but non trivial conditions by using a simulation model and compare the discrepancies between an optimal solution and the simulation result. By doing this, we identify the impact of several assumptions used at the pseudo node algorithm to simplify the problem statement.

2 - Continuous Border Surveillance Using Drones with a Dynamic Wireless Charging System

Navid Ahmadian, University of Houston, UH, Houston, TX, United States, nahmadian@uh.edu, Gino J. Lim, Maryam Torabbeigi, Seon Jin Kim

We propose a continuous surveillance system using unmanned aerial vehicles (UAVs) for border patrol. To overcome a short flight duration due to battery limitations, a dynamic wireless charging system using electrification line (E-line) is used to increase the flight time. A Mixed Integer Programming (MIP) model is introduced to minimize the total length of E-line and number of drones to minimize total expenses. This model can control the maximum time gap between two consecutive visits to a particular location of the border based on the criticality of that location.

3 - Vehicle Routing Problem with Flexible Drones

Ilke Bakir, University of Groningen, Herestraat, Netherlands, i.bakir@rug.nl, Gizem Ozbaygin

We study the vehicle routing problem with flexible drones, where the drones can switch between vehicles. We demonstrate the performance improvements provided by this flexibility compared to the setting where the drones must come back to their original vehicle. We model this problem using a time-expanded network, and provide optimal solutions for benchmark problem instances. To solve large problem instances, we present a dynamic discretization discovery (DDD) algorithm, which iteratively refines the time-expanded network. We present an extensive computational study that demonstrates the benefits provided by using flexible drones and the solution performance of DDD in this problem setting.

4 - Combined Operations for Multiple Drones and Multiple Trucks

Sung Hoon Chung, Binghamton University, Binghamton, NY, 13902, United States, Bhawesh Sah

In this talk, we discuss how combined operations for multiple doses and multiple trucks can be managed using the proposed model. In addition, a new heuristic method based on the combination of genetic algorithm, simulated annealing, and greedy algorithm in conjunction with the insertion method is proposed to solve the problem.

5 - Airship-based Drone Delivery System: Quantitative Approach for Managerial and Operational Guidelines

Ho Young Jeong, Purdue University, West Lafayette, IN, 47906, United States, Seokcheon Lee

This study aims to investigate transportation possibility by cooperative utilization of airship and drones. The airship is a type of lighter-than-air aircraft that works as a station for drones, and the drones work as a direct delivery mean to end customers. This collaborative delivery system selectively and synergistically exploits the strengths of the individual vehicles. The validity of the system is verified via a mathematical model on a realistic case study. Moreover, the quantitative analysis provides operational insight into the system and suggest managerial and operational guideline.

Transportation, Planning II

Contributed Session

Chair: Mohamad Kamal El Din Ahmad Hasan, Kuwait University, Department of Quantitative Methods & IS, CBA, Kuwait City, 13055, Kuwait

1 - Evaluating Curb Strategies to Mitigate the Impacts of Ridehailing Services on Traffic

Andisheh Ranjbari, University of Washington, Seattle, WA, United States, ranjbari@uw.edu, Anne V. Goodchild, Don MacKenzie, Jose Luis Machado, Giacomo Dalla Chiara

Increased ridehailing use leads to increased pick-up and drop-off activity. This may slow traffic or cause delays as vehicles increase curb use, conduct pick-up/drop-off activity in the travel lane, or slow to find and connect with passengers. How should cities respond to this change in an effort to keep travel lanes operating smoothly and efficiently? This research evaluates two strategies in Seattle, WA: 1) a curb allocation change from paid parking to passenger load zone, and 2) a geofencing approach, which restricts pick-up and drop-off activity to designated locations on a block. The results report the impacts on travel speeds, dwell times, curb use compliance, safety, and user satisfaction.

2 - Determining Urban Charging Infrastructure Requirement for Electric Ride Hailing Fleets

Zicheng Bi, Postdoctoral Appointee, Argonne National Laboratory, Lemont, IL, United States, zbi@anl.gov, Fei Xie, Yan Zhou, Zhenhong Lin

We propose a decision-making framework that estimates required charging infrastructure in an urban area to support electric ride-hailing operations based on specific travel demand. Without the requirement to conduct the actual network modeling, decisions are made based on probabilistic distributions of initial state of charge, geographic locations of destinations, lengths of passenger and deadheading trips, temporal arrival, and charging duration patterns, etc. This framework is used for estimating charging opportunity, market share of electric vehicles, and national energy consumption of light-duty vehicles.

3 - Developing a Sustainable Transport System under Electric and Autonomous Vehicles Dedicated Lane Deployment Scheme

Young Joun Ha, Purdue University, West Lafayette, IN, United States, ha55@purdue.edu, Mohammad Miralinaghi, Samuel Labi

While there is abundant research regarding AV-exclusive lane deployment schemes to minimize travel time, holistic considerations of sustainability are often ignored. This study presents a discrete network design problem to find an optimal AV-exclusive lane deployment scheme while considering three critical elements of sustainability: economic impact, environmental protection, and social equity. The problem is constructed as a bi-level optimization, where the upper-level captures the planner's goals to minimize travel cost and emissions while preserving equity; and the lower-level captures the behavior of travelers who seek to minimize their travel costs by choosing vehicle and route.

4 - The Morning Commute Problem with Braking and Overtaking Behaviors under Single Step Tolling

Da Xu, University of Windsor, Windsor, ON, Canada, Xiaolei Guo, Kevin W. Li

We develop a new bottleneck single step tolling model for the morning commute problem. This model considers that some commuters brake their cars to postpone their arrival at the bottleneck to avoid paying the toll, while others can overtake them to pay the toll. The overtaking cost is proportional to the number of braking commuters. Two classic single step tolling models, the separate waiting lane model and the braking model, are special cases of this new model. We seek to minimize the total system cost and find that the optimal tolling scheme depends on the unit overtaking cost.

5 - Service Network Design for Same-Day Delivery with Hub Capacity Constraints

Haotian Wu, Georgia Institute of Technology, Atlanta, GA, United States, hwu393@gatech.edu, Ian Hodara Herszterg, Martin W.P. Savelsbergh

We study a service network design problem for a same-day delivery system where the carrier must ensure that hub capacities, i.e., maximum number of vehicles that can be loaded and unloaded at the same time, are respected. We formulate the problem using an integer programming (IP) model on a time-expanded network, and develop two heuristic approaches (1) IP-based heuristic and (2) metaheuristic that solve the problem in di erent ways. We test and compare our approaches on three real-world instances with di erent geography scenarios, sizes, and planning horizon lengths from a leading Chinese package express company, and demonstrate the efficiency of proposed technologies.

6 - Supernetwork Representation Formulation of a Multiclass Simultaneous Transportation Equilibrium Model as a Fixed Demand User Equilibrium Problem

Mohamad Kamal El Din A. Hasan, Professor of Operations & Supply Chain Management, Kuwait University, Kuwait City, Kuwait, mkamal@cba.edu.kw, Mohammad Saoud, Raed Al-Husain

The Multiclass Simultaneous Transportation Equilibrium Model (MSTEM) explicitly distinguishes between different user classes in terms of socio-economic attributes, trip purpose, pure and combined transportation modes, as well as departure time, all interacting over a physically unique multimodal network. It enhance behaviorally the prediction process, however, the development of this concept of multiple classes increases the mathematical complexity of travel forecasting models. In this research, we reduce this mathematical complexity by using the Supernetwork Representation Formulation of the (MSTEM) as a Fixed Demand User Equilibrium (FDUE) Problem.

Chair: Susan Hotle, Virginia Tech, Blacksburg, VA, 24061, United States

1 - Analyzing Airport Surface Performance Using ASDX-X Surveillance Information

Susan Hotle, Virginia Tech, 200 Patton Hall, Blacksburg, VA, 24061, United States, shotle3@vt.edu

Currently, airport surface performance and delay is calculated by the FAA using a regression method where flights in the ASPM database are benchmarked based on the season of operation, airline, airport, and calendar year. The method utilizes airline-reported Gate-Out, Wheels-Off, Wheels-On, Gate-In times. The purpose of this study is to alternatively use ASDE-X surveillance information to evaluate the taxi-out and taxi-in operational performance at six large U.S. airports for the month of July 2015. Results show the benefits of using surveillance information, including spatial analysis which allows for identification of taxiway locations that were the most susceptible to delays.

2 - Delay Propagation and Causal Factors

Stephanie Atallah, Virginia Tech, Blacksburg, VA, United States, asteph93@vt.edu

Flight delay is an important metric to the FAA, providing an indicator of the NAS's operational performance by supporting ICAO's Key Performance Indicators (e.g. En-Route delay and Airport/Terminal delay). Since a single flight delay can have a chain effect in future flights operated by the same aircraft, it is important to link the propagated delay to the original source as well as identify areas in the system that promote schedule recovery. This presentation uses ASPM, OPSNET, and ASQP data to: 1) develop delay propagation performance metrics that incorporate the causal reasons for the original delay and 2) better understand factors that affect schedule recovery after the original delay occurred.

3 - Demand Forecasting and ULD Packing for the Air Cargo Industry

Bruno F. Santos, TU Delft, Kluyverweg 1, Faculty of Aerospace Engineering, Delft, 2629 HS, Netherlands, b.f.santos@tudelft.nl

We present a framework to assist air cargo revenue management. The main driver behind this research is that the dimensions of cargo are usually not known at the time of booking. The framework is composed of a forecast and an optimization block. The forecast block consists of a random forest method to predict bookings dimensions. The optimization block (i) recomputes the cargo loading strategy if the new booking is accepted, or (ii) declines the incoming request. Preliminary results are comparable, in terms of loaded cargo volume, with real cases. Booking origin was determined to be the most relevant feature when predicting piece dimensions, and an average prediction error of 9.89 cm was achieved.

4 - The Crew Pairing Problem with Language Constraints

Frederic Quesnel, GERAD, Montreal, QC, H2M 2H8, Canada, frederic.quesnel@gerad.ca

Air crew rostering is usually performed according to a two-step sequential procedure: crew pairing (CPP) and crew rostering (CRP). This talk focuses on language constraints, imposing requirements on the language skills of the crew composition of some legs, and usually included only in the CRP. One shortcoming of the sequential method is that the pairings returned by the CPP may be incompatible with the language skills of the crews. We propose a variant of the CPP, called CPP with language constraints, that includes language constraints limiting the amount of work that can be performed in any language. We present results highlighting the performance of the method on several large-scale instances.

Dynamic Algorithms for Revenue Management in Online Markets

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Shreyas Sekar, Harvard University, Cambridge, MA, 02138, United States

1 - Learning to Rank an Assortment of Products

Shreyas Sekar, Harvard University, Cambridge, MA, 02138, United States, Kris Johnson Ferreira, Sunanda Parthasarathy

We consider the product ranking challenge that online retailers face when their customers typically behave as window shoppers and have limited attention spans. We present a class of online learning-then-earning algorithms that prescribe a ranking to each customer, learning from preceding customers' clickstream data-our algorithms balance popularity with diversity. Finally, we partner with Wayfair, an online retailer, to estimate the impact of our algorithm in practice via simulations using actual clickstream data, and we find that our algorithm yields a significant increase (5-30%) in the number of customers that engage with the site.

2 - Personalized Dynamic Pricing with Machine Learning

N. Bora Keskin, Duke University, Fuqua School of Business, Durham, NC, 27708-0120, United States, bora.keskin@duke.edu, Gah-Yi Ban

Motivated by online retail applications, we consider a seller who offers personalized prices to individual customers. The seller initially does not know the impact of individual customer characteristics on demand, but can learn about this relationship via sales observations. We construct and analyze near-optimal policies that balance the learn-and-earn tradeoff in this setting.

3 - Menu Costs and the Bullwhip Effect: Supply Chain Implications of Dynamic Pricing

Ioannis Stamatopoulos, University of Texas at Austin, McCombs School of Business, Austin, TX, 78705, United States, yannis.stamos@mccombs.utexas.edu, Robert Louis Bray

We study the supply chain implications of dynamic pricing. Specifically, we estimate how reducing menu costs — the operational burden of adjusting prices — would affect supply chain stability.

4 - Sealed-bid Procurement Auction with a Conditional Right of First Refusal

Adithya Patil, Indian School of Business, Hyderabad, India, Adithya_Patil@isb.edu, Milind Sohoni, Kalyan Talluri

We examine equilibrium bidding behavior, auctioneer payment, and efficiency in a two-player sealed-bid procurement auction where a preferred player (Player 1) is granted a right of first refusal if his bid is within a certain percentage of the non-preferred player's (Player 2) bid.

Machine Learning for Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Xi Chen, New York University, New York, NY, 10012, United States

1 - Dynamic Assortment Optimization in The Presence of Outlier Customers

Yining Wang, University of Florida, Gainesville, FL, United States, ynwang.yining@gmail.com

In this paper, we study the problem of dynamic assortment planning in the presence of outlier customers. In our setting, while most customers follow multinomial logit choice models, a fraction of the arriving customers will be "outliers" and might have arbitrary preferences of the items. We show how to handle such outlier customers by developing an "active elimination" type algorithm that sequentially remove items not preferred by non-outlier customers. Rigorous theoretical results are established to show the near-optimality of our proposed algorithm. An adaptive algorithm which does not require prior knowledge of outlier portions is also given.

2 - Context-based Dynamic Pricing with Online Clustering

Sentao Miao, University of Michigan Ann Arbor, Ann Arbor, MI, United States, semiao@umich.edu

We consider a context-based dynamic pricing problem of online products with low sales, which have insufficient data samples. To address this challenge, we propose pricing policies that concurrently perform clustering over products and set individual pricing decisions on the fly. We evaluate the algorithms using the regret, and the result shows that when product demand functions come from multiple clusters, our algorithms significantly outperform traditional single-product pricing policies. Our algorithms were implemented in a field study at Alibaba with 40 products for 30 consecutive days with an overall revenue increase of 10.14%.

3 - Sequential Batch Learning in Linear Contextual Contexts

Zhengyuan Zhou, Stanford University, Stanford, CA, 94305, United States, Yanjun Han, Zhengqing Zhou, Jose Blanchet, Peter W. Glynn, Yinyu Ye

We study sequential batch learning in linear contextual bandits where the decision maker is constrained to only perform learning in batches, rather than observing the reward feedback from each individual unit immediately as in the standard online learning setting. We consider two different settings: the contexts may either be chosen arbitrarily by an adversary, or independently drawn from some known probability distribution. In each setting, we provide an algorithm that achieves the minimax optimal regret bound.

4 - Truth and Regret in Online Scheduling/Pricing

Rad Niazadeh, Stanford University, Stanford, CA, 94305, United States, rad@cs.stanford.edu, Shuchi Chawla, Nikhil Devanur, Janardhan Kulkarni

We consider scheduling in a cloud service provider that has multiple units of a resource available over time. Selfish clients submit jobs with private parameters. The provider's goal is to implement a truthful online mechanism for scheduling these jobs so as to maximize economic efficiency. It is known that under stochastic jobs a single-parameter family of FIFO-pricing mechanisms is near-optimal. We show that given any such family, there exists a new online mechanism that in the worst case performs nearly as well as the best of the given mechanisms. Our mechanism is truthful whenever the mechanisms in the given family are truthful and prompt, and achieves optimal (within constant factors) regret.

Online Marketplaces and the Sharing Economy

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Maxime Cohen, NYU Stern, New York, NY, 10012, United States

Chair: Gad Allon, University of Pennsylvania, University of Pennsylvania, Philadelphia, PA, 19104, United States

1 - Spatial or Temporal Pooling Solves the Wild Goose Chase

Ming Hu, Rotman School of Management, University of Toronto, Rotman School of Management, 105 St. George Street, Toronto, ON, M5S 3E6, Canada, ming.hu@rotman.utoronto.ca

We identify when the so-called "wild goose chase" problem may arise in the sharing system of vehicles such as cars, bicycles, and scooters. We show how to solve this problem using operational tools such as spatial and temporal pooling.

2 - Ride-Hailing Platforms: Competition and Autonomous Vehicles

Terry Taylor, U.C. Berkeley Haas School of Business, Business School, Berkeley, CA, 119245, United States, taylor@haas.berkeley.edu, Auyon Siddiq

A central feature of ride-hailing platforms (e.g., Lyft and Uber) is that they simultaneously compete over a common pool of supply—namely, independent driver-workers—and a common pool of demand—namely, rider-consumers. Perhaps no development is perceived to have a larger potential for transforming the economics of ride-hailing platforms than the introduction of autonomous vehicles. This paper examines the implications of competition and access to autonomous vehicles technology for the management of ride-hailing platforms.

3 - The Impact of Behavioral and Economic Drivers on GIG Economy Workers

Park Sinchaisri, The Wharton School, Jon M. Huntsman Hall, Philadelphia, PA, 19104, United States, swich@wharton.upenn.edu, Gad Allon, Maxime Cohen

Gig economy firms benefit from labor flexibility by hiring independent self-scheduling workers but such flexibility poses a great challenge in planning and committing to a service capacity. In collaboration with a ride-hailing company, we study how on-demand workers make labor decisions: when to work and for how long. We are interested not only in improving the prediction of the number of active workers but also in understanding how to better recruit them. Careful econometric analysis of actual work decisions and responses to incentives, accounted for sample selection and endogeneity, has revealed behavioral insights that can inform better incentive design.

4 - Information Disclosure in Service Platforms: Optimizing for Supply

Wenchang Zhang, Robert H. Smith School of Business, Silver Spring, MD, 20904, United States, wzhang@rhsmtih.umd.edu, Kostas Bimpikis, Yiangos Papanastasiou

The use of information provision as an operational lever in two-sided platforms has received significant attention recently as a means of aligning consumer incentives with those of the platform. This paper analyzes the as-of-yet unexplored interaction between information provision and supply-side incentives. We develop a dynamic model where providers of ex ante unknown quality choose whether to join a service platform and, if so, set their price in response to the platform's commission rates and feedback information-provision policy.

Sponsored Session

Chair: Ruxian Wang, Johns Hopkins University, Carey Business School, Kensington, MD, 20895, United States

1 - Display Ranking Optimization under Multinomial Logit Preferences

Ali Aouad, London Business School, London, NW64TG, United Kingdom, aaouad@london.edu, Danny Segev

Motivated by applications to online search and in-store merchandizing, we study a display optimization model in face of unit-buying customers, in a setting where the item rankings influence the likelihood that the customers consider the displayed alternatives. Under the widely-used Multinomial Logit choice model, we devise the first efficient algorithm that approximates the optimal ranking within any level of accuracy. We develop a notion of approximate subsets, which may be of broader interest in multiple-knapsack problems. Experiments on real and synthetic data sets demonstrate the value of the proposed display optimization approach.

2 - Consumer Choice and Market Expansion: Modeling, Optimization and Estimation

Ruxian Wang, Johns Hopkins University, Carey Business School, Washington DC, DC, 20895, United States, ruxian.wang@jhu.edu

Market size, measured by the number of people who are interested in products from the same category, may be highly influenced by assortment planning and pricing decisions. This effect is referred to as market expansion. In this paper, we incorporate the market expansion effects into consumer choice models and investigate various operations problems.

3 - Approximate Linear Programming for a Queueing Control Problem

Saied Samiedaluie, University of Alberta, Alberta School of Business, Edmonton, AB, T6G 2R6, Canada, Dan Zhang

We study a classical queueing control problem with multiple classes of customers. The queue is a loss system; i.e., arriving customers are rejected if all servers are busy. When a server is available, the decision is whether to admit an arriving customer and collect a lump-sum revenue. We model this problem as a continuous-time infinite-horizon dynamic program and propose approximate linear programming methods to solve the problem under three approximation architectures: affine, finite affine, and separable piecewise linear. We numerically investigate these approximation alternatives both in terms of the quality of the bounds and the policy performance.

4 - Reinforcement Learning under Drift

Ruihao Zhu, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, rzhu@mit.edu, Wang Chi Cheung, David Simchi-Levi

We study the problem of reinforcement learning under drift where both the reward functions and state transition distributions are allowed to evolve over time. For this problem, we propose learning algorithms that achieve state-of-the-art dynamic regret bounds. Our main contributions are: 1) A tuned Sliding Window Upper-Confidence bound for Reinforcement Learning algorithm armed with a crucial confidence widening technique, which attains provable dynamic regret bound against the optimal non-stationary policy. 2) The Bandit-over-Reinforcement Learning framework that further permits us to enjoy this dynamic regret bound in a parameter-free manner.

1 - A Content Analysis of Nike's Partnership with Colin Kaepernick

Xin Wang, PhD, Stonehill College, Easton, MA, United States

This research studies public's reactions to Nike's partnership with Colin Kaepernick to be the face of the 30th anniversary of its JustDoIt campaign in September 2018. The content analysis reveals the major topics and extract the hidden semantics from the text. In addition, it explores the degree of a user's connections and help identify the most influential users. This research not only will provide insights on people's sentiments toward the Nike's partnership decision but also shed lights on how brands can understand and influence customers attitude toward marketing campaigns.

2 - Content Sharing Strategy under Consumer Multi-Purchase

Min Jiang, Shanghai University of Finance and Economics, Shanghai, China, jiangminabc@163.com

This paper studies homemade content's sharing strategy in video streaming markets. This paper explicitly models the consumer's multi-product purchase behavior, and examines a content distributor's homemade content's sharing strategy. We find that content distributor's homemade content's sharing strategy under multi-product purchase differs from that under single-product purchase. The focal content distributor chooses to share its new content with its rival distributor under single-product purchase but not to share under multi-product purchase. However, when the two content distributors are asymmetric, we find some different results.

3 - Signaling Quality through Positive Leadtime in Advance Selling

Teng Niu, School of Management, Xi'an Jiaotong University, Xi'an, China, ntancjh31@stu.xjtu.edu.cn, Qin Su

Advance selling is an important way for a seller to introduce new products. Considering consumers always face the quality uncertainty when they buy in advance period, we introduce a signaling mechanism in which the seller deliver a credible signal of product quality through positive leadtime in advance selling. Our results underscore the significance of positive leadtime and identify two implications for seller's policy in advance selling: (a) the seller's incentive to disclose the positive leadtime will diminish the consumer's uncertainty about product quality; (b) high-quality seller can differentiate with low-quality seller through positive leadtime with profits sacrifices sometimes.

4 - The Length of Product Line in Distribution Channels under Fairness Concern Prospect

Ying Zha, PhD Candidate, University of Science and Technology of China, Hefei, China, zhazhadz@mail.ustc.edu.cn, Jie Wu, Xiang Ji

This paper studies a manufacturer's optimal decision on extending its product line when the manufacturer or retailer takes their fairness concern into consideration in a decentralized channel. We find that fairness concern will reduce the motivation of the manufacturer to extend the product line, because fairness may lead to a manufacturer's profit reduce. And the manufacturer may use their wholesale price to achieve product line extensions under its fairness concern.

5 - A Machine Learning Approach for Predicting Shopping Trip Motivations Using Retail Transactional Data

Andres I. Musalem, Ing.Ind. U. de Chile, Complex Engineering Systems Inst, Santiago, 8370456, Chile, amusalem7@gmail.com, Luis Aburto, Jochen De Weerdt, Maria Óskarsdóttir, Richard Weber

We formulate a Hierarchical Bayesian Latent Dirichlet Allocation (LDA) model, to detect and predict shopping trip motivations of customers visiting a store selling products from multiple categories. For each motivation, customers are more likely to purchase only certain products. The model allows these motivations to depend on the shopping basket size and customer characteristics (e.g., demographics and past behavior). The model is tested using supermarket data for a panel of customers.

6 - Consumer Information Sharing in a Distribution Channel: Hindering or Facilitating?

