ANNUAL MEETING
2019 Seattle

How to Navigate the Technical Sessions

There are four primary resources to help you understand and navigate the Technical Sessions:

- This Technical Session listing, which provides the most detailed information. The listing is presented chronologically by day/time, showing each session and the papers/abstracts/authors within each session.

The Session Codes

SA01

Room number. Room locations are also indicated in the listing for each session.

Time Block. Matches the time blocks shown in the Program Schedule.

The day of the week

Time Blocks

Sunday - Monday

8:00am - 9:30am

9:50am - 10:50am

11:00am – 12:30pm

1:30pm – 3:00pm

3:10pm - 4:00pm

4:30pm – 6:00pm

Tuesday

7:30am - 9:00am

9:30am - 10:20am

10:30am - 12:00pm

12:05pm - 1:35pm

2:00pm - 3:30pm

3:40pm - 4:30pm

4:35pm – 6:05pm

Wednesday

8:00am - 9:30am

10:00am - 10:50am

11:00am - 12:30pm

3:20pm - 4:50pm

Rooms and Locations /Tracks

All tracks / technical sessions will be held in the Washington State Convention Center

Sunday, 8:00AM - 9:30AM

Data Mining Best Student Paper

Sponsored: Data Mining

Sponsored Session

Chair: Ali Dag, Vermillion, SD, 57069, United States

Co-Chair: Evangelos Triantaphyllou, Louisiana State University, Division of Computer Science & Engineering, Baton Rouge, LA, 70803, United States

Co-Chair: Changqing Cheng, Binghamton University, Systems Science Industrial Engineering, Binghamton, NY, 13902, United States

1 - The Price of Interpretability: Optimal Explanations of Linear Models

Arthur J. Delarue, MIT, Cambridge, MA, 02139, United States, Dimitris Bertsimas, Patrick Jaillet, Sebastien Martin

The ability to explain a predictive model's reasoning to a decision-maker can increase trust and expose biases. However, attempts at interpreting models are often ad hoc, and interpretability is not a well-defined concept. We propose a general optimization framework to create explanations for any linear model, by decomposing it into a sequence of models of increasing complexity using coefficient coordinate updates. From this decomposition, we can derive a family of interpretability metrics generalizing typical proxies and study the tradeoff between interpretability and predictive accuracy.

2 - A Hierarchical Expected Improvement Method for Effective Bayesian Optimization

Zhehui Chen, Georgia Institute of Technology, Atlanta, GA, United States, Simon Mark, C.F. Jeff Wu

Expected improvement (EI) is a popular Bayesian optimization (BO) method, due to its closed-form acquisition function. However, EI is so greedy that it may stuck at suboptimal points. To address this, we propose a new hierarchical EI (HEI) framework. HEI preserves closed-form and corrects the over-greediness of EI. Under certain prior specifications and smoothness assumptions, we establish the rate of global convergence for HEI. We then introduce several hyperparameter estimation methods, which allow HEI to mimic a fully BO procedure while avoiding expensive Markov-chain Monte Carlo sampling. Numerical experiments show the improvement of HEI over existing BO methods.

3 - Optimal Hierarchical Clustering on a Graph

Gokce Kahvecioglu, Northwestern University, Evanston, IL, 60208, United States, David Morton

Given an undirected graph with positive weights on the edges we study a parametric bi-objective graph clustering problem. We remove a subset of edges to break the graph into smaller pieces, i.e., connected components, or clusters. We seek to maximize the number of clusters while minimizing the weight of the removed edges. We identify nested solutions that lie on the concave envelope of the efficient frontier, yielding a hierarchical family of clusters, in strongly polynomial time. We demonstrate the performance of our approach on a network defined by the schedule of football teams in the National Collegiate Athletic Association, and on a set of synthetic networks.

4 - A Spatiotemporal Prediction Approach for a 3D Thermal Field from Sensor Networks

Di Wang, Peking University, Beijing, 100871, China, Xi Zhang, Kaibo Liu

Please check the mobile app or online for this abstract.

■ SA02

CC- Room 202

Data-driven Decision Making

Sponsored: Data Mining

Sponsored Session

Chair: Mengqi Hu

1 - Energy-aware Task Planning for Solar-Powered Robot via Deep Reinforcement Learning

Di Wang, University of Illinois at Chicago, Chicago, IL, 60607, United States, dwang66@uic.edu, Mengqi Hu

To improve the operational life of robots, it is critical to combine task planning and energy schedule. In this paper, a novel data-driven decision approach based on deep reinforcement learning with a link information filter is proposed to ensure that robot can maximally harvest solar energy by considering time variance in solar irradiance. Our simulation results demonstrate that the data-driven approach can outperform existing heuristic optimizers.

2 - Online Model Adaptation for Building Energy Consumption Real-time Prediction

Jinghang Li, UIC, Chicago, IL, United States, jli238@uic.edu, Mengqi Hu

Building energy consumption prediction plays a critical role in achieving a sustainable smart building. Most of the existing data-driven predictive models are trained using historical data and fixed during the execution stage which cannot adapt well to real-time data. In this research, we develop a meta-learning-based approach to adaptively improve the pre-trained predictive model through efficiently digesting real-time data. Our simulation results demonstrate that the adaptive predictive model can efficiently capture the dynamics in real-time data and perform better than static models.

3 - Learning to Predict Real-time Electricity Price Based on Trusting Features

Rui Dai, University of South Florida, Tampa, FL, 33613, United States, Hadi Charkhgard

Real-time pricing in energy market is adopted by the utility companies as one of effective means for their demaSB44nd response programs. The end users of real-time pricing plan can create price arbitrage and adjust their electricity usages to reduce their costs, if they can predict the real-time price accurately. In order to capture a better prediction of real-time price, we propose a learning technique to predict the real-time price based on the weather data and trusting features. The trusting features is generated by operational results of the users participating the real-time pricing program. Computational study shows the effectiveness of our predicting technique.

4 - Spatial-temporal Wind Power Probabilistic Forecast with Quantile Regression

Zhi Zhou, Argonne National Laboratory, Argonne, IL, 60439, United States, zzhou@anl.gov, Bo Wang, Wei Xie

To support both planning and operational decisions for seamlessly integrating high penetration of wind energy into the power grids, in this paper, we introduce a nonparametric spatial-temporal wind power probabilistic forecast. Specifically, at any time and location, the wind power generation uncertainty is characterized by a sequence of quantiles. We develop a Gaussian process based metamodel to simultaneously model a sequence of quantiles with the spatial and temporal dependence. It can be used for both long-term and short-term wind power probabilistic forecast.

5 - Deep Learning Based Automatic Fault Detection and Diagnostics for a Multi-zone Office Building

Yang Chen, Oak Ridge National Laboratory, Oak Ridge, TN, 37830, United States, Miao He, Yiran Yang, Xiaochun Feng

Along the thriving of learning based artificial intelligence for decision making, automatic fault detection and diagnosis (AFDD) becomes more accurate and efficient with big data availability. In this study, a deep learning based AFDD framework is developed for a large office building focusing on air-handling units and rooftop units, where the adaptive learning method is explored to tackle the challenge of domain transferring. The proposed approach is validated and compared with several promising learning algorithms on a public accessible testing data set.

CC- Room 203

Fairness in Machine Learning

Sponsored: Data Mining

Sponsored Session

Chair: Himabindu Himabindu

Co-Chair: Berk Ustun

Presenter

Elisa Celis, Yale University, New Haven, CT, United States

1 - Debunking the Myth of the Fairness Versus Accuracy Trade-off

Joshua Loftus, Assistant Professor, New York University, New York City, NY, United States

Fairness in machine learning and AI is often posed as a trade-off between satisfying fairness constraints and achieving greater prediction accuracy. From a purely optimization perspective this seems reasonable, but fairness is a property concerning the real world and not just the model and its predictions. A causal modeling approach to fairness helps to make this explicit and allows us to highlight several reasons why the trade-off framing may be misleading. With causal models we can understand how sample selection bias, heterogeneous treatment effects, and interference can lead to situations where imposing fairness constraints results in a greater global optimum.

2 - Does Mitigating MI'S Impact Disparity Require Treatment Disparity?

Zachary Lipton, Carnegie Mellon University, Pittsburgh, PA, United States

ML algorithms are increasingly operationalized in real-world decision-making. Unfortunately, real-world tasks rarely fit the ML contract. Training data is seldom representative, and targets are often weak surrogates for real desiderata. While practical ML ignores interventions, predictions typically drive decisions. Questions concerning AI ethics necessarily concern the processes generating our data and the impacts of automated decisions, but proposed solutions fail to tackle these problems. This talk illustrates the shortcomings of proposed solutions for mitigating societal harms and contemplates when (today's) ML systems should be off the table altogether.

3 - A Critical Review of Fair Machine Learning

Sharad Goel, Stanford University, Huang Engineering Center, Stanford, CA, 94305-4121, United States, scgoel@stanford.edu

The nascent field of fair machine learning aims to ensure that decisions guided by algorithms are equitable, and over the last several years, several formal definitions of fairness have gained prominence. In this talk, I'll argue that these fairness definitions generally suffer from significant statistical limitations, and, perversely, can harm the very groups they were designed to protect. By highlighting these challenges in the foundation of fair machine learning, I hope to help researchers and practitioners productively advance the area.

CC- Room 204

Sequential Decision Making in Healthcare

Sponsored: Data Mining

Sponsored Session

Chair: Nick Street

1 - Personalized Heartsteps: A Reinforcement Learning Algorithm for Optimizing Physical Activity

Peng Liao, Harvard University, Cambridge, MA, United States, Kristjan Greenewald, Predrag Klasnja, Susan A. Murphy

With the recent evolution of mobile technologies, mobile devices can be used to provide treatment whenever needed and adapted to the user. Just-in-time Adaptive Interventions (JITAIs) are composed of decision rules that map user's context to a treatment, delivered via the mobile device in real-time. In this work, we develop a Reinforcement Learning (RL) algorithm that learns and improves the decision rules for JITAIs as the data is being collected from the user. This work is motivated by our collaboration on designing the RL algorithm in HeartSteps, a physical activity mobile health study, where the RL algorithm will be used to decide whether to deliver a context-tailored activity suggestion.

2 - Optimal Warfarin Dosing Using Reinforcement Learning

Sadjad Anzabi Zadeh, University of Iowa, Iowa City, IA, United States, sadjadanzabizadeh@uiowa.edu, Nick Street, Barrett Thomas

We explore solutions to optimal warfarin dosing, a sequential decision-making problem. The dose-response interaction for simulated patients is extracted from a PK/PD model that incorporates patient information, including age and CYP2C9 and VKORC1G enzymes. The objective to maximize patients' expected health indicator in a 90-day period is optimized using reinforcement learning. The resulting policies are then aggregated to provide easy-to-use protocols for practitioners.

3 - Dynamic Individualized Alarm Setting in the Intensive Care Unit

Steven Shechter, University of British Columbia, 2053 Main Mall, Vancouver, BC, V6T 1Z2, Canada, steven.shechter@sauder.ubc.ca, Hossein Piri, Tim Huh, Darren Hudson

ICUs are rife with alarms, many of which are false. This leads to "alarm fatigue" in which ICU clinicians may inadvertently ignore alarms. We develop a model to dynamically set alarm thresholds for patient's vital signs, as to balance the risks of false positives and negatives. We consider patient heterogeneity in safety limits for vital signs, which are initially only known through a population-based prior distribution. The model performs Bayesian updates during a patient's ICU stay. We also incorporate the "cry wolf" effect by reducing alarm response probabilities with increasing prior false alarms. We present structural properties and comparative statics of the optimal solution.

4 - Optimal Intervention Policies for TJR Postoperative Care Process

Hyo Kyung Lee, University of Pittsburgh, Pittsburgh, PA, 53703, United States, hlee555@wisc.edu, Jingshan Li, Christine Baker, Philip Bain

Successful outcomes of TJR depend not only on the surgery but also on the patients' postsurgical behaviors. To prevent complications or readmissions, patients go through postoperative intervention process in which they receive physical therapy and/or some form of rehabilitative services. While the costs of providing such interventions and readmission penalties are substantial, no methods exist that enable healthcare professionals to determine the optimal timing and target group of interventions. We formulate the post discharge intervention process as a finite-horizon discrete-time Markov decision process and inform the development of evidence-based practice guidelines.

CC- Room 205

Data Analytics and Machine Learning in Healthcare Informatics

Sponsored: Data Mining

Sponsored Session

Chair: Shouyi Wang

1 - Sensitivity Analysis of Tumor Cluster Radiomics to Predict Regional Response on Early-treatment FDG-PET/CT Imaging

Chunyan Duan, Tongji University, Shanghai, 200092, China, duanchunyan77@163.com, Wanpracha Art Chaovalitwongse, Kin Ming Puk, Phawis Thammasorn, Shouyi Wang, Daniel S. Hippe, Larry A. Pierce, Xiao Liu, Jianxin You, Robert S. Miyaoka, Hubert J. Vesselle, Paul E. Kinahan, Ramesh Rengan, Jing Zeng, Stephen R. Bowen

Defining tumor sub-regions on FDG PET for prediction of spatially variant response to radiation therapy can support oncologic management decisions. We conducted a sensitivity analysis of radiomics prediction algorithms (MLR, SVR, logistic, SVM) and tumor clustering algorithms (k-means, hierarchical) on early-RT FDG-PET/CT response prediction errors in lung cancer patients. Prediction performance was more sensitive to tumor region definition than machine learning algorithm.

2 - New Measurement of Information and its Potential Application to Healthcare

Maryam Moghimi, University of Texas at Arlington, Arlington, TX, United States, Herbert W. Corley

We propose a new metric of the information contained in a data set about some specified parameter as a measure of evidence for supporting a hypothesis or comparing alternate hypotheses about the underlying phenomena. Potential applications in healthcare are discussed.

3 - Estimation of Brain Source Activation with Hierarchical Graph Prior

Feng Liu, Harvard Medical School, Boston, MA, 02148, United States, fliu0@mgh.harvard.edu

To infer brain source activation patterns is an integral step to understand how our brain works. Traditional EEG/MEG Source Imaging (ESI) methods usually assume unrelated source activation patterns across different time points or very similar activation patterns across the whole studied period. In this research, we present a probabilistic ESI model based on hierarchical graph priors which renders the flexibility of maintaining consistency as well as allowing distinct activation patterns in the studied period. Comprehensive numerical studies using synthetic data from a real brain model as well as the application to the real data demonstrated the effectiveness of our proposed algorithm.

4 - Deep Representation Learning of Heterogeneous Patient Data for Treatment Response Prediction in Radiotherapy

Shouyi Wang, The University of Texas at Arlington, Arlington, TX, 76019, United States, shouyiw@uta.edu, Jie Han, Art Chaovalitwongse, Stephen Bowen

Learning and data fusion of massive patient data for effective decision making and treatment management is still a challenging problem in current precision medicine research. We present an unsupervised deep representation learning approach to perform data fusion and learn informative representations automatically from massive heterogeneous patient imaging and clinical data. Based on deep representation learning, a predictive treatment response model was developed for patients with lung cancer in radiotherapy. The developed deep representation learning based method is effective for heterogeneous data fusion and predictive modeling with broad applications in medical data analysis.

CC- Room 209

Data Mining in Complex Manufacturing

Sponsored: Data Mining

Sponsored Session

Chair: Byunghoon Kim

Co-Chair: Behnam Tavakkol

1 - A New Uncertain Data Classification Method and its Application in Semiconductor Manufacturing

Byunghoon Kim, Hanyang University, Ansan, 426-791, Korea, Republic of, byungkim@hanyang.ac.kr, Youngseon Jeong, Seung Hoon Tong, Myong Kee Jeong

Classification of defect chip patterns is an important task in semiconductor processing. Several learning algorithms have been developed to classify defect patterns on wafer maps. However, most of them focused on a single wafer bin map. We propose a novel approach to classify distinct defect patterns on multiple wafer maps. To this end, we propose a new uncertain data classification model. In addition, we propose an approach to extract uncertain features that describe the defect patterns on multiple wafer maps.

2 - Semiconductor Wafer Allocation Based on Reinforcement Learning

Minyoung Park, Myongji University, Yongin-si, Korea, Republic of, mypark@mju.ac.kr, Seungyeon lee, Dohyun (Norman) Kim

There are multiple stages in the semiconductor manufacturing process and the production line is more complex than a typical production line. Therefore, the quality of a semiconductor wafer depends on the equipment to which it is assigned. Therefore, assigning wafers to the right equipment is an important issue to maintain quality and productivity. To solve this problem, a new algorithm based on in-depth learning has been proposed.

3 - Deep Learning Based Feature Extraction with Fusion Regularization on Sensor Signals of Semiconductor Manufacturing Process

Jeongsub Choi, Rutgers University, Piscataway, NJ, United States, Jihoon Kang, Myong Kee Jeong, Heejung Lee

Feature extraction is an essential task to build an accurate predictive model for virtual metrology based on raw sensor signals on process equipment in semiconductor manufacturing. Autoencoder is an unsupervised feature extraction method that encodes input data in lower dimensional space. In this talk, we present a new virtual metrology method using the features extracted from deep autoencoder with the regularization on process signals. The experimental result from a case study shows that the proposed method improves the performance of predictive models for virtual metrology.

4 - Quality Degradation Index (QDI): A Novel Cluster-based Quality Index to Monitor Progressive Defects of Wafer

Ghil Ji-ho, Samsung Electronics, Hwaseong-si, Korea, Republic of

As a solution for the difficulties of early warning and inaccuracy in the monitoring of progressive defects in semiconductor manufacturing, a new cluster based Quality Degradation Index (QDI) is suggested. Hierarchical cluster analysis of machine learning technique is applied to merge progressive defect related test items in the wafer map. Through a case study and its simulation experiments we demonstrate how a quantitative quality measure can be obtained by the QDI. Experimental result has shown practical viability to efficiently detect possible progressive defects to improve the production yield effectively as well as enhance the outgoing products quality.

5 - Density-Based Index for Clustering Uncertain Data Objects
Behnam Tavakkol, Stockton University, Secaucus, NJ, 07094, United States, btavakkol66@gmail.com

Uncertain data problems are the type of data mining problems in which data objects are represented by either multiple points or probability distributions. For uncertain data objects, to the best of our knowledge, there are only two developed clustering validity indices in the literature. Clustering validity indices are numerical measures that are used to determine the quality of formed clusters or the optimal number of clusters. In this work, we propose a density-based clustering validity index for uncertain data objects.

CC- Room 210

Modeling and Optimization Methods for Machine Learning

Sponsored: Data Mining

Sponsored Session

Chair: Kristin Bennett

Co-Chair: Yangyang Xu

1 - Cadre Modeling: Simultaneously Discovering Subpopulations and Predictive Models
Kristin Bennett, Rensselaer Polytechnic Institute, Math Sciences Department, Troy, NY, 12180, United States, bennek@rpi.edu, Alex New

Cadre methods are a new class of explainable machine learning models. These methods simultaneously learn subpopulations called cadres as well as linear predictive models for each cadre. Unlike statistical cohorts, these subpopulations are not known a priori; thus, we refer to them as cadres. Since both the cadres and their associated models are interpretable, cadre modeling leads to insights about the subpopulations and the features predictive of the response for each cadre. We present cadre methods for regression, classification, and survival problems. We demonstrate how cadre methods lead to actionable insights via case studies in health care and in the data science job market.

2 - Stochastic Optimization for AUC Maximization in Machine Learning
Yiming Ying, PhD, SUN Y. Albany, Albany, NY, United States, yying@albany.edu

In this talk, I will present our recent work on developing novel SGD-type algorithms for AUC maximization. Our new algorithms can allow general loss functions and penalty terms which are achieved through the innovative interactions between machine learning and applied mathematics. Compared with the previous literature which requires high storage and per-iteration costs, our algorithms have both space and per-iteration costs of one datum while achieving optimal convergence rates.

3 - A Feasible Level Set Method for Stochastic Convex Optimization with Expectation Constraints
Negar Soheili, University of Illinois at Chicago, Chicago, IL, United States, nazad@uic.edu, Qihang Lin, Selvaprabu Nadarajah, Tianbao Yang

Stochastic optimization problems with expectation constraints (SOEC) arise in different applications. Only recently has an efficient stochastic subgradient method been developed for solving a SOEC defined by an objective and a single inequality constraint, where both are defined by expectations of stochastic convex functions. We develop a level-set method to compute near-optimal solutions to a generalization of this SOEC containing multiple inequality constraints, each involving an expectation of a stochastic convex function. We establish convergence guarantees for this method.

4 - Adaptive Primal-dual Stochastic Gradient Method
Yangyang Xu, Rensselaer Polytechnic Institute, Department of Mathematical Sciences, Troy, NY, 12118, United States, xuy21@rpi.edu

Several adaptive stochastic gradients have been designed to solve machine learning problems. They usually decrease the objective error significantly faster than well-tuned standard stochastic gradient method. In this talk, I will present a primal-dual adaptive stochastic gradient method for functional constrained problems and more general saddle-point problems. Convergence and numerical results will be shown.

5 - Mixed Integer Programming and Heuristics Approaches for Clustering with Cluster-Based Feature Selection
Cem Iyigun, Middle East Technical University, Inonu Blvd, Endustri Muhendisligi, Ankara, 06800, Turkey, Sena Onen Oz

In this study, we work on a clustering problem where it is assumed that the features identifying the clusters may differ for each cluster. Number of clusters and number of relevant features in each cluster are given in advance. A center-based clustering approach is proposed. Finding the cluster centers, assigning the data points and selecting relevant features for each cluster are performed simultaneously. A non-linear mixed integer mathematical model is proposed which minimizes the total distance between data points and their cluster center by using the selected features for each cluster. Different linearization methods have been used for solving the problem. Besides, two different heuristic algorithms have been developed by taking into account the nature of the mentioned problem. Experimental results have been presented.

■ SA08

CC- Room 211

Applied Probability

Contributed Session

Chair: Ehsan Salimi, University of Florida, Gainesville, FL, 32603, United States

1 - Optimal Scheduling of Critically Loaded Multiclass Many-server Queues with Service Interruptions
Yi Zheng, The Pennsylvania State University, State College, PA, United States, Ari Arapostathis, Guodong Pang

We study optimal control problems for multiclass many-server queues with asymptotically negligible service interruptions in the Halfin-Whitt regime. The arrival process is a renewal process, and the random environment is an alternative renewal process. We show that the limits of diffusion-scaled processes are controlled jump diffusions with compound Poisson jumps. By constructing auxiliary processes and suitable Lyapunov functions, we establish long-run average moment bounds of the diffusion-scaled process with different abandonment rates under some scheduling policies. We prove the asymptotic optimality of the infinite-horizon discounted and long-run average (ergodic) problems.

2 - Sample Path Large Deviations for Shot Noise Processes in the High Intensity Regime
Lan Jin, Pennsylvania State University, University Park, PA, United States, lxj84@psu.edu, Guodong Pang

We prove the sample path large deviation principles for shot noise processes in the high intensity asymptotic regime, where the arrival rates are scaled up while time is unscaled. The arrival process is assumed to satisfy an LDP, including renewal processes as a special case. The noises are assumed to be i.i.d. with a general distribution. The shot shape function includes the multiplicative models and indicator functions. The good rate function requires solving a path-dependent optimization problem. This is distinct from the LDPs in the conventional asymptotic regime, where the space and time are both scaled.

3 - Use of Generalized Additive Models in the Estimation of Non-homogeneous Discrete Markov Chains, Applications in Multi-state Modeling of Health Status
Sebastián Felipe Calcetero, Universidad de los Andes, Bogota, Colombia, sf.calcetero674@uniandes.edu.co

Non-homogeneous DTMCs requires the estimation of a probability matrix for each possible age of the process, which is a very complex task in statistical terms. In this paper, we discuss the application of generalized additive models for the parsimonious estimation of the several transition probabilities, with the possibility of including profiling variables, dynamic behaviors and perform statistical inference. Finally, we illustrate the methodology for the estimation of dynamic life tables with portfolio experience and multi-state models for health status, using real data from a health insurer.

4 - Managing Capacity in Face of Uncertainty
Melda Ormeci Matoglu, University of New Hampshire, Durham, NH, United States, melda.ormecimatoglu@unh.edu, John Vande Vate, Haiyue Yu

We solve a generalization of the classic average cost Brownian control problem in which a controller dynamically controls the drift rate of a diffusion process. At each instant, the controller chooses the drift rate from available set of rates and can invoke instantaneous controls to keep the process from falling or to keep it from rising. We minimize the long-run average cost consisting of holding or delay costs, processing costs, costs for invoking instantaneous controls and fixed costs for changing the drift rate. We provide necessary and sufficient conditions on the cost parameters to ensure the problem admits a finite optimal solution and the form and parameters of an optimal policy when it exists.

5 - Local Moment Matching in Dynamic Programming Approximations

Amy B.Z. Zhang, Cornell University, New York, NY, United States, Itai Gurvich

Approximate dynamic programming is a family of algorithms designed to overcome the curse of dimensionality that is inherent to standard solution methods like value or policy iteration. Aggregation is one family of approximation method, but limited results are available beyond the special case of hard aggregation. We make the connection of aggregation to a sister chain to derive theoretical guarantees, and based on it, develop a disciplined way to determine the aggregation structure. The main foundation of this algorithm rests on matching local transition moments, as a result of applying Taylor function approximation.