Buqing Ma, University of Science and Technology of China, Hefei, China, mabuqing@illinois.edu, Guang Li

We study the optimal management strategy of an online retailer's consumer information sharing system and investigate the effect of the retailer's strategy on the manufacturer's quality decision in a distribution channel. Counterintuitively, we find the retailer would hinder consumer communication even when the customer's perceived quality is lower than the true product quality. Furthermore, the manufacturer can be better off by keeping constant product quality than making the optimal decision in every period with myopic consumers. Our results also show that surprisingly, deterring customers from knowing the true product quality may generate more consumer surplus.

Joint Session PSOR/Practice Curated: Applied Advances in the Field of Emergency Response I

Sponsored: Public Sector OR

Sponsored Session

Chair: Jordan Srour

Co-Chair: Pieter van den Berg, RSM, Rotterdam, 3062 PA, Netherlands

1 - Strategic Games Among Decentralized Emergency Services in Emerging Economies

Lavanya Marla, University of Illinois Urbana Champaign, Urbana, IL, United States, lavanyam@illinois.edu, Peter McGlaughlin, Jungeun Shin

In emerging economies, centralized 911-type EMS is in nascent stages, with decentralized EMSs established by hospitals serving as the default option. We study such strategic behavior by considering a simplified line-model setting. Providers choose service regions to maximize utilities. We model this as a non-cooperative game, and use a renewal-theoretic model for the endogeneity between the providers' decisions. We show that the providers' utility functions are unimodal, and admit a pure strategy Nash equilibrium. We also analyze the Price of Anarchy (PoA), and demonstrate that bargaining mechanisms such as coco-decomposition can reduce negative externalities due to competition.

2 - Effective Use of Call Prioritization in EMS Control Rooms to Maximize Available Resources

Jerry Overton, President, International Academies of Emergency Dispatch, Salt Lake City, UT, United States, Jerry.Overton@emergencydispatch.org

Internationally, the demand for out of hospital care is growing at an alarming rate. This increase is taxing the capacity of emergency response systems worldwide. The problem, however, is not from an increase in higher acuity patients, but from those calling to resolve lower acuity problems. A solution to ensure resource preservation and better resource allocation to meet the patients' needs is to prioritize the request for service at the time of call taking by Emergency Medical Dispatchers. This evidence-based talk will demonstrate how protocols for prioritization can identify call types and in turn control and allocate the appropriate resources to improve overall system response.

3 - FireScore, a Visualization Tool for Firefighter Planning

Robert van der Mei, CWI & Vu University, Amsterdam, Netherlands, Guido Legemaate

This is a framework that acts as a front-end for other components. It visualizes the system in which the emergency service provider operates. On an operational level it is a near real time visualization of incidents, vehicles, status, and expected coverage. Manipulating vehicle status forces a recalculation and visualization. A data broker extracts and provides data to power i.a. a relocation engine. An additional simulator is currently used for a project in which a reinforcement learning algorithm is tasked to learn how to optimally relocate fire trucks during major incidents. The basic functionality is intended to go live on the Amsterdam emergency dispatch center in June 2019.

4 - Does GPS Data Matter for Emergency Call Volume Prediction?

Jordan Srour, Lebanese American University, Adnan Kassar School of Business, P.O. Box 13-5053, Beirut, 1102 2801, Lebanon, jordan.srour@lau.edu.lb

Emergency call prediction schemes serve to give emergency responders information on appropriate staffing levels in terms of both time and location. These prediction schemes are largely based on aggregating past call data at various levels of granularity. If GPS data is available, then the appropriate aggregation level is in the hands of the forecaster; if only call-region data is available, then the decision space on the aggregation level for the forecast shrinks. In this research we compare the accuracy of several emergency prediction schemes on these two types of emergency call data - GPS location data and call location at a predetermined regional level.

Resilient Infrastructure and Community Networks

Sponsored: Public Sector OR

Sponsored Session

Chair: Yasser Almoghathawi, PhD, King Fahd University of Petroleum and Minerals, University of Oklahoma, Dhahran, 73019, Saudi Arabia

1 - A Project Management Perspective on Network Restoration Scheduling

Kash Barker, University of Oklahoma, Norman, OK, 73019, United States, Deniz Berfin Karakoc

A number of optimization formulations have been proposed to determine a restoration order and work crew schedule for recovering disrupted single and interdependent infrastructure networks. This work considers restoration from a project management perspective, (i) analyzing critical restoration tasks and (ii) estimating restoration project delays.

2 - Co2 Emissions Reduction by Identifying Optimal Level of Co-firing Biomass and Natural Gas in Coal-burning Power Plants

Ashkan Mirzaee, PhD Student, University of Missouri, Columbia, MO, 65201, United States, Ronald McGarvey, Francisco Aguilar

Biopower, the electricity generated from woody biomass, is considered as a carbon neutral and renewable source of energy that can be co-fired in power plants in order to cut carbon pollution. In this research, an optimization model is developed to identify the optimal amount of electricity to be generated from woody biomass, natural gas, and coal at a candidate set of US power plants. The MILP model minimizes the total cost of generating the required electricity projected to be demanded by the EIA through 2030, with environmental and spatially-explicit woody biomass availability constraints.

3 - Component Importance Measure for a Network of Interdependent Infrastructure and Industry Sectors

Scott N. Clayman, Pennsylvania State University-Great Valley, Malvern, PA, United States, snc163@psu.edu, Devendra P. Jaiswal, Mohamad Darayi

This work studies sector criticality in a larger system of interdependent infrastructure and industry sectors. A data-driven network analysis methodology is developed to group the industry sectors within the US in order to highlight strongly coupled groups, with a focus on the most important states which are in trade with Pennsylvania. Considering a multi-regional input-output representation of the coupling among the industry sectors, this work offers a broader perspective on network vulnerability analysis with a means to measure importance of network components.

4 - Post-disruption Community Structures Restoration for Enhancing Interdependent Infrastructure Network Resilience

Yasser Almoghathawi, King Fahd University of Petroleum & Minerals, Dhahran, 31261, Saudi Arabia, moghathawi@kfupm.edu.sa

Community structures exist in many infrastructure networks such as power, water, and gas networks. Such community structures are formed based on physical connections, or spatial features, among others. However, Infrastructure networks are becoming more interdependent to be functional which make them highly vulnerable to any disruption. This work addresses the restoration problem of community structures in a system of infrastructure networks that are physically interdependent. Hence, an optimization model is developed with the objective of enhancing the resilience of the system, which is demonstrated with a system of interdependent networks considering different disruption scenarios.

2:00-2:45 AMPL / 2:45-3:30 Provalis Research

Vendor Tutorial

1 - Model-Based Optimization with AMPL: New Connections to Analytics Tools and Environments

Robert Fourer, AMPL Optimization Inc., Evanston, IL, 60201, United States

Built on the concept of model-based optimization, AMPL's intuitive algebraic modeling language and prototyping environment give you a fast start on prescriptive decision-making projects. AMPL then also helps you reach a successful conclusion, by providing connections to widely used analytics tools and environments. This presentation introduces and demonstrates a range of newly added and enhanced connections of general interest, including (1) expanded and enhanced interfaces to spreadsheet data, (2) access to solver callbacks, (3) building AMPL models in Jupyter notebooks, and (4) running AMPL as a flexible cloud service.

2 - An Insider's Look at Text Analytics: What Works, and What They Don't Tell You

Adam Bendriss Alami, Provalis Research, Montreal, QC, Canada

Text analytics provides real value to help shape and grow a business. That statement isn't up for analysis. Text analytics works but it doesn't necessarily work the same way for everyone. To make text analytics work for you, you need to know some of the pitfalls to avoid the pratfalls. We will show you techniques and methods you can deploy, what's behind them and what to watch out for.

Advancements in Spatial and Temporal Data Analytics - II

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Jian Liu, University of Arizona, Tucson, AZ, 85721, United States

Chair: Shyam Ranganathan, Virginia Polytechnic Institute and State University, Blacksburg, VA, 24061, United States

1 - A Semiparametric Integrated-spatial-temporal Mixed Effects Single Index Model

Inyoung Kim, Virginia Tech, Blacksburg, VA, United States, inyoungk@vt.edu

Environmental health studies are of often interest in human research to evaluate the relationship between mortality and temperature by incorporating spatial correlation and other weather variables. Since this relationship cannot be expressed by a parametric model, a nonparametric model is often used to estimate this relationship. A semiparametric integrated-spatial-temporal mixed effects single index model is proposed. It can detect subtle changes among spatial effects, covariates, and nonparametric function. It is useful when the spatial areas are located close to each other because the nonparametric function may not be separated from spatially correlated random effects.

2 - Graph-regularized Joint Tensor Subspace Clustering and Completion for Subway Ridership Analysis

Nurettin Dorukhan Sergin, Arizona State University, 1012 E. Marigold Lane, Tempe, AZ, 85281, United States, nsergin@asu.edu, Hao Yan, Fugee Tsung

Subway turnstiles in metropolitan areas collect vast amounts of data which can be used to address various problems. In this paper, we take the case for Hong Kong, which has a modern subway system that generates high-frequency, rider-level, large-scale turnstile data. We specifically address the problem of detecting system-level changes, which might be useful for gaining insights and proactive decision making for subway management. Our approach considers a graph-regularized joint subspace clustering and completion method to be able to group and forecast stations. The performances of these two tasks will be enhanced using some known network information using graph regularization techniques.

3 - Spatial-temporal Burst Detection in Water Distribution System via Penalized Model Decomposition

Yinwei Zhang, University of Arizona, Tucson, AZ, 85705, United States, zhangyinwei@email.arizona.edu, Jian Liu, Kevin Lansey

It is crucial to develop effective and efficient algorithms to detect bursts in water distribution systems from spatially and temporally correlated hydraulic measurements. Traditional anomaly detection methods based on basis expansion may be applicable, falling short of accurate estimations of burst magnitude and starting time. This research proposes a spatio-temporal decomposition based burst detection method, which estimates the ST profile parameters according to the expected magnitude of spars burst. The effectiveness of the proposed method is demonstrated by a simulation case study.

4 - A Spatiotemporal Prediction Approach for a Three-dimensional Thermal Field with Sparse Data

Di Wang, Peking University, Beijing, China, dwang375@wisc.edu, Kaibo Liu, Xi Zhang

An accurate prediction of thermal field distribution, that is, acquiring any location of interest in a thermal field at the present and future time, is essential to provide useful information for the surveillance, maintenance, and improvement of a thermal system. However, thermal field prediction using data acquired from sensor networks is challenging due to data sparsity and missing data problems. To address this issue, we propose a field spatiotemporal prediction approach based on transfer learning techniques by studying the dynamics of a 3D thermal field from multiple homogeneous fields. A real case study of thermal fields during grain storage is conducted to validate our proposed approach.

1 - Personalized Learning System for Smart Transportation Demand Management

Jingshuo Feng, University of Washington, Seattle, WA, United States, jingsf@uw.edu, Xi Zhu, Feilong Wang, Shuai Huang, Cynthia Chen

With the rapid proliferation of smart personal technologies, Transportation demand management (TDM) at the individual level is now possible. In this presentation, we will introduce our ongoing works in developing new analytic methods that can statistically accurately to estimate individual's travel preference from their behavior data (sample size limited and fragmented), computationally efficient to implement, and easy to be integrated with dynamic incentive optimization methods to modify individuals' travel behaviors to achieve optimal solutions in both system-level and individual-level goals.

2 - Weakly Dependent Tensor Completion with Multinetwork Information Based on Metro Passenger Flow Prediction

Ziyue Li, The Hong Kong University of Science and Technology, Kowloon, Hong Kong, Nurettin Dorukhan Sergin, Hao Yan, Chen Zhang, Fugee Tsung

Tensor completion has attracted amounts of research. Most of them focus on low-rank property either by adding nuclear norm on tensor or penalty on the decomposed components. But low-rank assumption cannot always be satisfied especially when the data present complex and diverse dependencies. Spatiotemporal data is one of the good examples. By introducing the weakly dependent penalty and forming the inter-dependency network, the completion accuracy is improved remarkably. This is formulated in both CANDECOMP / PARAFAC (CP) and Tucker decomposition form. In the end, an implementation based on passenger traffic flow data in Hong Kong is conducted and proves our method's accuracy.

3 - System-level Root Cause Diagnostics in Modern Multistage Manufacturing Systems

Andi Wang, GaTech, Atlanta, GA, United States, andi.wang@gatech.edu, Jianjun Shi

Modern multistage manufacturing processes (MMPs) generate heterogeneous data from different stages. This study proposes a modeling framework to describe the relationship between inputs and the process data, by considering distinct characteristics of the process data from stages, the sparsity of the inputs' effect and the limited variation pattern of the data from each stage and proposed a solution procedure.

4 - Predictive Analytics for Complex Systems Using High-dimensional Signals

Amirreza Sahebi Fakhrabad, NC, United States, Xiaolei Fang

The high-dimensionality and nonlinearity of degradation signals have posed significant challenges to the remaining useful lifetime prediction of complex engineering systems. To address these challenges, this talk proposes a new manifold learning-based methodology, which captures the nonlinear characteristic and reduces the dimensionality of degradation signals. In addition, an incremental updating algorithm is developed to speed up the computation. Numerical studies are used to validate the effectiveness of the proposed method.

5 - Interval-based Sequential Design for the Exploration and Estimation of a Response Surface

Alessia Benevento, University of Salento, Lecce, Italy, Swati Gupta, Massimo Pacella, Kamran Paynabar

Sequential sampling methods are used to estimate functions describing models subjected to expensive simulations. These methods provide rules for the selection of new points of the domain in order to capture the largest number of information about the function. We propose a new sequential method aiming at estimating a response surface. In contrast with the existing methods, our method is very simple and extremely fast, as it does not involve the estimation of the function at each iteration. On the other hand, it shows the same performances of other methods in terms of accuracy. The performance of the proposed algorithm is evaluated through numerical simulations and then applied to a real study-case.

Joint Session QSR/HAS: Data Analytics and Machine Learning: Methodologies and Applications in Healthcare Systems

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Bing Si, State University of New York at Binghamton, Binghamton, NY, 13905, United States

1 - Active Learning with Gaussian Processes for Determining Optimal Locations to Biopsy Brain Tumor

Nathan B. Gaw, Graduate Research Associate, Arizona State University, Tempe, AZ, 85258, United States, ngaw1@asu.edu, Jing Li

Glioblastoma (GBM) brain cancer ranks among the most deadly of all human cancers. Thus, it is crucial to have tools that accurately predict tumor heterogeneity and extent of tumor invasion. Previously, machine learning has been used to combine image-localized biopsies and imaging data to make predictive maps of tumor cell density. However, there has not been consideration to select biopsies to minimize prediction map uncertainty. The current study aims to utilize active learning with Gaussian processes to determine optimal locations to biopsy with the goal of minimizing uncertainty in tumor cell density prediction maps.

2 - Kidney Viability Forecasting by General Path Model and Biopsy Location Recommendation

Qing Lan, Virginia Tech, Blacksburg, VA, United States, qing83@vt.edu, Xiaoyu Chen, John Robertson, Ran Jin

The focus of this paper is to forecast the viability of heterogeneous kidneys leading to the success of transplantation. Current machine perfusion system does not provide guideline for selecting biopsy time and location which requires repeated biopsy to evaluate the viability. We propose a multi-task general path model with Bayesian updating that forecasts the viability during the preservation process, thus can provide recommend the time and location of conducting biopsy to reduce the risk of damaging kidney. This method is validated in a case study of preserving porcine kidney. Therefore, the utilization of donor kidney can be potentially increased to benefit more end-stage patients.

3 - Markov Optimal Intervention Strategies for Breast and Ovarian Cancers

Farhad Imani, The Pennsylvania State University, Leonhard Building, State College, PA, 16802, United States, Bing Yao, Conrad S. Tucker, Hui Yang

BRCA1/2 mutation carriers have a high risk of breast and ovarian cancers. While there is no decisive method for avoiding breast and ovarian cancer, making decisions about intervention strategies (i.e., consist of the prophylactic surgeries and screening) for early signs of the disease may lead to the efficient treatment. This paper presents a novel constrained Markov decision process to effectively determine policies for sequential stochastic decision problems where multiple rewards are concurrently considered. The optimization algorithms are developed to find cost and quality-adjusted life years optimal intervention strategies for those who are tested positive for a BRCA1/2 mutation.

4 - A Behavior Study on Swing Shift Dynamic Performance Response to Emergency Department Workload Uncertainty

Jianing Man, Mayo Clinic, Rochester, MN, 55902, United States, Man.Jianing@mayo.edu, Mustafa Y. Sir, Kalyan Pasupathy, David L. Kaufman, Daniel Cabrera

In the emergency department (ED), patient care demand fluctuates every day due to variability in patient arrivals and clinical acuity. In order to manage healthcare resource utilization and mitigate burnout among providers, the Department of Emergency at Mayo Clinic Saint Marys Hospital in Rochester, MN, developed and adopted an adaptive swing overnight shift, which runs parallel to a regular overnight shift. In this study, we explore if the trends in overnight score impact the admission rate, patients' length of stay, and other performance metrics through behavioral interventions for physicians staffing the swing shift compared to the regular shift.

5 - A Novel Structural Equation Model for Screening Behaviors Prediction and Health Promotion

Bing Si, State University of New York at Binghamton, Binghamton, NY, 13905, United States, bsi@binghamton.edu

Routine screening is a cost-effective secondary prevention administrated by healthcare providers (HCPs) for healthcare promotion. A newly developed Instruments of American Association of Nurse Practitioners (IAANP) enables quantitative data to be collected. A novel structural equation model is developed for the prediction of HCP's screening behaviros from IAANP data. The findings of the research can promote routine screening in healthcare settings by optimizing the HCPs' training, education, and practice environment, eventually leading to improved quality of care and clinical outcomes.

Co-Chair: Ozalp Ozer, The University of Texas at Dallas, Richardson, TX, 75080-3021, United States

1 - An Analytics Approach to Guiding Randomized Control Trial Design in Hypertension Management

Anthony Bonifonte, Denison University, Granville, OH, 30106, United States, bonifontea@denison.edu, Turgay Ayer, Ben A. Haaland

Antihypertensive drug treatment can control elevated blood pressure and reduce the risk of cardiovascular disease. We propose data-driven models that combine stochastic optimization and statistics to identify the optimal joint systolic and diastolic thresholds for initiating treatment. We analytically characterize the expected value of the hazard experience by patients and compute the optimal treatment initiation decisions. We conduct a simulation model to estimate the potential societal impact from implementing our treatment policy. Our findings may help guide future RCT design and suggest treatment thresholds should depend jointly on systolic and diastolic pressure.

2 - Adaptive Clinical Trial Design with Surrogates: When Should We Bother

Arielle E. Anderer, The Wharton School, Philadelphia, PA, United States, aanderer@wharton.upenn.edu, Hamsa Sridhar Bastani, John M. Silberholz

Surrogate outcomes have long been used in clinical trials when the true outcome of interest is expensive, time consuming, or otherwise difficult to measure. In this work we propose optimal adaptive clinical trial designs that integrate surrogate and true outcomes, and we analytically and empirically characterize regimes where our designs are especially beneficial.

3 - Predicting Patient-level Antibiotic Adherence

Isabelle Rao, Stanford University, Stanford, CA, United States, isarao@stanford.edu, Adir Shaham, Amir Yavneh, Dor Kahana, Itai Ashlagi, Dan Yamin, Margaret L. Brandeau

Low medication adherence is a leading problem in developed countries, causing a substantial health and economic burden. We develop machine learning algorithms that utilize demographic and electronic medical record data to predict the probability that a patient will purchase a prescribed antibiotic medication. In-depth analysis of patient-level data, leading to accurate prediction, can yield insights into individual decision making associated with prescription medications, and can help shape the next generation of personalized intervention strategies.

4 - Data-Driven Personalized Early Detection of Sepsis

Zahra Mobini, The University of Texas at Dallas, Richardson, TX, United States, zahra.mobinidehkordi@utdallas.edu, Mehmet Ayvaci, Ozalp Ozer

We develop an alerting mechanism for early detection of sepsis that accounts for both an individual patient's risk factors and the caregiver's compliance with alert-driven care processes. We formulate the problem of determining when to alert sepsis as a discrete-time, finite-horizon Markov Decision Process and structurally characterize threshold policies. We empirically validate our model using real clinical data and demonstrate how the proposed alerting mechanism can improve patient outcomes in the hospital.

1 - Optimizing Pediatric Vaccine Administration Policies in Developing Countries from a Societal Perspective

Gizem S. Nemutlu, Harvard Medical School and MGH, Boston, MA, United States, gnemutlu@mgh.harvard.edu, Fatih Safa Erenay, Osman Y. Ozaltin

Pediatric vaccination programs in developing countries suffer from open-vial wastage. We propose using multi-dose vaccine vials of different sizes and formulate a Markov decision process (MDP) model to minimize the societal cost of vaccine administration policies. Using data for routine pediatric vaccines, we show that the proposed policies significantly reduce the open-vial wastage. We also determine the best initial inventory level combination that improves the demand coverage up to target levels without early termination of service while incurring reasonably small or no additional cost.

2 - Integrating Mortality Prediction Algorithms with Physician Decisions to Improve End-of-Life Care

Junchao Ma, Yale SOM, New Haven, CT, 06511, United States, junchao.ma@yale.edu, Edieal J. Pinker, Donald Lee

End-of-life care for advanced cancer patients is aggressive and costly. Hospice referrals require a clinical judgment that a patient's survival time is less than six months. According to data we collected, the median length of hospice stays until death was only 17 days. Studies showed that physicians' estimates of patient survival time to be inconsistent and over-positive, leading to late referral to hospice. To address this issue, we developed a decision support tool that used a machine learning algorithm to predict short-term mortality based on EMR data feed. We will talk about our attempt to understand how our prognostic tool can augment oncologists' decision making.

3 - Robust Optimization on Healthcare Referral Networks: Engaging Providers in Developing Countries

Clara Stoesser, University of Toronto, Toronto, ON, Canada, clara.stoesser@mail.utoronto.ca, Timothy Chan, Sarang Deo, Justin J. Boutilier

Private healthcare providers (PPs) are commonly used in low- income countries but their diagnostic techniques are often inadequate, so third party agencies engage with PPs to improve their health practices. In this project, we develop a methodology to determine the set of providers that these engagement programs should interact with in order to maximize the number of patients who will be properly diagnosed given program budget constraints and uncertain referral data. We simulate potential instances of the referral network and then use a robust optimization model to determine the optimal set of PPs. Field data on improving tuberculosis diagnosis in Mumbai is applied to this framework.

4 - Allocation of Intensive Care Unit Beds with Patient Readmission

Huiyin Ouyang, Assistant Professor, The University of Hong Kong, Hong Kong, huiyin.ouyang@hku.hk, Zhankun Sun, Sukriye Nilay Argon, Serhan Ziya

This work aims to use mathematical modeling and analysis to develop insights into and policies for making priority decisions in Intensive Care Units (ICUs) with patient readmissions. We assume patients' health conditions may change over time, and patients who are early discharged from ICU due to capacity constraint might get readmitted to ICU when beds become available later. We propose a stylized mathematical model in which patients' health conditions change over time according to a Markov chain. We formulate this decision problem as a Markov decision process and provide some analysis of the structure of the optimal policy.

CC- Tahoma 3

Joint Session HAS/Practice Curated: Incentive and Policy Design

Sponsored: Health Applications

Sponsored Session

Chair: Tinglong Dai, Johns Hopkins University, Baltimore, MD, 21202, United States

1 - Reference Pricing for Healthcare Services

Hamed Mamani, University of Washington, Dept of Info Systems & Operations Management, Michael G. Foster School of Business, Seattle, WA, 98195-3226, United States, hmamani@uw.edu, Shima Nassiri, Elodie Adida

The traditional healthcare payment system does not incentivize hospitals to limit their prices. Reference pricing (RP) has been proposed as a way to better align incentives. Under RP, patients may be responsible for part of the cost. We propose a model to analyze RP and compare it to the traditional cost-sharing mechanisms.

2 - Vertical Integration and Quality: Evidence from the Specialists-hospital Integration

Lina Song, Harvard University, Cambridge, MA, United States, Soroush Saghafian, Mary Beth Landrum, John Hsu, Joseph P. Newhouse

Hospitals and physicians increasingly are consolidating (“vertical integration”) in the U.S. healthcare system. In theory, consolidation could achieve better clinical integration, but also increase unnecessary use or reduce quality. We empirically examine how vertical integration affects care quality through gastroenterologists’ provision of colorectal cancer screening and diagnosis. We find the evidence of a reduction in quality (i.e., increase in complications and bleeding post-colonoscopy) after physicians vertically integrate, which is mainly driven by lower use of appropriate anesthesia. Our results suggest that financial integration does not ensure quality improvement.

3 - Physician Peer Effects on Speed and Quality: Evidence from the Emergency Department

Raha Imanirad, Harvard Business School, Boston, MA, 02472, United States, rimanirad@hbs.edu, Soroush Saghafian, Stephen Traub

In this study, we estimate peer effects in the context of an Emergency Department (ED) setting by addressing the question of whether peer physicians’ characteristics including relative performance, experience, type of medical degree, and gender affect a physician’s performance. We find strong evidence that physicians affect each other’s speed and quality in opposite directions and scheduling diverse peers during the same shift could have a positive net impact on the operations of a hospital ED. We identify resource spillover as the main driver of peer effects and show that, under high ED volumes (when the shared resources are most constrained), the magnitude of the observed peer effects increases.

4 - Monitoring Policy Optimization for HIV Patients with Heterogeneous Adherence Types

Zhenhuan Zhang, PhD Candidate, University of Minnesota, Minneapolis, MN, 55414, United States, Diana Maria Negoescu

In chronic disease management, as many as 40% of patients fail to adhere to treatment recommendations. Poor adherence leads to a waste of medical resources, higher rates of treatment failure on designated therapies and worsened health outcomes. Personalized treatment plans adapted to heterogeneous patient adherence patterns might yield better health outcome. We develop a Markov decision process model to optimize the monitoring interval for HIV-infected patients on the first-line antiretroviral therapies (ART) regimen in resource-limited settings, with heterogeneous patient adherence behavior.

5 - Squeeze in: Can Last-minute Surgical Reservations Hurt Patient Outcomes?

Tinglong Dai, Johns Hopkins University, Baltimore, MD, 21202, United States, dai@jhu.edu, Soo-Hoo Lee, Philip H. Phan, Nehama Moran, Jerry Stonemetz

The newsvendor paradigm has influenced much of the empirical operations management literature on operating-room (OR) management. Our observations of actual clinical practice, however, revealed a pattern of scheduling accuracy that is opposite to what the newsvendor paradigm would predict. To account for this gap, we collected and analyzed a large dataset that captures not only ex antefactors that a surgeon is aware of when reserving an OR, but also ex postfactors that the surgeon might face on the day of the case. We show that surgeons consistently under-booked OR times when the time to surgery is short. We also establish how the squeeze-in effect drives patient outcomes.

Co-Chair: Han Ye, U. of Illinois at Urbana-Champaign, Champaign, IL, 61820, United States

1 - Examining the Impact of Hospital Internal and External Factors on Bias in Medical Treatment

Luv Sharma, University of South Carolina, Columbia, SC, 29206, United States, luv.sharma@moore.sc.edu

This study looks at hospitals, patients, legislative, and market specific factors that can lead to biases in medical treatment as well as conditions under which these biases negatively influence clinical outcomes.

2 - The Impact of Freelancers on Cost Performance in Hospitals

Yingchao Lan, Assistant Professor, University of Nebraska-Lincoln, Lincoln, NE, 68506, United States, yingchao.lan@unl.edu, Deepa Wani, Aravind Chandrasekaran

The share of hospitals with integrated physicians has been increasing recently. The implicit assumption is that integrated physicians can bring in more patient volume, improve efficiency, enable close collaboration through established familiarity, and thus reduce cost. However, the cost implications of such a trend is not clear. We assemble a unique patient-level panel data to empirically explore to what degree freelancers (physicians) explain the cost performance of hospitals? Further, if the relationship is moderated by physician-level (tenure) and hospital level (accountable care organization participation) characteristic.

3 - The Impacts of Patients’ Sentiment Trajectory Features on Their Willingness to Share in Online Support Groups

Yu Wei Lin, University of Illinois, Champaign, IL, United States, Mehmet Eren Ahsen, Michael J. Shaw, Sridhar Seshadri

Online support groups are valuable resources for patients by providing them emotional support from other patients with similar experiences. Little research has systematically examined how patients’ sentiment trajectory features affect patients’ engagement behaviors in OSGs. We study the impact of patients’ sentiment trajectory features in online social networks on their willingness to share. Our analysis suggests that patients’ sentiment positivity, stability, and dispersion positively affect patients’ willingness to share. Moreover, we found that patients’ sentiment trajectory features can be influenced by (1) their online interactions and (2) their offline life events.

4 - Towards Mitigation of Healthcare Outcome Disparity in Chronic Diabetes Care

Han Ye, U. of Illinois at Urbana-Champaign, Champaign, IL, 61820, United States, hanye@illinois.edu, Ujjal Mukherjee, Dilip Chhajed

In this paper we investigate moderating effect of spatial, infrastructural, and operational accesses that healthcare delivery organizations can use to mitigate some of the socioeconomic sources of disparity in diabetes care.

Joint Session QSR/DM: Statistical Data Mining Approaches for Diverse Manufacturing Processes

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Youngseon Jeong, Chonnam National University, Korea, Republic of

Co-Chair: Sangahn Kim, Siena College, Loudonville, NY, 12211, United States

1 - A New Cluster Validity Index in Feature Space

Youngseon Jeong, PhD, Chonnam National University

Please check the mobile app for this abstract.

2 - Monitoring and Control of High-dimensional Data via Sparse Group Lasso

Sangahn Kim, Siena College, Loudonville, NY, 12211, United States, skim@siena.edu, Myong Kee Jeong, Elsayed A. Elsayed, Mehmet Turkoz

In high-dimensional processes, a large number of process parameters or quality characteristics are found to be featured through their dependencies and relevance. The features that have similar characteristics or behaviors in the process operation can be categorized into multiple groups. This research proposes a new method to monitor the high-dimensional process when the grouped structure in the behavior of the process is observed.

3 - Residual-based Surface Segmentation for Monitoring Three-dimensional Surface Topography

Jaeseung Baek, Rutgers University, Piscataway, NJ, United States, Myong Kee Jeong, Elsayed A. Elsayed

Monitoring the three-dimensional (3D) surface topographic variations is important and challenging for quality engineers. This paper investigates a new approach for detecting topographic variations in 3D surfaces. We develop a residual-based separation deviation (RBSD) model to segment the surface and identify the topographic variations in the surface, and introduce a spatial randomness-based monitoring statistic to detect anomalies in the surface topography. Numerical simulation and case study of paper surface monitoring demonstrate the effectiveness of our approach.

Statistical Learning and Decision-Making

Sponsored: Simulation

Sponsored Session

Chair: Ilya O. Ryzhov, University of Maryland, College Park, MD, 20742, United States

1 - Adaptive Personalized Dose Finding Clinical Trials

Saeid Delshad, Clemson University, Clemson, SC, United States, sdelsha@g.clemson.edu, Amin Khademi

This work studies optimal sequential allocation of heterogeneous patients to treatment doses in a dose-finding clinical trial, where the decision maker seeks to find the best dose for each patient group. We follow a Bayesian set up for this problem and show several statistical properties of two heuristics. We show the results based on real data.

2 - Learning for Adaptive Elimination in Parallel Ranking and Selection

Linda Pei, Northwestern University, Evanston, IL, 60202, United States, Barry L. Nelson, Susan R. Hunter

Simulation ranking and selection methods, in which all feasible solutions are simulated, have traditionally exploited pairwise comparisons which are a computational bottleneck in large-scale problems. We propose a method for use within a parallel master-worker framework in which the master adaptively learns a standard that it communicates to workers who sequentially simulate solutions and eliminates solutions deemed inferior to the standard. We show that this method guarantees a desired expected false elimination rate, and we investigate computational advantages and asymptotic behavior.

3 - Inference on Average Treatment Effects in Aggregate Panel Data Settings

Yinchu Zhu, University of Oregon, Eugene, OR, 97401, United States, yzhu6@uoregon.edu, Victor Chernozhukov, Kaspar Wuthrich

This paper studies inference on treatment effects in aggregate panel data settings with a single treated unit and many control units. We propose new methods for making inference on average treatment effects in settings where both the number of pre-treatment and the number of post-treatment periods are large. The counterfactuals are estimated using constrained Lasso, an essentially tuning free regression approach that nests difference-in-differences and synthetic control as special cases. The test is very easy to implement and demonstrates an excellent performance in simulation experiments, and is taken to a data application, where we re-evaluate the economic consequences of terrorism.

4 - Data-Driven Robust Resource Allocation with Isotonic Cost Functions

Ilya O. Ryzhov, Associate Professor, University of Maryland, Robert H. Smith School of Business, College Park, MD, 20742, United States, iryzhov@rhsmith.umd.edu, Ye Chen, Nikola Markovic, Paul Schonfeld

We consider two-stage planning problems in which a resource is first divided among a set of independent regions, and then costs are incurred based on the allocation to each region. Costs are assumed to be decreasing in the quantity of the resource, but their precise values are unknown, for example if they represent difficult expected values. We develop a new data-driven uncertainty model for isotonic cost functions, which can be used in conjunction with robust optimization to obtain tractable allocation decisions that significantly improve worst-case performance outcomes.

Joint Session Sharing Econ & Crowdsourcing/Practice Curated: Shared Mobility Systems

Emerging Topic: Sharing Economy & Crowdsourcing

Emerging Topic Session

Chair: Samitha Samaranayake, Cornell University, Ithaca, NY, 14853, United States

1 - Where Do We Go from Here: Rebalancing an Autonomous Rideshare Fleet

Chinmoy Dutta, Lyft, San Francisco, CA, 94040, United States, cdutta@lyft.com, Garrett van Ryzin

A mobility-on-demand (MoD) system must cope with the time-varying asymmetry in demand flows leading to spatial imbalance of originating ride demand and available vehicles to service them. With ability to directly control the vehicles, an autonomous MoD (AMoD) system can tackle this challenge directly and effectively by rebalancing vehicles. We propose a novel approach to rebalancing by formulating the problem as a two-stage stochastic integer program with recourse. Our approach can cope with future uncertainty by making decisions hedging against possible future scenarios, while appropriately modeling the intricate interplay between dispatching and rebalancing.

2 - Algorithmic Challenges in Enabling High-capacity Ride Pooling Services

Juan Carlos M. Mori, Cornell University, Ithaca, NY, United States, Samitha Samaranayake

The rapid expansion of on-demand ride-hailing services has changed the transportation eco-system worldwide. While these services are a valuable alternative travel mode, as evident by their popularity, there are many questions regarding their scalability, efficiency, equity and negative externalities (e.g. congestion, pollution etc.). One way to mitigate some of these concerns is to consider high-capacity ride-pooling services that operate like an on-demand transit service. This talk will discuss the algorithmic challenges in operating such a system at-scale and present techniques for overcoming some of these challenges.

3 - Contracting for on Demand Public Transit

Sherwin Doroudi, University of Minnesota, MN, Minneapolis, MN, 55455, United States, sdoroudi@umn.edu, Philipp Afeche, Varun Gupta, Ankur Mani, Daniel F. Silva, Alexander Vinel

We present preliminary work addressing several questions on the design of an on demand public transit system contract between a transportation provider and a city. Specifically, we seek to investigate (i) the operator's optimal decisions given a contract and city structure (including demand patterns), (ii) the resulting quality of service in each region under said decisions, and (iii) the costs incurred by the city under said decisions. Together, addressing these questions should allow us to determine what types of contracts are most beneficial (or even feasible) for a city, given a set of (potentially region- and demographic-dependent) quality of service and equity constraints.

4 - Robust Trip Sharing for Urban Commuting

Pascal Van Hentenryck, Georgia Institute of Technology, Atlanta, GA, 30332, United States, Mohd Hafiz Hasan

This presentation considers the problem of minimizing the number of cars on the road for urban commuting, reducing parking pressure and congestion. It presents the robust trip sharing problem that combines stochastic optimization, branch and price, and real-time optimization in order to achieve this objective. Experimental results on a real case study demonstrate the potential benefits of the approach.

Resource Management in Network-based ICT Systems

Sponsored: Telecommunications and Network Analytics

Sponsored Session

Chair: Young Myoung Ko, Pohang University of Science and Technology, Pohang, 790-784, Korea, Republic of

1 - Optimizing Slicing Parameters on a 5g Transport Network

Neil Diaz, Texas A&M University, Dept of Industrial and Systems Engineering, College Station, TX, 77843-3131, United States, nodiaz@tamu.edu, Natarajan Gautam

Latency estimation on a 5G network slice is crucial to allow Infrastructure Providers to provision resources to satisfy customer's expected quality of service while securing isolation for their traffic. However, latency estimation is challenging since Time-Sensitive Networking uses a combination of statistical and time-division multiplexing to create these slices in the Transport Network. We adapt the fixed-cycle traffic-light queue in urban traffic literature to obtain quality-of-service metrics and optimize network-slicing parameters. We discuss the techniques' strengths and weaknesses after performing various numerical experiments.

2 - On the Possibility and Economic Impacts of Spectrum Sharing: A South Korean Case

Jeonghoon Mo, Yonsei University, Seoul, 03722, Korea, Republic of, j.mo@yonsei.ac.kr, Tae Yoel Kim

Due to reduced wireless network cycles, the higher infrastructure cost become a big burden for wireless operators. The spectrum sharing between providers can be a possible solution to save infrastructure cost for operators even though it has not been realized. In this study, we consider a few possible spectrum sharing scenarios between operators and evaluate possibility of the spectrum sharing and its economic impacts using the South Korean case. The study suggests that the direct spectrum sharing methods between mobile network operators are more effective than sharing the public frequency like LSA and CBRS. The economic impacts due to spectrum sharing for 5G service could be as large as $1.3~4.6B.

3 - Impact of Quality of Service Guarantee on Energy Efficiency in Data Centers

Soongeol Kwon, Binghamton University, SUNY, 4400 Vestal Pkwy E, Systems Science and Industrial Engineering, Binghamton, NY, 13902, United States, skwon@binghamton.edu

For the efforts to achieve energy-efficient and sustainable data center operations, quality of service (QoS) should be guaranteed at the desired level to respond to users' requests with their satisfaction. Given this context, this study intends to develop a two-stage stochastic programming that is designed to investigate optimal data center operations based on demand response to reduce energy cost while ensuring the desired QoS level against the stochastic workloads. Then, additional chance constraint and risk constraint are introduced as means of managing the level of QoS guarantee to evaluates the impact of QoS guarantee with different levels on energy efficiency.

4 - A Robust Optimization Approach for Server Speed Scaling and Load Balancing in Data Centers with Service-level Agreements

Seung Min Baik, Pohang University of Science and Technology, Korea, Republic of, seungmin.baik@lstlab.org, Minseok Kim, Young Myoung Ko, Soondo Hong

Data Centers are processing various ICT service requests for their customers, and service-level agreements (SLAs) with customers work as hard constraints that data centers should satisfy. Data centers tend to run servers faster than required to comply with the SLA under uncertainty, which may cause energy inefficiency in operations of data centers. In this talk, we model servers in data centers using G/G/1/PS queues and minimize energy consumption while maintaining the SLA - the probability of waiting time exceeding a threshold. We derive static server speeds and workload routing probabilities through a robust optimization model by expressing the random variables' domain as uncertainty sets.

1 - How Does Algorithmic Trading Influence Investor Participation in Peer-to-Peer Online Lending Markets?

Hongchang Wang, Georgia Institute of Technology, Atlanta, GA, 30126, United States, hongchang.wang@scheller.gatech.edu, Eric Overby

Algorithmic trading has reshaped equity markets and had significant effects on market performance. In this paper, we examine the effect of algorithmic trading in online peer-to-peer lending markets. To study this, we examine the effect of an API upgrade on Prosper.com that facilitated algorithmic trading. Using a difference-in-differences strategy, we find that individual "manual" investors were crowded out of the most quickly-funded and typically best-performing loans after the API upgrade. However, the API upgrade may have increased the size of the market, thereby allowing individual investors to continue investing in the market, albeit for somewhat lower quality loans.

2 - Home Bias in Online Employment: Evidence from an Online Labor Market

Chen Liang, University of Connecticut, Storrs, CT, 85282, United States, Yili Hong, Bin Gu

We study the nature of home bias in online employment—an employer preference for workers from his or her home country. Using a unique large-scale data set from a major online labor market containing employers' consideration sets and ultimate choices, we estimate employers' home bias. Further, we disentangle two types of home bias—statistical and taste-based home bias—using a quasi-natural experiment based on the introduction of a monitoring system, which enables employers to easily observe workers' effort on time-based projects. Finally, we study heterogeneity in home bias across employers from different countries with a post-treatment sample with minimal statistical discrimination.

3 - Preference, Profitability, and Ranking in Mobile App Monetization

Shengjun Mao, University of California Irvine, Irvine, CA, United States, shengjum@uci.edu, Sanjeev Dewan, Yi-Jen (Ian) Ho

We develop a structural empirical framework for estimating consumer click and conversion utility based on mobile clickstream data, readily available from server logs. We have access to unique data on app distribution, including individual CPA margins, from a large mobile services operator. Consumer click and conversion utilities are jointly estimated as a function of screen rank along with a variety of quantitative and qualitative factors. We conduct policy experiments to examine the effectiveness of alternative screen ranking strategies, finding that a personalized ranking scheme that accounts for both utility and margins outperforms methods based on margins alone or utility alone.

Behavioral Operations Topics

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Brent Moritz, Penn State University, University Park, PA, 16802, United States

1 - Construal Level and Inventory Decisions

Brent Moritz, Penn State University, Smeal College of Business, University Park, PA, 16802, United States, bmoritz@psu.edu, Sam Kirshner

We investigate whether construal levels impact inventory management in a newsvendor task. In two experiments, we find that individuals primed with a high construal level (abstract focus) are more pulled-to-center and have lower expected profits than the participants primed with a low construal level (concrete focus).

2 - Wholesale Price Contracts Versus Capacity Reservation Contracts under Information Sharing: A Behavioral Investigation

Sebastian Schiffels, Technical University Munich, Munich, 80333, Germany, Guido Voigt

We address the question whether non-linear contracts outperform wholesale price contracts in a setup where a manufacturer has private information on end-customer demand that is of relevance for the supplier's capacity decision. Our experimental study with 234 subjects provides an internally valid comparison of both contract types when information sharing is possible. The comparison reveals that non-linear contracts may outperform wholesale-price contracts even though we observe that wholesale price contracts perform better than theoretically predicted while non-linear contracts perform worse than theoretically predicted which is in line with previous studies.

3 - Delegation Between Humans and AI: An Experimental Investigation of the Future of Work

Andreas Fuegener, University of Cologne, Albertus-Magnus-Platz, Cologne, 50923, Germany, andreas.fuegener@gmail.com

A defining question of our age is how AI will influence the workplace of the future and, thereby, the human condition. The dominant perspective is that the competition between AI and humans will be won by either humans or machines. We argue that the future workplace may not belong exclusively to humans or machines. Instead, it is better to use AI together with humans by combining their unique characteristics and abilities. In three experimental studies, we let humans and a state of the art AI classify images alone and together. We present novel insights with impact on human-AI collaboration at the workplace.

4 - An Experimental Study of Strategic Inventories in Dual Channel

Yan Lang, University of Texas at Arlington, Arlington, TX, United States, yan.lang@mavs.uta.edu, Kay-Yut Chen

In this paper, we use game theory analysis to determine how the retailer can gain a strategic advantage by holding inventories, in order to effectively gain market share while competing by selling quantities with the supplier who has her own direct selling channel. We also conduct a series of controlled laboratory experiments on MTurk to examine whether our research hypotheses align with human decision makers in terms of behavior changes when facing different market power and cost issues. We finally build behavior models to explain the laboratory results with bounded rationality, fairness, and strategic inventory bias.

5 - Beauty is in the Eye of the Route Planner

Yingjie Fan, Erasmus University, Rotterdam, Netherlands, fan@rsm.nl, Niels Agatz, Daan Stam

Logistics service providers often have human planners interact with automated planning systems to plan their delivery routes. Anecdotal evidence suggests that planners may not use system-generated plans that `don't look nice'. However, as far as we know, the perceived quality and visual attractiveness of vehicle routes has not yet been empirically studied. We believe that such an empirical input is required to better understand why and when human planners are more likely or less likely to accept computer generated route plans.

Chair: Rakesh Mallipeddi

1 - A Framework for Analyzing Influencer Marketing in Social Networks: Selection and Scheduling of Influencers

Rakesh Reddy Mallipeddi, Tulane University, Mays Business School, Dept of Info & Operations, New Orleans, LA, 77843-4217, United States, Subodha Kumar, Chelliah Sriskandarajah, Yunxia Zhu

Influencer marketing, which involves employing influential users of social media, is being increasingly employed by organizations to market or advertise their products. In this talk, we present a data-driven analytical framework to answer the following questions from the marketer's perspective: • How many influencers to hire and whom to hire? • How to schedule and sequence marketer's content being promoted by multiple influencers? • What is the marginal benefit of hiring an influencer? • What are the strategies to augment the benefits of influencer marketing?

2 - How to Sell a Dataset? Pricing Policies for Data Monetization

Sameer Mehta, The University of Texas at Dallas, Richardson, TX, 75080, United States

The wide variety of pricing policies used in practice by data-sellers suggests that there are significant challenges in pricing datasets. We formulate a tractable model of a data-seller's problem of optimally pricing a dataset, and exploit its special structure to obtain near-optimal pricing policies.

3 - Rise and Fall of E-books: A Curious Case of Agency Pricing Model

Sailendra Prasanna Mishra, University of Texas at Dallas, Richardson, TX, 76201, United States, spm160530@utdallas.edu, Subodha Kumar, Liangfei Qiu

Agency pricing model allows publishers to take control over e-books and reduces the bargaining power of online retailers in setting retail prices. We study how the agency contract changes the pricing strategies for the publishers and the retailer with high cross-channel capability. The publishers with agency contract follow different pricing strategies for their books compared to strategies adopted by the retailer. Overall, our results show that the agency pricing model reduces the attractiveness of e-books from these publishers and makes their consumers worse off.

Chair: Erkin Otles, University of Michigan, Verona, WI, 53593, United States

1 - Managing Blood Inventory with Random Transfers

Srinivasa Kartikeya Puranam, Rutgers University, Camden, NJ, United States, David C. Novak, Marilyn T. Lucas

The primary objective of this research is to develop a practitioner-focused, easy-to-implement ordering heuristic to address the random transfer of blood via redistribution. Here, we present results of detailed sensitivity analyses which should provide practitioners with ordering guidance given the potentially high degree of uncertainty in some cost parameters.

2 - Supervised and Unsupervised Learning of Heart Disease Patients: A Case Study of Iranian Patients

Samaneh Davarzani, Mississippi State University, Starkville, MS, United States, Ruholla Jafari-Marandi, Brian K. Smith

In this work, we improve the prediction accuracy of supervised learning by identifying patterns in the dataset using unsupervised algorithms. This is accomplished by implementing self-organizing map and K-means to identify subgroups of patients in a dataset of heart disease patients from the Iranian population. Accuracy of three prediction models including, unsupervised learning model, supervised learning model, and the presented methodology is evaluated. We find employing unsupervised learning enhances performance of supervised learning and generates more plausible prediction models for practitioners due to procedure logic, which is based on inherent characteristics of the dataset.