6 - A Typical Set Approach to Longest Common Subsequence (LCS) Problems

Ehsan Salimi, University of Florida, Gainesville, FL, United States

The longest common sub-sequence (LCS) problem searches for the longest sub-sequence that is common to all given sequences, where the common sub-sequence is not necessarily repeated in the consecutive positions within the all sequences. Commonly used in bioinformatics, it searches for the closest common ancestors by comparing two DNA sequences. In this talk, we approach this problem from probabilistic point of view, introducing a new statistical framework for this problem. We utilize the notion of typical sequence borrowed from the information theory literature. An asymptotic bound on the maximum length of such sub-sequences are proposed under different underlying distributions.

Analytics and Optimization Approaches in Production and Service

Sponsored: Artificial Intelligence

Sponsored Session

Chair: Nooshin Hamidian, University of Tennessee-Knoxville, University of Tennessee-Knoxville, Knoxville, TN, 37920, United States

1 - Modeling and Analysis of Cascading Disruptions in Chain Network: A Cascading Simulation Model

Jafar Namdar, PhD, University of Iowa, Iowa city, IA, United States, Kang Zhao, Sadjad Anzabi Zadeh, Jennifer Blackhurst

Supply chain networks have extremely interconnected structures and due to the complex integration of the nodes (facilities) in the network, the failure of a single node might trigger extremely large scale failures and destroy a considerable part of the overall network. Thus, the firm's robustness to disruptions depends on the topology of supply chain structure. Our main goal in this study is providing the understanding regarding node characteristics and disruption propagation in the supply chain network through cascading failures. We simulated 13 different real-world supply chain network which are different in terms of size, echelons and products.

2 - Renewable Energy in Production Scheduling: A stochastic Approach

Samuel Trevino Martinez, PhD, University of Tennessee at Knoxville, Knoxville, TN, United States, strevin1@vols.utk.edu

Existing data points out that power interruptions in the United States can last up to 40 hours under major events affecting businesses and costing millions of dollars in losses. In light of the above, an optimal stochastic framework for production scheduling of a single machine is presented integrating on-site solar photovoltaic (PV) sizing decisions to mitigate energy disruptions and ultimately minimize energy and operational costs. To this end, a preliminary big data science is performed to estimate the random behavior of power frequency interruptions and duration, along with the finite random power availability from solar PV under different scenarios.

3 - Incentivizing Good Drivers: A New Data-driven Optimization Approach for Insurance Premiums

Masoud Barah, Northwestern University, University of Tennessee, Evanston, IL, United States

Incentivizing a driver with good driving behavior is a long-established agenda in the insurance business. However, insurance providers may not incentivize those drivers with appropriate lower insurance premiums. This research proposes a distributionally robust optimization framework to determine insurance premiums of transportation company drivers. Specifically, given a bulk discount offered by the insurance provider to the transportation company, the proposed framework produces a solution that assigns a discount rate to the transportation company's drivers with good driving records. We conduct a case study to evaluate the performance of the framework and provide analyses and insight.

4 - Simultaneous Detection of Adverse Drug Reaction and At-Risk Groups

Nooshin Hamidian, University of Tennessee-Knoxville, Knoxville, TN, 37920, United States, nhamidia@vols.utk.edu, Wenjun Zhou, Rapinder Sawhney

Association mining in high-dimensional data has been a core problem in data mining. While effectively measuring the association between item pairs has been challenging, studying the interplay among multiple factors is even more perplexing. In particular, association patterns discovered at the global level may not be consistent with its counterpart in a local segment. In this paper, we focus on the application of detecting adverse drug reactions that may not be visible at the global level, and we need to identify local segments in which the association between drugs and adverse reactions are strong. This will help identify conditions under which those patients are facing elevated risk.

CC- Room 213

Joint Session DAS/Practice Curated: Public Policy

Sponsored: Decision Analysis

Sponsored Session

Chair: Jonathan W. Welburn, RAND Corporation, RAND Corporation, Pittsburgh, PA, 15213, United States

1 - Analytical Method for Assessing Army Readiness, Risks, and Opportunity

Katharina Ley Best, Operations Researcher, The RAND Corporation, Pittsburgh, PA, 15217-1452, United States, Igor Mikolic-Torreira

Readiness implies the ability to generate trained, equipped, and manned forces as required for military operations. We introduce a novel way of quantifying one aspect of readiness, namely the ready forces that are likely to be available. This work simplifies the many dimensions of readiness into metrics related to the number of available units. The first simplification is common in the literature and suggests that force sufficiency based on "readiness ratios" can serve as a proxy for overall readiness. The second simplification is novel and reduces the output of such force sufficiency analysis to two simple metrics: the number of ready units and the number of potential additional ready units.

2 - Exploring Strategies to Optimize Technology Progression in Nasa's Small Business Innovation Research Program

Jeremy Eckhause, RAND Corporation, Arlington, VA, 22202, United States, eckhause@rand.org, Andrea Belz, Richard Terrile, Fernando Zapatero

Projects funded in NASA's two-stage Small Business Innovation Research (SBIR) program start at various Technology Readiness Levels (TRLs). Building from prior analysis generating realistic transition probability distributions from empirical data, we model funding strategies under the objective function that optimizes the expected number of projects achieving specific technology advancement, as well as accounting for grantee firm size. Our results highlight the role of optimizing each phase's budget and using a real options portfolio approach to maximize program outcomes.

3 - Bringing Evidence-based Decision Making to the Public Sector

Kara M. Morgan, Ohio State University, Dept. of Food Science and Tech, Parker Food Science and Tech, Columbus, OH, 43210, United States, kmmorgan42@gmail.com

Decision analysis has been a recognized field for over 50 years, but knowledge of research in decision making is not broadly understood. Further, although "evidence-based" is a new mantra for many interventions funded by the government, evidence-based decision-making methods have not been demanded. Use or even awareness of DA in the public sector is not common. This session will review the existing literature using DA for public sector decision making. This session will also begin to define, based on existing research, what a good decision process looks like for the public sector.

4 - Systemic Risk in the Broad Economy

Jonathan W. Welburn, RAND Corporation, Santa Monica, CA, 15213, United States, Aaron Strong, Justin Grana, Osonde Osoba, Florentine Eloundou, Claude Messan Setodji

In the years following the 2008 crisis, significant attention has been placed on systemic risk within interbank networks. However, little attention has been placed on systemic risks in the economy at large. Using an interdisciplinary approach that applies methods from economics, data science, and network analysis, we address this gap by estimating the network of firm-to-firm connections that occurs across business sectors within the broad U.S. economy. We expose heavily interconnected firms and identify areas of significant risk to the aggregate economy. The contributions of this work produce policy insights for managing risks ranging from economic crises to natural and manmade disasters.

Prosocial Behavior in Online Platforms

Sponsored: Social Media Analytics

Sponsored Session

Chair: Xue Tan, Indiana University, Bloomington, IN, 47405, United States

1 - The Impact of Online Platforms on Social Integration: Evidence from a Large-scale Volunteer Network

Yifan Yu, University of Washington, UW, Seattle, WA, United States, Xue Tan, Yong Tan

Social integration refers to the principles by which individuals or actors are related to one another in a society. Individuals participate more actively in collective actions under a high level of social integration. A critical indicator of social integration is the engagement of volunteering behavior. Based on a whole network of volunteers and volunteering organizations, this paper models the process of social integration and examines the impact of an online system that allows individuals to see a wider spectrum of volunteering projects. The paper has important managerial implications for online volunteer platforms.

2 - Temporal Dynamics and Diversity of Platform Groups: An Empirical Study on Kiva

Yue Jiao, University of Massachusetts Lowell, Lowell, MA, 06028, United States, Brian Lee

Self-organizing groups are commonly used as a means of engaging users in online platforms. We examine how self-organizing groups may affect user engagement in online platforms over time using a dataset from a crowdfunding platform Kiva.org. Leveraging the exogenous shock introduced by the platform, we show that the direction and magnitude of the group effect both depend on the tenure of a user joining a group. In addition, the contributing patterns of the group and the users have a significant impact on the platform group effect. Our results have important practical and theoretical implications.

3 - The Effects of Sponsored Videos on Facebook

Stephanie Lee, University of Washington, Foster School of Business, Seattle, WA, 98195, United States, stelee@uw.edu, Shahryar Doosti

Sponsored videos on social media have experienced a dramatic market growth. We study the effect of the creator-sponsor association on viewership and user engagement for videos on Facebook. We identify multiple aspects of creator-sponsor association and investigate their effect on the overall user engagement. First, we find that sponsorship leads to 65% reduction in views. While the industry category similarity has no significant effect on the sponsored views and engagements, both content similarity and audience overlap have positive effect on the performance measures. We conclude that the relevance between the creator and sponsor mitigates the negative effect of sponsorship on social media.

4 - Attention or Appreciation? The Impact of Computer-mediated Feedback on Online Volunteering

Fujie Jin, Kelley School of Business, Indiana University, Bloomington, IN, 47401, United States, Xue Tan, Alan R. Dennis

In this study, we examine how different types of feedback influence subsequent online volunteer contributions. We study a unique context of college application online consultation which requires the volunteer counselor and the person receiving help to be online at the same time. We investigate the impact of two types of feedback on volunteers' participation: 1) appreciation, as reflected in the number of positive ratings received by a counselor from counselees; 2) attention, as reflected in the readership of counselor's profile pages. We find that appreciation encourages the volunteer counselor to engage in more helping behavior, in contrast, attention discourages counselors to offer more help.

5 - Run for the Group: The Impacts of Offline Teambuilding, Social Comparison and Competitive Climate on Group Physical Activity - Evidence from a Mobile Fitness App

Jennifer Jie Zhang, University of Texas at Arlington, Arlington, TX, 76019, United States, Zilong Liu, Yuan Zhang, Xiaolong Song

To study the impacts of the within-group social comparison and between-group competitive climate on the group psychical activities, we conducted empirical analyses based on a dataset from a fitness app to test the main and moderating effects. Our results show that both the within-group social comparison and the between-group competitive climate can improve the group psychical activity.

Queueing and Learning

Sponsored: Applied Probability

Sponsored Session

Chair: Weina Wang, Carnegie Mellon University, Pittsburgh, PA, c15213, United States

1 - Almost Bolzmann Exploration

R. Srikant, University of Illinois at Urbana-Champaign, Urbana, IL, United States, rsrikant27@gmail.com

Boltzmann exploration is a widely-used technique in machine learning to provide a tradeoff between exploration and exploration. However, it is also known to perform poorly in many examples of multi-armed bandit problems due to a well-known under-exploration issue. We present a modification to Boltzmann exploration which solves the under-exploration problem and show that it performs well in practice in many large data sets. Joint work with Harsh Gupta, Seo Taek Kong, and Weina Wang.

2 - Simple Near-optimal Scheduling for the M/G/1

Ziv Scully, Graduate Student, Carnegie Mellon University, Pittsburgh, PA, United States, zscully@cs.cmu.edu

We consider preemptively scheduling jobs to minimize mean response time in the M/G/1. If we know the job size distribution but not individual job sizes, the Gittins policy is optimal, but it can be very difficult to implement. A potential alternative to Gittins is shortest expected remaining processing time (SERPT), but it is unknown how far SERPT is from optimal. We present a new policy, monotonic SERPT (M-SERPT), which is as simple as SERPT but has provably near-optimal mean response time. Specifically, we prove that M-SERPT is 3-competitive for load up to 8/9 and 5-competitive for any load. This makes M-SERPT the first policy other than Gittins known to be constant-competitive for mean response time.

3 - Concentration Bounds for Constant Step-size Temporal Difference Learning

Lei Ying, Arizona State University, Tempe, AZ, 85287, United States, lei.ying.2@asu.edu, R. Srikant

We consider constant step-size temporal difference learning with linear function approximation, and study the concentration of the parameter values Θ around the corresponding ODE equilibrium point $\theta^*.$ Given a constant step-size, we show hat the (2n)th moment of ||Θ-θ^*|| is Gaussian-like when n=o(1/step-size) but is unbounded at steady state when n=ω(1/step-size).

4 - Heavy-traffic Analysis of the Generalized Switch under Multidimensional State Space Collapse

Daniela A. Hurtado-Lange, Georgia Tech, Atlanta, GA, United States, d.hurtado@gatech.edu

The generalized switch is a queueing model that encapsulates several Stochastic Processing Networks. We study the generalized switch operating under MaxWeight algorithm in heavy-traffic regime, using the drift method. In particular, we study the case when the Complete Resource Pooling condition does not hold, i.e. the state space collapses into a multi-dimensional space. We prove that the state space of the system collapses to cone and use this to exactly characterize the mean of certain linear combinations of the queue lengths in heavy-traffic. This work builds upon and generalizes the results obtained by Eryilmaz and Srikant (2012) and Maguluri and Srikant (2016).

CC- Room 2B

From Stochastic Control to Data-Driven Decision Making

Sponsored: Applied Probability

Sponsored Session

Chair: Renyuan Xu, University of California-Berkeley, Berkeley, CA, 94720, United States

1 - Learning Mean-Field Game

Xin Guo, University of California-Berkeley, Piedmont, CA, 94611, United States, xinguo@berkeley.edu, Renyuan Xu, Anran Hu, Junzi Zhang

Motivated by the Ad auction problem for advertisers, we consider the general problem of simultaneous learning and decision-making in a stochastic game setting with a large population. We formulate this type of games with unknown rewards and dynamics as a generalized mean-field-game (GMFG), with incorporation of action distributions. We first analyze the existence and uniqueness of the GMFG solution, and show that naively combining Q-learning with the three-step fixed-point approach in classical MFGs yields unstable algorithms. We then propose an approximating Q-learning algorithm and establish its convergence result. The numerical performance shows superior computational efficiency.

2 - Continuous-Time Mean-Variance Portfolio Selection: A Reinforcement Learning Framework

Xunyu Zhou, Columbia University, Department of IEOR, New York, NY, 10027, United States, Haoran Wang

We approach the continuous-time mean-variance (MV) portfolio selection with reinforcement learning (RL). The problem is to achieve the best tradeoff between exploration and exploitation, and is formulated as an entropy-regularized, relaxed stochastic control problem. We prove that the optimal feedback policy for this problem must be Gaussian, with time-decaying variance. We then prove a policy improvement theorem, based on which we devise an implementable and data-driven RL algorithm. We find that our algorithm outperforms both an adaptive control-based method and a deep neural networks-based algorithm by a large margin in our simulations.

3 - A Unified Framework for Solving High-Dimensional Parabolic PDEs and FBSDEs with Deep Learning

Jiequn Han, Princeton University, Princeton, NJ, United States

We introduce the "deep BSDE method" as a unified framework to solve general high-dimensional parabolic PDEs and FBSDEs. Starting from the BSDE formulation, we approximate the unknown component by neural networks and design a least squares objective function to optimize parameters. Numerical results of a variety of examples demonstrate that the proposed algorithm is quite effective in high-dimensions, in terms of both accuracy and speed. We furthermore provide a theoretical error analysis to illustrate the validity and property of the objective function.

4 - Linear-quadratic Mean Field Type Reinforcement Learning

Mathieu Lauriere, Princeton University, 98 Charlton Street, Princeton, NJ, 08540, United States, lauriere@princeton.edu, Rene A. Carmona, Zongjun Tan

In this work, we develop reinforcement learning methods for mean field type control problems (also called problems of optimal control of McKean-Vlasov dynamics). Such problems arise, for instance, either when a single agent interacts with her own distribution or as the limit of games with a large number of collaborative agents when the number of agents goes to infinity. We prove global convergence of a policy gradient method in a linear-quadratic setting and provide numerical experiments. If time permits, other settings and methods will be discussed. Joint work with Rene Carmona and Zongjun Tan.

Analytics for E-commerce Operations

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Jing-Sheng Jeannette Song, Duke University, Durham, NC, 27708-0120, United States

Co-Chair: Shuyu Chen

1 - Randomized Product Display, Pricing, and Order Fulfillment for E-commerce Retailers

Murray Lei, Queen's University, Kingston, ON, K7L 3N6, Canada, yl64@queensu.ca, Stefanus Jasin, Joline Uichanco, Andrew Vakhutinsky

Consider an etailer selling multiple products stored in multiple warehouses to customers from multiple regions. For each customer, etailer may customize the pricing decision, the product display decision (i.e. which products to display in what manner on the website), and the fulfillment decision (i.e., where to dispatch individual items). We propose a tractable LP formulation and then construct a novel randomization scheme that translates the solutions to the LP into control parameters. We test the performance of the proposed control in large-scale numerical experiments with real retail data.

2 - The Operational Value of Personalized Return Policies in Retail

Aravind Govindarajan, Ross School of Business, University of Michigan, Ann Arbor, MI, 48104, United States, arav@umich.edu, Joline Uichanco, Hyun-Soo Ahn

The problem of customer returns is prevalent in modern retail where lenient return policies are popular; however, several customers take advantage of such policies, which leads to loss in revenue and increase in inventory costs. We study the value of personalizing return policies based on a customer's historical behavior. For a heterogeneous mass of customers, we derive the optimal personalized return policy and show that the knowledge of customer-specific information can help the firm strategically offer return policies to increase inventory efficiency.

3 - Data-driven E-commerce Transportation Network Design with Unknown Flow Response

Shuyu Chen, Duke University, Durham, NC, 27701, United States, shuyu.chen@duke.edu, Jing-Sheng Jeannette Song

We study a network design problem for an e-commerce marketplace. One novel feature in our model is that the decision maker has no control over flow decision once the network configuration is decided. We develop a flow prediction model using observational data and then embed it into the fixed-charge network design problem. The problem is NP-hard but can be characterized as a c-submodular maximization problem. We propose two linear time approximation algorithms to solve it.

4 - Understanding the Value of Fulfillment Flexibility in an Online Retailing Environment

Levi DeValve, University of Chicago, Chicago, IL, 27713, United States, Yehua Wei, Di Wu, Rong Yuan

We assess the value of partial flexibility in online retailing fulfillment networks. Motivated by practical constraints, we propose an intuitive spillover limit policy that is asymptotically optimal as the time horizon and inventory grow large. Motivated by the revenue management literature, we also derive the optimal spillover limits in a simplified model in the non-asymptotic regime and show that these spillover limits perform well numerically. Using this policy, we estimate a significant cost decrease for our industrial collaborator.

Healthcare Operations

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Lauren Xiaoyuan Lu, University of North Carolina at Chapel Hill - Kenan Flagler, Chapel Hill, NC, 27599, United States

Co-Chair: Susan F. Lu, Purdue University, West Lafayette, IN, 47907, United States

1 - An Empirical Study of On-demand Healthcare Platforms

Yixuan Liu, The University of Texas at Austin, Austin, TX, 78712, United States, Ashish Agarwal, Guoming Lai, Weihua Zhou

On-demand healthcare platforms allow patients to seek care from distributive healthcare providers, targeting the problems of healthcare resource misuse and mismatch. Collaborating with a mobile platform in China, we conduct an empirical study of healthcare platform design problem. We evaluate the effects of providing free service sampling on users' behaviors of purchasing premium services across geographical regions and disease categories. We find that there coexist cannibalization effects and acceleration effects.

2 - Consumer Online Reviews, Government Ratings and Nursing Home Operations: Evidence from Yelp

Yuanchen Li, Purdue University, West Lafayette, IN, 47906, United States, li1820@purdue.edu, Susan F. Lu, Lauren Xiaoyuan Lu

We study the effect of user-generated reviews on nursing homes' performance in the presence of government ratings. Employing the Yelp nursing home rating matched with OSCAR dataset from 2010 to 2017, we conduct a difference-in-differences analysis on nursing homes' financial performance and patient volume. We observe that a one-star increase in Yelp rating leads to a 1.9% increase in revenue. Our empirical analysis suggests that facilities increase their revenue by chasing more Medicare-covered patients while filtering Medicaid-covered patients.

3 - Effect of Multi-siting on Productivity and Quality

Diwas S. Kc, Emory University, Goizueta Business School, Atlanta, GA, 30322, United States, Sokol Tushe

Although multi-site workplace deployment is becoming increasingly common, its impact on people operations has not been examined in the operations management literature. We contribute to the literature by studying the effect of multi-siting on individual worker productivity and quality of output.

4 - Increasing Patient Engagement Through Shared Medical Appointments

Ryan Buell, Harvard Business School, Boston, MA, 02163, United States, rbuell@hbs.edu, Kamalini Ramdas, Nazli Sonmez

Through a randomized control trial, we examine the impact of shared medical appointments (SMAs), in which a group of patients with similar chronic conditions meet with a doctor simultaneously, on levels of patient engagement. Relative to traditional one-on-one care models, we study how SMAs affect engagement levels, both during the appointment (such as making eye contact with the physician, engaging in the proceedings, and asking questions) and after (such as complying with prescribed medications in the home). Preliminary evidence suggests that SMAs have the potential to increase patient engagement, both during and after the appointment, hinting at their potential to improve patient outcomes.

CC- Room 304

Operations for Knowledge-Intensive Services

Sponsored: Manufacturing & Service Oper. Mgmt/Service Operations

Sponsored Session

Chair: Guillaume Roels, INSEAD, Fontainebleau, 77305, France

1 - Service Designs as Quality Signals

Stylianos Kavadias, Margaret Thatcher Professor of Innovation & Growth, University of Cambridge, Judge Business School, Trumpington Street, Cambridge, CB2 1AG, United Kingdom, s.kavadias@jbs.cam.ac.uk, Ioannis Bellos

We follow up on prior work to conceptualise service designs as choices of how much of a customer journey should a service provider control. We consider, however, an asymmetry of information setting where the customers cannot be entirely sure about the service provision capability of a company. We analyse whether a service provider can use the amount of control as a signal of their quality in the market and we find that depending on the type of service more, or less, control is optimally chosen for the design. Our results have direct implications for new service design contexts.

2 - Effects of Mental Accounting on Project Performance

Manel Baucells, University of Virginia, Charlottesville, VA, United States, BaucellsM@darden.virginia.edu, Yael Grushka-Cockayne, Woonam Hwang

Projects often fail to meet their goals. We consider the implications of behavioral tendencies, both at launch and at the revision points, on decisions made and on overall project performance. Specifically, we offer a framework for modeling mental accounting—which includes loss aversion and reference point updating—and narrow framing. We show that mental accounting results in insufficient adjustments of project scope and cost during revisions and prevents abandoning projects even when doing so is optimal. We offer practical prescriptions for mitigating harmful effects of loss aversion, reference-point updating, and narrow framing.

3 - Complain About Too Many Meetings? Performance of Meeting Schedules for Team Coordination

Charles J. Corbett, University of California-Los Angeles, Anderson Graduate School of Mgmt, Los Angeles, CA, 90095-1481, United States, Guillaume Roels

In many knowledge-intensive operations (e.g., coding), workers produce individually but may benefit from periodic coordination with the others. As they keep producing, they encounter issues, which negatively impact their individual productivity, but can be resolved through a collective meeting. With a game-theoretic model, we evaluate different meeting schedule business rules: deterministic meeting schedule, preemptive coordination (i.e., coordination happens as soon as one worker wants to coordinate), and preemptive production (i.e., production happens as long as one worker wants to produce).

4 - New Venture Creation: a Drift-variance Diffusion Control Model

Zhengli Wang, Stanford University, Stanford, CA, 94305, United States, Stefanos Zenios

We model the creation of a new venture with a diffusion process, where an entrepreneur can control the drift and the variance of the process. The entrepreneur receives a huge reward or goes bankrupt, depending on whether the process reaches the upper boundary or the lower boundary. We characterize the optimal policy and show how the optimal policy depends on the model primitives.

Joint Session MSOM/SERV OP/Practice Curated: Empirical Studies in Health and Service Operations

Sponsored: Manufacturing & Service Oper. Mgmt/Service Operations

Sponsored Session

Chair: Fanyin Zheng, Columbia University, New York, NY, 10027, United States

Co-Chair: Carri Chan, Columbia Business School, New York, NY, 10027, United States

1 - Tax-induced Inequalities in the Sharing Economy

Yao Cui, Cornell University, Ithaca, NY, 14853, United States, yao.cui@cornell.edu, Andrew M. Davis

We use a machine learning method (generalized causal forest) to study the heterogeneous treatment effects of the tax policy on Airbnb. While the tax regulation is intended to alleviate the pressure that Airbnb creates to hotels, we find that it has led to unintended consequences for Airbnb participants. In particular, the tax policy adversely affects residential listings more than commercial listings, and adversely affects those listings whose service offerings are more differentiated from hotels. These distributional impacts indicate that the goal of the tax policy is not effectively achieved. We further provide insights to policy makers and sharing economy platforms regarding tax regulation.

2 - A Structural Estimation Approach to Study Agent Attrition

Seyed Emadi, UNC-Chapel Hill, Chapel Hill, NC, United States, seyed_emadi@kenan-flagler.unc.edu, Bradley R. Staats

We build a structural model that captures both the firm’s decision to terminate a workers’ employment (involuntary attrition) and uses an optimal stopping problem process to model a workers’ decision to leave the firm (voluntary attrition). We then estimate the parameters of the model and conduct counterfactual analyses on the population of 1,118 agents serving one client over three years for an Indian business process management (BPM) company.

3 - Scheduling of Primary Care Follow Up and Risk of Long Term Opioid Use

Katherine Bobroske, University of Cambridge, Trumpington Street, Cambridge, CB2 1AG, United Kingdom, kab80@jbs.cam.ac.uk, Lawrence Huan, Michael Freeman, Anita Cattrell, Stefan Scholtes

Many patients are initially prescribed opioids in the primary care setting. While clinical guidelines promote continuity of care for managing opioids, little is known about whether this recommendation is effective in the early stages of a patient’s opioid journey. We analyzed the medical claims of opioid-naive patients who received their first opioid prescription in a primary care office setting. Using data mining and econometric methods, we found that exposing patients to a second medical opinion early in their opioid journey may significantly curb rates of long-term opioid use.