3 - Comparing the Prediction of Length of Stay in Hospitals Between SMOTE and W-SIMO

Surya Ayyalasomayajula, Oklahoma State University, Stillwater, OK, United States, suryaba@okstate.edu, Ankita Srivastava, Dursun Delen

Length of Stay (LOS) prediction based on the information available at the time of admission to the hospital is very important for operational planning. The proportion of patients staying in a hospital for short, medium and long duration is imbalanced. Over-sampling the minority class or using SMOTE is one of the most promising remedies for imbalanced data learning. We test the performance of oversampling, SMOTE and the new weighted synthetic informative minority oversampling (WSIMO) algorithm proposed and tested on publicly available datasets by Piri & Delen (2017). The resultant balanced dataset will be used for prediction by single and ensemble machine learning algorithms.

4 - A Rare Event Classification Model Applied to Breast Cancer Diagnosis

Halenur Sahin, Middle East Technical University, Ankara, Turkey, halenur.sahin@metu.edu.tr, Serhan Duran, Ertan Yakici

We present a rare event classification model for the problems with class imbalance. For such problems, achieving high sensitivity and specificity simultaneously is important since it is possible to have high overall prediction rates just by assigning all the observations to the class that constitutes majority.

We utilize a MILP model with a genetic algorithm (PCM+RECGA). This model is tested with a breast cancer dataset and its performance is compared with some well-known machine learning methods. PCM+RECGA preserves its capability of detecting positive observations without sacrificing from its high detection ability of negatives in case of sparsity of positive observations.

Chair: Amitava Mitra, Auburn University, Auburn, AL

1 - Evolutionary Game Analysis of Employee-organization Relationship in Sharing Economy – Based on Platform Users Supervision

Miaomiao Wang, Nanjing University of Aeronautics and Astronautics, Nanjing, China, wangmiaom_nuaa@163.com, Jie Zhang, Lu Zhang, Yan Zhao Bi

In order to study the evolutionary mechanism of employee-organization relationship under the sharing economy context,this paper introduces the perspective of supervision of platform users,establishes an evolutionary game model.It shows that the choice of employee compliance behavior and platform enterprise control strategy depend on extent of the users' supervisory,and reinforcing the users supervision can make platform enterprise strengthen supervision and improve employees behaviors.Thus platform enterprise should taking full advantage of the supervisory effect of platform users to achieve mutual trust and harmonious employee-organization relationship.

2 - Explaining and Validating Second Prices for Combinatorial Auctions

William K. Schwartz, Co-founder, Ingraham and Schwartz Auction Advisers, LLC, Arlington, VA, United States, wkschwartz@gmail.com, Allan T. Ingraham, Shreyas Ravi, Christopher T. Sojourner

National auctions of radio spectrum—complicated by scores of products, each with multiple units, yielding astronomical numbers of combinatorial winning outcomes—often stipulate pricing rules based on opportunity costs. These prices are NP-hard to compute and NP-harder to explain to bidders and thus give participants confidence payments are correct. In theory, a full proof of prices requires seeing a number of counterfactual auction results exponential in the number of bidders. In practice, a very small number of counterfactuals determine prices. We present them in a novel interface that drastically simplifies both pedagogy and auditing.

3 - Fast and Exact Simulation of Spatially Cross-correlated Images Using Circulant Embedding Method

Shengfeng Chen, Western Michigan University, Kalamazoo, MI, United States

This paper presents a generic methodology for generating multivariate cross-correlated images with Gaussian random process. The proposed approach can fast simulate a pair of full-size images with exact auto- and cross-correlation structures extracted from original images through circulant embedding method. In there, a Toeplitz correlation matrix R is embedded into a positive definite circulant matrix S. The formulated circulant matrix reduce computational load and achieve extraordinary computational complexity of order O(nlogn) . Due to the low demand in computer memories, a full-size image with millions of pixels can be realized with exact spatial auto- and cross-correlations.

4 - Optimal Policy Parameters for Two-dimensional Warranties with Options To Extend

Amitava Mitra, Professor, Auburn University, Auburn, AL, United States, mitraam@auburn.edu

Certain products, such as automobiles, have warranty policies that incorporate two dimensions, namely time since purchase of the product and usage based on mileage accumulated. If both of these parameters are less than the stipulated values in the warranty policy, in case of product failure, the manufacturer replaces or repairs the product free of charge. In many consumer durable goods, an initial warranty is offered during purchase of the product. In the event of no failure during the initial warranty, the consumer is offered the option to extend the warranty. Here, we assume that the propensity to extend warranty is influenced by the unit product price and the consumer's threshold price level.

5 - Forecasting the Demand of Mobile Clinic Services Using Heterogeneous Data

Bilal Majeed, PhD. Candidate, University of Houston, Houston, TX, United States, bmajeed2@uh.edu, Jiming Peng, Ying Lin

Demand forecasting plays an important role in the deployment of mobile clinic services as it can help a mobile clinic to maximize its coverage under limited resource. In this paper, we present a new forecasting model to predict the vaccination delinquency in census tracts based on the vaccination data in schools and demographic data from school and census tracts. For this, we first develop an association between the delinquency data in census tracts and school zones. Then we use this association and the similarity structure of the census tracts to forecast the vaccination delinquency in the census tracts. A case study in Harris County is reported to demonstrate the efficacy of the new model and technique.

6 - Finding the Best Strategy to Allocate Medical Resources to the Affected Sites

Nazanin Naderi, Youngstown State University, Youngstown, OH, United States, nnaderi@ysu.edu

In this paper, we study the problem of allocating emergency units to affected sites and casualty groups in the initial hours after sudden-onset disasters to maximize the number of survivors. Survival rate of extricated casualtiesis high in the first hours following disasters, but the number of emergency (rescue and medical) units available to service casualties is often inadequate. Optimal allocation of units to the affected sites and casualty groups is necessary to maximize the number of survivors. In this paper, we determined the best strategy to allocate rescue and medical units to affected sites.

1 - Simultaneous vs. Sequential Bundling Strategies in a Distribution Channel

Chia-Wei Kuo, National Taiwan University, Taipei, Taiwan, cwkuo@ntu.edu.tw, Qianbo Yin, Kwei-Long Huang, Sean Zhou

Product bundling is a commonly used marketing tool. Our paper aims to provide explanations from the perspective of channel structure for a retailer selling a base and an add-on product/service. We consider a model in which a retailer sells base and add-on products supplied by two manufacturers. There are four channel configurations which firms are integrated or not. We find that the retail price of the sequential bundle could be lower when firms are integrated. In contrast, the sequential bundle price is lower than the simultaneous bundle when the retailer integrated with any other firm. When firms are independent, the consumers cannot enjoy the discount from sequential bundling price is lower.

2 - Channel Design and OEM Growth in a Multi-market Setup

Chia-Wei Kuo, National Taiwan University, Taipei City, Taiwan, cwkuo@ntu.edu.tw, Hsiao-Hui Lee, Ting-Kai Chang

We study how to design an OEM's direct selling channel in a multi-market setup so to sustain the OEM's business growth. In this paper, we consider an OEM producing for a brand buyer that operates in two markets: the domestic market and the international market. The OEM offer the brand a discount in exchange for using the excess capacity to produce products under the OEM's own brand and then sells these products through its selling channel. We find that the OEM direct selling channel can be a win-win-win strategy for the brand, the OEM, and consumers. Such insights are generally robust, even when we consider a cost for the OEM's selling channel, such that the OEM avoids selling the same product at too low a price.

3 - Showrooming and Webrooming: How Information Provision and Price Matching Help Retailers

Yuyun Zhong, Drexel University, Philadelphia, PA, United States, yz569@drexel.edu, Wenjing Shen, Oben Ceryan

Consumers strategically choose a product information gathering channel and product purchasing channel. Showrooming and webrooming exist when the two channels deviate. We endogenize consumers' choices of information gathering and purchasing, and examine how the online retailer provides information effectively when competing with a brick-and-mortar retailer. In addition, we study how price matching affects the two retailers.

4 - Product Bundling in Distribution Channels under Fairness Concerns

Xiang Ji, University of Science and Technology of China, Hefei, China, signji@mail.ustc.edu.cn, Yuwei Hu

We study firms' optimal decisions on product bundling in a bilateral monopoly distribution channel. We show how manufacturer-driven bundling and retailer-driven bundling are respectively influenced by the joint effect of channel decentralization and fairness concerns.

5 - Inducing Supply Chain Transparency Through Supplier Encroachment

Xu Guan, Huazhong University of Science and Technology, Wuhan, China, guanxu@hust.edu.cn, lei xiao, Baoshan Liu

This paper investigates the supplier's voluntary disclosure strategy when he can encroach on the retailer's operations by selling directly to final consumers. The establishment of direct channel expands the market potential, induces the supplier to adopt disclosure strategy more frequently, and finally leads to a higher level of information transparency in the supply chain. Since more quality information is revealed in the presence of dual-channel, the retailer is able to derive a higher ex-ante payoff from supplier encroachment while the supplier may become worse off under such a circumstance.

6 - The Strategic Role of Warm-Glow Effect in Product Bundling

Mingjun Li, University of Science and Technology of China, Hefei, Anhui, China, mjlee@mail.ustc.edu.cn, Jie Wu, Xiang Ji

Non-economic factors should be paid attention to when making business decisions. Here, we mainly focus on the social attributes of crowdfunding. We study a manufacturer's decisions on product bundling and receive an interesting finding that the manufacturer will also choose a bundle strategy when the cost is high enough.

Scheduling IV

Contributed Session

Chair: Xiaojuan Jiang, POSTECH, Pohang, 37673, Korea, Republic of

1 - Incorporating Consecutive Working Time Restrictions into Parallel Machine Scheduling

Kan Fang, Tianjin University, Tianjin, China, kfang@tju.edu.cn, Shijin Wang

We consider an unrelated parallel machine scheduling problem with restrictions on employees' working time and break time, and the objective is to minimize the weighted sum of the makespan, the machine depreciation costs and the labor costs. To solve this problem, we developed a combinatorial Benders' decomposition based algorithm, our extensive experimental results demonstrate the efficiency of our proposed solution approaches on solving this problem.

2 - A Stochastic Optimization Approach for Scheduling Flow Shops with On-site Renewable Generation

Shasha Wang, Clemson University, Central, SC, United States, shashaw@g.clemson.edu, Harsha Gangammanavar, Scott J. Mason

On-site renewable energy represents an attractive option for manufacturing plants to save energy costs when faced with variable electricity prices. We present a multi-objective, stochastic optimization framework for scheduling flow shops with on-site renewable energy generation to minimize both the total weighted completion time of jobs and energy costs. An epsilon-constraint algorithm integrated with a stochastic decomposition approach is proposed to analyze the problem. The results from our computational experiments demonstrate the effectiveness of our proposed methodology for minimizing the two objectives of interest.

3 - A Parallel Randomized Approximation Algorithm for the Non-preemptive Single Machine Scheduling Problem

Hossein Badri, Wayne State University, Detroit, MI, United States, hossein.badri@wayne.edu, Tayebeh Bahreini, Daniel Grosu

In this paper, we design a parallel randomized approximation algorithm for the non-preemptive single machine scheduling problem with release dates and delivery times, where the objective is to minimize the completion time of all jobs (i.e., makespan). To evaluate the performance of the proposed algorithm, we perform a comprehensive experimental analysis on several instances of the problem. The results indicate that the proposed parallel algorithm can efficiently solve large instances achieving significant speedup on parallel systems with multiple cores.

4 - Approximation Algorithms for Bi-criteria Scheduling Problems

Xiaojuan Jiang, POSTECH, Pohang, Korea, Republic of, xjjiang@postech.ac.kr, Kangbok Lee

The bi-criteria scheduling problems that minimize the two most popular scheduling objectives, namely the makespan and the total completion time, are considered. Since the ideal schedules, which simultaneously minimize both objectives, are usually unachievable, it makes sense to consider a balanced schedule with reasonable approximate objective values. Thus, several (1, 2)-approximation algorithms are developed with their worst-case performance analyses on several machine settings, where 1 and 2 are the approximation ratio for both criteria, respectively. Also, the lower bound curves or Pareto curves are explored.

5 - An Efficient MIP Model for Lot-sizing and Scheduling Problems with Tardiness, and Sequence-dependent and Overlapping Setups

Ching-Lun Lin, National Chiao Tung University, Hsinchu, Taiwan, asd102600@gmail.com, Sheng-I Chen, Jo-Ying Chang

This study focuses on minimizing weighted tardiness for orders due on different periods. The problem formulated as a MIP model is established on the multi-period with sequence-dependent, carryover, and overlapping setups. An alternative formulation of sub-tour eliminations is proposed by taking advantage of setup time properties for specific problem instances. We compare the performances between the alternative formulation and the valid inequality based on the dependent set concept. The result shows that the proposed method is capable to obtain a quality solution for large problem instances.

Data Envelopment Analysis II

Contributed Session

Chair: Yeming Gong, EM Lyon Business School, Ecully, 69134, France

1 - Two-stage Efficiency Measurement of Non-homogenous DMUs Using the DEA Methods: An Application to Major Banks in the Digital Age

Ting Cao, Phd Candidate, York University, Toronto, ON, Canada, tingc0109@gmail.com, Murat Kristal, Wade D. Cook

The impact of digitalization on banks' performance is an emerging topic. We propose a two-stage DEA approach to measure non-homogenous DMUs' efficiencies and explore the efficiencies determinants. Partial inputs to outputs impact are considered based on the nature of DMUs' internal structures. An illustrative application to major banks in North America is included.

2 - Workload Quantification and Distribution in Socio-technical Infrastructure Management Systems

Taylan Topcu, Virginia Tech, Falls Church, VA, United States, Ning-Yuan Liu, Konstantinos P. Triantis, Bart Roets

Infrastructures are complex socio-technical systems (STSs) that rely on the collaboration between human Controllers and autonomous systems (AS) for their safety-critical control activities. While modern STSs increasingly rely on automation, uncontrollable dynamic characteristics of the infrastructure render the use of automation sub-optimal and require manual control in certain instances. We use microeconomic production theory to investigate operational data from Belgian Railways and quantify the workload distribution between humans and AS. We then use machine-learning techniques to study which uncontrollable network characteristics influence the workload distribution.

3 - The Effects of Renewable Energy Sources on the Macroeconomic Efficiency of the High- and Low-income Economies

Umit Saglam, East Tennessee State University, Johnson City, TN, United States, saglam@etsu.edu

In this study, a two-stage Data Enveloped Analysis (DEA) is developed to quantitatively evaluate the impact of renewables on macroeconomic efficiencies of the high - and low-income economies by using pre-determined inputs (labor, capital stock, and renewable energy consumption) and outputs (real GDP and carbon dioxide emission) variables. The sensitivity analysis is conducted to test the robustness of the DEA models. Tobit regression models are conducted by using the DEA results for the second stage analysis to investigate the effects of renewable energy consumptions. We hope that the results of this study shed some light on this relationship for both energy practitioners and policymakers.

4 - A Dynamic Data Envelopment Analysis on IT and Performance

Yeming Gong, Em Lyon Business School, Ecully, France, gong@em-lyon.com, Jiawen Liu, Joe Zhu, Ryad Titah

Based on data envelopment analysis (DEA), this paper first examines the linkages between IT factors, intermediate performance metrics and ultimately business outcomes empirically in an IT productivity research and advances a new conceptual perspective to investigate the IT productivity paradox. We propose a theoretical framework based on dynamic network DEA models, considering multiple periods, multiple inputs and outputs, to study and understand the IT productivity paradox.

1 - MDP Algorithm for Wave Energy Conversion and Battery Storage

Trent Dillon, University of Washington, Seattle, WA, United States, tmaxd@uw.edu

We explore the application of a Markov Decision Process (MDP) algorithm to wave energy conversion and battery storage. Ocean waves are stochastic and intermittent. Wave power cannot be perfectly forecasted, and battery storage is necessary to overcome intermittencies. We developed an MDP algorithm that uses a stochastic wave forecast to make optimal operational decisions on power consumption versus storage. In simulation, we show that the incorporation of an MDP leads to more effective battery storage and power availability for autonomous wave-powered systems.

2 - The Optimisation of Public Sector Buildings Portfolio Energy Consumption

Paul McWilliams, Strategic Investment Board, Belfast, United Kingdom, pmcwilliams08@qub.ac.uk

A mathematic approach to develop dynamic building type energy reduction targets for the public sector building portfolio.

3 - Exploring the Effects of Persuasive Information on Local Residents Support for the Planning of Energy Facilities with Radioactive Hazard in China

Zhi Li, University of Science and Technology of China, hefei, China, 648893047@qq.com

Linking two routes of perceptible information from Elaboration Likelihood Model to different local residents' support level to the planning of energy facilities with radioactive hazard, we propose that local residents as direct stakeholders of energy facilities whose attitudes toward the project tend to rely on the positive central route information when faced with more self-interest signals from peripheral route, but rely on the negative central route information when faced with more false information. We provide empirical support for our theory by investigating the local residents' support level of large-scale energy facilities in China when those projects stay in planning phase.

4 - Ancilllary Market Designs to Incentivize Flexibility in Power Systems

Mort David Webster, Professor of Energy Engineering, Pennsylvania State University, University Park, PA, United States, mort@psu.edu

Generators that participate in electricity markets tend to get most of their revenue from energy and capacity markets. We demonstrate that this can create a disincentive to increasing some types of flexibility. We use a stochastic unit commitment model to explore how different ancillary service market designs can improve the incentives to owners to invest in operational flexibility, and compare the impacts of using an operating reserve demand curve and/or a flexi-ramp product.

5 - Impact of Psychological Factors on Energy-saving Behavior: Moderating Role of Government Subsidy Policy

Yi She, University of Science and Technology of China, Hefei, China, 599274427@qq.com

This paper studies the effect of government incentive measures and the moderating effect of psychological factors on the energy-saving behavior of Chinese residents. Results show that the energy-saving attitude and environmental responsibility of residents have a significant positive impact on energy-saving behavior, whereas consumer values have none. This result differs from the findings of previous studies. The subsidy policy has a vital role in promoting energy-saving behavior and a significant positive moderating effect on attitude and energy-saving behavior. However, it has a significant negative moderating effect on environmental responsibility and energy-saving behavior.

6 - Pathways to Carbon Neutrality for Turkish Energy System Using Leap and Osemosys

Emre Celebi, Assistant Professor, Kadir Has University, Istanbul, Turkey, ecelebi@khas.edu.tr, Gokhan Kirkil, Ahmet Deniz Yucekaya

This study compares two energy models, Long-range Energy Alternatives Planning (LEAP) and Open Source energy Modelling System (OSeMOSYS) for integrated assessment and energy planning of Turkish electricity system. We have studied three energy transition scenarios until 2050; the business as usual (BAU), energy conservation (EC) and renewable energy (REN) scenarios. EC scenario considers use of energy efficient appliances and imposing carbon tax, whereas REN scenario considers increasing the share of the renewables as much as possible in the power generation mix. We have evaluated these scenarios in terms of cost and environmental impacts and concluded that the REN scenario is the best option.

Sponsored Session

Chair: Gulru F Ozkan-Seely, University of Washington Bothell, Bothell, WA, 98011, United States

1 - Discovery vs. Repositioning: An Empirical Study of Time Allocation Contingencies in Drug Development

Moren Levesque, York University, Schulich School of Business, 4700 Keele Street, Toronto, ON, M3J 1P3, Canada, mlevesque@schulich.yorku.ca, Annapoornima Subramanian, Vareska Van De Vrande

The biotechnology and pharmaceutical industry employs two approaches in bringing drugs to market. The first is to engage in new drug discovery and development from scratch, while the second approach called drug repositioning, repurposes a previously approved and launched drug by identifying new therapeutic applications. Firms must give equal consideration to both approaches to maintain an effective and efficient drug portfolio. Drawing insights from the exploration-exploitation literature, our study formally models and empirically tests how firms operating in the industry can develop and maintain an optimal balance across the two approaches.

2 - Outsourcing and Offshoring in Complex Product Development Projects

Ole Frauen, Volkswagen AG, Brieffach 1853, Wolfsburg, 38436, Germany, Arnd H. Huchzermeier, Jurgen Mihm

Should a company outsource or offshore development? Globally operating organizations that develop complex products are faced with the question of how to efficiently decompose and allocate product development work across geographic, or organizational boundaries. The decisions must clearly depend on characteristics of the product (such as its architecture or its innovativeness). Based on an extensive data set involving all development projects of one of the largest car manufacturers worldwide, we study how different product characteristics affect the relationship between outsourcing and offshoring and product quality in complex product development.

3 - The Impact of Emission Policies on Technology Investment Decisions

Leonardo P. Santiago, Copenhagen Business School, Department of Operations Management, Solbjerg Plads 3, Blok B. 5. sal, Frederiksberg, Denmark, Franz Buchmann

We develop a model to investigate the investment decisions to cope with emission's target, which are subject to uncertainty stemming from economic and regulatory risks. The research is motivated by the case of the maritime industry. The results indicate that the optimal investment policy has to balance the trade-off between costs of installing technological measures today and expected future cost reductions through higher carbon efficiency. More importantly, the extent of the investment is increasing in the ship owner's current demand for pollution. Also, the optimal investment policy is significantly affected by the economic and regulatory risks and by the magnitude of their uncertainty.

4 - Knowledge-Based View of the Use of an Intermediary in New Product Manufacturing Outsourcing

Qiong Chen, University of Science and Technology of China, School of Management, University of Science and Technology of China, Hefei, 230026, China

We introduce a game-theoretic model to examine the impact of outsourcing knowledge, and firm- and market-level factors, on a buyer's decision of whether to employ an intermediary to identify a manufacturer for her new product. We find that indirect outsourcing is more attractive as the buyer's outsourcing knowledge increases but follows an inverse-U shape as that of the agent increases.

Stochastic Oilfield Optimization

Sponsored: Energy, Natural Res & the Environment/Natural Resources Petrochemicals

Sponsored Session

Chair: Atefeh Jahandideh, PhD, University of Southern California, CA, United States

1 - Stochastic Optimization Models for Short-term Oil Production

Thuener Silva, PUC-Rio LAMPS, Rio de Janeiro, Brazil, thuener@esp.puc-rio.br, Davi Valladao, Tito Homem-de-Mello, Bernardo Kulnig Pagnoncelli, Carlos Rodriguez, Bruno Vieira

The process of managing oil production on offshore platforms with multiple wells is complex. The decision maker has to deal with multiples production curves, platform constraints and the presence of uncertainties associated with oil production. Deterministic optimization models use the simulated points, along with binary variables, to express a piecewise linear proxy for the production curve. In this context, we propose a two-stage stochastic programming model that aims at obtaining the optimal target gas-lift injection and wellhead pressure under uncertainty, using a computationally tractable approximation of the production curves.

2 - Physics Embedded Machine Learning for Modeling and Optimization of Oil and Gas Assets

Pallav Sarma, Chief Scientist, Tachyus, Berkeley, CA, United States, Pallav@tachyus.com

This talk describes a unique modeling approach termed Data Physics. Data Physics is the amalgamation of the state-of-the-art in machine learning and the same underlying physics present in reservoir simulators. These models can be created as efficiently as machine learning models, integrate all kinds of data, and can be evaluated orders of magnitude faster than full scale simulation models. We present applications of Data Physics models to real steamflood and waterflood optimizations, wherein, the injectant is redistributed to maximize/minimize multiple objectives. A significant increase in actual incremental oil production and reduction in operational cost is demonstrated.

3 - Stochastic Optimization of Heavy Oil Reservoirs

Cenk Temizel

Please check the mobile app for this abstract.

4 - Well Location Optimization Using Reinforcement Learning

Kshitij Dawar, Graduate Research Assistant, The Pennsylvania State University, State College, PA, United States, Mort David Webster, Sanjay Srinivasan

A novel approach using Reinforcement Learning (RL) is developed to capture the uncertainties in petrophysical properties during reservoir development by developing several approximate solutions, in conjunction with existing geostatistical reservoir modeling techniques and Ensemble based Kalman Filtering, for developing reservoir models has been proposed. Seismic data along with well logs (to determine reservoir lithofacies) as they become available during the reservoir development process are utilized to suggest locations for future exploration. We demonstrate that the policies generated using RL outperforms a myopic policy of pure exploitation and improves future well exploration.

1 - Spatio Temporal Wind Power Prediction with a Case Study in ERCOT

Mario E. Arrieta-Prieto, Rensselaer Polytechnic Institute, Troy, NY, United States, arriem2@rpi.edu, Kristen Schell

Spatio-temporal prediction of renewable power output is critical for optimizing its integration into the power system. Making accurate predictions in the space-time domain is a difficult task due to asymmetric and nonlinear relationships as well as potential bounded/censored observations. Previous models have addressed these issues separately, however, few models provide an integrated solution. This work combines a time-varying copula approach to model spatial interactions with cutting-edge temporal models to jointly address the probabilistic forecasting in the short run. The model is tested and validated on geographically diverse wind farm locations in the Texas power system of ERCOT.

2 - Transitioning Towards an Energy Efficient and Low Carbon Economy: A Review of Strategies Being Implemented in Ghana

Papa Yaw Owusu-Obeng, Rensselaer Polytechnic Institute, Troy, NY, United States, pyowusuobeng@gmail.com

The inadequacies of the electricity sector of Ghana have resulted in persistent load shedding over the last three decades. Ghana's power shortages are mainly caused by the increasing rate of domestic electricity demand which on average, accounts for 51% of total consumption and continues to rise sharply at a rate of 6% - 7% p.a. The prevailing situation has created the need to accelerate demand-side management strategies to curtail electricity demand growth. This work presents a review of nationwide programs implemented in Ghana to improve end-use efficiency and promote distributed renewable energy generation. The results demonstrate significant reductions in peak demand.

3 - Generalized Hourly Wind Power Prediction Model

Kristen Schell, Rensselaer Polytechnic Institute, Troy, NY, 12180, United States, schelk@rpi.edu, Andrea Staid, Seth Guikema

Decarbonization of the power sector is predicted to provide 50 percent of the greenhouse gas emission reductions needed to prevent global temperature rise above 2 degrees Celsius. Wind power installation is expected to be a major contributor to power system decarbonization, yet accurate models do not exist for long-term wind power prediction. We have developed a machine learning model of hourly wind power output that performs well across varied geographic terrain. The results are useful for power system planners and operators in designing and managing the renewable energy transition.

4 - Optimizing the Use of Curtailed Power in the Electric Grid

Ahmed Abdulla, Carnegie Mellon University, Pittsburgh, PA, 92093, United States, Kristen Schell

In the past decade, decreasing costs and government incentives have led to a forty-fold increase in installed solar capacity worldwide; installed wind capacity has increased six-fold over the same period. As a result, several major electricity markets have seen an increase in curtailment: the shutting down of production from renewable generators because the system cannot integrate it. This work assesses the risks of renewable power curtailment in California using an hourly, five-year historical record. We analyze how to transform these risks into benefits by powering technologies that could exploit curtailed generation and evaluate the likely cost and performance of each of these.

Power System Expansion Analysis

Sponsored: Energy, Natural Res & the Environment/Electricity

Sponsored Session

Chair: Enzo E Sauma, Pontificia Universidad Catolica de Chile, Santiago, Chile

1 - The Role of Expectations for Market Design – on Structural Regulatory Uncertainty in Electricity Markets

Harry van der Weijde, The University of Edinburgh, Edinburgh, 0, United Kingdom, H.Vanderweijde@ed.ac.uk
Harry van der Weijde, The Alan Turing Institute, London, United Kingdom, H.Vanderweijde@ed.ac.uk, Mirjam Ambrosius, Jonas Egerer, Veronika Grimm

Ongoing policy discussions on the reconfiguration of bidding zones in European electricity markets induce structural uncertainty about the future market design. This paper deals with the question of how this structural uncertainty affects market participants and their long-run investment decisions in generation and transmission capacity. We propose a stochastic multilevel model, which incorporates generation capacity investment, network expansion and redispatch, taking into account uncertainty about the future market design. Our results reveal that expectations about future market structures have an important effect on investment decisions.

2 - Long-term Planning Models on Steroids: Representation of Short-term Operation for Long-term Decision Making

David Pozo, PhD, Skolkovo Institute of Science and Technology, Moscow, Russian Federation, d.pozo@skoltech.ru

Long-term power system planning requires a representation of the many, possibly infinite, operational setpoints of the future states of the system. A couple of decades ago, Planners used a few aggregated values of system demand for incorporating into their optimization models. An avalanche of new models with an extensive representation of the operation has appeared with the same premise: clustering high-dimensional data into low-dimensional one (typical days or periods). In this presentation, we will describe the most common approaches, and we will propose an alternative for embedding an infinite-dimensional set of short-term operation into long-term planning models.

3 - Incorporating Cooperative Game Theory Principles into Cross-Border Transmission Expansion Planning Algorithms

Andrey Churkin, Skoltech, Moscow, Russian Federation, andrey.churkin@skolkovotech.ru, David Pozo, Enzo E. Sauma, Janusz Bialek, Nikolay Korgin

Cooperative game theory found an extensive application in power system studies. The particular interest lies in power systems interconnection projects where each system (or country) is an independent player who can accept the terms of cooperation or veto construction of interconnections. Various solution concepts such as the Shapley value and the Core have been exploited in order to share possible benefits of cooperation. However, all of the concepts were implemented as ex-post add-ins. We suggest a novel approach to cross-border transmission expansion planning that explicitly embeds cooperative game theory principles into the optimization and leads to more realistic solutions.

4 - Impact of Introducing Flexibility in Transmission Expansion Planning: An Application in the Chilean Power System

Enzo E. Sauma, Pontificia Universidad Catolica de Chile, Santiago, Chile, esauma@ing.puc.cl, Francisco Mariscal, Tomás Reyes

We study the value of adding flexibility to Transmission Expansion Planning (TEP) projects from the perspective of a social planner using real options. The existence of multiple sources of uncertainty often cause traditional project valuation methods to recommend sub-optimal investment decisions. To properly incorporate the effects of uncertainties on the valuation of TEP projects, we propose a methodology that values the net discounted social welfare of adding flexibility through real options, using Least Squares Monte Carlo. The methodology is applied to determine the value of adding flexibility to a portion of the project that connects the main two systems in Chile since 2018.

Sustainable and Resilient Energy Systems

Sponsored: Energy, Natural Res & the Environment/Energy Sponsored Session

Chair: Roshanak Nateghi, Purdue, IN, 47907, United States

1 - Understanding the Regional Impacts of Climate Change on Natural Gas Sector with CGE Modeling

Duan Zhang, University of California Santa Cruz, Santa Cruz, CA, 95062, United States, dzhang33@ucsc.edu, Yihsu Chen

Exploring resilience options and adaptation measures to climate change impacts are becoming an important issue in regional planning. In order to implement the cost-effective resilience options, it’s important for the regional planner and policymakers to understand not only the local economic impacts of climate-change-induced hazards, but also the spillover effect to other sectors and regions. We studied the regional economic impacts of such hazards with a focus on California natural gas sector. A computable general equilibrium (CGE) model with bilateral trade flow was constructed to represent the impacts of gas service disruption.

2 - Modeling the Impact of Climate Change on the New York State Energy Consumption

Renee Obringer, Purdue University, West Lafayette, IN, United States, robringe@purdue.edu, Sayanti Mukherjee, Roshanak Nateghi

As the climate continues to change, current models for projecting future energy demand (i.e., electricity and natural gas) need to be revisited. The role of climate on the coupled electricity-natural gas nexus has been understudied. Moreover, given the interdependence within energy sectors, it is important to consider the demand co-variance across the sectors. Unlike previous studies, here we present a study that evaluates the impact of a wide array of climate factors on end-use energy consumption while accounting for the covariance across the electricity and natural gas demand of the residential, commercial and industrial sectors, using the state of New York as a case study.

3 - A Generalized Predictive Modeling Framework to Assess Climate Sensitivity of Peak Electricity Load

Sayanti Mukherjee, Assistant Professor, University at Buffalo (SUNY), 342 Bell Hall, North Campus, Buffalo, NY, 14260, United States, sayantim@buffalo.edu, Panteha Alipour, Roshanak Nateghi

Peak electricity load forecasting is an important area of research in electricity markets, and power systems planning and operation. Unanticipated climate-induced surges in peak load can lead to supply shortages causing frequent brownouts / blackouts, and large-scale socioeconomic impacts. In this research, we present a data-driven generalized predictive modeling framework to assess the climate sensitivity of daily peak load, using Texas as our case study. We found that maximum temperature and dew point are the two most important predictors of the climate-sensitive portion of daily peak load. Our model can also be used to make short-term predictions of the climate-sensitive daily peak load.

Incorporating Equity and Justice Concerns in the Design of Energy Systems

Sponsored: Energy, Natural Res & the Environment/Energy Sponsored Session

Chair: Arvind Ravikumar, Harrisburg University, PA, United States

1 - How Do We Reconcile Priorities During the Energy Transition?

Emily Grubert, Georgia Institute of Technology, Atlanta, GA, United States, gruberte@gatech.edu

Energy systems are vast collections of infrastructure with local, landscape, and global implications associated with a wide variety of impacts. Climate change is a major driver of current efforts to transition the energy system, but it is neither the only issue, nor for many people, the most salient issue associated with energy system transition. Designing energy systems for equity and justice requires explicit consideration of both outcomes and processes, with attention to multiple value systems. This talk addresses some of those value systems and their implications.

2 - Energy Systems Impacts on Pollution, Environmental Health, and Environmental Justice

Amanda Giang, Assistant Professor, University of British Columbia, Vancouver, BC, Canada, amanda.giang@ubc.ca

Energy systems may have adverse impacts for human and community health and well-being, and these impacts have been found to disproportionately be borne by marginalized communities. In this talk, focusing on air pollution and toxic chemicals, we describe illustrative examples of distributive injustice for low-income, racialized, and Indigenous communities in North America, using geospatial, integrated modelling, and case study research methods. Finally, we discuss potential opportunities for environmental and energy systems modellers and impacted communities to work together to better integrate health, wellbeing, and justice concerns in energy systems planning.

3 - Planning with Justice: Using Spatial Modelling to Incorporate Justice in Electricity Pricing - The Case of Tanzania

Hisham Zerriffi, Associate Professor, University of British Columbia, Vancouver, BC, Canada, hisham.zerriffi@ubc.ca, Vikas Menghwani, Alexandros Korkovelos, Babak Khavari, Andreas Sahlberg, Mark Howells, Dimitris Mentis

SDG7 strives to ensure modern energy access for all. Diversification of electricity through expansion of off-grid or mini-grid solutions poses challenges for both affordability and fairness. We demonstrate a methodology to apply equality and equity principles of justice in quantitative electrification planning. We use an open source spatial electrification model to arrive at cost-recovery price levels for Tanzania based on principle(s) of justice. We then calculate location-specific subsidy levels needed to ensure those price levels. Through our analysis, we put forth a methodological framework to examine concerns around distributive justice using quantitative energy modelling tools.

4 - Social Impacts of Carbon-beneficial Forest Management in California

Daniel Sanchez, Assistant Cooperative Extension Specialist, University of California, Berkeley, Berkeley, CA, United States, sanchezd@berkeley.edu, Bodie Cabiyo, Jun Wong

Responsible stewardship of forests can address key challenges posed by climate change including carbon sequestration, producing low-carbon products, and reducing the risk of catastrophic wildfire. However, little is known about the distributional and equity impacts of expanded forest management across the State. Here, we quantify the social impacts of carbon-beneficial forest management. We accomplished this by examining the potential for innovative wood products to drive forest management across California. We develop several metrics for the social impact of expanded management, including real estate values, economically disadvantaged communities, and high risk to life and property.

Emerging Topic Session

Chair: Changqing Cheng, Binghamton University, Binghamton, NY, 13902, United States

1 - Spatio-temporal Modeling for Tool Wear Propagation in Micro Friction Stir Welding

Weihong (Grace) Guo, Rutgers, The State University of New Jersey, Piscataway, NJ, 08854, United States, wg152@rutgers.edu, Zhe Gao

Solid state joining processes usually require a custom-made tool that rotates at high speed. When joining high-strength, lightweight materials, the tool condition is subject to severe strain, friction, and temperature. It is well acknowledged that tool wear affects joint quality. In this study, we develop a spatio-temporal model to characterize the dynamic tool wear propagation in micro-friction stir welding. The proposed model is developed in a hierarchical Bayesian structure with the first level being a data-driven regression model for the high-resolution tool pin profile and the second level being a physics-based advection-diffusion model for the latent (unobserved) welding temperature.

2 - Optimal Shape Control via L Infinity Loss for Large Space Structures

Juan Du, Oregon State University, College of Engineering, Corvallis, WA, 100871, United States, Shanshan Cao, Xiaoming Huao, Jianjun Shi

Natural dimensional variabilities of incoming large structures affect the assembly speed and quality of joins in large space structure assembly process. Thus, shape control is critical to ensure the quality of assembly. This paper proposes an optimal shape control methodology based on l infinity loss for large structure assembly process by considering the initial dimensional gap between the incoming pair of structures. Some related theoretical properties are shown. Compared to the current practice, the case study shows that our proposed method significantly reduces the maximum gap between two structures after shape adjustments.

3 - Decentralized Learning Enabled Control for Streaming Data in Distributed Manufacturing Agents

Hongyue Sun, University at Buffalo, Industrial and Systems Engineering, Buffalo, NY, 14260, United States, hongyues@buffalo.edu, Xinran Shi, Yi Zhou

Many manufacturing agents are being connected due to the advancement of information and sensing technology. However, most existing modeling and control methods are designed for individual agents. We propose a Decentralized Learning enabled Control (DLC) scheme for streaming data in distributed agents. In the proposed scheme, we dynamically learn the neighborhood of an agent to be controlled as new data stream in. Then, Decentralized Communication Sliding (DCS) algorithm is used for process modeling and control based on the agent's neighborhood information. We demonstrate the proposed DLC scheme in distributed agents in a crystal growth process.

Health Care, Public Health I

Contributed Session

Chair: Karen Angulo, Universidad de los Andes, Bogotá, 110111, Colombia

1 - Will Organizational Change Improve Healthcare Service Efficiency? A Natural Experiment Study Says Yes

Ai Ren, University of Maryland-College Park, Robert H. Smith School of Business, College Park, MD, 20740, United States, renai@rhsmith.umd.edu, Qi Li, Liye Ma

We studied a natural experiment in the largest cancer specialized hospital in the northern China. After introducing a new group of physicians to the hospital, the existing physicians group changed their behavior by ordering more tests and exams but at lower total cost. The overall healthcare outcomes were also improved.

2 - Global Budget Revenue Policy Impact on Emergency Department Efficiency in Maryland

Ai Ren, University of Maryland-College Park, Robert H. Smith School of Business, College Park, MD, 20740, United States, renai@rhsmith.umd.edu, Bruce L. Golden, Edward Andrew Wasil, Frank B. Alt, Margrét Bjarnadóttir, Jon Mark Hirshon, Laura Pimentel

We conduct an empirical analysis of the impact of Global Budget Revenue (GBR) implementation on Emergency Department (ED) efficiency measures for inpatients from January 2014 to April 2016 in Maryland. We use public data from the Centers for Medicare and Medicaid Services, the Census Bureau, and the Kaiser Family Foundation. Our study uses the difference-in-difference model with mixed effect. We find GBR has a statistically significant negative impact on Maryland ED efficiency performance for inpatients.

3 - Dta-driven Decision Support System for Assessment of Tertiary Healthcare Facilities

Zainul Abidin, LUMS University, Lahore, Pakistan, zain.khawaja@lums.edu.pk, Adeel Zaffar, Khudeja Ali, Fareed Zaffar

Development spending in third world countries is scarce and we need to identify conduits and targets that have the maximum potential for impact. This translates to channeling development funds into the most efficient public health care facilities. Unfortunately no system exists for a comparative assessment of such facilities to identify the most deserving targets. We present a data-fed ranking system for tertiary health facilities, that takes into account metrics like footfall, patient/doctor ratio, equipment efficiency, unplanned overheads, chain of referral etc, creating a weighted ranking that identifies which facilities can have the highest impact with incoming development funds.

4 - Improving Physical Activity Measurements with Data Analytics

María A. Wilches-Mogollon, Universidad de los Andes, Bogotá, Colombia, ma.wilches529@uniandes.edu.co, Olga L. Sarmiento

Accelerometers are able to capture the intensity of physical activity (PA) by measuring acceleration along the 3 movement axes. In health studies that measure PA, a typical valid sample consists of data collected for more than 10 hours over 4 consecutive days for a given participant. Yet, the relatively low adherence rates to accelerometers often threaten the sample size. A typical valid rate reaches up to 50% of the total collected data. To increase the number of valid samples, we developed a data protocol that creates synthetic weeks and selects the best data for each participant using data analytics. We calibrated our model using 300 accelerometer measurements. The valid sample size increased by 20%.

5 - Advancing Equity in the Mental Healthcare Supply Chain: Empirical Evaluation of a Mobile App

Yi Tang, Carlson School of Management, Minneapolis, MN, United States, tangx688@umn.edu, Kingshuk K. Sinha, Adam Moen

We empirically investigate user usage behavior of a mental health mobile app which consists of a self-monitoring function and an anonymous online community and its impact on users' mental wellbeing conditions. The results indicate that mobile apps can create capacity in a mental healthcare supply chain so as to reduce the disparities associated with gender, sexual orientation, and ethnicity. Specifically, traditionally underserved populations in the mental healthcare supply chain access and benefit from the mental health mobile app indifferent from or more than their better-served counterparts.

6 - Risk of Autoimmune, Neurological and Thromboembolic Diseases Due to Human Papilloma Virus Vaccination in Colombia

Karen Daniela Angulo, Universidad de los Andes, Bogotá, Colombia, kd.angulo2295@uniandes.edu.co, Ivan Mura

Cervical Cancer is the second leading cause of cancer-related deaths in Colombia. Although there are vaccines that protect against high risk HPV strains, questions about whether such vaccines increase the risk of autoimmune diseases have contributed to low percentage of immunization coverage in Colombia. This study aims to epidemiologically evaluate and analyze if the incidence of autoimmune, neurological, and thromboembolic diseases is associated with HPV vaccination. We use nationwide databases for a case-control study. Cases were matched by sociodemographic characteristics. Risk differences were studied using generalized equations estimation and multivariate logistic regression.

Quantitative Risk Management

Sponsored: Finance

Sponsored Session

Chair: Ruodu Wang, ON, Canada

1 - Optimal Insurance Design with a Variance Constraint on the Ceded Loss

Shengchao Zhuang, University of Nebraska Lincoln, Lincoln, NE, United States, szhuang3@unl.edu, Yichun Chi, Xunyu Zhou

We study an optimal insurance design from the perspective of the insured, who maximizes the expected utility of the final wealth when an upper limit is imposed by the insurer on the variance of the risk exposure. We show that the optimal insurance policy is in the form of stop-loss for a high boundary value or partial insurance above a deductible for a low boundary value. Especially, the deductible disappears if and only if the safety loading coefficient is zero. Through a comparative analysis, the effect of the insured's initial wealth and upper limit of the variance of the insurer's risk exposure on the insurance demand is then examined, when the insured's risk aversion and prudence are taken into account.

2 - Smart Order Routing via Machine Learning

Renyuan Xu, University of California-Berkeley, Berkeley, CA, 94720, United States, dorisxu1026@gmail.com
Renyuan Xu, University of Oxford, Oxford, United Kingdom, dorisxu1026@gmail.com, Robert Almgren

Cash treasuries, unlike most of the financial products, are available to trade on multiple venues. As a result, cash treasuries market allows traders to be opportunistic with respect to where to place the orders.

In this talk, we formulate this decision-making problem as an optimization problem. We then construct an ensemble model with four machine learning methods to predict the order fulfillment on different venues. These methods are logistic regression, neural networks, random forests and gradient-boosting. We then design a parameterized trading algorithm based on the ensemble model to route limit orders in real time. Our algorithm shows superior performance compared with existing methods.

3 - Robust Distortion Risk Measures

Silvana M. Pesenti, University of Toronto, Toronto, ON, Canada, Carole Bernard, Steven Vanduffel

In the presence of distributional uncertainty, robustness of risk measures is crucial, and can be accounted for by providing bounds on the values of the risk measure, so-called worst- and best-case risk measures. Worst-case risk measures that only take the knowledge of the first moments of the distribution in consideration are, however, too large to be practically relevant. In this paper, we provide sharp bounds for the class of distortion risk measures with constraints on the first two moments combined with a constraint on the Wasserstein distance to a baseline distribution. Adding the Wasserstein distance, leads to significantly improved bounds and more realistic worst-case distributions.

4 - An Axiomatic Foundation of Expected Shortfall

Ruodu Wang, University of Waterloo, Waterloo, ON, N2L 3G1, Canada, wang@uwaterloo.ca

The Value-at-Risk (VaR) and the Expected Shortfall (ES) are the two most popular risk measures used in banking and insurance regulation. According to the recent Basel Accords, ES replaces VaR as the standard risk measure for market risk in the banking sector. The class of VaR has been characterized in the literature with several different sets of economic axioms, whereas the class of ES, although being coherent risk measures, does not have an axiomatic foundation yet. We propose four simple and intuitive economic axioms to uniquely characterize an ES. Our results provide the economic foundation for using ES as the globally dominating regulatory risk measure currently employed in Basel III/IV.

Logistics II

Contributed Session

Chair: Matthieu Gruson, HEC Montréal, Montréal, QC, H2E 1W8, Canada

1 - A Benders Decomposition Approach for Biomass Feedstock Logistics with Mobile Equipment

Fangzhou Sun, Virginia Tech, Blacksburg, VA, United States, fangzhou@vt.edu, Subhash C. Sarin

We address the optimal design and operation of a biomass feedstock logistics supply chain (BFLSC) where sharing of some equipment in the supply chain is allowed. The BFLSC problem is a combination of facility location problem, single-item capacitated lot-sizing problem, and vehicle routing problem. We formulate this problem as a mixed-integer program (MIP) and propose an efficient Benders decomposition-based solution method. Computational investigation reveals the advantage of the proposed method over a direct application of MIP solver. Our case study has shown substantial cost reduction due to mobilization.

2 - A Heuristic Approach to Solve the Multi-Node Replenishment Problem in the Fast Food Supply Chain

Alejandro Vigo Camargo, University of Michigan, Ann Arbor, MI, United States, avigo@umich.edu, Yavuz A. Bozer

Per the USDA, in 2017, consumers spent over $310 billion at fast food stores. Given the size of this segment, there is a surprising scarcity of work focused on the logistics of fast food supply chains. This study focuses on replenishing multiple stores in a fast food network. We present a heuristic to optimize the multi-store, multi-period replenishment problem, by minimizing the distance traveled and the number of trucks needed. Preliminary results using industry data show that the heuristic generally provides good solutions compared to those used by our industrial collaborator.

3 - Warehouse Outsourcing Decisions for Green Supply Chain Management

Chen Yu, The University of Hong Kong, Hong Kong, yuchenhku@gmail.com

The research proposes a model that adds warehouse outsourcing decisions to a green supply chain via mixed linear programming technique to give suggestions on whether and to what extent should a company use third party warehouses. Carbon footprint is analyzed in the model to facilitate a lower carbon emission supply chain under carbon taxing policy and carbon trading system.