4 - Structural Estimation of Intertemporal Externalities on ICU Admission Decisions

Yiwen Shen, Columbia Business School, New York, NY, 10025, United States, YShen21@gsb.columbia.edu, Carri Chan, Fanyin Zheng

The ICU in a hospital often has the highest cost and congestion level. Since a large proportion of the patients in ICU are the patients admitted from the Emergency Department (ED), we can gain insights on how physicians make ICU admission decisions and how to improve overall outcomes by studying the ED physicians’ ICU admission decisions. Our study focuses on the intertemporal externalities on these ICU admission decisions. We take the structural estimation approach to estimate the intertemporal externalities from data. We use two years of detailed patient-level data from 21 Kaiser hospitals. We find that there is substantial heterogeneity in the estimated discount factor across hospitals.

Operational Innovations and Innovative Operations

Sponsored: Manufacturing & Service Oper. Mgmt/Supply Chain

Sponsored Session

Chair: Vish Krishnan

1 - An Investigation of Drug Shortage Recovery

Junghee Lee, Tulane University, New Orleans, LA, 70118, United States, jlee56@tulane.edu, Hyun Seok (Huck) Lee, Hyoduk Shin, Vish Krishnan

Ongoing shortages of pharmaceutical drugs in the U.S. have critically threatened public health. As the primary reason for the shortages is manufacturing related issues, how soon the shortage is resolved depends on the firm’s investment in recovering its production line. We investigate the effects of various features of drugs on this firm’s decision through time-to-recovery (TTR) in conjunction with the intervention of the Food and Drug Administration (FDA) which aims to lower “entry cost” particularly for drugs in short supply. We find that the TTR of drugs with low (high) economic incentives is longer (shorter) and becomes even longer (shorter) after the intervention.

2 - Pooled Transportation: Consumer Preferences and System Design

Kashish Arora, Cornell Tech/Johnson, New York, NY, United States, ka522@cornell.edu, Karan Girotra, Fanyin Zheng

Pooled ride services alleviate the problems of traffic congestion and air pollution. This study builds a structural model to estimate drivers of choices between an on-demand taxi service and a pre-determined and scheduled shuttle service. Using large scale data from a transportation service provider, we estimate the ``inconvenience costs” to customers associated with the shuttle service (walking to the shuttle, waiting for its arrival, and traveling extra distance on the shuttle). We then use these estimates to quantify the environmental benefits of the shuttle service and provide policy recommendations for designing the pricing scheme and introducing new routes for the shuttle service.

3 - Managing Exploration and Execution

Sina Moghadas, University of California San Diego, San Diego, CA, United States, Lakshminarayana Nittala, Viswanathan Krishnan

We consider the design of innovation contests while conceptualizing solution development as an incremental process involving idea generation and implementation. Such a perspective provides extra levers to the seeker, which, when managed optimally, can increase the returns to the seeker by increasing the chances of realizing high quality feasible solutions.

4 - Does Real-time Feedback Make You Try Less Hard? A Study of Automotive Telematics

Vivek Choudhary, INSEAD Business School, Singapore, vivek.choudhary@insead.edu, Maria Shunko, Serguei Netessine

IoT devices increasingly enable tracking of user behavior and they often provide real-time feedback to the consumers in an effort to improve their conduct. Growing adoption of such technologies leads to an important question, “Does real-time feedback provided to users improve their behavior?” We study real-time feedback in the context of automotive telematics that has been recognized as the most disruptive technology in the automotive insurance industry. Contrary to much of the existing feedback literature, we find that, on average, the driving performance of users post-detailed feedback is 13.3% worse than the performance of users who do not review their detailed feedback.

Co-Chair: Juan Camilo Serpa, Indiana University, Montreal, QC, H2L 3S2, Canada

1 - Manufacturing Productivity with Worker Turnover

Ken Moon, The Wharton School, Philadelphia, PA, United States, kenmoon@wharton.upenn.edu

We investigate turnover’s effects on manufacturing productivity using data from China-based facilities producing millions of electronic goods weekly yet exhibit worker turnover exceeding 300% annually. Worker turnover significantly disrupts the productivity of responsive manufacturers facing uncertain product demand. We extend production planning to include endogenous worker turnover as an Experience-Based Equilibrium and use reinforcement learning and approximate DP to estimate and simulate our model. Well-calibrated increases to worker compensation reduce production costs by at least 5%, or $135M, by stabilizing a leaner workforce and improving the reliability of production.

2 - When to Be Agile

Amandeep Singh, The Wharton School, Philadelphia, PA, 19104, United States, amansin@wharton.upenn.edu, Kenneth Moon, Gad Allon

Mobile apps release version updates, motivating interest in agile operational responses to app store ratings. We characterize the optimal strategy for timing such updates and structurally estimate the extent to which developers are agile, exhibiting both reactive capacity and responsiveness to customer feedback. We discuss implications for platform design.

3 - The Value of Free Shipping: Field Experiment on O2o Platform

Yuqian Xu, University of Illinois at Urbana-Champaign, Champaign, IL, 61820, United States, Hongyan Dai, Yan Wen

In this paper, we aim to investigate the impact of free shipping on consumer behaviors in O2O platforms. More specifically, we want to study: (1) the impact of the free shipping and its magnitude on customer behaviors; (2) the impact of tipping behavior of the consumers on the crowd-sourced delivery staffs; (3) how free shopping promotion interactively affects tipping behavior. We collect field experiment data from one leading O2O platform in China to explore these questions.

4 - Supply Chain Structure and Contract Performance

Vibhuti Dhingra, University of British Columbia, Vancouver, BC, V6T1Z2, Canada, vibhuti.dhingra@sauder.ubc.ca, Harish Krishnan, Juan Serpa

In the US public projects, federal agencies award contracts to a prime recipient. In many cases, the prime contractor then outsources a significant proportion of the work to a network of subcontractors. Subcontractor misconduct can adversely impact contract performance leading to delays or cost overruns. As the government does not have privity of contract with the subcontractors, it cannot directly control their actions. Instead, the task of subcontractor oversight is given to the prime contractor. In this setting, we empirically examine the impact of multi-tier supply chain structure on contract performance.

Whose Project is it Anyway? Designing Industry Collaborations for Learning AND Impact

Sponsored: Education

Sponsored Session

Chair: Sanjay Saigal, University of California-Davis, Menlo Park, CA

1 - Lessons from Managing Student Consulting Projects

Vijay Mehrotra, University of San Francisco, 2130 Fulton St., School of Business and Professional Studies, San Francisco, CA, 94117, United States, vmehrotra@usfca.edu

For the past ten years, I have been supervising MBA student consulting projects in business analytics and related areas. In this session, I will share what I’ve learned along the way, including both pleasant and unpleasant lessons, offer some suggestions for best practices, and solicit input from the attendees. My intent is to have a highly interactive session with lots of dialogue.

2 - Capstone Projects: Learning from the “Real World” While Still in School

Scott Nestler, University of Notre Dame, Granger, IN, 46530, United States

The capstone project is the culmination of the MS in Business Analytics (MSBA) program and provides an intensive and integrative experiential-learning opportunity. Student teams work to analyze a problem on behalf of a sponsoring organization, which provides the business problem and gives students access to relevant data and in-house personnel. Using skills acquired throughout the program, students develop a thorough understanding of the problem and the associated data, then develop and execute a project work plan that analyzes the data, develops actionable recommendations and conclusions, and provides insight into the basis for those recommendations. Skills developed include the ability to provide effective communication regarding the analytics process and results, and an understanding of key aspects of analytics solution development.

3 - The Care, Feeding, and Nurturing of Unicorns

Raymond Pettit, UC San Diego, San Diego, CA, 92093, United States

Master’s degrees in business analytics claim to develop managerial, personal and communication skills beyond a data science core, in other words, to create “unicorns”. Programs often launch students into ‘sink or swim’ capstone projects that fulfill the letter but belie the spirit of such lofty goals. Guidance by a multi-faceted support team can enable a learning experience that advances the value of the degree and the student’s career. We describe the three-fold academic support team at UCSD that embeds technical, managerial, and communication training at each step of the capstone.

4 - Integrating Experiential Learning in Analytics Master’s Programs

Sanjay Saigal, Graduate School of Management, UC Davis, Menlo Park, CA, 94025, United States

Analytics graduate programs meet employment-focused outcomes through “learning-by-doing” activities - capstones, internships, and practicums. Deans hope that projects complement traditional course in OR, statistics, computing, etc. We ask: are such combinations of experiential and theoretical learning interventions stylistically coherent and pedagogically integrated? And do they increase employability? Using the experience of a new, practice-centric MS program in Business Analytics - its core is an intensive, nearly year-long, industry practicum - we answer those, and related, questions.

New Topics in Logistics, Manufacturing and Risk Management

Sponsored: Manufacturing & Service Oper. Mgmt/iFORM

Sponsored Session

Chair: Sebastian Maier, EPFL, Lausanne, 1015, Switzerland

1 - Choice-based Electric Vehicle Smart Charging: Discovering and Exploiting Latent Demand Flexibility

Nicolò Daina, Imperial College London, London, United Kingdom, n.daina@imperial.ac.uk

Traditional smart charging considers charging requests from electric vehicles (EV) drivers as fixed, neglecting potential additional demand flexibility from drivers with flexible charging and departure times preferences. We integrate into operations management of a charging service provider a negotiation phase in which flexible charging alternatives are presented to EV drivers. A choice-based optimisation approach is used to identify the offer set of charging alternatives and their pricing. We show the additional load flexibility potential of this approach in a simulation study based on published charging preference information and real-world charging demand data.

2 - Modeling Supply Change Disruptions via a Sequence of Optimized Regrets

René Yves Glogg, EPFL, Lausanne, 1015, Switzerland

We present a stochastic optimization problem that obtains a resilient production plan for a convex minimum cost network flow problem which models a simple supply chain. We do so by introducing a function into the optimization that models the regret a decision-maker incurs whenever some supply chain disruption scenario occurs. We adapt a generalized Benders decomposition approach in order to be able to solve this problem for sufficiently large instances and perform some managerial analysis on the results.

3 - Additive Manufacturing: Towards Flexible Operations and Profitable Mass Customization

Rachel Lacroix, PhD Candidate, EPFL, Lausanne, 1015, Switzerland, rachel.lacroix@epfl.ch, Anna Timonina-Farkas, Ralf W. Seifert

Technology enablers of Industry 4.0 paired with an increasing demand for product customization create a challenging push-pull situation for supply chains. We quantify the economic benefits of integrating additive manufacturing into existing mass production systems. Through customer-specific utilities, we derive an endogenous, time-varying demand and formulate an optimization problem to jointly optimize pricing, process-switching and product-variety decisions. Numerical experiments provide managerial insights to better satisfy individual customer preferences while maximizing profit.

5 - Risk-averse Pathwise Dynamic Programming: a Simple Simulation-and-regression Approach

Sebastian Maier, EPFL, Lausanne, 1015, Switzerland, Imperial College-London, London, United Kingdom, Georg Pflug

Pathwise dynamic programming is a powerful algorithmic strategy to solve sequential stochastic decision problems such as valuing options; however, existing valuation approaches generally neglect decision-makers' attitude towards risk. We propose an approach to solve risk-averse stochastic dynamic programs by simulation-and-regression. Applying the dynamic entropic risk measure, we use simulation in combination with parametric regression to approximate the conditional risk measure. Using the examples of put and call options, we investigate the way in which the option value is affected by risk aversion and illustrate its impact on both optimal decisions and the probability of investment.

Going the Extra Mile for Sustainable Supply Chains

Sponsored: Manufacturing & Service Oper. Mgmt/Sustainable Operations

Sponsored Session

Chair: Tarkan Tan, Eindhoven University of Technology, Eindhoven, 5612AZ, Netherlands

Co-Chair: Osman Alp, University of Calgary, Calgary, AB, T2N1N4, Canada

1 - Improving the Environmental Impact of E-commerce via Better Truck Consolidation

Josue Cuauhtemoc Velazquez Martinez, Massachusetts Institute of Technology, Cambridge, MA, United States, josuevm@mit.edu, Karla Gamez-Perez, Andres Mulos-Villamizar

With e-commerce companies (e.g. Amazon) move toward offering fast shipping options, we predict lower truck utilization and more frequency of home deliveries. As a consequence, transportation emissions are expected to grow significantly, having negative impact on the environment and human health. In this article, we study the evolution of home delivery in e-commerce. We conduct an econometric analysis for two of the largest cities in the US by considering urbanization, aging, income, GDP, internet accessibility, and shopping habits. We study the effect in transportation emissions during home delivery, and provide managerial insights for key stakeholders: Carriers, Consumers and Government.

2 - Information Asymmetry and Firm Non-compliance: Effective Policies in Waste Disposal

Sytske Wijnsma, University of Cambridge, Christ's College, Cambridge, CB23BU, United Kingdom, Dominique Lauga

Illicit waste disposal is one of the fastest growing areas in crime today. This paper examines the effect of waste regulations, intended to induce proper waste disposal, on firm non-compliance and its interaction with the underlying information structure. We find that decentralisation of the waste management chain, aggravating information problems, can either exacerbate non-compliance or improve economic and environmental outcomes. The allocation of enforcement efforts between firms and the orientation of these efforts between domestic and international regulations play a critical role in determining which outcome is attained.

3 - Efficient Supplier Assessment for Sustainability in Supply Chains

Tarkan Tan, Eindhoven University of Technology, School of Industrial Engineering, Den Dolech 2 Paviljoen F-07, Eindhoven, 5612AZ, Netherlands, t.tan@tue.nl, Hakan Akyüz

The last few decades have witnessed a complete globalization of supply chains, resulting in a typical Multi National Enterprise (MNE) having tens of thousands of suppliers in developing countries. Socioeconomic state of these countries lead to social, environmental, and ethical problems at factories which directly or indirectly supply goods and services to MNEs. To address this, the common practice by many MNEs is to assess the sustainability levels of their suppliers through means like audits or verified self-assessments provided by the suppliers. In this talk we address how this assessment can be conducted in an efficient manner, taking the supplier characteristics into account.

4 - Sustainable Fleet Management with Alternative Fuel Vehicles

Osman Alp, University of Calgary, Haskayne School of Business, Calgary, AB, T2N1N4, Canada, osman.alp@ucalgary.ca, Tarkan Tan, Maximiliano Udenio

We analyze a fleet management problem of a freight transportation company, which aims to adopt a fleet of sustainable vehicles in a finite planning horizon. In particular, we optimize the transformation of their fleet into a mixed fleet of electric and diesel trucks. Our model also optimizes for the choice of charging technology as well as the number of charging facilities and their capacities. The objective of the decision maker is to minimize the investment costs for vehicles and the charging infrastructure, and the carbon emission related costs. We present a numerical study to generate insights about how to facilitate and incentivize the adoption of sustainable vehicle technologies in practice.

Operations and Supply Chain Management

Sponsored: Decision Analysis

Sponsored Session

Chair: Barry R Cobb, Virginia Military Institute, Lexington, VA, 24450, United States

1 - Library Book Shifting

Linda Li, Missouri State University, Springfield, MO, United States, Joshua D. Lambert

A mathematical programming model is built to efficiently use library shelf space when moving books. As a benchmark, we also suggest a myopic method. The comparison of the two methods is based on simulation, which uses empirical data.

2 - The Design Decision Supply Chain

Robert F. Bordley, PMP, MBA, University of Michigan Ann Arbor, Troy, MI, 48085, United States, rbordley@umich.edu

This paper focuses on eliminating the disconnect between strategic, tactical and operational decision-making using systems engineering. After a need is identified, the requirements for addressing the need are first defined at the system level, then the subsystem level and then the component level. Solutions are then developed at the component level, then the subsystem level and finally the overall level. This paper argues that this process for making designs can be used to define a value-focused decision supply chain for drawing on diverse skills and expertise for creating a detailed plan (or decision) to address fundamental objectives.

3 - Attribute Statistical Process Control with Limited Information

Barry R. Cobb, Virginia Military Institute, Department of Economics and Business, 344 Scott Shipp Hall, Lexington, VA, 24450, United States, cobbbr@vmi.edu

A limited memory influence diagram model is utilized for statistical process control in a system where attribute data on number of defects is available each sampling period. Based on the number of defects observed, a decision is made on whether to stop the process and repair an assignable cause of variation. The model has no requirement to maintain the history of sample results and/or corrective actions taken in previous sampling periods.

4 - Using Genetic Algorithms for Additive Production Scheduling

Maaz Saleem Kapadia, North Carolina State University, Raleigh, NC, United States, Reha Uzsoy, Donald Paul Warsing, Binil Starly, Alec Thomas

We study an additive manufacturing system that fulfills due-date-specific orders for custom parts with varying shapes, sizes, structures, and surface quality requirements. We use a genetic algorithm to determine part sequences and orientations that maximize profit for this system. Experiments in a simulated environment demonstrate that some implementations of the genetic algorithm exhibit significant advantages in terms of computational effort and system profitability.

Advances in Multiobjective Optimization

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Margaret M. Wiecek, Clemson University, Clemson, SC, 29634-1907, United States

1 - Generating Well-dispersed Nondominated Solutions for a Multiobjective SVM Formulation

Serpil Sayin, Koc University, Istanbul, Turkey, Gokhan Kirlik

We present a multiobjective L1-norm SVM formulation that treats sum of empirical errors for different classes as separate objective functions. We propose obtaining a representation of the nondominated set by solving a subproblem that is based on the achievement scalarizing function. The proposed approach does not provide quality guarantees on the representation that is delivered, and it relies on the ability of the achievement scalarizing function to target specific regions in the outcome set. We demonstrate that the approach can deliver good classifiers when applied to difficult imbalanced classification problems.

2 - Generalized Set Covering Problem with Conflict Objective Functions: Algorithm and Applications in Ecological Conservation

Lakmali Weerasena, University of Tennessee at Chattanooga, Chattanooga, TN, United States, lakmali-weerasena@utc.edu

In this research, we propose a generalization to the Set Covering Problem (SCP). We define the new problem as the generalized multi-objective SCP (GMOSCP) and propose an algorithm to approximate the Pareto set of the GMOSCP. Developing an algorithm to approximate the Pareto set of the GMOSCP is merited since it is a NP-hard problem. The performances of the algorithm are verified using a real data in ecological conservation and conflicting objective functions are proposed. Several experiments have been conducted to analyze the performance of the proposed algorithm. The results show that algorithm performs well and finds approximated solutions efficiently.

3 - Portfolio Optimization with Multiple Quadratic Functions

Margaret Wiecek, Clemson University, Clemson, SC, United States, wmalgor@clemson.edu

The classical mean-variance portfolio optimization problem is formulated as a multiobjective quadratic program (MOQP) and its efficient set is computed with a state-of-the-art algorithm for solving parametric linear complementarity problems with parameters in general locations (Adelgren, 2016). The MOQP is scalarized with a newly developed approach being a modification of the hybrid method (Wendell and Lee, 1977; Corley, 1980). The scalarization allows for quantifying tradeoffs for groups of objective functions which, in the case of the portfolio optimization, are the weighted risk and the return. A triobjective example is provided.

4 - A Solution Algorithm for Biobjective Mixed Integer Programming Problems

Ozlem Karsu, Bilkent University, Ankara, 06800, Turkey, ozlemkarsu@bilkent.edu.tr, Firdevs Ulus, Deniz Emre

We propose an objective space based exact solution algorithm for biobjective mixed integer programming problems. The algorithm solves scalarization models in order to explore predetermined regions of the objective space called boxes, defined by two nondominated points. The initial box is defined by the two extreme nondominated points of the Pareto frontier, which includes all nondominated points. At each iteration of the algorithm, a box is explored either by a weighted sum or a Pascoletti-Serafini scalarization to determine nondominated line segments and points. We demonstrate the applicability of the algorithm through computational experiments.

5 - Approximation Algorithms for the Multiple Knapsack Problem with Grouped Items

Pinar Keskinocak, Georgia Institute of Technology, School of Indust/System Eng, Atlanta, GA, 30332, United States, Francisco Javier Castillo Zunino

Motivated by patient scheduling, the multiple knapsack problem with grouped items aims to maximize profits by assign a subset of items among multiple knapsacks, without exceeding their capacities. Additionally, items are partitioned into groups where either all items in a group are assigned or none at all. We propose three algorithms for this problem that respectively solve: a linear relaxation, a knapsack problem, and a multi-dimensional knapsack problem. All solutions guarantee that profits are not less than the optimal solution but can exceed knapsack capacities. We finally test the performance of the algorithms on randomly generated instances.

Analytical Models in Marketing-Operations Interface

Emerging Topic: Interface of Marketing & Operations

Emerging Topic Session

Chair: Jeffrey Shulman, University of Washington, Seattle, WA, 98195-3226, United States

1 - Spot Pricing in Cloud Computing: Diversification of Cloud Resources under Supply Uncertainty

Amir Fazli, Indiana University, Bloomington, IN, United States

Cloud computing providers often sell their excess resources on a spot market, where resources could be interrupted at any time. In order to alleviate the effects of such interruptions, cloud providers offer spot users the option to diversify cloud resources across different server types. It is commonly believed that a diversified cloud strategy is used primarily when interruptions are highly likely. However, we show that when the value difference between spot users is moderately high, diversification occurs only when interruption likelihood is low. This is because an interruption in one pool can increase the price of the remaining pools when diversification is chosen.

2 - Competitive Pricing under Observational Learning

Amin Sayedi, University of Washington, Seattle, University of Washington, Seattle, Seattle, WA, 98195, United States

We look at the problem of pricing in a duopoly with observational learning. Prior literature shows that when the number of customers in a monopoly is sufficiently large and the monopolist is sufficiently patient, an informational cascade always happens; furthermore, the probability that the cascade is wrong, i.e., virtually all customers receive negative utility ex post, is always positive. We find similar results in a duopoly with static pricing. Interestingly, and in contrast to the previous literature, we show that in a duopoly with dynamic pricing, there are equilibria in which no cascade happens. More importantly, we show that a wrong cascade cannot happen in equilibrium.

3 - Social Enterprise Welfare and New Product Diffusion: Model and Empirical Validation at World Bicycle Relief

Vadim Glinsky, Kellogg School of Management, Evanston, IL, United States, vadim.glinskiy@kellogg.northwestern.edu, Jan A. Van Mieghem

We present a dynamic model of a social enterprise (SE) that offers a product through its not-for-profit and for-profit channels. Product offered in either channel stimulates future market (for-profit) demand. We present a continuous-time, 2 channel product diffusion model and a closed-form expression for the optimal production policy. We perform sensitivity analysis on two conflicting objectives: maximize social welfare or profitability. Our theoretical results are validated with a rigorous empirical study of World Bicycle Relief. We find conditions for which the for-profit channel can increase social welfare and the not-for-profit channel can increase profitability.

4 - The Perils of Personalized Pricing with Network Effects

Jeffrey Shulman, University of Washington, Seattle, WA, 98195-3226, United States, Amin Sayedi, Bita Hajehashemi

Given technological advances, a growing number of companies charge different prices to different customers based on their anticipated willingness to pay. This paper uses an analytical model to examine the impact of personalized pricing in markets for which there exist positive network effects. Video games are an example of a product with positive network effects. There's value to playing the game alone, but this value increases when playing with another person who owns the game. Rather than amplify benefits of personalized pricing, network effects can actually cause personalized pricing to diminish firm profitability and produce counterintuitive findings about prices and consumer surplus.

Research in E-commerce Platform

General Session

Chair: Hyun Seok (Huck) Lee, College of Business, Oregon State University, Corvallis, OR, 97330, United States

Co-Chair: Junghee Lee, Tulane University, New Orleans, LA, 70118, United States

1 - Disclosing Product Availability in Online Retail

Eduard Calvo, IESE Business School, Barcelona, Spain, ecalvo@iese.edu, Laura Wagner, Ruomeng Cui

Online retailers disclose product availability to influence customer decisions, as a form of pressure selling designed to compel customers to rush into a purchase. Can the revelation of this information drive sales and profitability? We study the effect of disclosing product availability on product sales and returns. We find that the disclosure of scarcity signals causally increases sales by13.6% but product return rates increase by 17.0%. Net sales increase by 12.5%. In addition, we propose a data-driven, machine learning algorithm that exploits these results by prescribing the timing of disclosure of scarcity signals in order to boost sales without spiking returns.

2 - Unpacking E-retail Platform Owner Intervention in Order Fulfillment

Hyun Seok (Huck) Lee, College of Business, Oregon State University, Corvallis, OR, 97330, United States, HyunSeok.Lee@oregonstate.edu, Yusoon Kim, Junbo Son

Large e-commerce marketplaces increasingly bring order fulfillment function in-house, resulting in the two internally competing order fulfillment channels – conventional fulfillment by merchant (FBM) and emergent fulfillment by platform (FBP). Using transactions and logistics data in the e-commerce setting, we examine whether the FBP system has a positive intervention effect on order fulfillment performance. We further decompose the entire fulfillment process into three sub-processes (pre-delivery, main delivery, and last-mile delivery) and investigate whether the intervention effect is differential across three sub-processes.