4 - Closing the Gap Between Research and Practice in Manual Order Picking: State-of-the-art Classification and Review

Sarah Vanheusden, UHasselt, Hasselt, Belgium, sarah.vanheusden@uhasselt.be, Teun van Gils, Katrien Ramaekers

Research on planning problems in manual order picking is extensive. However, practical applicability of the developed algorithms is rather limited due to a lack of incorporation of practical issues (e.g., safety issues, human characteristics) within these models. A state-of-the art classification and review of order picking literature is performed in order to identify and analyse practical considerations in order picking operations. Future research opportunities are provided to support the development of practically relevant decision support models.

5 - Benders Decomposition for a Two-stage Three-level Lot Sizing and Replenishment Problem

Matthieu Gruson, HEC Montréal, Montréal, QC, Canada, matthieu.gruson@hec.ca, Jean-François Cordeau, Raf Jans

We address a stochastic and uncapacitated three-level lot sizing and replenishment problem with a distribution structure. We consider one production plant that produces one type of item over a discrete and finite planning horizon. The items produced are transported to warehouses and then to retailers using direct shipments. We develop a Benders-based branch-and-cut algorithm to efficiently solve the problem. We propose computational enhancements. In particular, we design an algorithm to derive Pareto-optimal cuts without solving an auxiliary problem. The algorithm we propose outperforms CPLEX.

Using Predictive Modeling to Improve Hospital Operations

Sponsored: Manufacturing & Service Oper. Mgmt/Healthcare Operations

Sponsored Session

Chair: Song-Hee Kim, University of Southern California, Los Angeles, CA, 90089, United States

1 - Adventures in Personalized Predictive Modeling in Healthcare

Edieal J. Pinker, Yale School of Management, Yale University, New Haven, CT, 06520, United States, Junchao Ma

Attempts to use machine learning techniques to create personalized predictions in healthcare are becoming common. Adoption of such methods in practice will require integrating them into the decisionmaking processes of physicians. We will discuss how accuracy of predictions should be reported and how the usefulness of these methods should be assessed.

2 - Timing it Right: Balancing Inpatient Congestion Versus Readmission Risk at Discharge

Pengyi Shi, Purdue University, West Lafayette, IN, 47907, United States, shi178@purdue.edu, Jonathan Helm, Jivan Deglise-Hawkinson, Julian Pan

When to discharge a patient plays an important role in hospital patient flow management as well as quality of care and patient outcomes. We develop and implement a practical decision support tool to aid hospitals in managing the delicate balance between individual readmission risk and ward congestion. Our framework integrates an individualized prediction model that updates the readmission risk over a patient's hospital stay with a large-scale Markov Decision Process (MDP) to optimize the day-to-day discharge decisions. We overcome challenges in the prediction and the curse of dimensionality in solving the MDP. Lastly, we discuss on-going implementation efforts of this discharge tool.

3 - Dynamic Prediction of Length-of-stay in the Neonatal Intensive Care Unit

Kanix Wang, University of Chicago, Booth School of Business, Chicago, IL, 60637, United States, Kanix.Wang@chicagobooth.edu, Walid Hussain, John R. Birge, Michael D. Schreiber, Daniel Adelman

The widespread implementation of electronic medical record (EMR) systems has enabled hospitals to collect massive amounts of health data. We propose a framework grounded in established clinical knowledge to model patients' LOS using EMR data. In particular, we impose expert knowledge when grouping raw clinical data into medically meaningful variables. We use dynamic predictive models to output patients' remaining lengths of stay, future discharges, and census probability distributions. Evaluated with large-scale EMR data, the dynamic model significantly improves predictive power over the performance of any model in previous literature and remains medically interpretable.

Operations/Economics Interface

Contributed Session

Chair: Seyedmohsen Hosseini, University of Southern Mississippi

1 - Combining Leximax Fairness and Utilitarianism in a Mathematical Programming Model

Violet Xinying Chen, Carnegie Mellon University, Pittsburgh, PA, United States, xinyingc@andrew.cmu.edu, John Hooker

We study the problem of combining equity and efficiency in optimization models. Previous work defined social welfare functions combining Rawlsian maximin fairness and utilitarianism with a single parameter, which measures the utility disparity allowed before utilitarian objective takes over fairness objective. We propose a vector-valued social welfare function combining Rawlsian leximax fairness and utilitarianism. Optimization of the vector-valued function requires a sequential procedure, where the problem in each iteration has a MILP formulation. Besides methodological exploration, we show that proposed social welfare function satisfies a weaker form of Pigou-Dalton condition.

2 - Relational Contracts with Prediction

Parinaz Naghizadeh, Ohio State Univeristy, Columbus, OH, United States, Thanh Nguyen, Shai Vardi

We consider supplier-retailer long term relationships sustained through relational incentive contracts. We evaluate the effects of availability of predictions of future production values to retailers and/or suppliers on the contracts. Specifically, a retailer can choose to fire their currently contracted supplier if they predict that next stage production value is low. We show that prediction undermines the ability of the parties to commit to long-term relationships. In particular, compared to the case where such forecasts are not available and cannot be used in the contracts, prediction may benefit the retailer but lowers product quality.

3 - Inventory Risk Management in Supply Chain: Pricing and Contracts

Houcai Shen, Nanjing University, Nanjing, China, hcshen@nju.edu.cn, Weili Xue

In this paper, we consider a supply chain in which a supplier produces and sells a single product to an independent retailer who faces price-dependent stochastic demand. The contracting strategy can be chosen between pull contract or push contract. The retail pricing strategy, on the other hand, can be chosen between committed pricing or responsive pricing. We show the effect of different combinations of contracting and pricing strategies on the operational decisions of the supply chain parties, and the supply chain parties' preferences.

4 - The Impact of Supply Chain Complexity on a Plant's Recovery Time

Laharish Guntuka, University of Maryland-College Park, College Park, MD, United States, lguntuka@rhsmith.umd.edu, Thomas Corsi, David E. Cantor

We investigate how the three dimensions of supply chain complexity: upstream, internal and downstream can impact a plant's recovery time from a supply chain disruption. In addition, we study how exogenous vulnerability risks, revenue at risk and the plant characteristics can moderate this relationship.

5 - Ripple Effect Analysis of Supply Chains Using Probabilistic Graphical Models

Seyedmohsen Hosseini, University of Southern Mississippi, Long Beach, MS, United States

Supply chain disruptions are increasingly caused by growing global supply sourcing, complexity, and interconnectedness of supply chains. A key challenge in the context of supply chain disruption management is how to model and simulate the ripple effect of SCs. The ripple effects occur when the impact of disruption on upstream cannot be harnessed or controlled and propagates downstream. This work presents a probabilistic graphical approach that formulates and simulate the ripple effect in SCs.

Risk Analysis II

Contributed Session

Chair: Chao Guo, Tongji University

1 - Developing Risk Analysis Tools for Capacity-constrained Networks

Sinan Tas, Assistant Professor, University of Wisconsin-Platteville, Platteville, WI, United States, tass@uwplatt.edu

This simulation model is used to create a risk framework so that the likelihood of failure of a component, such as attack, cascade, random failures, together with the impact due to failure can be analyzed in order to prioritize and visualize critical components of the network based on various attack and failure scenarios, and decide how to allocate defensive investments accordingly. We use IEEE 118- and 300-bus power flow systems to test our framework and compare the results.

2 - Risk Analysis as a Critical Tool to Combat Human Trafficking

Julia Coxen, University of Michigan, Ann Arbor, MI, United States, juliaoh@umich.edu

Human trafficking is a global crisis that continues to be difficult to detect, prosecute, and examine. Although human trafficking manifests in all forms of modern slavery, this paper will specifically examine the sexual exploitation component of human trafficking. We show that risk analysis is a critical tool in combating human trafficking and introduce current policy levers emplaced globally. We make comparisons with Terrorism Risk Analysis and establish lessons learned from intelligent adversarial analysis that can help policymakers unpack the complexities of this criminal enterprise.

3 - A Continuous Time Markov Decision Process to Increase Resilience in Physical Systems

Weimar Ardila, PhD Student, University of South Florida, Tampa, FL, United States, weimar@mail.usf.edu, Daniel Romero, Alex Savachkin, Devashish Das

Given the occurrence of a disruption event the idea of building a resilient system makes sense, however many actions that can increase resilience conflict with traditional business goals such as reducing costs and increasing operational efficiency, which makes the implementation of such actions a really complicated task if there is no a trade off between being resilient and the costs of being resilient. The main research objective is to propose an initial approach for a Markov Decision Process formulation focused on minimizing the cost related to the implementation of actions to reduce a system's total recovery time, under the framework of a multi-stage recovery process.

4 - A Resilience Assessment Framework for Metro Systems Considering Multitype Failures

Yue Gao, The University of Hong Kong, Hong Kong, yuegao@hku.hk, Junwei Wang

Unforeseen failures in metro systems may cause catastrophic impacts on their structure and functionality. Research on the resilience, i.e., the ability to recover from disruptions—is thus essential considering the safety of metro systems. However, no studies have analysed resilience considering different combinations of platform-based and track-based failures. To address this issue, this research established a novel resilience assessment approach with application in Hangzhou metro system. The results assist companies in planning a more resilient metro system by constructing more turning lines and reconfiguring a less concentrated passenger demand distribution.

5 - Do CEO Personality Traits Introduce Risk Into Firms?

Tiange WANG, PhD Candidate, Tsinghua University, Beijing, China

As top manager, CEO directly lead the firm's development. Plenty of studies have focused on CEO characteristics' impact on firm policies. However, these poicies and consequences are more related with CEO capability, performance and compensation. So, we argue that CEO personality traits are a critical factor on firm risk, which is almost unrelated with the compensation and is more likely to reflect the impact of personality. However, it is unpractical to gather information about CEO psychology. In this study, the Big Five theory is employed to describe CEO personality traits through their posts on Twitter. We try to investigate whether specific personality trait is related with firm risk.

6 - Quality Risk Evaluation of Aircraft Development under Main Manufacturer – Suppliers Mode Based on Flight Test Engineer View

Chao Guo, Tongji University, Shanghai, China, gcdzq@163.com and Commercial Aircraft Corporation of China LTD, Shanghai, China, gcdzq@163.com, Jianxin You, Xiaoyue You, Youxiang Cui

The "Main manufacturer - Supplier" model of the aircraft development introduces multiple risks into the flight test. By using the analytic hierarchy process, the readiness evaluation of flight test aircrafts was decomposed into eight evaluation indexes. Based on flight test engineers' view, the risk distribution of the main manufacturer and the suppliers was measured, and the main risk factor was selected.

Data Mining III

Contributed Session

Chair: Mehmet Yildirim, Binghamton University, Binghamton, NY, 13905, United States

1 - Multi-channel Attribution: A Survive Analysis Based Approach

Aslan Lotfi, Iowa State University, Ames, IA, United States, alotfi@iastate.edu, Xinxue Qu, Zhengrui Jiang

Using the survival analysis methodology, we study digital advertising channel attribution. Our data records customer exposures to ads for a video game through different digital advertising channels and corresponding conversions. We study how consumers' exposures to online ads through different channels affect their probability and timing of conversion as well as how an exposure's effect changes over time. Our results show that the effects of exposures do vary significantly across channels and that the maximum effect of an exposure may not be achieved at the time of its occurrence.

2 - Weibull Racing Time-to-event Modeling and Analysis of Online Borrowers' Loan Repaying and Default

Quan Zhang, PhD Candidate, University of Texas at Austin, Austin, TX, United States, quan.zhang@mccombs.utexas.edu, Qiang Gao, Mingfeng Lin

p { margin-bottom: 0.1in; line-height: 115%; } p { margin-bottom: 0.1in; line-height: 115%; } We propose Weibull racing (WR) to model the mechanism of time to competing events and to interpret how features accelerate or decelerate the time. WR explains potential non-monotonic feature effects data-adaptively, resulting in a good way for data mining. Furthermore, we use WR on an online peer-to-peer lending dataset from Prosper and analyze how borrowers' loan repaying and defaults are affected by features. We found features that reduce the hazard of borrowers' default may also accelerate their loan pay-off, leading to a trade-off between low risk and low return of investment for lenders.

3 - Anomaly Detection and Prediction for Multiple Channel Multi-time Series Data in Military Vehicle Reliability System

Morteza Alizadeh, Graduate Research Assistant, Mississippi State University, Starkville, MS, United States, ma1845@msstate.edu, Junfeng Ma

We develop a multivariate autoregressive model to predict temporal anomalies in a real-case multiple time series data channels. This model aims to detect contextual outliers based on deviations of time-stamps values from predictions. Individual time-stamp value at each channel is predicted as a linear function of immediately preceding window of last p time-stamps values in all channels. Proposed model leverages both successive correlations of time series data at each channel and other channels to predict each time stamp value. Large absolute values of deviations exhibit anomalies of channels. Obtained results verifies the capability of the proposed model.

4 - Online Non-linear Feature Imputation for Predictive Models in Healthcare

Sadaf Kabir, West Virginia University, Morgantown, WV, United States, Leily Farrokhvar

Accurate disease diagnosis and prediction of patient outcomes can improve hospital performance, optimize resources allocation, and reduce costs and time of patient care. In this study, we propose a non-linear feature imputation method to estimate the missing patient related data. The estimated values are then used to provide more accurate predictions for patient outcomes.

5 - An Entropy Based Novel Feature Selection Algorithm for Clustering a Healthcare Dataset

Mehmet F. Yildirim, PhD Candidate, Binghamton University, Binghamton, NY, United States, myildir3@binghamton.edu

Different feature subsets could lead to different clusters in a large and high-dimensional dataset. However, a true clustering result may not be chosen among many possible options for a correct interpretation of the dataset. One of the viable solutions is to choose the best feature subset for clustering which would lead to better understanding and processing of the dataset as well as expedite the clustering algorithm. For this purpose, an entropy-based feature selection algorithm is proposed to cluster a healthcare dataset where the redundant features are removed to make the clustering algorithm robust. The clustering result is evaluated using two different performance criteria.

Chair: Seyed Ali Haji Esmaeili, North Dakota State University, Fargo, ND, 58102, United States

1 - Designing Distribution Networks for Low-demand Items with Given Delivery Time Targets

Geert-Jan Van Houtum, Eindhoven University of Technology, Eindhoven, Netherlands, g.j.v.houtum@tue.nl, Ahmadreza Marandi

We look at the design of a distribution network for multiple low-demand items with stochastic single-unit demand processes (e.g., spare parts). Demands from geographically dispersed customers have to be satisfied within given delivery time targets. Local warehouses can be chosen from a given set of candidate locations. We include in our design that, at the executional level, a given demand can be satisfied from multiple chosen local warehouses. We follow a robust optimization approach.

2 - Additive Manufacturing Spare Parts Supply Chain with Repair Decisions

Brett A. Shields, Assistant Professor, Francis Marion University, Florence, SC, United States, bshields@fmarion.edu, Dante Ahquin

Strategic decisions in spare-parts supply chains have significant implications within the supply chain configuration. In this research, additive manufacturing machine procurement, make-or-buy, and repair decisions for critical spare parts are considered. A mixed-integer linear programming model is formulated to minimize the cost of satisfying critical spare parts demand over a long-term planning horizon. The presented methodology provides a solution for spare-parts supply chains where repairing parts is viable through additive manufacturing, without the limitations of the current models.

3 - Stochastic Model for Optimizing Transparency and Traceability in Food Supply Chain

Meghna Maity, Kansas State University, Manhattan, KS, United States, mmaity@ksu.edu

Absence of food transparency and traceability has led to severe problems like product recall, consumer dissatisfaction, and contamination insecurities in the past. These issues escalate with demand uncertainty. We overcome traceability in food supply chain by developing a stochastic batch dispersion model that integrates an emerging blockchain technology to provide insight in supply chain transparency.

4 - Supply Chain Finance with Smart Contract

Jing Luo, University of Pittsburgh, Pittsburgh, PA, United States, JIL204@pitt.edu

Blockchain receives great popularty in recent year. We summarize the unique features of smart contract from blockchain and apply this new technique in supply chain finance to improve the working capital of SME.

5 - An Optimization Approach to the Market Incentive Analysis of Second-generation Bioethanol Supply Chains

Seyed Ali Haji Esmaeili, North Dakota State University, Fargo, ND, United States, ali.hajiesmaeili@ndsu.edu, Joseph Szmerekovsky, Ahmad Sobhani

First-generation bioethanol produced from food-based biomass has been produced globally which has increased new social issues such as the food versus fuel debate. Thus, this study promotes second-generation bioethanol which is produced from non-edible biomass feedstocks by considering monetary incentives. This incentive policy would be offered to already-existing first-generation bioethanol producers only if they change their production technology to second-generation. To analyze the impacts of incentives, first-generation and second-generation bioethanol supply chains are compared.

Keynote: Predictive Data Science for Physical Systems: From Physics-based Models to Scientific Machine Learning

Emerging Topic: Keynote

1 - Predictive Data Science for Physical Systems: From Physics-based Models to Scientific Machine Learning

Karen Willcox, University of Texas at Austin, Austin, TX, United States

For high-consequence decisions in science, engineering and medicine—big decisions—we need more than just big data, we need big models too. These problems are characterized by complex multi-scale multi-physics dynamics, where small changes in parameters can lead to drastic changes in system behavior. They are also typically characterized by high-dimensional uncertain parameters that cannot be observed directly, and by a need to issue predictions that go well beyond the specific conditions where data may be available. For these reasons, a purely data-focused perspective will fall short. Achieving predictive data science for these complex physical systems requires a synergistic combination of data and physics-based models. Learning from data through the lens of models is a way to bring structure to an otherwise intractable problem: it is a way to respect physical constraints, to embed domain knowledge, to bring interpretability to results, and to endow the resulting predictions with quantified uncertainties. As one example, this talk shows how formulations from projection-based model reduction can be combined with machine learning methods to achieve this. Case studies in aerospace engineering applications demonstrate the importance of embedding physical constraints within learned models, and also highlight the important point that the amount of model training data available in an engineering setting is often much less than it is in other machine learning applications, making it essential to incorporate knowledge from physical models.

Interpretable Predictive Models

Sponsored: Data Mining

Sponsored Session

Chair: Ozge Surer, Northwestern University, Evanston, IL, United States

1 - Actionable Recourse in Linear Classification

Berk Ustun, Harvard University, Cambridge, MA, United States, berk@seas.harvard.edu, Alexander Spangher, Yang Liu

In machine learning, recourse refers to the ability of a person to change the decision of a model by altering actionable input variables (e.g., income rather than age). We present integer programming tools to check recourse in linear classifiers. Given a classifier, our tools can (1) measure the feasibility and difficulty of recourse in a population of interest and (2) list actions for a person to obtain a desired outcome from a classifier. We demonstrate how our tools can inform key stakeholders in credit scoring, and discuss why we should evaluate recourse in automated decision-making.

2 - Model-Agnostic Linear Substitutes for Black-box Machine Learning Models

Tong Wang, University of Iowa, Pappajohn Business Build, Iowa City, IA, 52245, United States, tong-wang@uiowa.edu, Qihang Lin, Rafique Hassan

This work proposed a novel framework that builds hybrid models which combine interpretable models with a black-box model. A hybrid model builds linear models to substitute a provided black-box model on a subset of data where the black box is overkill to gain partial transparency while leaving the rest to the black-box model. With various parameter setting, the hybrid model gains an efficient trade-off between transparency and accuracy. The proposed model applies to multiclass classification and can solve structured data and text data. It provides more model choices for users and unify interpretable models and black-box models into the same framework.

3 - Joint Learning of Prototypes and Decision Boundary for Multiple Instance Learning Problems

Mustafa Gokce Baydogan, Assistant Professor, Bogazici University, Istanbul, Turkey, mustafa.baydogan@boun.edu.tr, Ozgur Emre Sivrikaya, Mert Yuksekgonul

In Multiple Instance Learning (MIL), each bag can be represented with their distances (or dissimilarities) to certain prototypes in dissimilarity space. These prototypes are important for interpretability in some tasks. Learning algorithm developed in this work jointly learns prototypes in the feature space and logistic regression classifier that minimizes logistic loss of misclassification. Our experimental results show that proposed approach works well on common MIL data sets from diverse domains.

4 - Interpretable Machine Learning: Models and Applications

Xia Ben Hu, Assistant Professor, Texas A&M University, Computer Science and Engineering, 330B HRBB, College Station, TX, 77843, United States, hu@cse.tamu.edu

This talk will cover the recent progress of ongoing efforts directed by Dr. Xia "Ben" Hu on interpretable machine learning. Though machine learning models have achieved a lot of success in different applications, they are often regarded as black-boxes and criticized by the lack of interpretability. To bridge the gap, we propose to develop interpretable systems to enhance the transparency of machine learning models. We will discuss the system architecture and main algorithms, as well as our current progress, to develop post-hoc interpretation approaches for convolutional neural network predictions of images, recurrent neural network predictions of text, and recommender system decisions.

5 - Coefficient Tree Regression for Discovering Structure in Generalized Linear Models

Ozge Surer, Northwestern University, Evanston, IL, 60201, United States, ozgesurer2019@u.northwestern.edu, Daniel Apley, Edward C. Malthouse

Massive regression data sets are now commonplace, with so many predictors that they cannot or should not all be included individually. In practice, derived predictors that are the sum of groups of individual predictors (which is equivalent to predictors within groups sharing the same coefficient) are often relevant. However, the groups of predictors are often not known in advance, and they must be discovered from the data. In this study, we extend our coefficient tree regression algorithm to generalized linear models to discover the group structure from the data.

Learning and Optimization in Social Media

Sponsored: Data Mining

Sponsored Session

Chair: Zhecheng Qiang

1 - Link Predictions for Social Networks in Online Health Communities

Sulyun Lee, The University of Iowa, Iowa City, IA, United States, sulyun-lee@uiowa.edu

Online Health Communities (OHCs) are popular sources for patients and their families to get informational and emotional support related to the diseases or symptoms. As users interact with each other, they also form a social network. We try to predict the links that are likely to be formed in such a network to improve patients' experience in an OHC. Our model considers the different types of relationships among users, users' levels of online activities, as well as the topics of their online discussions. We show that our model outperforms benchmark methods in predicting future social network links.

2 - Sequential Stochastic Assignment with Unknown Worker Quality

Siddhartha Nambiar, North Carolina State University, Raleigh, NC, 27603, United States, snambia@ncsu.edu, Alexander Nikolaev, Alexander Semenov

We consider a worker assignment problem where the quality of the workers is not fully known prior to making assignments. We frame this problem as a variant of the Sequential Stochastic Assignment Problem (SSAP), workers with given success rates are assigned non-anticipatively to sequentially-arriving tasks in order to maximize the total expected reward; every task value follows a given distribution and remains unknown until the task presents itself to the workers. In our case, we tackle the lack of the worker success rate information by using a number of techniques for inferring a consensus ranking of objects from a limited number of available pairwise comparisons between these objects.

3 - Reinforcement Learning in Information Cascade Based on Dynamic User Behavior

Mengnan Chen, University of Central Florida, Orlando, FL, United States

Cascading phenomena are typically characterized by a dynamic process of information propagation between nodes in a network, where nodes can rebroadcast or repost information from and to their neighbors. Our model is based on the Markov Decision Process (MDP) with uncertain nodes/users behavior and dynamic network topology, which aims to find the optimal policy for agents to select the information source seed to maximizing the influence in the information cascade within finite-time horizon. To model their autonomous behaviors, we will implement the concepts of discrete choice models from behavioral economics.

4 - Model-based Learning of Information Diffusion Dynamics in Social Media Networks

Zhecheng (Jennifer) Qiang, University of Central Florida, Orlando, FL, 32826, United States, Eduardo Pasiliao, Qipeng Phil Zheng

Learning the information diffusion process is essential for successful applications of viral marketing and cyber security in social media networks. We propose two learning models that aim at learning person-to-person influence in information diffusion from historical cascades based on the threshold propagation model. The first model is based on the Linear Threshold Propagation Model. In addition, by considering multi-step information propagation, we build a learning model for multi-step diffusion influence based on the idea of random walk. For large-scale networks, we develop approximate methods of learning models using artificial neural networks to learn the pairwise influence.