3 - Online-to-offline Platform Models

Joseph Jiaqi Xu, Carnegie Mellon University, Tepper School of Business, Pittsburgh, PA, 15213, United States, jiaqixu@andrew.cmu.edu, Hui Li, Sridhar R. Tayur

We study commonly observed business models for online-to-offline (O2O) platforms. We derive optimal strategies and equilibrium outcomes to understand: how the models function, how best to avoid incentive misalignment and system loss, which model is better for the platform, the merchant, the system, and under what market conditions.

4 - Observed Choices and Unobserved Talents in Online Labor Markets

Jiding Zhang, The Wharton School, Jon M. Huntsman Hall, Philadelphia, PA, 19104, United States, jiding@wharton.upenn.edu, Elena Belavina, Karan Girotra, Kenneth Moon

Our work shows the significance of relationships and flexibility in online labor markets.

CC- Room 4C-2

Supply Chain, Shipping and Transportation

Contributed Session

Chair: Nastaran Khalili, Virginia Tech

1 - Factors Associated with Truck Dwell Times

Haena Kim, University of Washington, Seattle, WA, United States, haenakim@uw.edu

There has been a lack of data to understand the delivery activities that could lengthen truck dwell times; times spent on off-vehicular activities that delivery workers performed while the truck is parked. We focus on analyzing the factors associated with truck dwell times. Ordered logit regression was used as modeling methods in this study. Factors that found to influence the truck dwell time was found to be building type, vehicle type (compact sized, with rolling or swing doors) and type of delivery goods (food, mail, oversized supplies, parcels, office supplies) and number(s) of delivery destination (one or more than one).

2 - Olefin Supply Chain Network Design with Seasonal Feedstock and Uncertain Carbon Tax Rate

Morteza Alizadeh, Graduate Research Assistant, Mississippi State University, Starkville, MS, United States, ma1845@msstate.edu, Junfeng Ma, Mohammad Marufuzzaman, Fei Yu

We propose a three-stage stochastic model for logistics network of producing olefin from biomass. First stage makes facility location decisions. Second stage plans multi-period decisions for feedstock storage, transportation units and olefin production after realizing feedstock seasonality. Third stage finds processing feedstock throughout network by realizing carbon tax uncertainty. Municipal solid waste ensures reliable supply for olefin production. Integrating affinely adjustable robust problem and sample average approximation, a robust approximation method is developed to solve problem. Results by solving real case problem of Mississippi state reveal capability of this model.

3 - A System of Systems Approach to Evaluate the Emergence of Technology on International Regulations for Preventing Collisions at Sea

M.J. Press, George Washington University, Washington, DC, United States

Thirty-seven years ago, the International Maritime Organization (IMO), a specialized agency of the United Nations, adopted nine amendments to the 1972 Convention on the International Regulations for Preventing Collisions at Sea (COLREG). Since 1981, the world has experienced a rapid growth of naval transport technology; however, the international navigational rules remain unchanged. While industry and academic research continue to present technological maritime advances, a statistical examination of simulated data illuminates the inadequacies (increased risk of collision and need for further research) of the current regulations.

4 - Wildfire Catastrophe as a Complex Socio-ecological System Outcome

Farshad Farkhondehmaal, Virginia Polytechnic Institute, Blacksburg, VA, United States, farshad1@vt.edu

The size of wildfires in the Western United States has increased during the last three decades and endangered both society and wildlands while still there is no consensus on the causes of this trend. In the United States, 71499 incidents of wildfire happened just in 2017 which burned over 10 million acres with the estimated cost of $2.9 billion. Different scientists consider varying factors as the main reasons for this trend including climate change and human wildfire ignition. In this paper, I examine the impact of each factor on current wildfire activity. The case study of California wildfires is used for the case study.

5 - Varying Dynamics of False and True News Diffusion under Different Conditions

Nastaran Khalili, Blacksburg, VA, United States, nkhalili@vt.edu

In this paper, I simulate the diffusion of false vs. true news in different conditions. Building on the more generic model of information diffusion which often does not differentiate true vs. false news, I propose “news validation” as a mechanism for individuals seeking validity of a piece of information. I then simulate the model for different levels of sensitivity of society to validation before diffusion. The results demonstrate different modes of information diffusion, beyond what previously are suggested in the literature. The analysis shows explicitly that false news diffusion pattern is different from true ones. The study has significant implications for addressing fake news problems.

Model-Based Analysis of the Education System

Sponsored: Service Science

Sponsored Session

Chair: Maryam Andalib, PhD, Ford Motor Company, Dearborn, MI, United States

1 - Policy Modeling for Science Workforce Analysis

Navid Ghaffarzadegan, Virginia Tech, Falls Chruch, VA, 24061, United States, navidg@vt.edu

The US higher education system acts as a very large enterprise with several objectives including production of talented PhD graduates. This outcome, however, turns to the future workforce within the same large enterprise, leading to more outcomes. I use system dynamics modeling to analyze science workforce production and related policies.

2 - Using Simulation Modeling to Examine the Effects of Federal Research Funding on the Academic Science Workforce

Julie A. Maurer, Lead Research Manager, Ohio State University, Columbus, OH, 43210, United States, maurer.99@osu.edu

Past research demonstrates that there are unintended negative outcomes on the academic science workforce when federal higher education research funding fluctuates. This study extends these findings by using hybrid simulation modeling to examine the effects of unstable federal research funding policies on the academic science workforce. Insights into how the workforce structure, federal funding policies and employer preferences interact to influence the career development of academic scientists using ABM and SD modeling techniques will be shared.

3 - University Diversity Performance: A Data Envelopment Analysis Approach

Maryam Andalib, Data Scientist, Ford Motor Company, Dearborn, MI, 48067, United States, maryam.andalib@gmail.com, Konstantinos P. Triantis, Navid Ghaffarzadegan

Despite all the attention and progress to diversify university campuses, many educational institutions are still far from gender and racial parity in their faculty and student populations. An important question is what makes an institution perform better regarding its diversity and the outcomes of under-represented minorities (URM). We construct an institution-level dataset from multiple sources and apply DEA to systematically benchmark, compare, and contrast organizational performance with respect to the educational and work outcomes of URM. We discuss the findings, policy and methodological implications.

4 - A Sentence-based Text Analytic Framework for understanding Voice of the Customer

Sukhwa Hong, Virginia Institue of Technology, Pamplin College of Business, Blacksburg, VA, 24061, United States, sukhwa@vt.edu, Onur Seref, Michelle M.H. Seref

In our study, we propose a sentence-level neural network language model to understand sentence-level elements in which customer satisfaction related information is presented. Our model mimics how human detect customer satisfaction related documents (by finding sentences that contain customer satisfaction related information) for better performance and enhanced interpretability of the model's output.

Joint Session AMD/Practice Curated: Applications in Market Design

Sponsored: Auction and Market Design

Sponsored Session

Chair: Robert Day, University of Connecticut, Storrs, CT, 06269-1041, United States

1 - Algorithm Bias - The Case of Medical Resident Matching

Srinivasa Kartikeya Puranam, LaSalle University, Philadelphia, PA, 19141, United States, Michael N. katehakis, Briance Mascarenhas

Artificial Intelligence is a major technical innovation transforming the world, but ethical and bias concerns are emerging about the use of algorithms. This study of the national resident matching program (NRMP) provides insights into its algorithmic biases. We present analytical and numerical evidence.

2 - Using Machine Learning for Modeling Human Behavior and Analyzing Friction in Generalized Second Price Auctions

Karthik Kannan, Purdue University, West Lafayette, IN, 47906, United States, Vandith Pamuru, Yaroslav Rosokha

Recent advances in technology have reduced frictions in various markets. In this research, we specifically investigate the role of frictions in determiningthe efficiency and bidding behavior in a Generalized Second Price Auction (GSP) — the most preferred mechanism for sponsored search advertisements. First, we simulate computational agents in the GSP auction setting and obtain predictions for the metrics of interest. Second, we test these predictions by conducting a human subject experiment. We find that, contrary to the theoretical prediction, the lower valued advertisers (who do not win the auction) substantially overbid. Moreover, we find that the presence of market frictions moderates this phenomenon and results in higher allocative efficiency. These results have implications for policymakers and auction platform managers in designing incentives for more efficient auctions. Finally, after establishing the validity of our computational model, we simulate counterfactuals that provide additional insights into the role that frictions play in the markets that are not feasible (or practical) to investigate with human-subject experiments.

3 - " Now or Later?": When to Deploy Qualification Screening in Open-bid Auction for Re-sourcing

Wen Zhang, University of Texas at Dallas, Richardson, Texas, Richardson, TX, 75080, United States, Wen.Zhang4@utdallas.edu, Qi Chen, Elena Katok

We consider a re-sourcing setting in which a qualified supplier and multiple unqualified suppliers (entrants) compete in an open-bid auction. Conventionally, the buyer screens entrants before the auction (prequalification). We explore an alternative that the buyer postpones the screenings after the auction (post qualification). By characterizing the dynamic structure of the suppliers' equilibrium strategy, we can calculate the buyer's expected cost under post qualification, which is computationally impossible without this characterization. Our comprehensive numerical study shows that post qualification can save cost significantly. We also identify the most beneficial scenarios.

4 - Multiple Vickrey Auctions for Sustainable Electric Vehicle Charging

Konstantina Valogianni, IE Business School, Madrid, Spain, Alok Gupta, Wolfgang Ketter, Soumya Sen, Eric Van Heck

We propose an auction mechanism to optimally schedule EV charging in a sustainable way so that the grid is not overloaded. Our solution has lower computational complexity, compared to state-of-the-art mechanisms, making it easily applicable to practice. Our mechanism creates electricity peak demand reduction and provides optimized charging speed design recommendations. We prove the optimal conditions that must hold, so that different stakeholder objectives are satisfied. We validate our mechanism on real-world data and examine how different trade-offs affect social welfare and revenues, providing a holistic view to grid stakeholders that must satisfy potentially conflicting objectives.

5 - Expansion and Seller Competition in Online Marketplaces

Wenchang Zhang, PhD Student, University of Maryland, College Park, MD, 20904, United States, zhangwenchang89@gmail.com, Wedad Jasmine Elmaghraby, Ashish Kabra

Market expansion is one of the key elements to the success of an online platform, especially for platform startups. Using a proprietary dataset from a leading B2B liquidation platform, we estimate that the supply-side market shocks have a significant positive effect in accelerating the market growth by substantially incentivizing incumbent sellers to increase their listings. We further show that incumbents adopt such listing expansion strategy in response to the increased competition.

Health Care, Modeling and Optimization III

Contributed Session

Chair: Mehmet Aydemir, CMU, Pittsburgh, PA, 15217, United States

1 - A New Medical Staff Allocation via Simulation Optimization for an Emergency Department in Hong Kong

Wenjie Chen, City University of Hong Kong, Hong Kong SAR, Hong Kong, wenjichen8-c@my.cityu.edu.hk

Whether triage targets can be achieved has been an imperative assessment of service qualities for an emergency department. We focus on triage targets and try to fully meet the target of fast emergency response for critical patient's subject to triage requirements for other category patients by optimizing the medical staff allocation. We develop a discrete-event simulation model and propose a simulated-annealing-based algorithm called ConSA that adopts a special searching mechanism and an efficient simulation budget allocation rule to find a high-quality configuration of medical staff.

2 - Applications of Difference-in-difference Design in Emergency Medicine

Ai Ren, University of Maryland-College Park, College Park, MD, United States, renai@rhsmith.umd.edu, Bruce L. Golden, Edward Andrew Wasil

Difference-in-difference (DID) is a popular and important economics model for estimating causal effects. By reviewing DID-related articles published in top emergency medicine journals since 1990, our survey reports the application of DID models in this domain. Our results indicate that, since 2011, the DID model has been gaining traction and becoming more recognized by top emergency medicine journals.

3 - Data Mining of Hospital Alerts in Emergency Department in Maryland

Xu Zhang, University of Maryland, College Park, MD, United States, Sean Barnes, Bruce L. Golden, Paul Smith

Understanding the underlying connection between emergency rooms can better support decision-making for both patients and hospitals. County/Hospital Alert Tracking System provides real-time and historical information for alerts to describe utilization for hospital emergency room at Maryland. We propose two-steps clustering methods for 21 hospitals in Region III, make comparisons for behavior of alerts between alerts, and evaluate potential time factors that may associate with alerts in clusters. Then we suggest two ways to find cascading event in Region III, explore patterns for such event, and how hospitals are connected.

4 - Enhancing Emergency Department Patient Flow by Increasing the Efficiency of Physician-related Processes by Use of Discrete-event Simulation

Lien Vanbrabant, Hasselt University, Hasselt, Belgium, lien.vanbrabant@uhasselt.be, Kris Braekers, Katrien Ramaekers

Emergency departments (EDs) are continuously exploring opportunities to increase their operational efficiency. Physicians are a major bottleneck and strongly impact ED patient flow, as they have multiple consultations with each patient. Moreover, physicians are a costly resource, resulting in multiple patients being assigned to a single physician simultaneously to make optimal use of their capacity. By use of discrete-event simulation, multiple ways to improve the efficiency of physician-related processes in EDs can be investigated, such as applying appropriate queueing disciplines or limiting physician multitasking.

5 - Stochastic Models for Inpatient Discharge Planning

Mark Alan Lawley, Texas A&M University, College Station, TX, 77843-3131, United States, Maryam Khatami

Delay in discharging inpatients deteriorates patient satisfaction, increases hospital costs, and results in overcrowded units such as emergency department. The inpatient discharge planning problem requires the efficient assignment and sequencing of ready-for-discharge (RFD) patients to resources. Some RFD patients are discharged to home, and some are transferred to rehabilitation centers (RCs). Bed unavailability in RCs could result in inpatient boarding. Taking these bed availability times into account, we model and solve the inpatient discharge planning problem as a two-stage stochastic program with uncertain inpatient discharge processing time and bed request time.

6 - Incorporation of Ride-sharing Platforms into Emergency Medical Services

Mehmet Aydemir, Carnegie Mellon University, Pittsburgh, PA, United States, maydemir@andrew.cmu.edu, Jacquillat Alexandre

In this study, we aim to incorporate services offered by ride-sharing platforms into emergency medical services (EMS). These services can complement the EMS for high-priority patients while it can substitute it for the low priority cases. By doing so, the scarce resources of the EMS can be utilized for more severe patients and hence lead to saving of lives. We model this problem with approximate dynamic programming and calibrate it using real data.

Military Maintenance and Logistics

Sponsored: Military and Security

Sponsored Session

Chair: Javier Salmeron, Naval Postgraduate School, Monterey, CA, 93943, United States

1 - Analyzing Recurrent Events of Aircraft Using Survival Analysis

Seong-Jong Joo, Associate Professor, Air Force Institute of Technology, Wright-Patterson AFB, OH, United States, sludoc95@gmail.com, Gawon Yun

Although there are various applications of survival analysis on recurrent events in the medical field, it is not easy to find those in other areas. We choose aircraft and analyze their recurrent failures using survival analysis. We apply Kaplan-Meier estimators and Cox proportional-hazards models to the failure records of the aircraft, which include categorical and time-varying covariates. We found that mission types and flight hours were significant for explaining the failures of the aircraft.

2 - Simulation-optimization for Wholesale Inventory Planning at Naval Supply Systems Command

Javier Salmeron, Naval Postgraduate School, Monterey, CA, United States, jsalmero@nps.edu, Arnold H. Buss, Emily Craparo, Duncan Robert Ellis, Anton Rowe

The U.S. Naval Supply Systems Command, Weapon Systems Support, manages an inventory of approximately 400,000 maritime and aviation line items valued at over $20 billion. This talk discusses the models developed to plan optimal inventory levels by combining multiple metrics, such as expected fill rate, backorders, safety stock cost, and “churn” (deviation from legacy plan). Most of these metrics require simulation in order to be estimated precisely due to uncertainty in demand and lead time, internal rules for reordering parts, and complex processes for repairable items.

3 - Cyber Physical System Model Implementation and Platform Construction Framework for Defense Industry (in the Missile Manufacturing Process)

Jinbae Kim, Kumoh National Institute of Technology, Gumi, Korea, Republic of, dbk0508@gmail.com

A missile with controller board, such as a guided weapon, produces a controller board through a Surface Mounted Technology (SMT) process. The controller board manufacturing process is composed of automation equipment, and various information related to productivity and quality are generated. In this study, Cyber Physical System (CPS) model is implemented to manage, analyze and control manufacturing process information. We also propose a platform configuration framework for implementing the CPS model. The CPS model proposed in this study and the effects of the platform configuration framework has been proven through actual cases introduced to the Republic of Korea defense industry.

4 - Rethinking Government Supplier Decisions: The Economic Evaluation of Alternatives (EEoA)

James Fan, Assistant Professor, Naval Postgraduate School, Monterey, CA, United States, james.fan@nps.edu, Francois Melese

This paper offers an economic model to assist public procurement officials to rank competing vendors when benefits cannot be monetized. An important defense application is “source selection” - choosing the most cost-effective vendor to supply military equipment, facilities, services or supplies. The problem of ranking public investment alternatives when benefits cannot be monetized has spawned an extensive literature that underpins widely applied decision tools. The “Economic Evaluation of Alternatives” (EEoA) extends the analysis to the supply-side. A unique feature of EEoA is to model vendor decisions in response to government funding projections.

Operations Research Methods in Support of Planning and Analysis

Sponsored: Military and Security

Sponsored Session

Chair: Jonathon Leverenz, Systems Planning and Analysis, Inc, Alexandria, VA, 22302, United States

1 - A Bayesian Perspective on Optimization under Uncertainty

Christopher C. Grubb, Grubb, Fairfax, VA, 22030, United States, chrisgrubb@me.com

Optimization under uncertainty often begins with strategies for mitigating a lack of ‘exact’ knowledge of underlying distributions. This presentation explores Bayesian solution approaches that attempt to characterize the distribution of optimal decisions while accepting uncertainty in the characterization of underlying constraint or cost distributions. More specifically, this presentation covers approaches to optimization under uncertainty, with a focus on comparisons between optimization methods such as robust optimization, chance constraint formulations, distributional robust optimization, and Bayesian decision-making with support from optimization approaches.

2 - Insights on Inventory Management

Stephanie Brown, LMI, Tysons, VA, United States

LMI has developed two models, Peak Policy and NextGen, to address the challenges of managing spare parts when demand is sparse or highly variable and a simulation environment, Financial and Inventory Simulation Model (FINISIM), to test and evaluate any number of inventory policies. This presentation will explore several key insights that have been obtained through this work. For example, simulating transactions with FINISIM highlights the weakness of key assumptions by revealing significant differences between metrics from analytical models and what would likely be attainable in the real world.

3 - Computing Advances in Nuclear Forces

Derek R. Shortt, Systems Planning and Analysis Inc., Alexandria, VA, United States, dshortt@spa.com, Jonathon Leverenz, Christopher C. Grubb, Stephanie Brown

The United States is currently recapitalizing their nuclear weapon systems. There exists legacy computational tools to aid the design and development of nuclear weapons. However, many of these were limited in their ability to understand the design solution space in a comprehensive manner due to limits of computing at the time. Today, computing power is plentiful allowing military operations analysts to combine multiple computational models together to explore the realm of comprehensive solutions while remaining computationally tractable. This presentation covers a tool that explores solutions to nuclear weapon design issues using modern computational tools and techniques.

4 - Force Structure Analysis Optimization and Simulation

Jonathon Leverenz, Systems Planning and Analysis, Inc, Alexandria, VA, 22302, United States, jonathon.leverenz@gmail.com, Roy Shortt, Rivka Howell, Will Garcia, Christopher C. Grubb, Stephanie Brown

Multiple factors influence the ability of a force to meet strategic mission goals. The Force Structure Model (FSM) tool measures the ability and likelihood of meeting mission goals for a given time period while satisfying constraints on asset size, mission areas, operational cycles and other requirements. This presentation discusses the optimization and simulation models used by FSM to create a schedule that maximizes fulfillment of mission goals and to perturb the schedule by disrupting asset availability. The result establishes a probability that the force will be able to fulfill the mission goals and provides a quantifiable prediction of the effective bounds on a force for its intended missions.

1 - Enhancing the Effectiveness and Efficiency of Food Aid Supply Chains: An Economic Optimization Model for USAID Food for Peace Program's Operations

Weijia Jing, Northeastern University, Boston, MA, 02215, United States

Please check the mobile app for this abstract.

2 - Multiregional Oligopoly with Capacity Constraints

Humoud Alsabah, Columbia University, New York, NY, 10025, United States

Please check the mobile app for this abstract.

3 - Atlanta Police Zone Redesign via Data-Driven Optimization

Shixiang Zhu, Georgia Institute of Technology, Atlanta, GA, United States

With fast population growth, Atlanta's old police zone districting caused inefficient police operations and long response time. Since 2017, we collaborated with Atlanta Police Department to redesign its police zones. We built statistical model to predict police workload and optimized zone districting for workload rebalance. Our proposed plan was approved by Atlanta City Council and implemented in March 2019.

4 - Unifying Agricultural Wholesale Markets to Increase Farmers' Income: Evidence from the Field

Somya Singhvi, MIT, 235 Albany Street, Cambridge, MA, 02139, United States

Online agri-platforms, that attempt to tackle inefficiencies in traditional agricultural markets, have been launched in many developing countries. In this work, we collaborate with one such government platform, UMP, to (i) rigorously evaluate the empirical impact of UMP on farmers' income, and (ii) design and implement an updated auction design for the platform to further benefit farmers.

Advances in Convex and Nonconvex Optimization

Sponsored: Optimization/Computational Optimization and Software

Sponsored Session

1 - Global Optimization of Nonconvex Quadratic Programs and Mixed-integer Quadratic Programs

Carlos Nohra, Carnegie Mellon University, Pittsburgh, PA, United States, cnohrakh@andrew.cmu.edu, Arvind Raghunathan, Nick Sahinidis

This work addresses the global optimization of nonconvex quadratic programs and mixed-integer quadratic programs. We derive convex quadratic relaxations by convexifying nonconvex quadratic functions through perturbations of the quadratic matrix. We also introduce novel branching variable selection strategies which can be used in conjunction with these quadratic relaxations. We integrate the proposed techniques into the global optimization solver BARON and demonstrate their benefits by conducting an extensive computational study on a large collection of problems selected from publicly available test sets.

2 - Truss Topology Design Optimization with Guaranteed Kinematic Stability

Ramin Fakhimi, PhD student, Lehigh University, Bethlehem, PA, United States, raf318@lehigh.edu, Mohammad Shahabsafa, Weiming Lei, Sicheng He, Luis Zuluaga, Joaquim R.R.A. Martins, Tamas Terlaky

Kinematic stability of the truss topology design and sizing optimization (TTDSO) problems is a crucial aspect which is often overlooked in the mathematical optimization models. In this work, we propose a novel mathematical optimization model for the discrete TTDSO problem with Euler buckling constraints. Random perturbations of external forces are used to obtain kinematically stable structures. We prove that by considering the perturbed external forces, the resulting structure is kinematically stable with probability one. Furthermore, we show that necessary conditions for kinematic stability can be used to speed up the solution of discrete TTDSO problem.

3 - A Modified Augmented Lagrangian for Solving Generalized Nash Equilibrium Problems

Jong Gwang Kim, Purdue University, West Lafayette, IN, 47906, United States, kim2133@purdue.edu, Andrew Lu Liu

We present a new primal-dual method, based on a novel, modified augmented Lagrangian (MAL), for solving generalized Nash equilibrium problems (GNEP) where each player's feasible action set depends on other players' actions. We reformulate the GNEP as a saddle point computation using the MAL and propose a provably convergent algorithm to compute a saddle-point, which is shown to be equivalent to an equilibrium of the GNEP. Our method leads to a (Jacobi-like) distributed implementation, and it does not require any boundedness assumptions on variables. The effectiveness of the proposed method is verified by numerical experiments on benchmark test problems.

4 - A Distributed Algorithm to Solve Large-scale Convex Quadratically Constrained Quadratic Programs

Run Chen, Purdue University, West Lafayette, IN, 47906, United States, chen885@purdue.edu, Andrew Lu Liu

Convex quadratically constrained quadratic programs (QCQPs) have many application areas, including signal processing, machine learning, and data analysis. The increasing scales of the resulting QCQPs pose more challenges to the traditional interior point method and call for distributed algorithms. We propose a novel, proximal primal-dual decomposition method, which uses the idea of predictor/corrector to lead to parallelization of the algorithm to solve QCQPs without separable structures. Convergence is proven and numerical results show that the algorithm exhibits favorable performance compared to CPLEX (barrier algorithm) when the problem scales become really large.

5 - Binary Reformulations of Positive Multi-linear Programs with Affine Constraints

Fabian Rigterink, University of Newcastle, University Drive, Callaghan, 2308, Australia

We study positive multi-linear programs with affine constraints—a class of problems that arise in game theory settings and involve large integer products. The large integer products induce numerical instabilities. In this talk, we describe exact binary reformulations that bypass the numerical instabilities. To our surprise, the reformulations in some cases are computationally advantageous when compared to much more sophisticated, state-of-the-art algorithms that exploit the problem's structure.