Chair: Md Noor E Alam

1 - Evaluating Hospital Readmission Reduction Program with Robust Causal Inference Test

Noor E. Alam, Northeastern University, Boston, MA, MA 02115, United States, Md Saiful Islam, Md Sarowar Morshed, Gary Young

Evaluating policy is essentially a causal inference problem. Matching methods, especially propensity score matching, has been widely used for policy evaluation from observational data. However, in one-to-one matching, multiple matching methods can produce different results which make the evaluation process dependent on the choice of the experimenter. In this study, we develop algorithms which ensure robustness in making causal inference and are scalable to large-scale observational studies. We test the algorithms by evaluating the Hospital Readmission Reduction Program (HRRP) policy.

2 - Causal Impact Analysis of the Impact of Homecare Services on Patient Discharge Disposition

Sabrina Casucci, Assistant Professor of Teaching, Buffalo, NY, 14227, United States, scasucci@buffalo.edu, Yuan Zhou, Biplab Sudhin Bhattacharya, Lei Sun, Alexander Nikolaev, Li Lin

This study uses observational causal inference to evaluate the impact of different combinations of home care services (nursing, therapies, social work, home aides) on end-of-episode disposition for individuals with chronic diseases associated with the circulatory, endocrine, and musculoskeletal systems. The potential to generate actionable recommendations in policy for personalizing home care services, or treatment plans, from limited clinical and care needs data is demonstrated through the results.

3 - Smooth Contextual Bandits: Bridging the Parametric and Non-differentiable Regret Regimes

Yichun Hu, Cornell University, New York, NY, United States, yh767@cornell.edu, Nathan Kallus, Xiaojie Mao

We study a non-parametric contextual bandit problem where the arms are Holder functions with smoothness parameter . We show how this interpolates between two extremes that were previously studied in separation: non-differentiable bandits (≤1) and parametric bandits (->∞). We develop a novel algorithm that carefully adjusts to all smoothness settings and achieves rate-optimal regret in either extreme, recovering existing results. In this sense, our result bridges the gap between the existing literatures on parametric and non-parametric contextual bandit problems and between bandit algorithms that use global and local reward information.

4 - Hospital Readmissions to Non-index Hospitals: Patterns and Determinants Following the Medicare Readmission Reduction Penalty Program

Noor E. Alam, Northeastern University, Boston, MA, MA 02115, United States, Mahmudul Hasan, Xiaoyi Wang, E. David Zepeda, Gary J. Young

Leveraging the state of California hospital discharge data, this study investigates the patterns and determinants of non-index readmissions for Medicare and non-Medicare patients to identify whether or not such general pattern of non-index readmission have significantly changed following the adoption of Hospital Readmission Reduction Program (HRRP).

1 - Sparsity Double Robust Inference of Average Treatment Effects

Yinchu Zhu, PhD, University of Oregon, Eugene, OR, 97403, United States, yzhu6@uoregon.edu, Jelena Bradic, Stefan Wager

Popular methods for building confidence intervals on causal effects under high-dimensional confounding require strong "ultra-sparsity" assumptions that may be difficult to validate in practice. To alleviate this difficulty, we study a new method for average treatment effect estimation that yields asymptotically exact confidence intervals assuming that either the conditional response or the propensity score allows for an ultra-sparse representation (but not necessarily both). This guarantee allows us to provide valid inference for average treatment effect in high dimensions under considerably more generality. We also show that our results are semi-parametrically efficient.

2 - Simultaneous Estimation for Semi-parametric Multi-index Models

Wenbo Wu, PhD, University of Texas at San Antonio, San Antonio, TX, 78249, United States

Estimation of a general multi-index model comprises determining the number of linear combinations of predictors (structural dimension) that are related to the response, estimating the loadings of each index vector, selecting the active predictors, and estimating the underlying link function. These objectives are often achieved sequentially at different stages of the estimation process. In this study, we propose a unified estimation approach under a semi-parametric model framework to attain these estimation goals simultaneously. The proposed estimation method is more efficient and stable than many existing methods.

3 - High-Dimensional Interaction Detection with False Sign Rate Control

Daoji Li, Assistant Professor, California State University-Fullerton, Fullerton, CA, 92831, United States

Understanding how features interact with each other is of paramount importance in many scientific discoveries and contemporary applications, such as Marketing, Economics, social science, medicine, and environmental science. Yet interaction identification becomes challenging even for a moderate number of covariates. In this talk, I will introduce an efficient and flexible procedure for interaction identification in ultra-high dimensions. Our method enjoys oracle inequalities in interactions and main effects selection and admits an explicit bound on the false sign rate, which can be asymptotically vanishing. Our method and theoretical results are supported by several numerical studies.

4 - Efficient Estimation of Multivariate Models for Longitudinal Data under Local Box-Cox Transformation

Mohammed Chowdhury, PhD, Kennesaw State University, Kennesaw, GA, 30144, United States, mchowd10@kennesaw.edu

An efficient method to estimate functional linear models and bivariate probability models has been proposed and developed for the longitudinal data under the framework of Local Box-Cox transformation (LBCT). First, we split the data. We then apply LBCT on each data in second step, and in third step, we accomplish efficient estimation of our models by incorporating three nonparametric smoothers on entire time range. Relevant asymptotic properties of the smoothing estimators are derived. Application of our method is demonstrated through a longitudinal study of childhood growth and blood pressure. Finite sample properties our procedures are investigated by simulation study.

1 - Constrained Markov Decision Process Modeling for Sequential Optimization of Additive Manufacturing Build Quality

Bing Yao, PSU, State College, PA, 16801, United States, Hui Yang

Additive manufacturing enables the creation of complex and freeform geometries, but lacks the ability to perform real-time quality control. This paper presents a new sequential decision-making framework for in-situ control of AM build quality, which optimizes corrective actions to be taken for repairing incipient defects prior to completion.

2 - Collusion Detection and Ground Truth Inference in Crowdsourcing for Labeling Tasks

Changyue Song, University of Wisconsin-Madison, Mechanical Engineering Building, 1513 University Ave, Madison, WI, 53715, United States, csong39@wisc.edu, Kaibo Liu, Xi Zhang

Crowdsourcing has been a prompt and cost-effective way of obtaining labels in many machine learning applications. In the literature, a number of algorithms have been developed to infer the ground truth based on the collected labels. However, most existing studies assume workers to be independent and are vulnerable to worker collusion. This paper aims at detecting the collusive behaviors of workers in labeling tasks. Specifically, we propose a penalized pairwise profile likelihood method based on the adaptive LASSO penalty and investigate the theoretical properties. Numerical studies using synthetic and real data sets are conducted to test the performance of the method.

3 - Motion Artifact Removal Using Joint Basis Pursuit Linear Program for Accurate Heart Monitoring

Amirhossein Koneshloo, TexasTech University, Lubbock, TX, 79415, United States, Dongping Du

This study develops a novel method to effectively attenuate the impact of motion artifact (MA) on Photoplethysmography (PPG) signals and accurately identify Heart Rate (HR) variations during physical exercise. Joint basis pursuit linear program is used to decompose PPG signal into different time series. The time series that are highly correlated with acceleration signals are removed to eliminate MA. A new sparse spectra reconstruction method is designed to rebuild the spectrum of HR in current time window based on the previous time frame. The algorithm shows good robustness as it requires a small set of parameters and can provide accurate estimations when PPG signals are contaminated by strong MA.

4 - Multi-printer Co-learning of Kinematics-induced Variations for Inter-connected Extrusion-based Additive Manufacturing

Hui Wang, Assistant Professor, FAMU-FSU College of Engineering, Tallahassee, FL, 32303, United States, huiwz.wang@gmail.com, Jie Ren, An-Tsun Wei

For extrusion-based additive manufacturing, the inconsistent amount of deposited material along the printing path greatly affects the product quality and are usually affected by kinematic variations of the printer extruders. This talk presents a mathematical model that quantifies the printing line variations induced by extruder kinematics characteristics. It provides a way of between-printer knowledge sharing and transfers on estimating the extrusion variations. Based on the model, a co-learning method is developed to improve the quality prediction model for a 3D printer with limited historical data by leveraging the data from similar 3D printers.

1 - A Causal Analysis of Patient Portal and its Impact on Primary Care Service Utilization and Appointment Adherence

Xiang Zhong, University of Florida, Gainesville, FL, United States, Jaeyoung Park, Muxuan Liang

The objective of this study was to investigate the characteristics of primary care patients using different patient portal functions and the impact of portal usage on patients' primary care service utilization and appointment adherence. A retrospective observational study using a large dataset from the University of Florida (UF) Health was conducted. Patients were classified into different user subgroups based on their portal usage of messaging, laboratory, appointment, and medication functions. Generalized linear models were built and a difference-in-differences analysis was conducted to compare the time-dependent portal usage effects across different user subgroups and nonusers.

2 - Learning Severity of Illness Scores from EHR Data: A Mixed-integer Programming Approach

Joseph Kapena Agor, Oregon State University, Corvallis, OR, 27606, United States, agorj@oregonstate.edu, Osman Ozaltin

The current state of the art in the development of scoring systems in health care is to take weights that are generated by statistical learning models and round them to obtain integer point values for the scores. This could potentially eliminate important variables, reduce calibration of the score and also leads to sub-optimality. Therefore, we propose a mixed integer programming framework for the development of severity of illness scores. We apply the framework to construct a score that can be used to track the acuity of patients who are susceptible to sepsis. We find that our model produces an interpretable and accurate score compared to others in the current literature.

3 - Optimizing Screening Policies for Hospital-acquired Infections using MDP: The Case of MRSA Surveillance among Exposed Roommates in Canadian Hospitals

Esma Akgun, University of Waterloo, 350 Columbia Street West, Waterloo, ON, N2L 6P8, Canada, F. Safa Erenay, Sibel Alumur Alev

We develop a Markov Decision Process (MDP) model to predict the spread of hospital-acquired infections and apply it to optimize the screening policy for the exposed roommates of Methicillin-Resistant Staphylococcus Aureus (MRSA) carriers in a Canadian hospital. Unlike the existing analytic models, our model captures the spread of the infection within the room structure of a hospital. We consider several performance measures including quality-adjusted life years, cost of mitigating MRSA spread, number of colonized patients, and the number of missed MRSA cases.

4 - A Progressive Prediction Modelling Approach in Evaluating Vancomycin Dosing Strategy

Transforming Markets through Data Mining: New Tools and Cutting-Edge Techniques

Sponsored: Data Mining

Sponsored Session

Chair: Pankhuri Malhotra

1 - The Power of Online Brand Ecosystems

Pankhuri Malhotra, University of illiinois-Chicago, Chicago, IL, 60613, United States, pmalho3@uic.edu, Siddhartha Bhattacharyya

Mining consumer-brand perceptions is a dominant area of research. We address this knowledge area by exploiting Twitter brand communities to generate a large-scale brand network, that implicitly captures consumer perceptions. We statistically examine the network using Exponential-Random-Graph-Models and confirm that associations between brands do not arise from randomness. Network measures are used to create perceptual maps along the dimensions: mainstream and diverseness. Our work conceptualizes brands as relationships rather than as isolated objects; thus, allowing managers to quantify the impact of their branding efforts on consumers' perceptions and performance simultaneously.

2 - Topic Modeling of Textual Data

Yuan Cheng, Cornell College of Business, Ithaca, NY, United States

Analyzing text for business applications requires interpretable summaries in addition to prediction accuracy. We propose a new constrained matrix factorization model, which balances maximizing statistical and predictive power of regression models with capturing the underlying textual themes. We validate the effectiveness of our proposed model in terms of the combined goal with a comprehensive benchmarking study with online reviews.

3 - Understanding Physicians' Online-offline Behavior Dynamics: An Empirical Study

Tongxin Zhou, University of Washington, Seattle, WA, 98105, United States, Liuan Wang, Lu Yan, Xitong Guo, Gregory R. Heim

Physicians' online participation serves to integrate online healthcare resources with offline medical systems. This integration brings opportunities for reshaping healthcare delivery systems. Although, there has been extensive discussion about physician participation, little is known about how physicians actually participate in both online and offline channels. In this study, we investigate physicians' online-offline behavior dynamics. By using a time-series technique: a structural vector autoregression (SVAR) model, we find that physicians' online activities can lead to a higher offline service quantity, whereas offline activities may reduce physicians' online contribution.

4 - The Impact of Emotion on Social Media Content Consumption: Evidence from Video Analysis on Live Streaming Platforms

Keran Zhao, University of Illinois at Chicago, Chicago, IL, 60613, United States, kzhao23@uic.edu, Yuheng Hu, Yingda Lu, Ning Shi

As an emerging social media service, live streaming has been widely adopted by advertisers and companies as a powerful market tool. In this study, we examine how streamers' emotional expression influence the audience's engagement. To answer this question, we utilize the deep-learning methods to acquire both the emotional expression and audience attention from streaming video and chatting script. Our analysis yields that there is a positive relationship between emotion fluctuation and audience engagement. Our results provide actionable suggestions and shed light on understanding the live interaction on the live streaming platforms.

5 - Inferring Brand Knowledge from Online Consumer Associative Brand Networks

Minghong Xu, Johns Hopkins Carey Business School, Baltimore, MD, 60201, United States

Consumer perceptions of a brand is key to brand value. Traditional methods rely on time-consuming and expensive approaches like surveys and focus groups to elicit such perceptions; these are also very limited in terms of reach across consumers and brands. This paper examines consumer associative brand networks inferred from large-scale data on consumers' engagement across a broad collection of brands. It presents a statistical analyses of brand networks, to help determine whether such networks obtained from large-scale data on consumer co-interest in social media provide a valid and reliable source of brand insights and knowledge.

1 - Automated Training Data Discovery and Labelling for Machine Learning in a Low Resource Domain

Yang Gu, The University of Arizona, Tucson, AZ, United States, Gondy Leroy

The CDC's surveillance program on Autism Spectrum Disorder (ASD) has found that ASD affects one in 59 children in the US. Its prevalence has more than doubled since 2000. To better study this condition, we leverage natural language processing techniques, including machine and deep learning, to automate the identification of ASD diagnostic criteria in electronic health records (EHRs). This presentation will discuss some work undertaken to supplement machine learning training data when working in a low-resource domain with small amounts of labelled data.

2 - Predicting User Activities in Online Health Communities via Trajectory Mining

Xiangyu Wang, University of Iowa, Iowa City, IA, United States, xiangyu-wang-1@uiowa.edu, Kang Zhao, Xun Zhou, Nick Street

Online Health Communities (OHCs) are a great source of social support for patients and their caregivers. Better predictions of user activities from OHCs can help to manage and sustain a successful OHC. This paper addresses the problem of predicting OHC user activities, especially for active users who suddenly disappear. Our approach uses LSTMs to learn from users' temporal activity trajectories and incorporates users' topics distributions over time. Experiments based on data from a popular OHC for cancer survivors show that the proposed model can improve the performance of user activity prediction.

3 - Health Suggestion Mining from Online Health Forums

Zhengchao Yang, University of Arizona, School of Computing, Informatics, and, Decision System Engr, Tucson, AZ, 85281, United States

Suggestion mining is to identify good suggestions for given questions. In the study, we focus on suggestions ranking problem for an online health forum where users can ask questions and suggestions are provided by qualified doctors or patients with similar conditions. We propose a novel word/sentence level attention CNN based on contextual word embeddings to automatically rank the suggestions for health questions based on the suggestion quality. Our framework requires minimal feature engineering and receives good performance in detecting quality suggestions for questions. The method is also able to extract key terms of questions that a quality suggestion is targeting in solving problems for.

4 - Data-Driven Optimization for Team Formation

Teng Huang, University of Connecticut, Storrs, CT, United States, teng.huang@uconn.edu, David Bergman, John Mathieu

We propose a predictive-and-prescriptive analytics framework for a team formation problem. First, we train predictive models to learn the relationships between the collection team member's characteristics and the outcome or success of the team they compose. The maximum scores in a team predict better than the average scores. The best model is a polynomial regression model. Next, we propose five algorithms for partition N people into t teams and maximize the average team performance. The BDD-based algorithm can solve instances in which it's hard to enumerate all possible team formation.

1 - QUBO Models in Optimization, Machine Learning, and Quantum Computing

Yu Du, University of Colorado Denver, Denver, CO, 80202, United States, duyu197@gmail.com, Fred Glover, Gary Kochenberger

The Quadratic Unconstrained Binary Optimization model, associated with the Ising problem in physics, has emerged as an underpinning of the quantum annealing area and neuromorphic computing. This talk discloses the basic features of the QUBO model. Computational experience is being amassed by both the classical and the quantum computing communities that highlights not only the potential of the QUBO model but also its effectiveness as an alternative to traditional modeling and solution methodologies. We also describe recent innovations for solving QUBO models that offer a fertile avenue for integrating classical and quantum computing and for applying these models in machine learning.

2 - What to Learn and What Not to Learn: A Mathematical View on Ethical Learning

Endre Boros, Distinguished Professor, Rutgers University, Piscataway, NJ, 08854-8003, United States, Endre.Boros@rutgers.edu

Learning algorithms are struggling with large data sets, and miss information present in the data simply for computational reasons. A larger and mostly hidden problem is that many algorithms learn (unintentionally and unnoticed) patterns that are not supported by data. Both errors imply potential problems: missing important triggers and/or using unsupported ones. This brings up both ethical and legal questions. In this talk we demonstrate these issues with an example. We propose a mathematically sound notion of a “justifiable” classifier AND learning algorithm. On the positive side, we show some results about the existence of learning algorithms that always produce a “justifiable” classifier.

3 - Model Based Tabu Search Algorithms for the Independent Quadratic Assignment Problem

Wei Yang, Northwestern Polytechnical University, Xi’an, V3S 8M9, China, Yang Wang, Abraham P. Punnen, Ante usti

We study the independent quadratic assignment problem (IndQAP) which is a special case of the bilinear assignment problem. A characterization of linearizable cost matrices for the IndQAP is presented. Further, we propose several model based tabu search algorithms that explore the underlying large scale neighborhoods by solving corresponding linear assignment problems with appropriate guiding mechanism. Extensive experimental results are presented. We also introduce a set of benchmark test instances that can be used for future experimental study on IndQAP.

1 - Recent Results in Simulating Social Networks

Jiang Wu, Wuhan University, School of Information Management, Wuchang, Wuhan, 430072, China

This presentation describes recent results in simulating social network evolution.

2 - Cross Cultural Comparisons of User Participation and Social Support Exchange in Online Health Communities

Xi Wang, Central University of Finance and Economics, School of Information, Beijing, 100080, China, xiwang@cufe.edu.cn

Online Health Communities (OHCs) are used worldwide, but it remains unclear how people from various culturalbackgrounds utilize this channel. By analyzing two representative breast-cancer-related OHCs from China and the US respectively, this study is the first attempt to investigate cultural differences in terms of social support exchange through user-generated content by data mining methods. The findings have both theoretical and practical implications for researchers and OHC stakeholders.

3 - Factors Influencing Online Giving Performance: An Integration of the Elaboration Likelihood Model and Social Influence Theory

Danyang Song, Zhejiang University, Hangzhou, China, dysong@zju.edu.cn, Yin Pan, Xi Chen

By integrating the two traditionally separate areas of elaboration likelihood model (ELM) and social influence theory, our research aims to build a more complete theoretical model for online giving. The results manifest that both ELM and social influence have significant effects on fundraising performance of charitable giving projects. Contrary to our expectation, the central route of ELM is negatively related with fundraising performance. In addition, both informational and normative social influences as well as the urgency of demand play a strengthening role in moderating the relationship between the peripheral route of persuasion and fundraising performance, but not the central route.

4 - Knowledge Enhanced Best Answer Selection in Community Question Answering Systems

Qingpeng Zhang, City University of Hong Kong, Kowloon, 12180, Hong Kong, qingpeng.zhang@cityu.edu.hk, Fengshi Jing

In this research, we present a novel attentive-pooling deep learning approach to selecting the best answers in online community question answering (CQA) systems. The model is enhanced with knowledge extracted from the community including prior questions, answers, and social networking behaviors. Experiments with both general and vertical CQA systems demonstrate the superior performance of the proposed approach.

Sponsored Session

Chair: Jamol Pender, Cornell University, Ithaca, NY, 14850, United States

1 - The Queue- Hawkes Process: Ephemeral Self-excitement

Andrew Monroe Daw, Cornell University, Ithaca, NY, 14853, United States, amd399@cornell.edu, Jamol Pender

In this talk, we define a novel generalization of the self-exciting Hawkes process called the Queue-Hawkes process. This new stochastic process combines the dynamics of a self-exciting process and an infinite server queueing model: arrivals increase the arrival rate, but departures decrease it. Our study of this model includes connections to well-known stochastic models such as branching processes, random walks, epidemics, and Bayesian mixture models. Our results for the Queue-Hawkes process include a batch scaling construction of general Hawkes processes from a special affine case of the Queue-Hawkes process.

2 - Delay Announcements with Weighted Moving Averages

Jamol Pender, Cornell University, Ithaca, NY, 14850, United States, jjp274@cornell.edu

Many service systems use technology to notify customers about their expected waiting times or queue lengths via delay announcements. However, in many cases, either the information might be delayed or customers might require time to travel to the queue of their choice, thus causing a lag in information. In this work, we show that if the variance of the travel time is higher for a specific distribution, then oscillations are less likely to occur.

3 - Epidemic Spreading on Networks with Communities

Emily M. Fischer, PhD, Cornell University, Ithaca, NY, 14850, United States, ef363@cornell.edu

Online social networks and other networks of interest are known to exhibit community structure, where a community is a highly interconnected group of nodes. It is important to understand the role of community structure in the spread of information and infectious diseases. We show that under the Susceptible-Infected-Susceptible (SIS) epidemic model, the lifetime of an infection is constrained by the structure of individual communities and is highly dependent on the location of the initial infection. Without relying on any particular definition of community or method of community detection, we give a result bounding the epidemic threshold closely around the threshold of the strongest community.

4 - The Value of Flexible Customers via Join the Shortest of "d" Queues

Shuang Tao, Cornell University, Ithaca, NY, 14853, United States, st754@cornell.edu

We propose a multi-server queueing model that captures a performance trade-off between customers valuing flexibility or wanting dedicated service, which is motivated by healthcare platforms like Zocdoc where patients may choose to see a dedicated physician or choose among readily available physicians. In our model, a fraction of the customers are flexible and willing to join the shortest of d queues, while the remaining fraction only join the queue of their choice. We prove both a fluid and diffusion limit for the queueing model for the transient and steady-state dynamics. Our analysis illustrates not only the power of a bit of flexibility, but that flexibility benefits all and not just the flexible.

Sponsored Session

Chair: Susan R. Hunter, Purdue University, West Lafayette, IN, 47907-2023, United States

1 - Simulation Optimization Using Biased Gradient Estimates

Shane Henderson, Cornell University, Cornell University, Ithaca, NY, 14853, United States, David J. Eckman

Solving simulation-optimization problems with continuous decision variables is eased with gradient estimates. Unfortunately, gradient estimates are often, or even usually, biased. For example, when using infinitesimal perturbation analysis such bias arises when there are discontinuities in the simulation output as a function of the decision variables, roughly speaking. In contrast to standard practice, we propose using the estimated gradients in a local search technique, even though they are biased. The resulting algorithm cannot converge to even a local minimum, but can yield practically significant improvements in a number of examples.