Bilevel Optimization

Sponsored: Optimization/Global Optimization

Sponsored Session

Chair: Xueyu Shi, University of Pittsburgh, Pittsburgh, PA, United States

1 - Sequential Shortest Path Interdiction with Incomplete Information and Limited Feedback

Jing Yang, University of Pittsburgh, Pittsburgh, PA, 15232, United States, jiy75@pitt.edu, Juan Sebastian Borrero, Oleg A. Prokopyev, Denis Saure

We study sequential shortest path interdiction, where an interdictor with incomplete knowledge of the network, and an evader traverses a shortest path in the network. The interdictor, who aims at maximizing the evader's cost, observes only the total cost. The interdictor then uses this limited information feedback to refine her knowledge of the network. Focusing on minimizing the number of periods to recover a full information decision, we show that a greedy interdiction policy requires, in the worst case, an exponential number of periods to converge. Moreover, we consider different versions of imperfect randomized feedback that allows establishing polynomial expected convergence bounds.

2 - Designing Networks Resilient to Clique Blockers

Haonan Zhong, University of Massachusetts-Boston, Boston, MA, 02188, United States, Foad Mahdavi Pajouh

The network design resilient to clique blockers problem (denoted as NDRCB) is to find the minimum cost of connecting a set of vertices such that the cost of blocking cliques via vertex removals is not less than a given constant. We addressed the computational complexity of this problem, proposed an integer programming (IP) formulation, and solved the IP by enforcing constraints in a lazy fashion. We also proposed an exact combinatorial branch and bound algorithm to solve this problem.

3 - A Hierarchy of Bounds for Bilevel Mixed 0-1 Programs

Xueyu Shi, University of Pittsburgh, Pittsburgh, PA, United States, Ted K. Ralphs, Oleg A. Prokopyev

We consider general bilevel programs in which the decision variables of the lower-level problem are binary. A sequence of mixed-integer programming formulations are developed to obtain a hierarchy of bounds for the optimal objective function value of the bilevel programs. The proposed bounds are stronger to those provided by single-level relaxations. Computational study is performed to explore the efficiency of our bounds.

4 - Parametric Inequalities in Multistage/Multilevel Optimization

Ted K. Ralphs, Lehigh University, Industrial and Systems Engineering, Bethlehem, PA, 18015, United States, ted@lehigh.edu, Suresh Bolusani, Sahar Tahernejad

In this talk, we'll discuss the theoretical framework underlying solution algorithms based on the generation of so-called parametric valid inequalities for a general class of optimization problems that includes multi-stage and multi-level problems. We describe the theory of such inequalities, present methods for generating them, and describe a generalized branch-and-cut framework that incorporates them.

Network Optimization and Approximation Algorithms for Operations

Sponsored: Optimization/Integer and Discrete Optimization

Sponsored Session

Chair: Fatemeh Navidi, University of Michigan, Ann Arbor, MI, 48105, United States

1 - Constrained Assortment Optimization under the Paired Combinatorial Logit Model

Rohan Ghuge, University of Michigan, Ann Arbor, MI, United States, Viswanath Nagarajan

We study the assortment optimization problem under the paired combinatorial logit model. We study uncapacitated, capacitated and space constrained versions of this problem, which are all known to be NP-hard. We design efficient algorithms that compute approximately optimal solutions, using a novel relation to the maximum-directed-cut problem, a fundamental and well-studied optimization problem. We obtain performance guarantees of 87.4%, 50% and ≈ 50% for the uncapacitated, capacitated and space constrained versions respectively. We also study the assortment problem under more general constraints, for which we obtain a performance guarantee of 38.5%.

2 - Leveraging Information in Online Matching

Yam Huo Ow, Northwestern University, Evanston, IL, United States, yamhuo.ow@kellogg.northwestern.edu, Chaithanya Bandi

Online matching platforms require efficient scaling and quick solution times in highly competitive markets. In this work, we design an online algorithm, which is a variant of the 'Balance' algorithm, that allows us to leverage on distributional information on the bidders' behaviors. Using techniques from Robust Optimization and Factor Revealing LP, we model the informational constraints and incorporate uncertainty sets to bound the feasibility set of our algorithm's performance metrics. We also characterize the improvements gained in the competitive ratios using numerical experiments and data from a major online freelancers' platform.

3 - Approximating Max-Cut under Graph Constraints

Viswanath Nagarajan, University of Michigan, Ann Arbor, MI, 48109, United States

We consider the maximum cut and maximum k-cut problems under graph-based constraints. Our approach can handle any constraint specified in monadic second-order logic on graphs of constant treewidth. Examples of such constraints include stable set, connectivity, dominating set and Hamiltonicity. We give a 0.5-approximation algorithm for this class of problems. Our main technique is the use of linear program relaxations from the Sherali-Adams hierarchy.

4 - Optimal Decision Tree Problem with Noisy Outcomes

Fatemeh Navidi, University of Michigan, Ann Arbor, MI, 48105, United States, navidi@umich.edu

A fundamental task in active learning, known as optimal decision tree problem, involves performing a sequence of tests to identify an unknown hypothesis that is drawn from a known distribution. We design approximation algorithms for a generalization of this problem where certain test outcomes are noisy in both adaptive and non-adaptive setting. Unlike previous work in this area, our algorithms provide guarantees that are nearly best-possible and work for a large number of noisy outcomes per test or per hypothesis where the performance degrades smoothly with this number. We evaluate the performance of our algorithms on real-world and synthetic datasets and observe almost optimal solutions.

Robust Satisficing under Uncertainty

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Melvyn Sim, National University of Singapore, Singapore, 119245, Singapore

1 - Exploiting Hidden Convexity for Optimal Flow Control in Queueing Networks

Gar Goei Loke, National University of Singapore, Singapore, 419440, Singapore, gargoeiloke@gmail.com, Chaithanya Bandi

Optimal flow control in queues is a challenging problem occurring in many contexts, such as cloud computing, healthcare, revenue management. Motivated by emerging techniques in Robust Optimization, we propose a framework, which additionally tracks present waiting time. We show that the dynamics of a traditional queueing system can be equivalently modeled using our approach. Our key contribution is uncovering the hidden convexity in our model, leading to tractable formulations for obtaining performance guarantees on average and quantiles of waiting time, under arbitrary arrival and service distributions. Our policies are near optimal and perform significantly better than present heuristics.

2 - Advance Admission Scheduling via Resource Satisficing

Minglong Zhou, National University of Singapore, Singapore, Melvyn Sim, Shao-Wei Lam

We study the problem of advance scheduling of admission requests in a public hospital, which affects the usage of critical resources such as operating theaters and hospital beds. The difficulty of quantifying overloading costs and the need to mitigate overutilization lead us to propose a resource satisficing framework that renders resource overutilization less likely and diminishes their impact whenever they occur. The risk of resource overutilization is captured by our resource satisficing index, which better mitigates the risks of overutilization. Our approach aims to balance out the overutilization risks and can be solved via a converging sequence of mixed-integer optimization problems.

3 - Robust Data-driven Vehicle Routing with Time Windows

Zhenzhen Zhang, National University of Singapore, Tat Chee Avenue, Kowloon Tong, Singapore, Singapore, Yu Zhang, Andrew Lim, Melvyn Sim

We propose a distributional robust optimization model for the data-driven Vehicle Routing Problem with Time Windows under uncertain travel times. Our model minimizes an innovative decision criterion, Service Fulfillment Risk Index, which accounts for both the late arrival probability and its magnitude, captures the risk and the Wasserstein ambiguity in travel times, and is efficiently evaluable in closed form. To solve the problem, we develop a branch-and-cut algorithm and a variable neighborhood search meta-heuristic. Computational studies show that our SRI outperforms the canonical decision criteria, lateness probability and expected lateness duration.

4 - Repositioning for Vehicle Sharing: A Risk Mitigation Perspective

Qinshen Tang, National University of Singapore, Singapore, 117592, Singapore, oratq@nus.edu.sg, Yu Zhang, Minglong Zhou

We develop a practical model to support repositioning decisions for platforms such as bicycle-sharing systems, free-float car sharing systems. From a risk mitigation perspective, we model the problem as jointly reducing the risk of violating various constraints. Our model is flexible enough to incorporate random demand, uncertain travel destination and duration, and uncertain repositioning duration. In an N period time horizon, we use a rolling horizon heuristic and reformulate the model to a linear program. The implementation of the model on a real data set from Citi Bike and an operational data set from Car2Go shows that our model is computationally efficient and managerially sound.

1 - Chance-Constrained Scheduling of Underground Pumped Hydro Energy Storage in Presence of Model Uncertainties

Kenneth Bruninx, KU Leuven, Celestijnenlaan, Leuven, B3001, Belgium, kenneth.bruninx@kuleuven.be, Jean-François Toubeau

The optimal operation of underground pumped hydro energy storage system (UPHES) is affected by (i) modeling inaccuracies (e.g., the approximation of nonlinear pump/turbine performance curves) and (ii) model uncertainties (e.g., due to limited knowledge the underground cavity's geometry and hydraulic properties). We leverage chance constrained programming to immunize the day-ahead scheduling of an UPHES against both types of uncertainty. Results demonstrate that this approach allows finding a compromise between conservativeness and economic performance, while being computationally efficient.

2 - Bandit Models of Cyber Intrusion

Jefferson Huang, Naval Postgraduate School, Monterey, CA, 93943-5219, United States, jefferson.huang@nps.edu, Roberto Szechtman

We consider multi-armed bandit models for the attack of computer networks, from the point of view of an attacker. At each time step, the attacker may devote effort to one of a subset of nodes on a network. These nodes may correspond to already infected computers from which useful intelligence can be gained, accessible computers that have yet to be infiltrated, or routers through which snippets of intel from multiple computers can be observed. The objective of the attacker is to collect as much useful intelligence as possible. Algorithms and associated performance guarantees are presented for different policies.

3 - Optimal Genetic Screening for Cystic Fibrosis

Hussein El Hajj, Virginia Tech, Blacksburg, VA, 24060, United States, hme35@vt.edu, Douglas R. Bish, Ebru Korular Bish

Cystic fibrosis (CF) is among the most prevalent life-threatening genetic disorders. Early diagnosis improves quality of life and reduces healthcare expenditures. Most CF newborn screening processes start with a bio-marker test; followed by a genetic test, ending with diagnostic testing, which corrects false-positives. On the other hand, a false-negative represents a missed CF diagnosis. An important decision is which variants to include in the screening panel to reduce the false-negative probability under a testing budget. We develop novel stochastic optimization models, and identify key structural properties of optimal panels, and use these properties to develop efficient algorithms.

4 - Optimization of Active Surveillance Strategies for Prostate Cancer: An Application to Non-markov Disease Models

Zheng Zhang, Zhejiang University, Hangzhou, 48109-2117, China, zzhang0409@gmail.com, Brian T. Denton

Problems involving sequential decisions under uncertainty and imperfect information are often formulated as POMDPs that are difficult to solve and require strong assumptions. In contrast, this article presents an alternative approach based on a two-stage stochastic integer program. We study this problem in the context of active surveillance of prostate cancer where the goal is to maximize a cumulative reward function associated with cancer detection, missed detection, and the cost to test patients. The first stage decision variables include the selection of years to test patients in each strategy and assignment of patients to strategies. We conduct a case study based on validated data.

Chair: Yingqiu Zhang, Virginia Tech, Blacksburg, VA, 24060, United States

Co-Chair: Manish Bansal, Virginia Tech., Blacksburg, VA, 24060, United States

1 - Sample Generation for the Stochastic Unit Commitment Problem

Arnab Sur, IIT Bombay, D-1 Joyashree Park, Behala, Kolkata, 700034, India, John R. Birge

Stochastic unit commitment problems involve discrete variables on unit commitments and continuous variables relating to generation. Sample generation is, however, key to making robust decisions. This talk will describe methods for generating such samples that represent underlying relay states and solving the resulting stochastic MIPs.

2 - Topology Control for Load Shed Recovery under Uncertainty

Yingqiu Zhang, Virginia Tech, Blacksburg, VA, 24060, United States, yqzhang7@vt.edu, Manish Bansal, Adolfo Raphael Escobedo

Maintaining an uninterrupted supply of electricity is a fundamental goal of power systems operators. However, due to critical outage events, customer demand or load is at times disconnected or shed temporarily. This work introduces a two-stage stochastic programming model to deal with the uncertain demand of electric power with known probability distribution, and it uses a conditional value-at-risk to measure the risk level of unrecovered load shed. It maximizes load shed recovery in bulk transmission network by switching transmission lines and performing other corrective actions after the topology is modified. The proposed approach can serve as an online/offline contingency analysis tool.

3 - Assessing Solution Quality for Stochastic Unit Commitment with Economic Dispatch Models

Nahal Sakhavand, University of Texas at Arlington, Arlington, TX, United States, Harsha Gangammanavar

Extensive power flow approximations to the nonlinear non-convex nature of the power systems has introduced inaccuracy in the quality of the optimal solution. In this paper, we present a stochastic optimization and simulation-based framework to apply sampling-based techniques to assess the solution quality of power systems. We present a unit commitment with economic dispatch model under renewable energy uncertainty as our case study.

4 - Survey of Software for Mixed-integer Optimization under Uncertainty

David L. Woodruff, University of California-Davis, Graduate School of Management, Davis, CA, 95616, United States, dlwoodruff@ucdavis.edu

We present a brief survey of software for mixed-integer optimization under uncertainty that is currently available for download as open-source or commercially.

Community-Based Operations Research I

Sponsored: Public Sector OR

Sponsored Session

Chair: Michael P Johnson, University of Massachusetts-Boston, Boston, MA, 02125-3393, United States

1 - Local Knowledge in Technical Models of Planning and Evaluation: A Case Study

Jason Wright, MS, University of Massachusetts Boston, Boston, MA, 02125-3393, United States, Jason.Wright004@umb.edu

Rural school districts continue to shrink, and district consolidation is still used to address shrinkage despite community opposition and mixed evidence of effectiveness. The prevailing model of planning and evaluation has often emphasized technical knowledge over meaningful inclusion of local knowledge. Two case studies are used to examine the promises, practices, and results of the technical model of evaluation and interrogate the extent to which this model can incorporate and be sensitive to public input.

2 - Urban Planning and Operations Research: A Review and Critique

Tayo Fabusuyi, PhD, University of Michigan, Ann Arbor, MI, 15206, United States, Michael Johnson

While inquiry in Operations Research (OR) modeling of Urban Planning (UP) processes is long-standing, the OR discipline has not influenced UP at a level of other domains such as public policy and information technology. Could an OR approach which focuses on the complex, emergent nature of cities and the institutional environment enable interventions that better address challenges that are complex, multi-stakeholder and stochastic in nature? Based on a critique of research and practice in OR and UP, we argue that a prospective and prescriptive approach to planning that embraces mixed-methods can help researchers and practitioners develop programs that reflect community needs and concerns.

3 - Smart Shrinkage: Better Planning and Decision-making for Legacy Cities

Michael P. Johnson, PhD, University of Massachusetts-Boston, Department of Public Policy & Public Aff, 100 Morrissey Boulevard, Boston, MA, 02125-3393, United States, michael.johnson@umb.edu

Neighborhoods, cities and regions facing long-term declines in population and economic activity may consider alternative responses, such as revitalization, regeneration, shrinkage and abandonment. In this presentation I show that planning decisions intended to improve quality of life, informed by qualitative and quantitative data and analytic methods, implemented through accessible and affordable technologies, and based on notions of social impact and social justice, can enable residents to play a leading role in the positive transformation of shrinking cities and distressed communities.

4 - Understanding Decision-making Strategies to Access Basic Services: A Community Based Study of Slum Dwellers in Small Cities of India

Namesh Killemsetty, MS, University of Massachusetts-Boston, Boston, MA, 02124, United States, namesh.killemsett001@umb.edu

The paper aims to understand the priorities of slum dwellers in small cities of India for better access to housing & basic services. The study intends to document and analyze how slum dwellers structure their problems and, based on these values, identify tradeoffs that may support difficult decisions to enable increased access to stable housing and basic services. The study supports the use of Community Based Operations Research (CBOR) as a framework that accommodates multiple analytical methods such as Strategic Options Development and Analysis (SODA) and Value-Focused Thinking (VFT) to highlight the voices of slum dwellers and identify solutions to optimize their efficiency and social equity.

Optimization Algorithms for Learning Models

Sponsored: Optimization/Nonlinear Programming

Sponsored Session

Chair: Dongdong Ge, Shanghai University of Finance and Economics, Shanghai, China

1 - Principal Component Projection and Regression in Nearly Linear Time through Asymmetric SVRG

Yujia Jin, Stanford University, Stanford, CA, United States

Given a data matrix A and a vector v, solving principal component projection (PCP), projecting v onto the top-eigenvalue-space of A, and principal component regression (PCR), solving regression restricted to the top-eigenvalue-space are fundamental problems in machine learning, optimization, and numerical analysis. In this work we provide first algorithms that solve these problems in nearly linear time for sufficiently large data matrices for any fixed eigenvalue gap. We achieve our results by providing a reduction from PCR and PCA to solving asymmetric linear systems which we then solve efficiently through an asymmetric variant of SVRG that we believe is of independent interest.

2 - Optimization Methods for Learning Models: Adaptation, Acceleration, and Subsampling

Bo Jiang, Shanghai University of Finance and Economics, Shanghai, China, jiang.bo@mail.shufe.edu.cn, Xi Chen, Tianyi Lin, Shuzhong Zhang

In this talk we present a suite of algorithms for solving optimization models arising from applications in machine learning and statistics. Typically, the objective in such models may involve a large number of terms, hence subsampling is appealing. In general, popular optimization methods for solving such problems include the high-order tensor approximation approach, which requires the knowledge on some problem parameters. To make such methods practical, one will need to find ways of implementation without such knowledge. We discuss methods that exhibit an accelerated iteration bound while maintaining the traits of being adaptive and allowing subsampling.

3 - New Coordinate Descent Methods for Structured Nonconvex Optimization

Qi Deng, Shanghai University of Finance and Economics, Shanghai, China, qideng@sufe.edu.cn, Chenghao Lan

We study a class of structured nonconvex problems in which the objective function is both nonconvex and nonsmooth. Several new coordinate descent methods are developed for solving such problems in the large-scale setting. For the proposed methods, we prove asymptotic convergence to the critical points and establish sublinear convergence rates for some optimality measures. Empirical studies on sparsity-inducing learning models demonstrate the advantages of our proposed methods.

4 - Interior-point Methods Strike Back: Solving the Wasserstein Barycenter Problem

Zikai Xiong, Fudan University, Shanghai, China, zkxiong16@fudan.edu.cn, Dongdong Ge, Haoyue Wang, Yinyu Ye

Computing the Wasserstein barycenter of a set of probability measures under the optimal transport metric can quickly become prohibitive for traditional second-order algorithms, as the support size of these measures increases. In this paper, we overcome the difficulty by developing a new adapted interior-point method that fully exploits the problem's special matrix structure to reduce the iteration complexity and speed up the Newton procedure. Different from existing regularization approaches, our method achieves a well-balanced tradeoff between accuracy and speed. A numerical comparison with emerging algorithms exhibits its computational advantages and practical effectiveness.

Optimization in Clustering and Dense Submatrix Localization

Sponsored: Optimization/Linear and Conic Optimization

Sponsored Session

Chair: Brendan Peter William Ames, University of Alabama, Tuscaloosa, AL, 35406, United States

1 - Exact Semidefinite Clustering under the Heterogeneous Planted Cluster Model

Brendan Peter William Ames, University of Alabama, Tuscaloosa, AL, 35406, United States, Aleksis Pirinen

Clustering, the sorting of data into groups of similar items, is a fundamental task in machine learning and statistical analysis. Until recently, most computational methods for clustering relied on heuristics with no theoretical guarantee ensuring that clusters would be correctly identified. I will present recent results partially addressing this issue. Specifically, I will discuss a new probabilistic model for clusterable data, called the heterogeneous planted cluster model, and establish conditions on the parameters in this model that ensure that the underlying clusters can be recovered using the solution of a particular semidefinite program.

2 - Convex Optimization for Dense Submatrix Discovery

Polina Bombina, University of Alabama, Tuscaloosa, AL, United States, Brendan Ames

We consider the problem of identifying the densest mn-submatrix in a given binary matrix. We propose a new convex relaxation for this problem. Further, we propose a first-order method for solving this relaxation based on the alternating direction method of multipliers and empirically confirm our predicted recovery thresholds using simulations involving randomly generated graphs, as well as social and collaborative networks.

3 - Data-dependent Distances for Unsupervised Learning

James Murphy, Tufts University, Medford, MA, United States, jm.murphy@tufts.edu, Anna Little, Mauro Maggioni

Approaches to unsupervised clustering with data-dependent distances are proposed. By considering metrics derived from data-driven graphs, robustness to noise and cluster geometry is achieved. The proposed algorithms enjoy theoretical guarantees on flexible data models, and also have quasilinear computational complexity in the number of data points. Applications to a range of real data will be shown, demonstrating the practical applicability of our methods.

4 - Universality of Computational Lower Bounds for Submatrix Detection

Matthew Brennan, Massachusetts Institute of Technology, Cambridge, MA, United States, Guy Bresler, Wasim Huleihel

In submatrix detection, the task is to detect a k by k submatrix with entries sampled from a distribution P in an n by n matrix of samples from Q. This generalizes well-studied problems such as biclustering and community detection. These problems seem to exhibit a universal phenomenon: there is a statistical-computational gap depending on P and Q between the minimum k at which this task can be solved and at which it can be solved efficiently. We characterize this gap as a tradeoff between k and the KL divergence between P and Q through average-case reductions, for a wide class of pairs (P, Q).

Network Optimization Models for Evacuation, Resilience, and Infrastructure Restoration

Contributed Session

Chair: Shwetank Sharan, Indian Institute of Technology-Kharagpur, LBS Hall, Kharagpur, 721302, India

1 - A Mixed Integer Linear Programming Model for Road

Sachin Mhatre, Research Assistant, North Carolina Agricultural & Technical State University, Greensboro, NC, United States, shmhatre@aggies.ncat.edu

Natural disasters always have an upsetting effect on infrastructure and human life in many ways. The effective restoration of the damaged road network of the affected areas minimizes the number of casualties and delay in relief operations. In this study, a MILP model is developed to address a short-term road restoration problem to maximize the accessibility to the critical locations within the first three days of a disaster strike. The model identifies critical roads to be restored to reconnect the network and allocates the resources to repair those roads. The model aids decision making during the response stage of the disaster, which will improve the disaster making in disaster management.

2 - Stochastic Optimal Control Model for Evacuation Planning under Capacity Uncertainty

Hyeong Suk Na, Pennsylvania State University, University Park, PA, United States, hxn144@psu.edu, S. Ilgin Guler, Necdet Serhat Aybat, Soundar Kumara

The emergency management agencies are faced with numerous challenges during the evacuation due to several unpredictable traffic conditions. This study addresses uncertainties of the road capacity induced by traffic congestion in a real evacuation situation. To partially describe the capacity drop phenomenon, we define the new fundamental relation between traffic flow and density. An evacuation network flow model based on the Cell Transmission Model with joint chance constraints is proposed to deal with the uncertainties and the model reliability is investigated. Several numerical case studies are provided to examine the applicability of our models on various evacuation scenarios.

3 - Critical Infrastructure Resilience-based Restoration Optimization under Uncertainty

Basem Alkhaleel, University of Arkansas, Fayetteville, AR, United States, baalkhal@email.uark.edu

In this research, a mixed integer linear program (MILP) network-based flow model is proposed to optimize the resilience of disrupted critical infrastructures (CIs) under uncertainty. The concept of value at risk (VAR) and total expected resilience were used as different objective values for planning comparisons. A scenario analysis approach was used to quantify uncertainty. Different solutions were found to perform better than the expected value (deterministic) case. A case study based on the French RTE power transmission network was provided for testing.

4 - Interdependent Critical Infrastructure Network Expansion for Resilience Optimization

Achara Tiong, Oregon State University, Corvallis, OR, 97330, United States, tionga@oregonstate.edu, Hector Vergara

A resilient system of interconnected critical infrastructure networks is key to reduce vulnerability to disruptions and maintain expected functionality. For interdependent networks, resilience can be evaluated using a framework based on the network configuration design. We propose a mathematical formulation that optimizes resilience through strategically expanding the interdependent network with new facilities. Preliminary results are presented for two interconnected infrastructures.

5 - Assessing Supply Chains in Era of Industry 4.0 Using Attack Graphs

Shwetank Sharan, Indian Institute of Technology, Kharagpur, India, shwetank@iitkgp.ac.in, Manish Agrawal, Akhilesh Kumar

Supply chains are becoming more complicated attributing to rising vulnerabilities. With the advent of IoT, information handling has become easier but adding to the vulnerabilities. In this article, we have modeled the disruptions using a graphical model to assess the resilience of the supply chain. The transition of the state of the system is stochastically modeled as an absorbing state Markov Chain. The probabilistic transitions of the states are governed based on the defined metric which incorporates the effect of vulnerabilities of the sensors involved. The proposed model enables us to assess the risk of the nodes and formulate risk mitigation strategies to improve overall security.

Decision Diagrams for Mathematical Programming

Sponsored: Computing

Sponsored Session

Chair: Margarita Castro, University of Toronto, Toronto, ON, Canada

1 - Compact Representation of Near-optimal Integer Programming Solutions

Thiago Serra, Bucknell University, Lewisburg, PA, 02139, United States, John Hooker

We show how all solutions within a given tolerance of the optimal value can be efficiently and compactly represented in a weighted decision diagram. The structure of the diagram facilitates rapid processing of a wide range of queries about the near-optimal solution space, as well as reoptimization after changes in the objective function. We also exploit the paradoxical fact that the diagram can be reduced in size by including additional solutions. We show that a “sound reduction” operation, applied repeatedly, yields the smallest such diagram that is suitable for post optimality analysis, and one that is typically far smaller than a tree that represents the same set of near-optimal solutions.

2 - Solving MINLPs via Decision Diagrams

Danial Davarnia, Iowa State University, Ames, IA, 50010, United States, Willem van Hoeve, Christian Tjandraatmadja

We give an update on the recent developments for Dexter: An algorithmic framework based on Decision Diagrams to solve mixed integer nonlinear programs.

3 - Lifting and Cut-generation Techniques Using Decision Diagrams

Margarita Paz Castro, University of Toronto, Toronto, ON, M5S 3G8, Canada, mpcastro@mie.utoronto.ca, Andre Augusto Cire, Chris Beck

Lifting and cut-generation procedures are critical components for the performance of state-of-the-art integer programming solvers. Recent work has shown that decision diagrams (DDs) provide a basis to efficiently compute and strengthen a variety of cuts in both linear and non-linear problems. This talk reviews the main advances in the area and introduces a new lifting procedure based on DDs for 0-1 integer programs. In particular, our algorithm leverages the DD structure to efficiently find facet-defining constraints under certain conditions.

Computational Advances in Routing Problems with Emerging Technologies

Sponsored: Computing

Sponsored Session

Chair: Ahmed Ghoniem, University of Massachusetts, Amherst, MA, 01003, United States

1 - The TSP with Drone: Exact and Heuristic Approaches

Amro El-Adle, University of Massachusetts, Amherst, MA, 01003, United States, Ahmed Ghoniem, Mohamed Haouari

We investigate routing a vehicle and its companion autonomous aerial drone, known as the Traveling Salesman Problem with Drone (TSP-D). We propose an an exact mixed-integer programming approach for this problem., which also serves as a cornerstone for a heuristic methodology. Computational results are discussed.

2 - Asymptotics of Truck and Multiple Robot Routing

Bo Jones, PhD Student, University of Southern California, Los Angeles, CA, United States, bojones@usc.edu, John Gunnar Carlsson

We consider a new method for package delivery employing both a truck and ground or aerial robots. The truck launches one of multiple robots to deliver a package and continues along its route. Later the robot returns to the truck and readies for its next delivery. With hardware already in place, this new routing promises a way to leverage both the range of the truck and the autonomy of the robots in the near future. We perform an asymptotic analysis of the time needed to complete these robot-assisted routes in the Euclidean plane assuming a smooth demand distribution. We can thus characterize how this time scales as we add more and more customer points as well as the improvement to be gained by introducing robots.

3 - The Mothership and Drone Routing Problem with Obstacles

Stefan Poikonen, University of Colorado Denver, Denver, CO, 80202, United States, Bruce L. Golden

The Mothership and Drone Routing Problem contains a larger vehicle (“Mothership”) and a smaller, faster vehicle (“drone”), which work in tandem to service a set of customers. Both vehicles move in Euclidean space. The introduction of obstacles (dry land, shallow water, political boundaries, etc.) may restrict the path of the mothership. We describe applications and present a solution method that contains a discrete initialization followed by a local continuous improvement via sequential second order cone programs.

4 - An Exact Approach for the Electric Vehicle Routing Problem

Hesamoddin Tahami, Old Dominion University, Norfolk, VA, 23508, United States, htahami@odu.edu, Mohamed Haouari, Ghaith Rabadi

We investigate exact approaches for the Capacitated Electric Vehicle Routing Problem. We propose a novel compact formulation as well as an exponential-size one. We solve this latter formulation by branch-and-cut. A peculiar feature of this approach is that it embeds an exact separation algorithm of the so-called rounded capacity inequalities. We report the results of extensive computational experiments which provide evidence that the compact formulation can be easily used for solving medium-sized instances, and that the proposed exact approach can solve some instances with up to 100 nodes while requiring moderate CPU time.

Advances in First-Order Methods

Sponsored: Optimization/Nonlinear Programming

Sponsored Session

Chair: Benjamin Grimmer, Cornell University, Ithaca, NY, 14850, United States

Co-Chair: James Renegar, Cornell University, Ithaca, NY, 14850, United States

1 - An Inexact Primal-dual Smoothing Framework for Large-scale Non-bilinear Saddle Point Problems

Renbo Zhao, MIT, Muckley Bldg, Cambridge, MA, 02142, United States, renboz@mit.edu, Le Thi Khanh Hien, William Haskell

We develop an inexact primal-dual first-order smoothing framework to solve non-bilinear saddle point problems with primal strong convexity. Compared with existing methods, our framework significantly improves over the primal oracle complexity, while it has competitive dual oracle complexity. In addition, we consider the situation where the primal-dual coupling term has many component functions. To efficiently handle this situation, we develop a randomized version of our smoothing framework, which allows the primal and dual sub-problems to be solved by randomized algorithms inexactly. We adapt both frameworks for solving convex optimization problems with many functional constraints.

2 - A Unified Framework for Bregman Proximal Methods

David H. Gutman, Texas Tech University, Lubbock, TX, 15232, United States, Javier F. Peña

In this talk we propose a novel framework for the convergence analysis of Bregman proximal methods. This framework enables us to derive the standard O(1/k) rate for the proximal gradient method and new rates for its accelerated variant. The crux of our framework is an upper bound constructed via the convex conjugate of the objective function.

3 - A New Stochastic Optimization Framework for Empirical Risk Minimization

Haihao Lu, Cambridge, MA, 02142, United States

We propose a new stochastic optimization framework for empirical risk minimization. We show that the proposed algorithm is guaranteed to converge at a sublinear, and we prove a generalization bound for the proposed algorithm. Empirically, our proposed method consistently improves the test errors compared with the standard mini-batch SGD in various models.

4 - General Convergence Rates Follow from Rates Assuming Growth Bounds

Benjamin Grimmer, Cornell University, Ithaca, NY, 14850, United States, bdg79@cornell.edu

Often in the analysis of first-order methods, assuming the existence of a quadratic growth bound (a generalization of strong convexity) facilitates much stronger convergence analysis. Hence the analysis is done twice, once for the general case and once for the growth bounded case. We give a meta-theorem for deriving general convergence rates from those assuming a growth bound. Applying this simple but conceptually powerful tool to the proximal point, subgradient, and bundle methods immediately recovers their known convergence rates for general problems from their specialized rates. Future works can assume growth bounds for the sake of analysis without hampering the generality of the results.

Sponsored: Transportation Science & Logistics/Intelligent Transportation Systems (ITS)

Sponsored Session

Chair: Zhen Qian, Carnegie Mellon University, Pittsburgh, PA, 15213, United States

Co-Chair: Wei Ma, Carnegie Mellon University, Pittsburgh, PA, United States

1 - Driver Strategy and Multi-market Oligopoly: Evidence From New York City

Ruda Zhang, Postdoctoral Fellow, The Statistical and Applied Mathematical Sciences Institute, Durham, NC, 90020, United States, rudazhan@usc.edu

We study the street-hailing industry as a multi-market competition among firms of equal capacity and prove that the game has a Nash equilibrium which is (1) symmetric, (2) essentially unique in that marginal player payoffs are uniform across all invested markets, and (3) globally asymptotically stable under gradient adjustment process and imitative learning. With 868 million trip records of all 13,237 Medallion taxis in New York City from 2009 to 2013, we validate that taxi drivers' behavior conform to this equilibrium under fixed traffic speeds and taxi demand, and drivers learn the equilibrium strategy over time. We also analyze the effect of the launch of an alternative service on the equilibrium.

2 - Learning Traffic as a Graph: Graph Based Neural Networks for Network-scale Traffic Prediction

Zhiyong Cui, University of Washington, Seattle, WA, United States, zhiyongc@uw.edu

Network-wide traffic forecasting is a critical component of modern intelligent transportation systems for urban traffic management and control. With the rise of artificial intelligence, many recent studies attempted to use deep neural networks to enhance prediction performance, given the volume and variety of traffic data has been greatly increased. To capture the complex spatial-temporal dependencies in network-wide traffic data, we learn the traffic network as a graph and propose a graph wavelet gated recurrent (GWGR) neural network. Comparing to baseline models, the proposed model can achieve state-of-the-art prediction performance and training efficiency on two real-world datasets.

3 - Predicting Real-time Surge Pricing of Ride-sourcing Companies

Matthew Battifarano, Carnegie Mellon University, Pittsburgh, PA, United States, mbattifa@andrew.cmu.edu

Ride-sourcing companies such as Uber and Lyft employ surge pricing to balance supply and demand. Surge pricing, if effectively predicted and disseminated, can more efficiently allocate vehicles, save users money and time, and provide profitable insight to drivers, ultimately improving the efficiency and reliability of transportation networks. We propose a general framework to predict the short-term evolution of surge multipliers in real-time using a log-linear model with L1 regularization, coupled with pattern clustering. The model is able to predict Uber surge multipliers in Pittsburgh up to two hours in advance, out-performing naive and non-linear methods across several locations.

4 - A Data-driven Approach for Managing Queues at Signalized Intersections

Liang Zhang, University of Arizona, Tuscon, AZ, United States, liangzhang@email.arizona.edu

We propose a data-driven approach that manages queues at signalized intersections. Instead of using conventional data sources (e.g. roadside traffic surveillance systems), vehicle-based positioning and speed data are utilized to generate flow and queue information used in our approach. The performance of this approach is assessed via the VISSIM platform.

Transportation, Operations I

Contributed Session

Chair: Yineng Wang, Tsinghua University, Li Zhaoji Building, Beijing, China

1 - Exact Solution Approaches to Robust Competitive Hub Location Problem

Richa Tiwari, IIM Ahmedabad, Ahmedabad, India, richat@iima.ac.in

In this paper, we study the hub location problem in the presence of competition caused by the presence of already existing airlines in the network. For this, we model the market share captured by the entrant airline as a proportional gravity-based attraction function. But in real life situations, there exists uncertainty around customer demand which may effect the optimal solution to the problem. To overcome this shortcoming, we model demand uncertainty using an ellipse, a box, an interval and specific budget. This leads to a mixed integer second order conic program, for which we propose several customized exact methods.

2 - Vehicle Scheduling under Stochastic Trip Times: An Approximate Dynamic Programming Approach

Jie Yang, Tsinghua University, Beijing, China, yangjie17@mails.tsinghua.edu.cn

With the full consideration of delay propagation effects, this paper intends to formulate the stochastic dynamic vehicle scheduling problem, which dynamically schedules an urban bus fleet to tackle the trip time stochasticity, reduce the delay and minimize the total costs of a transit system. To address the challenge of "curse of dimensionality", we adopt an approximate dynamic programming approach (ADP) where the value function is approximated through a three-layer feed-forward neural network so that we are capable of stepping forward to make decisions and solving the Bellman's equation through sequentially solving multiple mixed integer linear programs.

3 - Choosing the Optimal Battery Swapping Stations in Smart e-bus System Based on the Location Routing Problem

Joon Moon, Korea University, Seoul, Korea, Republic of, nrbam123@korea.ac.kr, Taesu Cheong, SangHwa Song

When managing public electric vehicles like e-bus, the major problem is the infrastructure of charging stations that can charge electricity. In other words, the deployment of a network of recharging stations is essential due to their limited travel range. This paper considers the problem of choosing battery swapping stations among bus stops for electric vehicles on a traffic network with flow-based demand, based on the location routing problem. We suggest three different mathematical programming models to address this problem and evaluate each model.

4 - Strategic Location Problem for Synchronized Last-mile Delivery with Relaying Drones

Kangbok Lee, POSTECH, Pohang, Korea, Republic of, kangbok.lee3@gmail.com, Kyungduk Moon, Seokwon Kim, Sunil Chopra

This study suggests a two-echelon last-mile delivery system in which packages are relayed from a truck to drones sequentially through docking stations. Following JIT principle, arrivals and departures of the two fleets are to be synchronized at each station by locating stations and allocating demands. To synchronize the operation, a location problem is formulated under continuous demand. Based on the analysis of the mathematical model, key factors of a decision are discovered. Strategic method and algorithmic method are developed to find a solution. After the decision on location is made, the operation problem for the vehicles' schedule with realized demands is modeled and solved for validation.

5 - A Dynamic Deployment Strategy of Public Electric Vehicles' Charging Infrastructures with Demand Uncertainties

Cheng Zhu, Assistant Professor, Texas State University, San Marcos, TX, H2L 0B7, United States, cheng.zhu@mail.mcgill.ca, Ting Wu

Our goal of this data-driven study is to design a dynamic deployment strategy of establishing public EV infrastructure over a medium-term horizon. We first build an Erlang-B queueing model with non-homogeneous arrival rates to gauge random EV demands in a certain region using historical traffic flows. This approach ensures the dynamic update of the EV demands throughout the study horizon. Then we depict the uncertainty set of EV demands and establish a dynamic robust optimization model to solve the deployment-optimization problems, namely, location, quantity and pricing of all types of charging facilities, based on the up-to-date information on costs and technology of EV charging infrastructure.

6 - Online Operation Strategies for Multi-storey Parking Facility

Yineng Wang, LEAD group, Tsinghua University, Beijing, China, ludengxiadeyhc@sohu.com

In response to the situation where there is heavy regular demand in the city center, an online optimization model with two tiers has been promoted to provide advice on the operation policy of the automated multi-storey parking facility and reduce customers' waiting time. The distribution tier leverages on the regularity of parking demand and optimally distributes the parking spots with reinforcement learning, whereas the execution tier plans the operations of elevator with a network model. We have conducted tests based on several possible demand sequences, and the proposed model has commonly improved the efficiency. Moreover, we have shed light on the preferences of design parameter selection.

Sponsored Session

Chair: Barrett Thomas, University of Iowa, Iowa City, IA, 52242-1000, United States

1 - An Information Collecting Vehicle Routing Problem: Cleaning Up After the Storm

Warren B. Powell, Princeton University, Dept. of Operations Research and Financial Eng, Princeton, NJ, 08544, United States, powell@princeton.edu, Lina al-Kanj, Daniel Jiang

We consider the problem of fixing the distribution grid following a storm, where we have to manage a utility truck that has to learn where outages have occurred while also fixing the grid. We have to capture observable states (location of the truck, visited regions of the grid), and beliefs about regions we have not visited using inferences derived from lights-out calls. We use a novel form of Monte Carlo tree search as a lookahead policy which uses information relaxation to obtain an optimistic estimate of the value of visiting a node. The policy is asymptotically optimal without requiring that all actions be visited. The logic is demonstrated on an actual distribution grid in New Jersey.

2 - Learning a Storage Policy for E-commerce Warehouses

Adrien Rimélé, Polytechnique Montréal, Montréal, QC, Canada, adrien.rimele@polymtl.ca, Michel Gamache, Michel Gendreau, Philippe Grangier, Louis-Martin Rousseau

We consider an Amazon-type warehouse where a fleet of robots stores and retrieves shelves of objects to fulfill customers' orders. To adapt to a changing demand, one can dynamically modify the storage allocation of a shelf, with the goal of improving overall access time for future uncertain requests. We modelled this problem as a stochastic dynamic model and we propose a solution approach to learn a good storage policy using reinforcement learning on an associated partially observable MDP, with the objective to minimize the average cycle time. Preliminary results suggest a gain of about 11% in average cycle time compared to a more traditional approach from the literature.

3 - Enabling Anticipatory Decision-making for Dynamic Vehicle Routing

Ninja Soeffker, TU Braunschweig, Braunschweig, Germany, Marlin Wolf Ulmer, Dirk C. Mattfeld

We consider a dynamic vehicle routing problem with stochastic customer requests. To make anticipatory decisions about accepting or rejecting new customer requests, we apply value function approximation, an approximate dynamic programming approach. Due to the usually large size of state spaces for such problems, we use an adaptive state space partitioning approach. In this presentation, we also show the impact of state space aggregation and routing choices on the solution quality.

4 - Time Window Sizing for Service Routing

Barrett Thomas, Professor, University of Iowa, Iowa City, IA, 52242-1000, United States, barrett-thomas@uiowa.edu, Marlin Wolf Ulmer, Justin Goodson

Firms serving customers at their homes face the challenge of assigning time windows small enough to respect busy schedules, but large enough to allow for routing flexibility. This task is difficult because firms do not know all of the customers who will need service before the customers are notified what their time window is. For a special case, we derive features of the optimal policy. We use these features to motivate a function of arrival time variance that sets time window widths. We learn the parameters of the function and demonstrate significantly better performance than static policies.

Advancement in Last-Mile Urban Delivery

Sponsored: Transportation Science & Logistics/Urban Transportation

Sponsored Session

Chair: Bo Zou, University of Illinois, Chicago, IL, 60607, United States

1 - Optimizing Delivery Guarantees to Maximize Customer Satisfaction and Sales in Same-day Delivery Operations

Hossein Fotouhi, George Mason University, Fairfax, VA, 22033, United States, hfotouhi@gmu.edu, Yutong Liu, Elise Miller-Hooks

A mathematical formulation for a same-day delivery problem is presented. The problem consists of an online retailer/distributor whose objective is to maximize customer satisfaction through offering suitable delivery deadlines to customers while trying to minimize total delivery costs assuming a fleet of occasional drivers.

2 - Modeling Crowdshipping as a New Form of Last-Mile On-Demand Urban Delivery: Multiwave Algorithm with Relocation Strategy

Bo Zou, Associate Professor, University of Illinois at Chicago, 2073 Engineering Research Facility, 842 W. Taylor Street, Chicago, IL, 60607, United States, bzou@uic.edu

Our crowdshipping research concerns a specific type of urban delivery dealing with shipments from spatially distributed pickup locations (e.g., restaurants, and retail, grocery, and drug stores) to spatially distributed customers within a guaranteed delivery time. We present a new multiwave algorithm which enables fast and cost-efficient dynamic assignment of shipments to compatible crowdsourcees. The use of the multiwave algorithm is further combined with a clustering-based scheme to strategically reposition crowdsourcees to better match with current and anticipated future shipping demands.

3 - The Omni-channel Vehicle Routing Problem with Time Windows

Albina Galiullina, PhD Candidate, Eindhoven University of Technology, Eindhoven, Netherlands, a.galiullina@tue.nl, Nevin Mutlu, Joris Kinable, Tom Van Woensel

We consider a Vehicle Routing Problem with two fulfilment options: either pickup point (PUP) delivery or home delivery. The use of PUPs resolves the need for visiting all customers' homes, which decreases transportation costs. However, the routing efficiency comes at a price, as the firm needs to provide discounts for PUP delivery to influence customers to choose this delivery option. We optimize the use of these two fulfilment channels with the objective to minimize the total delivery cost that equals to the sum of routing costs and discounts. The potential impacts of our model and policies are illustrated by numerical experiments.

4 - An Urban Shopping Delivery System with Shared Autonomous Vehicles

Marjan Mosslemi, University of California-Irvine, Irvine, CA, 92617, United States

Motivated by the growth of ride sourcing services and expected advent of autonomous vehicles, this research proposes an optimization model and solution algorithm for a system of shared autonomous vehicles (SAVs) which substitutes all the existing personal daily shopping trips. The SAVs, controlled by a central operator, provide origin-to-destination delivery service to households who expect to receive their orders by the end of the time window of their original shopping activity. The AVs are not assigned to open requests in real-time. All the requests enter the system at the same time (not dynamically or stochastically) based on the existing daily activity schedule of the subscribed households.

Design and Planning of Parcel Logistics Centers

Sponsored: Transportation Science & Logistics/Facility Logistics

Sponsored Session

Chair: Benoit Montreuil, Georgia Institute of Technology, Atlanta, GA, 30332-0205, United States

1 - Sort Plan Design for Express Parcel Sortation Systems

Reem Khir, Georgia Institute of Technology, Atlanta, GA, United States, reem.khir@gatech.edu, Alan Erera, Alejandro Toriello

We present a two-phase solution approach for creating sort plans operated by express parcel service providers. A sort plan determines how parcels are routed within a sortation hub by specifying their assignment to sort equipment and generating their sort schedules. The objective is to complete sorting parcels by their cutoff times while maximizing resource utilization and balancing parcel flow within the hub.

2 - Using Augmented Reality in Warehouse Design

Sabahattin Gokhan Ozden, Assistant Professor, Penn State Abington, Abington, PA, 19001, United States, gokhan@psu.edu

Augmented reality (AR) is a live direct or indirect view of a physical, real-world environment whose elements are augmented (or supplemented) by computer-generated sensory input such as sound, video, graphics or GPS data. In this presentation, we will demonstrate how to use augmented reality to test different warehouse aisle structures including non-traditional layouts such as Fishbone by only using a smartphone.

3 - How to Get Advantage of Mixed Shelves Storage Policy to Effectively Integrate Picker Routing and Order Batching Planning in a Warehouse

Seyyed Amir Babak Rasmi, Postdoctoral Research Fellow, National University of Singapore, Singapore, Singapore, isesabr@nus.edu.sg, Yuan Wang, Loo Hay Lee, Ek Peng Chew

Order picking (OP) is a time and cost consuming operation in a warehouse to retrieve the items ordered by customers from its storage locations. In this contribution, we present a method to consolidate picker routing and order batching in a mixed-shelves warehouse. We consider two objective functions: minimizing OP makespan and the number of pickers. We apply a heuristic to get advantage of shared storage strategy such that the probability of aisle congestion decreases. We show that how our approach results in effective solutions for OP systems.

4 - Integrate Autonomous Delivery Vehicle and Parcel Locker into Urban E-grocery Distribution Network

Dan Liu, Florida Atlantic University, Boca Raton, FL, United States, liud@fau.edu

Dan Liu, Chang'an University, Xi'an, China, liud@fau.edu, Evangelos I. Kaisar

Motivated by the adaption of autonomous delivery vehicle, parcel locker in the E-Grocery distribution industry, a two-echelon location-routing problem adopting a mixed fleet (2E-VRP-MVMS) for sustainable E-Grocery delivery is studied. A multi-objective optimization model is developed to capture the characteristics of cost component and environmental impact. The goal of the 2E-VRP-MVMS is to determine the location facilities, to optimize the number of parcels delivered to lower stages and routes at each level, also to reduce costs caused by carbon emissions. This research contributes to the last-mile delivery network design domain by adopting mixed fleets.

Chair: Heng Chen, University of Nebraska-Lincoln, Lincoln, NE, 68588, United States

1 - Rerouting Aircraft during Space Launches using Adaptive Spatial Discretization

Rachael Tompa, Stanford University, Stanford, CA, 94305, United States

To ensure safety during space launches, the FAA restricts a large column of airspace that aircraft are rerouted around. With the increase of space launches, airlines are often penalized with rerouting expenses. Recent research has focused on making these restrictions smaller and dynamic. The problem has been modeled as a Markov decision process and solved using dynamic programming. A major challenge with this formulation is its computational tractability. This talk uses an adaptive spatial discretization method, to increase computational tractability while providing a finer state space discretization. This scalable method results in less disruption in the airspace while reducing risk.

2 - Capacity and Safety Analysis for a Flow Corridor with Dynamic Wake Separation

Azin Zare Noghabi, George Mason University, Seattle, WA, United States

This research presents a simulation framework to investigate the capacity benefits of employing a proposed dynamic wake separation policy in a single lane flow corridor. A new dynamic wake separation concept is suggested that uses information about actual weight and airspeed of aircraft and meteorological conditions to determine the minimum separation between aircraft, which is updated periodically. To show the safety of flow corridor, a rare event methodology is used to estimate the probability of potential wake encounters for a pair of trailing aircraft in cruise altitudes. This analysis is extended to the flow corridor and demonstrates the safety of flow corridor in terms of wake vortex hazard.

3 - A Spectral Approach Towards Analyzing Air Traffic Network Disruptions

Max Zhaoyu Li, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States

The network structure of the air transportation system causes complex delay dynamics; analysis of system performance requires understanding airport connectivities. We apply Graph Signal Processing to analyze flight delay networks, yielding two novel contributions: (1) We use the total variation (TV) of a graph signal to identify and quantify unexpected distributions of airport delays; and (2) we present a spectral eigendecomposition analysis of airport delay networks. We use 10 years' worth of operational data from major US airports in order to spectrally analyze different delay distributions.

Innovations in Demand Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Chung-Piaw Teo, National University of Singapore Business School, Singapore, 119245, Singapore

1 - Segmenting Demand at Retail Locations Based on Aggregate Data

Yihui Huang, Tsinghua University, Qinghuayuan Street, Haidian District, Beijing, 100084, China, huangyih15@mails.tsinghua.edu.cn, Chen (Mavis) Wang, Lei Zhao

Expected demand is an important measure for a retailer to decide whether to open a new store at a candidate location. Noticing varied shopping behaviors of different customer types, e.g., from residential or office areas, we propose estimation models to segment demand based on aggregate-level store visits, considering temporal and cyclic shopping patterns. We develop an expectation-maximization (EM) algorithm to learn the model parameters and test its efficacy with simulation and real retailer data.

2 - Promotion Design with Network Effects and Path Dependence

Sheng Bi, National University of Singapore, Singapore, bisheng@u.nus.edu

In monopoly-type promotion, a consumer's choice on a product not only depends on its attributes but also on the product eligibility and historic purchases. In this paper, we investigate how to design promotion product set when network effects and path dependence arise in consumer choice models. We first model the network effects and path dependence using Polya's urn process. Then we study the assortment optimization problem under such effects. Under different settings of Polya's urn model, we show that revenue-ordered promotion set is either optimal or near optimal. Data is provided by a fast food company who runs monopoly-type promotion annually.