2 - Solving Bayesian Risk Optimization via Nested Stochastic Derivative Estimation

Sait Cakmak, Georgia Institute of Technology, School of Industrial and Systems Engineering, Atlanta, GA, 30332, United States, scakmak3@gatech.edu, Di Wu, Enlu Zhou

Stochastic simulation is driven by input parameters that are often estimated from finite data, leading to input uncertainty. To account for input uncertainty in simulation optimization, the Bayesian Risk Optimization (BRO) framework has been proposed, which aims to optimize the objective while hedging against input uncertainty. In order to efficiently solve the BRO problem, we derive stochastic derivative estimators and propose corresponding stochastic-approximation algorithms. Our estimators extend the literature of stochastic derivative estimation to the case of nested risk functions.

3 - Derivative Free Multiobjective Optimization with Surrogate Models

Juliane Mueller, Lawrence Berkeley National Lab, Berkeley, CA, 94702, United States, juliane.mueller2901@gmail.com

We present our algorithm development for derivative-free multiobjective optimization of computationally expensive simulation functions. We use surrogate models to approximate the expensive simulation objective functions. A variety of sampling methods allow us to explore the extrema of the approximated Pareto front, to fill gaps in the approximated Pareto front, and to search locally for improvements of current Pareto optimal solutions. We show that our algorithm performs better than widely used multiobjective genetic algorithms for a large number of fast-to-compute test problems and two applications from optimal design.

4 - Algorithms for Multi-objective Simulation Optimization on Integer Lattices with Three or More Objectives

Eric A. Applegate, Purdue University, School of Industrial Engineering, West Lafayette, IN, 47907-2023, United States, applegae@purdue.edu, Susan R. Hunter

We consider the multi-objective simulation optimization problem on integer lattices with three or more objectives. In this nonlinear optimization problem, the objectives can only be observed with stochastic error, and the decision variables are integer-valued. Among other recent advances, we discuss the Retrospective Multi-Gradient Search with Piecewise Linear Interpolation and Neighborhood Enumeration (R-MGSPLINE) algorithm for finding a local efficient point.

1 - Markov Chain Approximation of Sticky Diffusions with Financial Applications

Christian Meier, Chinese University of Hong Kong, Shatin, N. T, Hong Kong, Lingfei Li, Gongqiu Zhang

We consider general one-dimensional sticky diffusions defined as weak solutions of SDEs and show that there exists a unique weak solution under rather mild conditions. We develop continuous time Markov chain (CTMC) approximation for sticky diffusions and prove that it achieves second order convergence. We also propose a simulation scheme for stick diffusions based on CTMC approximation and show that it attains a weak convergence order of two. In contrast, traditional time discretization methods such as the Euler scheme completely fails. Computations for stick diffusion models for yield curves in low interest rate environment are given to illustrate the accuracy of our method.

2 - Dynamic Mean-variance Efficient Fractional Kelly Portfolios in a Stochastic Volatility Model

Xuedong He, The Chinese University of Hong Kong, Shatin, Hong Kong, xdhe@se.cuhk.edu.hk, Zhaoli Jiang

We improve the dynamic mean-variance efficiency of fractional Kelly strategies in a continuous-time stochastic volatility model by studying a mean-variance portfolio selection problem in which an agent achieves an expected return of her investment as high as that of a fractional Kelly strategy and minimizes the variance of her investment return. We solve in closed form the equilibrium strategy for the agent and find that the return rate of this strategy has smaller variance than that of the fractional Kelly strategy at any time. Finally, we derive an implied risk aversion degree of the agent and find that it is decreasing with respect to the market condition and to the investment horizon.

3 - Tail Risk Monotonicity under Temporal Aggregation in the GARCH(1,1) Model

Dan Pirjol, Stevens Institute of Technology, Hoboken, NJ, 07306, United States, dpirjol@gmail.com, Paul Glasserman, Qi Wu

The talk considers the properties of the tail asymptotics of the unconditional distribution of returns in the GARCH(1,1) model under temporal aggregation. The unconditional distribution of the n-step returns rn has power-law tails P(rn> x) x-k(n) with a calculable exponent (n). We derive a criterion for strict (increasing) monotonicity of the map n > (n), and show that it is satisfied in a large region of the GARCH(1,1) parameter space, for a wide choice of innovations. Exceptions to the monotonicity criterion appear in a small corner of the GARCH(1,1) parameter space whch is mapped explicitly for the most popular innovations (normal, doubly-exponential and Student-t).

4 - Affine Point Processes: Refinements to Large-time Asymptotics

Xuefeng Gao, Chinese University of Hong Kong, Shatin, Hong Kong, xfgao@se.cuhk.edu.hk

Affine point processes are a class of simple point processes with self- and mutually- exciting properties, and they have found applications in many areas. In this paper, we obtain large-time asymptotic expansions in large deviations and refined central limit theorem for affine point processes, using the framework of mod- convergence. Our results extend the large-time limit theorems in [Zhang et al. 2015. Math. Oper. Res. 40(4), 797-819]. The resulting explicit approximations for large deviation probabilities and tail expectations can be used as an alternative to importance sampling Monte Carlo simulations. Numerical experiments illustrate our results. This is a joint work with Lingjiong Zhu.

Issues in Supply Chain Management in the Pharmaceutical Industry

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Eda Kemahlioglu-Ziya

1 - A Portfolio Optimization Approach to Pharmaceutical Capacity Allocations

Iva Rashkova, Washington University in St Louis, St Louis, MO, United States, irashkova@wustl.edu, Panos Kouvelis

Insufficient manufacturing capacity is a reason for nationwide drug shortages. We use a portfolio optimization approach to study the drug capacity allocation problem. A manufacturer's drug portfolio changes over time as new drugs are approved and existing drugs are discontinued. A mathematical model illustrates the relationships between pipeline and existing drugs in a portfolio. We examine empirically these relationships using time series data of drug shortages, clinical trials, approvals and discontinuations. Furthermore, we build predictive models of aggregate drug shortages and test them on out-of-sample data.

2 - Studying Trust Dynamics in a Disrupted Supply Chain

Rozhin Doroudi, Northeastern University, Boston, MA, United States, doroudi.r@husky.neu.edu, Ozlem Ergun, Jacqueline Griffin

Prolonged drug shortages in United States threatens public health and patients' safety. Despite drastic effects of these shortages, more than half of the time the reason for them are unknown. However anecdotal evidence suggests that part of these shortages is resulted from human behavior. Driven by the public safety risk in this setting, we model a pharmaceutical supply chain with boundedly rational decision makers which are capable of reasoning about reaction of other decision makers. Having these realistic models of human behavior enables us to study effects of trust dynamics in a disrupted supply chain.

3 - Drug Shortages and Paths to Capacity Creation

Eda Kemahlioglu Ziya, North Carolina State, Poole College of Management, Raleigh, NC, 27695-7229, United States, ekemahl@ncsu.edu, H. Sebastian Heese

Drug shortages are becoming more prevalent in the U.S. We study why manufacturers refrain from adding/maintaining capacity and why so few manufacturers enter the generic drugs market where most drug shortages arise. To moderate drug shortages, the government can either directly affect the reimbursement policies for pharmaceutical companies and/or the cost of entering and remaining in the market. In this paper, our goal is to study the effectiveness of these two levers in increasing the industry supply for one drug.

4 - Does Medicare's Drug Reimbursement Policy Reform Aggravate Drug Shortages? Theoretical and Scenario Analyses

Hui Zhao, The Pennsylvania State University, Smeal College of Business, University Park, PA, 16802, United States, huz10@psu.edu, Xuejun Zhao, Justin Jia

In 2005, Medicare reforms its drug reimbursement policy from an Average Wholesale Price regime to an Average Sales Price regime. The years following the reform witnessed severe drug shortages. We use analytical model and data analysis to address the continued arguments on whether the policy reform aggravated the drug shortages.

Strategic Behavior in Service Systems

Sponsored: Manufacturing & Service Oper. Mgmt/Service Operations

Sponsored Session

Chair: Pnina Feldman, Boston University, Boston, MA, 02215, United States

Co-Chair: Ricky Roet-Green, University of Rochester, Rochester, NY, 14627, United States

1 - A Model of Queue-Scalping

Luyi Yang, Johns Hopkins University, Baltimore, MD, 21202, United States, luyi.yang@jhu.edu, Shiliang Cui

Recent years have witnessed the rise of queue-scalping in congestion-prone service systems. A queue-scalper has no material interest in the primary service but proactively enters the queue in hopes of selling his spot later. This paper develops a queueing-game-theoretic model of queue-scalping and examines its implications for the service system. Contrary to conventional wisdom, we find that queues with an intermediate demand volume are most susceptible to scalping, rather than queues with either very small or very large demand volume. This result implies that an effort to mitigate scalping through capacity expansion may only lead to the presence of more scalpers.

2 - The Paradox of Choice: The False Premise of Omnichannel Services and How to Realize it

Yang Li, The Chinese University of Hong Kong, Hong Kong, Opher Baron, Xiaole Chen

Omni-channel service, an integration of in-store service with online ordering, has been thriving. This work studies the impacts of the omni-channel capability in the service industry. We adopt a game-theoretical queueing framework to explore customer channel choices and investigate the efficiency of the omni-channel system in comparison with a conventional walk-in only system. Our results unveil the inefficiency of the omni-channel system due to self-interested channel choices. We, thus, suggest several operational strategies that may curtail this inefficiency for a win-win outcome: the provider is able to improve her revenue while customers also enjoy higher social welfare.

3 - Impatience and Learning in Queues

Senthil Veeraraghavan, University of Pennsylvania, Wharton School OPIM Department, 545 3730 Walnut Street, Philadelphia, PA, 19104, United States, senthilv@wharton.upenn.edu, Li Xiao, Hanqin Zhang

Customers often abandon waiting in queues when they get impatient. Prior literature on Markovian queues shows that it is not rational for customers to quit "midway": Customers should either quit immediately on arrival (balk) or wait till the completion of their service. We show how in-queue abandonment behavior can be rational in queues because of learning. We compare how rational Bayesian customers make abandonment decisions under different information disclosures. Our paper reveals interesting features in waiting behavior, showing that customers can be (rationally) more patient in slower, shorter queues, than in faster, longer queues.

4 - Paying by the Hour: Are Wages the Cost of Waiting?

Simin Li, Kellogg School of Management, Northwestern University, 2211 Campus Drive, Evanston, IL, 60208, United States, simin.li@kellogg.northwestern.edu, Achal Bassamboo, Martin Lariviere

We investigate how an agent's cost of waiting depends on compensation structures and non-market activities. We find the conventional metric, marginal wage, is only a fair estimation to marginal cost of waiting if earnings are smooth. The equality breaks down once any friction is introduced. The marginal wage can over or under estimate agent's true cost of waiting. In fact, with frictions in the compensation structures, the hourly wage by itself tells almost nothing about agent's cost of waiting.

Stochast Models in Service Operations

Sponsored: Manufacturing & Service Oper. Mgmt/Service Operations

Sponsored Session

Chair: Baris Ata, University of Chicago, Chicago, IL, 60637, United States

Co-Chair: Xiaoshan Peng, Indiana University, Bloomington, IN, United States

1 - Self-exciting Poisson Auto-regressive Models for Arrival Data

Zeyu Zheng, Assistant Professor, University of California, Berkeley, Berkeley, CA, United States, zyzheng@berkeley.edu, Peter W. Glynn

Self-exciting features are commonly seen in arrival data to various stochastic systems. Appropriately modeling and statistically characterize such features are important for decisions and performance prediction in such systems. In this talk, we discuss a toolbox that involves statistical estimation, inference, applied probability properties, and model selection for general Poisson auto-regressive models.

2 - A New Approach to High Dimensional Dynamic Pricing

Yilun Chen, Cornell, Ithaca, NY, 14853, United States, yc2436@cornell.edu, David Goldberg

Recently there has been considerable interest in studying dynamic pricing problems with more realistic/complex demand and supply structures. These problems are often formulated as high-dimensional stochastic dynamic programs which suffer from the curse of dimensionality. We propose an algorithm that overcomes this computational challenge for a fairly general class of pricing problems, subject to the retailer only being able to change the price of goods a small number of times. Our results leverage a recent algorithm for optimal stopping, hold for arbitrarily complex demand/supply structure, and have runtime effectively independent of the dimension.

3 - Revenue Maximization in Two-Station Tandem Queueing Systems

Xinchang Wang, Washington State University, Marketing Department, Pullman, WA, 39762, United States, Sigrun Andradottir, Hayriye Ayhan, Tonghoon Suk

We study optimal pricing for tandem queueing systems with finite buffers. The service provider dynamically quotes prices to customers to maximize the long-run average revenue. We build a Markov decision process model for the problem. For systems with general buffers, we describe the structure of the optimal dynamic pricing policy and develop tailored policy iteration to find an optimal pricing policy. For systems with no intermediate buffers, we characterize conditions under which quoting either a high or a low price to all customers is optimal and provide an algorithm to solve the problem. Numerical experiments are provided to compare the algorithms with the regular policy iteration algorithm.

4 - Optimal Admission Control Policies for Non-stationary Arrivals: A Dual Approach

Xiaoshan Peng, Indiana University, Kelley School, Bloomington, IN, United States, xp1@iu.edu

We consider the classical admission control problem for a single-server queue. The system incurs a waiting cost of h per unit time for each customer waiting in the queue, whereas it incurs a one-time penalty of p if the customer is rejected. We allow the arrival process to be a general stochastic process. We formulate the problem as a finite-horizon stochastic control problem and derive its dual. The solution to the dual problem can be interpreted as the expected cost incurred by the incoming customer at the moment. The solution to the dual problem can be interpreted as the shadow price process. We show that this process can be characterized using the conditional expectation time to empty the system.

1 - Last-mile Shared Delivery: A Discrete Sequential Packing Approach

Junyu Cao, University of California Berkeley, Berkeley, CA, 94706, United States, jycao@berkeley.edu, Mariana Olvera-Craviotoo, Zuo-Jun Max Shen

We propose a model for optimizing the last-mile delivery of n packages from a distribution center to their final recipients, using a strategy that combines the use of ride-sharing platforms (e.g. Uber or Lyft) with a traditional van infrastructure. Our technical approach is based on the formulation of a discrete sequential packing problem, which is closely related to Renyi's parking problem. The main objective is to compute the optimal reward offered to private drivers for each individual package in a way that minimizes the total expected cost for delivering all packages. We show that under natural assumptions our mixed strategy can achieve significant improvements compared to a van-only strategy.

2 - The Impact of Last Mile in Service Industry

Meng Li, Rutgers University, Camden, NJ, 08102, United States, Ruomeng Cui, Jingbo Zhou

This paper investigates the price and quality response strategies of restaurants to people's easier last-mile travel. Our identification strategy exploits a quasi-randomized entry of the bike-sharing service—-a recent disruptive innovation which enables people to travel conveniently to places like restaurants—-to different cities. We construct a unique dataset of 980,511 restaurants' pricing and service rating before and after the entry of bike-sharing in China. We find that the entry of bike-sharing (1) reduces restaurants' pricing by 2%, (2) increases service quality by 2%, and (3) does not cause more entries or exits.

3 - Distributionally Robust Quantile Prediction Conditioning on Covariates

Meng Qi, University of California, Berkeley, Berkeley, CA, 94704, United States, Ying Cao, Zuo-Jun Max Shen

This work provides a robust approach for the quantile regression problem under a data-driven environment. In contrast to the convention which assumes the samples are i.i.d., we consider a fixed-design setting of the covariates, which fits the real-life applications better. This work proposed a two-step distributionally robust approach with a simple and practical solution. Finite sample performance guarantees and asymptotic consistency are also developed under mild conditions.

4 - A 1.79-approximation Algorithm for a Continuous Review Lost-sales Inventory Model

Linwei Xin, University of Chicago, Chicago, IL, 60637, United States, Linwei.Xin@chicagobooth.edu

Single-sourcing lost-sales inventory systems with lead times are notoriously difficult to optimize. Following Remain (2004), we consider a single-item continuous review lost-sales inventory model with lead times and Poisson demand. We study the performance of a so-called capped base-stock policy. Recent numerical experiments have suggested that such a policy demonstrates superior performance compared with many existing heuristics. In this work, we provide a theoretical foundation for this phenomenon and prove that this policy has a worst-case performance guarantee of 1.79.

Sponsored Session

Chair: Robert Batt, Wisconsin School of Business, UW-Madison

1 - The Effects of Performance Pay on Discretionary Task Sequence, Learning and Performance

Maria R. Ibanez, Northwestern University, Evanston, IL, 60208, United States

Analyzing records of millions of radiological diagnoses from doctors working across the US, we investigate how performance pay induces workers to work not only harder but also smarter—learning how to be more productive and to sequence their work better.

2 - Text and Visual Analytics Versus Thematic Analysis of Medical Residents' Responses to Questions Regarding Hand-hygiene and Infection Control

Reidar Hagtvedt, University of Alberta School of Business, Edmonton, AB, Canada, hagtvedt@ualberta.ca, Devika Dixit, Lorraine M. Thirsk, Trish Reay, Kenneth L. Schultz, Gregory Jones, Sarah Forgie

We investigate if newer text analytics tools will lead to different results than a traditional thematic analysis, specifically using structured interviews in the area of infection control and hand-hygiene. A dataset from medical residents at a tertiary hospital provides the setting, with a published qualitative analysis. A novel social network algorithm is then applied to discover potential further detail in the data.

3 - Turnover Among Part-Time Nursing Aides: Scheduling Smarter

Kevin Mayo, Indiana University, Bloomington, IN, 47408, United States, Eric Michael Webb, George Ball, Kurt Bretthauer

Extremely high turnover rates among part-time nurse aides can have significant negative effects on patient outcomes. We examine 6,634 part-time nurse aides and 5,305 turnovers to determine how scheduling affects turnover. We identify the turnover impacts of the amount and variation of scheduling, along with the effects of co-worker consistency, providing managerial insights to reduce turnover.

4 - What's Next?: Task Sequencing in the Emergency Department

Robert Batt, Wisconsin School of Business, UW-Madison, Madison, WI, 53706, United States

We examine the task sequencing behavior of emergency department physicians. We also propose and analyze several task sequencing heuristics with to determine their impact on length of stay and throughput.

Students' Professional Skills Development and Assessment

Sponsored: Education

Sponsored Session

Chair: Sadan Kulturel-Konak, Penn State Berks, Reading, PA, 19610, United States

1 - Integrating Creative Problem Solving Techniques into Engineering and Technology Classes

Sadan Kulturel-Konak, Penn State Berks, Tulpehocken Road, Reading, PA, 19610, United States, sadan@psu.edu, Abdullah Konak

There are different methods suggested in the literature to help students develop creative problem solving abilities. In this study, we will first explain how we integrate creative problem solving modules into undergraduate engineering and technology classes (design and capstone). Then, we will present our findings on how those students find these modules affecting them being more innovative in their class projects based on empirical data.

2 - Teamwork Attitude Differences Between Online and Face-to-face Students

Abdullah Konak, Penn State Berks, Tulpehocken Road, Reading, PA, 19610, United States, konak@psu.edu, Sadan Kulturel-Konak

Challenges of virtual teams may result in negative attitudes toward teamwork and adversely affect students' experiences with online classes. We compare online and face-to-face students' attitudes toward teamwork, their interest in learning their teamwork skills, and teamwork self-efficacy based on an empirical study. The analyses showed that students in online classes had negative attitudes towards teamwork compared to students in face-to-face settings although students in online classes have a higher level of interest in and self-efficacy of teamwork.

3 - Assessment of Students' Creativity

Gul Kremer, Iowa State University, 2529 Union Drive, 3004 Black, Ames, IA, 50011, United States

Science, Technology, Engineering and Mathematics (STEM) fields are applied fields that benefited from the creativity of individuals. Given the complexity level of contemporary problems, continuation of a prepared workforce that is skilled in creative problem solving is very important. However, studies have found that STEM fields, specifically engineering, might be perceived to be "uncomfortable" for some students. Findings such as this have also been suggested as concerns for recruitment and retention of capable students in these fields. This is problematic because science and engineering graduates are among the important innovation drivers as noted in the Global and European Innovation reports. Studies have also shown that a potential exists through pedagogical approaches to counter negative sentiments on the part of students, specifically in design-focused courses, by allowing students to be creative and to further stimulate their creativity. The presentation will summarize a series of studies undertaken to examine the extent to which creativity is covered in the engineering classrooms, and how it has been assessed.

4 - Examining Mentoring Practices in STEM

Joi-Lynn Mondisa, Assistant Professor, University of Michigan, Ann Arbor, MI, United States, jmondisa@umich.edu

Mentoring can be a mechanism that aids in diversifying who participates and persists in STEM fields. Mentors provide emotional, psychosocial, and career support which can help protégés persist in their chosen STEM disciplines. Thus, mentoring can support the production of future engineers. Unfortunately, minimal research studies exist that examine the mentoring approaches, practices, and interactions that occur in underrepresented minority STEM mentoring relationships. In this session, I will discuss findings from my research that examines the individual experiences of exemplar African-American STEM mentors and their mentoring practices with their African-American protégés.

Risk Management in Supply Chains

Sponsored: Manufacturing & Service Oper. Mgmt/iFORM

Sponsored Session

Chair: Mert Hakan Hekimoglu, Rensselaer Polytechnic Institute, Troy, NY, 12180, United States

1 - Mitigating Supply Chain Risks and Uncertainty Through On-demand Distribution Systems

Kaan Unnu, Rensselaer Polytechnic Institute, Center for Industrial Innovation, Troy, NY, 12180-3590, United States, unnuk@rpi.edu, Jennifer A. Pazour

Traditionally, companies have responded to fast delivery requests by storing a larger diversity of products in a broader distribution network by increasing the number and capacity of their distribution locations. Considering today's demand uncertainty and volatility, this approach possibly leads to underutilized or under-capacitated distribution centers and additional cost risks. However, on-demand distribution systems enable another option which creates flexibility and provides new directions for cost-effective improvements. These systems offer unique advantages and create new dynamics that require new knowledge and methods for the design and operations of distribution networks.

2 - When Are Retailer's Instruments to Induce Higher Supplier Social Responsibility Level Effective?

Haiying Yang, Syracuse University, Syracuse, NY, United States, hyang20@syr.edu, Zhengping Wu

Different instruments (e.g., cost subsidy) have been used in practice by retailers to induce improved social responsibility level of their upstream. We use principal-agent theory to explain how retailers design contract menus to motivate suppliers to truly report production cost after suppliers' decision of social responsibility level. We examine parametric conditions under which such measures are effective.

3 - React or Wait? Optimal Response to Disruptions and the Role of Disruption Monitoring

Shailesh Divey, Rensselaer Polytechnic Institute, Troy, NY, 12180, United States, diveys@rpi.edu, Mert Hakan Hekimoglu, T. Ravichandran

This study examines the benefits of AI- and cloud-based platforms (e.g, IBM's Watson Supply Chain, Elementum) that enable real-time monitoring of events like supply chain disruptions, and how such monitoring capabilities influence firms' optimal response strategies to resolve the uncertainty associated with the length of these disruptions. Using a multi-stage stochastic program, we show that real-time monitoring capabilities offer the flexibility of revising the firm's initial response to a disruption in real time while the event continues to unfold.

4 - Mitigating Disruption Risks in Delivery Supply Chains to Serve Contracted Customers

Mert Hakan Hekimoglu, Rensselaer Polytechnic Institute, Pittsburgh Building, Troy, NY, 12180, United States, hekimm@rpi.edu, John H. Park, Burak Kazaz

Motivated by a Fortune 150 company, this paper helps a firm determine its capacity expansion decisions as a mitigation strategy against disruptions in a delivery supply chain. We formulate the firm's capacity planning problem using a two-stage stochastic model. The firm determines the capacity expansion amount in each fulfillment center in stage 1. If a disruption occurs in stage 2, then the firm determines the optimal allocation of the backup capacity in order to satisfy the orders arriving at the disrupted fulfillment center. The firm restricts the probability of the number of late deliveries exceeding a tolerable threshold under risk aversion that we define as service-at-risk.