3 - Thompson Sampling Algorithms for Gaussian Mean-variance Bandits

Qiuyu Zhu, National University of Singapore, Singapore, qiuyu_zhu@u.nus.edu

The mean-variance risk measure is one of the most widely-used risk measures. In the context of the multi-armed bandits (MAB), existing algorithms are LCB-based algorithms. However, these algorithms have strict and often unrealistic assumptions on the reward distributions. In this paper, we develop two Thompson sampling-style algorithms for mean-variance Gaussian MAB with comprehensive regret analyses. Both theoretical analyses and empirical simulations show that our algorithms are better than LCB algorithm. Inspired by numerical simulations, we also propose a combined Thompson sampling algorithm for mean-variance MAB and empirically show that it uniformly dominates LCB algorithm.

4 - An Approximate Dynamic Programming Approach to Dynamic Matching

Fan You, University of Colorado-Boulder, 995 Regent Drive, Boulder, CO, 80302, United States

We study dynamic matching problems with random arrivals and departures, and the objective is to maximize the total reward over a finite planning horizon. We formulate the problem as a Markov Decision Process and approximate the value function using the linear programming-based approach. We show that the Approximate Linear Programs allow for a compact LP formulation that can be solved efficiently. The ALPs provide both upper bounds on the expected reward and can be used to construct control policies. We test our approach numerically on kidney exchange instances taken from the literature.

Co-Chair: Kostas Bimpikis, Stanford University, Stanford, CA, 94305, United States

1 - Myopic Equilibria via Expander Graphs in Large Trading Networks

Evan Storms, Stanford University, Stanford, CA, United States, estorms@stanford.edu

We study when myopic behavior constitutes an approximate equilibrium in a decentralized, cumulative offer trading network formation game. We show that when firms' preferences satisfy full substitutability, the formation game implements a stable outcome of the related cooperative game, and so an epsilon-Bayes Nash Equilibrium in myopic strategies exists if and only if there is a stable mechanism which is epsilon-Bayesian incentive compatible. A sufficient condition for the existence of an epsilon-Bayesian incentive compatible stable mechanism is that influence graphs, which track how manipulations propagate through the network, belong to the class of vertex-expander graphs.

2 - Optimal Information Provision in Traffic

Emily Meigs, MIT, Cambridge, MA, United States, emeigs@mit.edu, Francesca Parise, Asu Ozdaglar, Daron Acemoglu

We consider a two-road repeated routing game where the state of one road (i.e. the risky road) may change. We investigate how a central planner should provide information to agents about the current state of the risky road to minimize total travel time. We first characterize the optimal incentive compatible recommendation scheme for two steps. We then extend our analysis to the infinite horizon case under the assumption that the condition of the risky road changes according to a Markov chain. We find that full information is not the best recommendation strategy. Instead the central planner should reward experimentation by sending less agents to the risky road when the condition of that road is favorable.

3 - Capability Accumulation and Conglomeratization in the Information Age

Jun Chen, Assistant Professor of Finance, Renmin University of China, Beijing, China

The past twenty years have witnessed the emergence of internet conglomerates fuelled by acquisitions. We provide a simple theoretical model to shed light on this. Firms can combine their capabilities by merging and also spin-off new firms to partition them. We study the stable industry structures, where there no longer exist any profitable mergers or demergers. Positing that recent changes have caused markets to value new capabilities, particularly those held by internet firms, we show this can explain the conglomeratization of internet firms. Moreover, we find that as markets value more capabilities, there is a sharp phase transition in the potential size of the largest firms at a key threshold.

4 - Learning Through the Grapevine

Suraj Malladi, Stanford Graduate School of Business, Stanford, CA, United States, surajm@stanford.edu

We study whether learning is simply difficult or impossible when first-hand information is relayed through long chains of noisy communication. When noise consists of random mutations and transmission failures, difficulty of information acquisition to learn increases, though information processing can still be simple. However, learning is typically impossible in the presence of even an arbitrarily small fraction of biased agents. This can explain why people become stuck at different priors, even if primary evidence points to one answer. We show that a planner can recover partial learning by limiting the number of message forwards, a policy some messaging platforms are starting to use.

Pricing and Promotion

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Chung-Piaw Teo, National University of Singapore Business School, Singapore, 119245, Singapore

Co-Chair: Xiaobo Li, Singapore

1 - Bundle Size Pricing

Sun Hailong, National University of Singapore, Singapore

We study the bundle size pricing (BSP) problem where a monopoly sells bundles of products to customers, and the price of each bundle depends only on the size (number of items) of the bundle. We show that the BSP problem can be approximated as a convex optimization problem under a class of representative agent model (RAM), which is based on a particular semidefinite programming formulation for a family of semiparametric choice model, using only the first and second moments of customer valuations. The resulting convex approximation model can be efficiently solved using off-the-shelf solvers. Numerical results show that our approach performs very well compared with state-of-the-art heuristics.

2 - Discrete Choice Models with Different Levels of Utility Uncertainty

Ruxian Wang, Johns Hopkins University, Carey Business School, 5345 Strathmore Ave, Kensington, MD, 20895, United States, ruxian.wang@jhu.edu

In this paper, we relax the restriction on the identical distribution for the random utility parts under discrete choice models. The derived new choice model can allow more flexible substitution pattern and has the potential to describe choice behavior more accurately. We also investigate a variety of operations problems under the new class of choice model.

3 - Large-scale Dynamic Pricing for a Tour Operator

Alper Sen, Bilkent University, Department of Industrial Engineering, Bilkent, Ankara, 06800, Turkey, Savas Dayanik, Bahar Kara, Oya Ekin Karasan

We consider the problem of a tour operator which needs to set the prices of its holiday packages on a daily basis. The company is a large operator in Europe and contracts with airlines and hotels to reserve capacity in advance of a holiday season. Using reservations for the past 8 years, the price-demand relationship is estimated at the travel time, origin, destination, hotel category and package duration level. These estimates are fed into a large-scale optimization model which creates price recommendations based on remaining capacity and time. Recommendations are then customized for specific packages. Initial results show that the model leads to significant improvements in revenue.

4 - A Constant-factor Approximation Algorithm for Dynamic Pricing of Rental Product with Advance Reservation

Chungseung Lee, UT at Dallas, Dallas, TX, 75080, United States

We develop a constant-factor approximation algorithm for a dynamic pricing problem where a firm has a limited inventory of rental product and is equipped with an advance reservation system. Customers pay upfront rental fees and use the product for a certain deterministic period of time. Upon the end of the rental, the product is returned and is available to serve future customers. The firm's objective is to maximize the expected total revenue over a finite selling horizon by dynamically adjusting upfront rental fees. We demonstrate that our approximate policy leads to noticeable revenue improvements over the deterministic and the fixed pricing policies, which are widely used in academia and industry.

Structural Estimation in Revenue Management & Pricing

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Ioannis Stamatopoulos, University of Texas at Austin, McCombs School of Business, Austin, TX, 78705, United States

1 - Economies of Scope in Reverse Auctions: An Application to Road Salt Procurement

Ioannis Stamatopoulos, University of Texas at Austin, McCombs School of Business, Austin, TX, 78705, United States, yannis.stamos@mccombs.utexas.edu, Diwakar Gupta, Matt Schmitt

We study the supply chain implications of dynamic pricing. Specifically, we estimate how reducing menu costs — the operational burden of adjusting prices — would affect supply chain stability.

2 - Loss Aversion in Managers' Pricing Decision Making at a Fast Fashion Retailer

Anna Saez de Tejada Cuenca, Georgetown University, McDonough School of Business, Washington, DC, 90024, United States, as4594@georgetown.edu, Felipe Caro, Keith Chen

We analyze managers' pricing decision making during the sales season of a fast fashion retailer. We observe empirically that, even when assisted by a DSS that recommends revenue-maximizing prices, they systematically deviate from the optimal prices, in a way that is compatible with a number of behavioral biases: loss aversion, salience of the inventory, time discounting, and status quo. We build a structural model to disentangle their degree of loss aversion from other biases, and compare loss aversion coefficients across managers and across product groups (e.g., fashion vs. basics).

3 - The Consequences of Organic Waste Bans: A Dynamic Supply-Side Model of Grocery Retailers

Robbie E. Sanders, UCSD

Each year, the perishable grocery industry produces substantial waste, resulting in considerable costs to firms and generating harmful greenhouse gas emissions. I study the incentives to produce such waste using a novel data set that matches a large supermarket chain's loyalty-card database, including the time stamp for customer trips, with the firm's product-level information on marginal cost, shelf life (perishability), and daily production-processes. In a descriptive analysis, I first show the firm's production of waste correlates positively with the degree of demand uncertainty and with its market power. This relationship is consistent with the classic newsvendor problem and suggests positive waste levels are an endogenously-determined outcome. I then conduct a structural analysis of the artisanal bread category to assess the supermarket chain's incentives to mitigate waste. Currently, grocery retailers have not yet adopted revenue management (intraday markdowns) due to insufficient scale. A hypothetical policy that reduces the costs of revenue management sufficiently to induce adoption would reduce total planned waste for the chain by 13%. Surprisingly, the incentive to reduce waste varies across the individual stores: in several stores, the firm endogenously increases planned waste, suggesting revenue management alone may be insufficient to curb grocery waste. I then simulate the effects of a ban recently enacted in California. The ban increases firms' waste-disposal-costs by mandating composting. For the supermarket chain, this policy increases the returns to revenue management adoption from 3% to 7% and induces the firm to use intraday markdowns, resulting in a combined waste reduction of 31%, though this result depends on the new disposal cost.

4 - Anticipated Regret in Online Common Value Auctions: Empirical Evidence from Ebay

A. Serdar Simsek, Assistant Professor, The University of Texas at Dallas, Naveen Jindal School of Management, Richardson, TX, 75080, United States, serdar.simsek@utdallas.edu, Meisam Hejazi Nia, Ozalp Ozer

We develop a structural model that accounts for bidders' learning and their anticipation of winner and loser regrets in an auction platform. Using a data set from eBay, we show that bidders anticipate significant levels of winner and loser regret and learn from other bidders' bids during the auction. This learning decreases both winner and loser regret anticipation. We also show how regret varies across auction categories (e.g., stamps versus antiques) as well as how bidder experience impact regret. Finally, shutting down bidder regret via appropriate notification policies can increase eBay's revenue by 8.17%, on average.

Modeling Healthcare Equity, Access, and Outcomes

Sponsored: Public Sector OR

Sponsored Session

Chair: Andreas Holger Thorsen, Montana State University, Bozeman, MT, 59718-6211, United States

1 - Facility Location: A Cumulative Opportunity Approach

Andreas Holger Thorsen, Assistant Professor of Management, Montana State University, Bozeman, MT, 59718-6211, United States, andreas.thorsen@montana.edu, Ronald McGarvey, Maggie L. Thorsen

This paper is concerned with the intersection of facility-location modeling with the measurement of access to health services and health equity. We develop an approach to evaluate the impact of facility location decisions on the population's accessibility to services. Specifically, we describe an approach called the cumulative opportunities measure that has been widely used for measuring access in the field of transport geography, and we then formulate an optimization model that maximizes the cumulative access score over a geographic region. We contend that this approach is a new and useful way to optimize population's access to services.

2 - Evaluating Management of Chronic Diseases at Community Health Centers

Ronald McGarvey, University of Missouri, Columbia, MO, 65211, United States, mcgarveyr@missouri.edu, Andreas Holger Thorsen, Maggie L. Thorsen

Community health centers (CHCs) are federally funded safety-net organizations that provide comprehensive health services to medically-underserved populations. CHCs provide an organizational structure to address widespread health disparities, including outcomes related to chronic diseases. In this paper, we test the relationships between CHC staffing patterns, efficiency, and quality of chronic disease care (specifically, diabetes and hypertension).

3 - An Optimization Model to Reduce Geographic Disparity in Access to Heart Transplant in the United States

Fatemeh Karami, University of Louisville, Louisville, KY, United States, fatemeh.karami@louisville.edu, Monica Gentili, Sean Barnes, Naoru Koizumi

Heart failure is a growing health problem affecting nearly 6 million in the United States, with approximately 200,000 patients suffering from a progressed to end-stage or Stage D heart disease. Heart transplantation is the definitive therapy for end-stage heart disease patients. However, the geographic disparity in access to heart transplant in the United States is substantial. This research uses a mathematical optimization model to design new geographic boundaries for the heart allocation system to reduce geographic disparity in access to transplant.

4 - Trade-off Between Healthcare Accessibility and Individual Liberty

Fan E, PhD Candidate, McGill University, Montreal, QC, Canada, fan.e@mail.mcgill.ca, Angelos Georghiou, Vedat Verter

Community treatment order (CTO) is a coercive legal measure employed by the psychiatrist to enforce medical treatment on severely ill psychiatric patients. Despite its wide use, decisions surrounding CTOs are made based on individual psychiatrist's experience. Essential questions remain to be answered structurally: Who needs a CTO? When to apply a CTO? And, how to implement a CTO? We aim to find the trade-off between maximizing the healthcare accessibility for all patients while minimizing the coercive effects of CTO on individual patients. To counter limitations on data, we calibrate a robust Markov decision model using evidence from both the literature and our empirical research.

Optimization-based Approaches to Housing Allocation

Emerging Topic: Policy & Government

Emerging Topic Session

Chair: John Dickerson

1 - Allocating Homelessness Interventions Based on Predicted Outcomes

Sanmay Das, Washington University in St. Louis, Dept. of Computer Science & Eng., Saint Louis, MO, 63130, United States, Amanda Kube, Patrick Fowler

We consider possible improvements to the allocation of homelessness services by optimizing over predicted outcomes (re-entry probabilities) given limited resources. We discuss the importance of counterfactual reasoning in predicting outcomes for different types of households given existing administrative datasets, as well as issues of equity and fairness in allocation.

2 - Optimizing Public Policy for Allocating Homelessness Assistance

Duncan C. McElfresh, University of Maryland, College Park, MD, 20742, United States, dmcelfre@math.umd.edu, Phebe Vayanos, Eric Rice

Allocating scarce housing assistance resources to the homeless raises many logistical and practical challenges. Recent OR- and ML-based allocation policies promise to improve the efficiency of these resources, and raise several new questions: How do we earn the trust of policymakers and social workers? What objective should these policies optimize? How do we ensure a policy does not discriminate (e.g., by race or gender)? We present a broad overview of this topic, and recent work addressing each of these questions. We share our own experience collaborating with a municipal housing authority.

3 - Design of Lotteries and Waitlists for Affordable Housing Allocation

Nick Arnosti, Columbia Business School, 3022 Broadway, New York, NY, 10027, United States, Peng Shi

We study a setting in which dynamically arriving items are assigned to waiting agents, who have heterogeneous values for distinct items and heterogeneous outside options. An ideal match would both target items to agents with the worst outside options, and match them to items for which they have high value. Our first finding is that two common approaches - using independent lotteries for each item and using a waitlist in which agents lose priority when they reject an offer - lead to identical outcomes in equilibrium. Both approaches encourage agents to accept items that are marginal fits. We show that the quality of the match can be improved by using a common lottery for all items.

4 - Algorithmic Fairness in Suicide Prevention Interventions for the Homeless Population

Aida Rahmattalabi, University of Southern California, Los Angeles, CA, 90007, United States, Phebe Vayanos, Anthony Fulginiti, Eric Rice, Bryan Wilder, Amulya Yadav, Milind Tambe

We study the social-network based suicide prevention programs as a robust graph covering problem. Unfortunately, state-of-the-art algorithms tend to discriminate individuals (nodes) based on membership in marginalized groups. To remedy this issue, we propose a novel formulation of the problem with group fairness constraints. We provide a formal study of Price of Group Fairness. Further, we develop a tractable approximation scheme applicable to real world instances. Finally, we demonstrate the effectiveness of our approach on several real-world social networks and we show competitive coverage and a significant improvement in group fairness relative to state-of-the-art methods.

8:00-8:45 Automation Anywhere / 8:45-9:30 Processim Labs

Vendor Tutorial

1 - Increasing Operational Efficiency with Automation Anywhere's Digital Workforce Platform

Amitai Jacobsen, Automation Anywhere, San Jose, CA, United States

The Automation Anywhere bot building tutorial is designed to showcase Robotic Process Automation (RPA), Cognitive Automation and Analytics tools that make up Automation Anywhere's Digital Workforce Platform. We will demonstrate the process of building digital workers, or bots, on our platform and within minutes. These bots can collect and analyze data and perform tasks that otherwise would be performed by humans, making processes more efficient, reducing errors and improving operational efficiency. The tutorial will feature Automation Anywhere Enterprise, IQ Bot, and Bot Insight and will show that these tools are not meant exclusively for engineers or IT experts but indeed also for business users. Participants will learn the process of creating bots, automating common processes and will have a chance to familiarize themselves with Automation Anywhere's software solutions.

2 - Learning Reimagined | How to Increase Student Engagement through Introducing Innovation into the Classroom

Javier Chan, Processim Labs, San Jose, Costa Rica

Processim Labs uses the concept of gamification to help business school students put classroom concepts into practice. Our tutorial will walk you through how our operations management simulation is used as well as illustrate the many topics that are covered in the game. Over the course of the presentation, attendees will have the opportunity to play the game for themselves in a fun and dynamic virtual world! Don't forget to bring your smartphone!

Joint Session QSR/Energy: Data Analytics for Renewable Operations

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Hoon Hwangbo, University of Tennessee-Knoxville, Knoxville, TN, 37996-2315, United States

Co-Chair: Ahmed Aziz Ezzat, Rutgers University

1 - Statistical Comparison of Two Wind Power Curves Using Gaussian Process Regression Framework

Abhinav Prakash, Texas A&M University, College Station, TX, United States, abhinavp@tamu.edu, Rui Tuo, Yu Ding

Wind power curve has a lot of information about the performance of a wind turbine. Wind farm operators are often interested in comparing the power curve of a turbine for two time periods to see if there is any change in turbine performance. In this work, we propose a non parametric method (based on Gaussian process) to model the power curve and detect if there is any change in the underlying functional curve given two noisy datasets. We exploit some properties of Gaussian process to build statistical test for determining the change in function for different confidence levels. We apply our method to some wind turbine datasets and compare our result with existing results in the literature.

2 - Adaptive Gaussian Process for Modeling Conflicting Spatial Correlations of Wind Power Output

Hoon Hwangbo, University of Tennessee, Knoxville, TN, 37996-2315, United States, hhwangb1@utk.edu

Wind power output varies by the locations of turbines, and this variation involves two conflicting spatial effects. The closer the locations, turbines' power outputs are (1) more similar due to the nature of wind but, at the same time, (2) more different in the presence of turbine wake effect. We propose an adaptive Gaussian process method to model the conflicting spatial phenomena while identifying the turbine wake effect that preserves the inverse structure of a general spatial correlation.

3 - Short Term Wind Forecasting Using Statistical Models with a Fully Observable Wind Flow

Perr-Sauer Jordan, National Renewable Energy Laboratory, Golden, CO, United States, jordan.perr-sauer@nrel.gov

Accurate short-term forecasting of wind power production is critical to the effective large-scale integration of wind resources on the autonomous renewable energy grid. This study addresses the upper bound of very short-term forecasting accuracy by introducing a fully known and observable atmospheric state. We consider simulation data at 5-min temporal and 2-km spatial resolution from the National Renewable Energy Laboratory's Wind Integration National Dataset (WIND) Toolkit. As a proof of concept, we pick one geographical point and illustrate the correlation of 5-minute lagged surrounding wind speeds for both easterly and westerly flows.

4 - Uncertainty Quantification for Extreme Quantile Estimation Using Importance Sampling with Stochastic Simulation Model

Qiyun Pan, University of Michigan, Ann Arbor, MI, 48109-2117, United States, Eunshin Byon

The increasing wind turbine size and mass entail serious concerns on the reliability of wind turbines. Accordingly, the international standard requires turbine designers to estimate extreme loads in an effort to ensure reliable operations during a design life. At the design stage, physics-based aeroelastic simulators can be used for this purpose. Due to the large uncertainty in extreme load estimations, importance sampling method has been introduced to reduce the estimation uncertainty. This study aims to quantify extreme load estimation uncertainties by constructing asymptotically valid confidence intervals using importance sampling with stochastic simulation models.

Disaster and Emergency Management I

Contributed Session

Chair: Daniel Suarez, Universidad de Los Andes, Bogotá, 111021647, Colombia

1 - Managing Gas Supplies in a Short-notice Hurricane Evacuation

Monir Sabbaghtorkan, University at Buffalo (SUNY), Amherst, NY, United States, monirsab@buffalo.edu, Rajan Batta, Qing He

Gasoline shortages and long lines at the pump spread at stations is not a new issue during large-scale evacuations ahead of hurricanes. One of the reasons for this problem is that evacuees rush to fuel up in a panic. Therefore, they try to get gas as much as they can without considering their true need and without considering other evacuees. This work presents a formulation to assign evacuees to specific gas stations along evacuation routes (based on their initial fuel level) and to restrict the amount of gas each gas station is allowed to give to each client. The objective we seek in this work is to maximize the number of evacuees that successfully reach the safe zone.

2 - Leveraging Social Media Data for Disaster Relief Management

Jonathan D. Lonski, Clemson University, Clemson, SC, United States, jdlonsk@g.clemson.edu, Scott J. Mason, Pamela Murray-Tuite

Recent natural disasters like Hurricane Sandy (2012) and Hurricane Harvey (2017) have left survivors stranded without basic supplies necessary for survival. During such disasters, nonprofit organizations receive donations of supplies, and then must transport them to survivors. While data regarding survivor needs is being collected, decision makers often must allocate donated supplies before all information is available. We investigate supplementing traditional data collection methods with input from social media platforms to improve transportation system planning. We discuss the use of machine learning to analyze Twitter data (tweets) to develop improved survivor demand forecasts.

3 - Bi Objective Bi Level Robust and Possibilistic Humanitarian Logistic Model Considering Social Cost and User Equilibria

Luis Yañez, PhD Candidate, Universidad de Chile, Valparaiso, Chile, luis.yanez@usm.cl, Cristian Cortés, Pablo Rey

In this paper, we propose a bi-objective and bi-level possibilistic robust model for humanitarian logistics, considering social costs of deprivation and user equilibria. In an integrated manner for stages prior to and following the occurrence of a natural disaster, this paper consider decisions like location and allocation of inventories, distribution and routing of vehicles for critical supplies such as drinking water, considering the users equilibria as a decision for a lower level of modeling, where the route choice seeks an equilibrium based on the Wardrop principle.

4 - Incorporating Social Media Information in Search Planning: Application on Gasoline Search During Hurricane Irma

Abhinav Khare, University at Buffalo, Buffalo, NY, United States, abhinavk@buffalo.edu, Rajan Batta, Qing He

Shortages of essential commodities like gasoline & water during the evacuation period of a forecasted disaster gives rise to search problem for the evacuees. Evacuees of Hurricane Irma in Florida drove around searching for gasoline and reported long lines or stations without gasoline. We develop a methodology that infers probabilistic information about ground truth from social media and incorporates it in a search planning model. The model plans the path for searching a target on the nodes of a graph (network connecting gas stations) with an inferred probability of finding target on the node. This method can be generalised for other node search problems with probabilistic information.

5 - A Sampling-based, Math-heuristic Stochastic Programming Approach to Support Risk Management Decisions

Daniel Suarez, Universidad de los Andes, Bogotá, Colombia, de.suarez12@uniandes.edu.co, Natalia Torres, Camilo H. Gomez

Stochastic programming is a compelling tool to address risk management decisions (e.g., mitigation and preparedness investments, and response actions) related to natural disasters. However, exact optimization methods and traditional decomposition techniques (e.g., Benders) face convergence issues when considering integer variables and dealing with the large number of scenarios required to represent hazard variability in risk analysis. We explore sampling-based, as well as math-heuristic strategies, to improve the computational efficiency of stochastic programming for risk management decisions without sacrificing the accuracy in the modeling of hazard-related uncertainties.

IEEE Transactions on Automation Science and Engineering Invited Session

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Shiyu Zhou, University of Wisconsin-Madison, Madison, WI, 53706-1572, United States

1 - A Generic Health Index Approach for Multisensor Degradation Modeling and Sensor Selection

Minhee Kim, University of Wisconsin–Madison, Madison, WI, United States, mkim555@wisc.edu, Changyue Song, Kaibo Liu

The challenge of multisensor degradation modeling lies in that the sensor signals are often correlated and may contain only partial or even no information on the degradation status of a unit. To address these issues, this study proposes a novel data fusion method which develops a latent linear model to select informative sensors and construct a 1-D health index (HI) from their signals. Compared to the existing literature, the proposed method enjoys several unique advantages including general applicability and high computational efficiency.

2 - A Sequential Bayesian Partitioning Approach for Online Steady State Detection of Multivariate System

Jianguo Wu, Peking University, Beijing, China, j.wu@pku.edu.cn

Steady state detection is critically important in many engineering fields, such as process monitoring and control. In this paper, we propose an efficient online steady state detection method for multivariate systems through a sequential Bayesian partitioning approach. The signal is modeled by a Bayesian piecewise constant mean and covariance model, and a recursive updating method is developed to calculate the posterior distributions analytically. The duration of the current segment is utilized for steady state testing. Insightful guidance is also provided for hyperparameter selection. The effectiveness of the proposed method is demonstrated through thorough numerical and real case studies

3 - Dirichlet Process Gaussian Mixture Models for Real-time Monitoring and Their Application to Chemical Mechanical Planarization

Zhenyu Kong, Virginia Tech, Dept of Industrial and Systems Engineering, Blacksburg, VA, 24061, United States, zkong@vt.edu, Jia Liu

The goal of this work is to use sensor data for online detection and identification of process anomalies (faults). In pursuit of this goal, we propose Dirichlet process Gaussian mixture (DPGM) models. The proposed DPGM models have two novel outcomes: 1) DP-based statistical process control (SPC) chart for anomaly detection and 2) unsupervised recurrent hierarchical DP clustering model for identification of specific process anomalies. The presented DPGM models are validated using numerical simulation studies as well as wireless vibration signals acquired from an experimental semiconductor chemical mechanical planarization (CMP) test bed.

4 - Dynamic Inspection of Latent Variables in State-space Systems

Shuai Huang, University of Washington, Seattle, WA, 98195, United States, shuai.huang.ie@gmail.com, Tianshu Feng, Xiaoning Qian, Kaibo Liu

The state-space models are widely used in a variety of areas where a set of observable variables are used to track some latent variables. It comes to our awareness that an important problem has been largely neglected. In many applications, although the latent variables cannot be routinely acquired, they can be occasionally acquired to enhance the monitoring of the state-space system. In this paper, novel dynamic inspection methods under a general framework of state-space models are developed to identify and inspect the latent variables that are most uncertain.

Statistical Design for Controlled Experiments in the Big Data Era

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Qiong Zhang, Clemson University, Clemson, SC, 29634, United States

Co-Chair: Lulu Kang, Illinois Institute of Technology, Chicago, IL, United States

1 - Pairwise Sequential Randomization and its Properties

Yichen Qin, Assistant Professor, University of Cincinnati, Cincinnati, OH, United States

In comparative studies, such as in causal inference and clinical trials, balancing important covariates is often one of the most important concerns. However, chance imbalance still exists in many randomized experiments. To address this issue, we introduce a new randomization procedure, called pairwise sequential randomization (PSR). With a large number of covariates or a large number of units, the proposed method shows substantial advantages over the traditional methods in terms of the covariate balance, estimation accuracy, and computational time. Numerical studies and real data analysis provide further evidence of the advantages of the proposed method.

2 - Design for Controlled Experiments for Social Networks with Covariates

Lulu Kang, Associate Professor, Illinois Institute of Technology, Chicago, IL, 60616, United States, lkang2@iit.edu, Qiong Zhang

A/B testing refers to the statistical procedure of conducting an experiment to compare two treatments applied to different testing subjects. The subjects participating in the online A/B testing experiments are users who are connected in social networks. Two connected users are similar in terms of their social behaviors. Hence, it is natural to assume that their reactions to online products and services are related to their network adjacency. We propose to use the conditional auto-regressive model to present the network structure and include the network effects and covariate effects in the estimation and inference of the treatment effect and develop a D-optimal design accordingly.

3 - Heavy User Effect in A/B Testing: Identification and Estimation

Jiannan Lu, Microsoft Corporation, Redmond, WA, United States, jiannl@microsoft.com, Yu Wang, Somit Gupta, Ali Mahmoudzadeh, Sophia Liu

On-line experimentation has become an integral part of software development. To timely incorporate user feedback and continuously improve products, many software companies have adopted the culture of agile deployment, requiring online experiments to be conducted and concluded on limited sets of users for a short period. While conceptually efficient, the result observed during the experiment duration can deviate from what is seen after the feature deployment, which makes the A/B test result highly biased. We provide theoretical analysis as well as empirical evidence to show that the heavy user effect can contribute significantly to it.

4 - A Discrepancy-based Design for A/B Testing Experiments

Yiou Li, Assistant Professor, DePaul University, Chicago, IL, United States, yli139@depaul.edu, Lulu Kang

The aim of this work is to introduce a new design of experiment method for A/B tests in order to achieve an accurate estimate of treatment effect under model uncertainty. We propose a model-free discrepancy-based criterion and show that the design minimizing this criterion significantly improves the accuracy of the treatment effect(s) estimates under model uncertainty. More importantly, the proposed design is applicable to both continuous and categorical response measurements. We develop two efficient algorithms to construct the designs by optimizing the criterion for both offline and online A/B tests.

Joint Session HAS/Practice Curated: Healthcare Public Policy

Sponsored: Health Applications

Sponsored Session

Chair: Hui Zhao, The Pennsylvania State University, University Park, PA, 16802, United States

1 - Big Data in Non-profits: Insights from Staffing in Blood Donation

Wilson Lin, University of Southern California, Los Angeles, CA, United States, Susan F. Lu, Tianshu Sun

How can organizations leverage staffing to achieve better outcomes, beyond fulfilling operational needs? In collaboration with a Chinese blood bank, we observe whether and how different nurses may influence donors' donation decisions through interaction on the bloodmobile. Using a unique dataset at the interaction level, we estimate the effect of nurse donor matching on a donor's donation volume and that improved matching can provide economically significant benefits for the blood bank.

2 - Government Ideology and Responses from Hospitals to the Affordable Care Act Legislation

Justin Kistler, University of South Carolina, Columbia, SC, 29212, United States, justin.kistler@grad.moore.sc.edu, Luv Sharma, Donald J. Schepker, Manoj Malhotra

Following the passage of the Patient Protection and Affordable Care Act, hospitals were financially incentivized to improve patient experience, requiring a significant investment of resources. Using real options theory, we argue that subjective assessments of the legislation's future biased firms' valuations of investing in compliance. In particular, we investigate how government ideology influenced perceptions of the legislation's future to affect organizations' decisions to invest in compliance. Results indicate that government ideology has a significant impact on how and when hospitals invest in compliance with the new legislation.

3 - Optimizing Colorectal Cancer Screening Policies Using a Combination of Fecal Immunochemical Test and Colonoscopy

Zhichao Zheng, Singapore Management University, 50 Stamford Road, Lee Kong Chian School of Business, Singapore, 178899, Singapore, danielzheng@smu.edu.sg, Jing Li, Mabel Chou, Ming Dong

Most public guidelines for colorectal cancer (CRC) screening and surveillance recommend two consecutive fecal immunochemical tests (FIT) annually after age 50 and immediate colonoscopy if at least one FIT outcome is positive. The guidelines have not been followed closely in practice and patient compliance is very low. There is still is on-going debate in practice about the values of having FIT before colonoscopy. We propose a partially observable Markov decision process model to optimize the screening policy that combines FIT and colonoscopy and find that FITs can help identify CRC in a timely manner and significantly reduce the number of colonoscopies required when FIT sensitivity is not too low.

4 - Global Drug Diffusion and Innovation with a Patent Pool: The Case of HIV Drug Cocktails

Lucy Xiaolu Wang, Cornell University, Ithaca, NY, United States, xw377@cornell.edu

Designed to reward innovation, patent often leads to high drug prices and then patent infringement. The situation is severe for therapies that require multiple drugs with many patents, notably for HIV. I study the impact of the Medicines Patent Pool that allows generic firms to sublicense drug bundles cheaply for sales in low-income countries. I construct a novel dataset from contracts, procurement, clinical trials, and drug approvals. Using diff-in-diff methods, I find that the pool causes a 7% increase in generic drug supply. In addition, branded-drug makers and others respond to the pool with more clinical trials and drug approvals. Finally, I estimate a structural model to quantify welfare gains.

5 - Inducing Compliance with Post-market Studies for Drugs under FDA's Accelerated Approval Pathway

Hui Zhao, The Pennsylvania State University, Smeal College of Business, University Park, PA, 16802, United States, huz10@psu.edu, Liang Xu, Nicholas C. Petruzzi

To encourage drug innovation, FDA instituted the accelerated drug approval pathway (AP), allowing promising drugs to enter market based on limited evidence with required post-market studies (PMS) to verify drugs' true clinical benefits. However, most PMS are not completed due to incentive issues and challenges FDA faces, including information asymmetry and moral hazard, posing considerable public health risk. We propose an internally consistent and potentially implementable solution through a mechanism design framework. Using data for a real drug, we quantify the value of our solution. Based on interactions with FDA, we also discuss many alternative solutions under different situations.

Predictive Analytics & Decision Making in Healthcare

Sponsored: Health Applications

Sponsored Session

Chair: Esmaeil Keyvanshokooh, University of Michigan, Ann Arbor, MI, 48108-1020, United States

Co-Chair: Mark P. Van Oyen, University of Michigan, Ann Arbor, MI, 48109-2117, United States

1 - A Cost-based Analysis for Risk-averse Explore-then-commit Finite-time Bandits

Ali Yekkehkhany, PhD Student, University of Illinois at Urbana-Champaign, Urbana, IL, United States, yekkehk2@illinois.edu, Ebrahim Arian, Rakesh Nagi, Ilan Shomorony

We study an explore-then-commit bandit with finite exploitations. We propose the OTE/FTE-MAB algorithms and obtain an upper bound of order ln(1/e) for the minimum number of explorations that should be done to guarantee the upper bound e for their regret. We further study the case where the cost of arm exploration is not negligible, so a trade-off between cost and regret should be considered. We propose the c-OTE-MAB algorithm that addresses this trade-off by minimizing a linear combination of cost and regret that is called cost-regret function. The c-OTE-MAB cost-regret value approaches the minimum value of the cost-regret function at the rate 1/sqrt(n), where n is the number of each arm exploration.

2 - An Inverse Optimization Approach to Measuring Clinical Pathway Concordance

Yusuf Shalaby, University of Toronto, Toronto, ON, Canada, yusuf.shalaby@mail.utoronto.ca, Timothy Chan, Maria Eberg, Katharina Forster, Claire Holloway, Luciano Ieraci, Nasrin Yousefi

Clinical pathways outline standardized processes in the delivery of care for a specific disease. Disease pathway concordance (DPC) refers to the degree of alignment between the actual care patients receive and the ideal care described in a clinical pathway. It is important to measure DPC so that variations in health system performance and bottlenecks in the delivery of care can be detected, monitored and acted upon. We develop a general methodology for measuring DPC based on inverse optimization, apply our novel concordance metric to a real dataset of colon cancer patients, and show that it has a statistically significant association with survival.

3 - Personalizing Treatment with Non-stationary Bandits

Yonatan Mintz, Georgia Tech, Atlanta, GA, 30308, United States, Anil Aswani, Philip Kaminsky, Elena Flowers, Yoshimi Fukuoka

Due to their busy lives many individuals have a hard time adhering to daily exercise programs. In this talk, we address this problem by leveraging the data and infrastructure of mobile fitness tracking devices to personalize exercise programs for participating individuals. We develop and analyze a new multi-armed bandit model, which we call the ROGUE multi-armed bandit, to adaptively learn each participant's exercise preferences and personalize their exercise programs to increase adherence. We present both computational and theoretical results that show the efficacy of this modeling approach when compared to existing precision fitness approaches.

4 - Personalized Hospital Admission Control: A Contextual Learning Approach

Mohammad Zhalechian, University of Michigan, Ann Arbor, MI, 48109-2117, United States, mzhale@umich.edu, Esmaeil Keyvanshokooh, Cong Shi, Mark P. Van Oyen

We study hospital admission control to select the initial care unit (ICU, SDU, or General) to reduce readmission risks, which are highly heterogeneous due to patient differences. We provide an online contextual learning algorithm, called PAC, which continually learns to make the best personalized care unit assignment under the presence of dynamic capacity constraints. We provide a rigorous performance guarantee for our algorithm. A case study is conducted and the performance of PAC is compared with several alternatives using hospital data.

5 - Dynamic Online Learning and Optimization of Personalized Patient Progression in Chronic Diseases

Esmaeil Keyvanshokooh, University of Michigan-Ann Arbor, Ann Arbor, MI, 48108-1020, United States, keyvan@umich.edu, Mark P. Van Oyen, Mariel Sofia Lavieri, Joshua Stein

We develop new online learning and optimization algorithms for learning personalized patient progression in chronic diseases to alert clinicians and patients. Our Thompson sampling-based approach can handle large sets of covariates and we are able to incorporate the dynamic nature of disease progression. We identify the progression of Glaucoma.

Models and Data in Healthcare Analytics

Sponsored: Health Applications

Sponsored Session

Chair: Joel Goh, NUS Business School, Singapore, 119245, Singapore

1 - Deployment Guidelines for Community Health Workers in Sub-saharan Africa

Jonas Oddur Jonasson, MIT Sloan School of Management, Cambridge, MA, 02142, United States, joj@mit.edu, Carri Chan, Sarang Deo, Jeremie Gallien

Community health workers (CHWs) are increasingly important to healthcare delivery in many African countries. Leveraging an extensive dataset featuring time, clinical findings, and GPS information for CHW visits in sub-Saharan Africa, we develop a stochastic model describing the health dynamics of a population served by a time-constrained CHW. We report closed-form solutions quantifying the impact of CHW deployment on public health for a special case and build a heuristic to solve a policy maker s CHW deployment problem.

2 - Learning Decision Rules with Observational Data

Stefan Wager, Stanford GSB, Stanford, CA, 94305, United States

In many areas, practitioners seek to use observational data to learn a treatment assignment policy that satisfies application-specific constraints, such as budget, fairness, simplicity, or other functional form constraints. For example, policies may be restricted to take the form of decision trees based on a limited set of easily observable individual characteristics. In this talk, I will present some recent advances on structured decision-making stochastic systems based on observational data.

3 - Batch Bayesian Optimization for Healthcare Policy Optimization

John M. Silberholz, University of Michigan, Ann Arbor, MI, 02134, United States, Xueze Song

When establishing health policies, policymakers in a number of domains rely on input from comparative modeling exercises, in which multiple independent groups each model a complex health system with the goal of informing the same policy decision. For a variety of reasons, these groups rarely share their model source code or executables, making it challenging to identify the most effective policy decisions when selecting among a large number of possible decisions. In this work, we overcome this challenge using batch Bayesian optimization, and we demonstrate the promise of our approach with an example from prostate cancer screening policy.

4 - Off-service Placement in Inpatient Flow Management

Pengyi Shi, Purdue University, Krannert School of Management, West Lafayette, IN, 47907, United States, shi178@purdue.edu, Jing Dong, Fanyin Zheng, Xin Jin

When waiting time is excessively long before a bed in the primary ward becomes available, patients may be assigned to beds in a non-primary ward. This is referred to as off-service placement. We take a full data-driven approach to study off-service placement by accounting for three salient features: the network structure of the wards, the complex bed assignment decisions, and the casual effect of off-service placement on patient length-of-stay. Our analyses quantify the trade-off between off-service placement and admission delay and generate insights into how the negative impact of off-service propagate through the network.

5 - Financial Incentives under CPC+

Fernanda Bravo, UCLA Anderson School of Management, Los Angeles, CA, 90024, United States, fernanda.bravo@anderson.ucla.edu, Elodie Adida

CMS launched the Comprehensive Primary Care Plus (CPC+) payment initiative, aiming at improving primary care delivery. Under CPC+, physicians are encouraged to use alternative care delivery methods (phone calls, e-visit, in-home nurse visits). We study how CPC+ impacts providers' care delivery decisions, patient welfare, and payer cost.

Intersection of Healthcare Policy and Healthcare Operations

Sponsored: Health Applications

Sponsored Session

Chair: Soroush Saghafian, Harvard Univeristy, Cambridge, MA, 02138, United States

1 - Learning Principal Agent Models: Application to Medicare Shared Savings Contracts

Auyon Siddiq, University of California, Los Angeles, CA, 90024, United States, auyon.siddiq@anderson.ucla.edu, Nur Kaynar

Principal-agent models are common in health insurance settings. In this work, we propose an estimator for a general class of principal-agent models where agent actions are hidden. We show the estimator to be statistically consistent and NP-hard. We then present an approximation of the estimator, and propose a solution technique based on column generation that uses non-parametric hypothesis tests to identify variables to introduce into the model. We finally demonstrate the predictive performance of our estimator using empirical data related to a class of widely implemented Medicare contracts.

2 - Nonprofit Versus For-profit: Optimizing Bed Allocations Between Medicare and Medicaid Residents in Nursing Homes

Yangzi Jiang, Northwestern University, Kellogg School of Management, Evanston, IL, 60201, United States, Lauren Xiaoyuan Lu, Jan A. Van Mieghem

Nursing homes in the USA serve two types of residents: (1) Medicare-covered residents with high daily reimbursement rate but short length of stay (LOS); (2) Medicaid-covered residents with low daily reimbursement rate but long LOS. We study how nursing homes react to fluctuations in the demand of these to residents' types to explain the high conversion from nonprofit to for-profit nursing home. Our paper proposes a queueing model to determine the optimal bed allocation policy that maximizes revenue in for-profit nursing homes and that maintains a required service level in nonprofit nursing homes.

3 - The Spillover Effects of Hospital Closures on The Efficiency and Quality of Other Hospitals

Lina Song, Harvard University, Cambridge, MA, 02138, United States, dsong@fas.harvard.edu, Soroush Saghafian

We investigate the impact of U.S. hospital closures on the surrounding hospitals' efficiency and quality. We find that when a hospital closes, its nearby hospitals improve their operational efficiency without expanding their resources. However, they do so via a speed-up behavior (i.e., by reducing their service durations) instead of lowering their average bed idle time. This speed-up response by nearby hospitals negatively affects some aspect of the care (e.g., 30-day patient mortality). Furthermore, hospital closures induce changes in directions that widen social disparity, as their adverse consequences fall disproportionately among hospitals or patients with limited resources.

4 - Can Public Reporting Cure Healthcare? The Role of Quality Transparency in Improving Patient-provider Alignment

Soroush Saghafian, Harvard University, Kennedy School of Government, Cambridge, MA, 02138, United States, soroush_saghafian@hks.harvard.edu, Wallace J. Hopp

Public reporting of medical treatment outcomes is being widely adopted by policymakers in an effort to increase quality transparency and improve alignment between patient choices and provider capabilities. We examine the soundness of this approach by studying the effects of quality transparency on patient choices, hospital investments, societal outcomes (e.g., patients' social welfare and inequality), and the healthcare market structure (e.g., medical or geographical specialization). Our results offer insights into why previous public reporting efforts have been less than fully successful and suggest ways in which future efforts can be more effective.

Outpatient Care

Sponsored: Health Applications

Sponsored Session

Chair: Hummy Song, Philadelphia, PA, 19104, United States

1 - Managing Outpatient Care Services with Strategic Walk-in Patients

Nan Liu, Boston College, Chestnut Hill, MA, 02467, United States, nan.liu@bc.edu, Willem van Jaarsveld, Shan Wang, Guanlian Xiao

In addition to serving patients with scheduled appointments, outpatient care providers often set aside some time to see walk-in patients, who arrive without making an appointment in advance. Facing these two channels of accessing care, patients make choices based on their health conditions and the utilities of these two options. In this talk, we discuss how an outpatient care provider should manage her capacity, taking into account such strategic behavior of patients.

2 - Customized Office Revisit Intervals and E-Visits in Primary Care

Hessam Bavafa, Wisconsin School of Business, Madison, WI, 53706, United States, Christian Terwiesch, Sergei Savin

The demand for physician services in primary care is shaped by the number of patients associated with each physician and the frequency of scheduled office visits. While a physician can typically set the size of her patient panel without regard for individual patient preferences, office revisit intervals are determined jointly by the physician and her patients. In our model, a physician can manage the demand for her services using two "customization" approaches: (1) adjusting the office revisit intervals based on patient health status, and (2) diverting some of the patient demand away from the office visits and into "e-visits".

3 - Efficient Transition to Post-acute Care

Alex Mills, Baruch College, City University of New York, New York, NY, 10010, United States, Alex.Mills@baruch.cuny.edu, Jonathan Helm, Pengyi Shi

New payment models are changing the way hospitals arrange for short-stay skilled post-acute care. We show that value-based payment with gainsharing may surprisingly lead patients to be worse off by de-pooling skilled nursing capacity.

4 - Evaluating the Efficacy of Connected Healthcare: An Empirical Examination of the Impact of Patient Engagement and Feedback Systems

Tan Lekwijit, University of Pennsylvania-Wharton School, Philadelphia, PA, 19104, United States, slek@wharton.upenn.edu, Christian Terwiesch, Kevin Volpp

Connected Health (CH) is a form of telehealth in which patients and doctors are connected by means of timely information sharing. The benefits of CH are oftentimes ambiguous. We study CH in a setting where patients received electronic pill bottles and social support that involved different types of feedback. Our work aims to investigate the efficacy of feedback systems in promoting medication adherence, and to establish the relationship between medication adherence and readmission. Our findings suggest that spontaneous manual interventions can effectively turn nonadherence into adherence. Moreover, we also find that better adherence substantially reduces the risk of readmission.

Case Competition

Award Session

Chair: James J Cochran, University of Alabama, Tuscaloosa, AL, 35487-0226, United States

1 - The Kampala Alternative: Optimizing the Humanitarian Supply Chain in East Africa

Marie-Ève Rancourt, HEC Montréal, 3000 Chemin de la Cÿte Sainte Catherine, Montréal, QC, Canada, Émilie Dufour, Selene Silvestri, Yossiri Adulyasak

The case presents the United Nations Humanitarian Response Depot (UNHRD), its operational context and main challenges, as well as the two options considered to improve its supply chain and reduce costs. Pierre, chief manager of UNHRD, and his team have decided to evaluate two options for optimizing the supply chain: 1) keeping the current network as is and reduce its costs by modifying the service offers and 2) adding a regional storage level to the current network, in Kampala, to serve East Africa. Data are provided to solve this case, inspired from a real problem, by means of optimization techniques.

2 - Suncrest AgriBusiness: Exploiting the Flexibility of Backup Capacity

Saurabh Bansal, Pennsylvania State University, State College, PA, 16801, United States, Philip C. Jones, Timothy J. Lowe

Suncrest was a large agribusiness firm based in the Midwestern United States, with a $1 Billion business focused on seed corn (i.e., the seed that farmers buy to grow corn in their fields). Natural variations result in uncertain yields during the firm's production of seeds. To mitigate the risk of low yield, the firm had acquired a secondary production capability in Chile. This capability could be used to produce the seed if an earlier production in North America had low yields. In this environment, Suncrest needed to determine how to best use both its production capacity in North America and in Chile.

3 - Data-Driven Investment Strategies for Peer-to-Peer Lending

Daniel Guetta, Columbia Business School, New York, NY, United States, Maxime C. Cohen, Kevin Jiao, Foster Provost

We develop a number of data-driven investment strategies that demonstrate how machine learning and data analytics can be used to guide investments in peer-to-peer loans. We detail the process starting with the acquisition of (real) data from a peer-to-peer lending platform all the way to the development and evaluation of investment strategies based on a variety of approaches. We focus heavily on how to apply and evaluate the data science methods, and resulting strategies, in a real-world business setting. The material presented in this case study can be used by instructors who teach data-related courses, at the undergraduate or graduate levels (e.g., decision models, decisions under risk, business analytics). Importantly, we go beyond just evaluating the predictive performance of models, to assess how well the strategies would actually perform, using real, publicly available data. Our treatment is comprehensive and ranges from qualitative to technical, but is also modular—-which gives instructors the flexibility to focus on specific parts of the case, depending on the topics they want to cover. The learning concepts include: data cleaning and ingestion, classification/probability estimation modeling, regression modeling, analytical engineering, calibration curves, data leakage, evaluation of model performance, basic portfolio optimization, evaluation of investment strategies, and using Python for data science. Thus far, this case has been taught to over 200 students at Columbia and NYU, and a number of instructors are considering the case for teaching in their own classes.

Strategic and Tactical Issues in Warehousing and Logistics

Sponsored: Location Analysis

Sponsored Session

Chair: John Gunnar Carlsson, University of Southern California, Los Angeles, 90089, United States

1 - Inventory Placement in Online Retailing to Reduce Order Splits

Stephen C. Graves, Massachusetts Institute of Technology, Cambridge, MA, 02139-4307, United States, sgraves@mit.edu, Pin Yi Chen

In online retailing when a customer orders multiple items, the retailer tries to supply the order from a single fulfillment center (FC) to reduce shipping costs. This is possible as long as there is a FC that holds all of the times required by the order. When this is not possible, the order is split and the customer will receive multiple shipments from multiple FCs at a much higher shipping cost. We examine how to place inventory across multiple FCs so as to minimize the number of split orders, subject to a limit on how many items can be placed at each FC. We formulate this as an optimization problem and provide theoretical and numerical results on solving this problem for a range of settings.

2 - Asymptotic Bounds on Generalized Traveling Salesman Problem

Mohammad Javad Azizi, University of Southern California, Los Angeles, CA, United States, azizim@usc.edu, John Gunnar Carlsson

Warehouse Traveling Salesman Problem (WTSP) is a special case of generalized Traveling Salesman Problem (GTSP) in a warehouse random stow which gives the shortest path to pick up items for an order. Random Stow systems use a random distribution of inventory, so we studied the probabilistic behavior of GTSP. In particular, given n point sets each with k points in it, we try to bound the tour length of a GTSP which visits (picks up) m items of each point set. Another setting is when tj items of type j are to be picked up. We provide asymptotic upper and lower bounds when n approaches infinity for the tour length and for the average tour length depending on the dimension of the space, d.

3 - The Warehouse Traveling Salesman Problem

Jiachuan Chen, University of Southern California, Los Angeles, CA, United States, jiachuac@usc.edu, John Gunnar Carlsson, Denial karapetyan

The warehouse traveling salesman problem (WTSP) is a generalization of the generalized traveling salesman problem (GTSP). Given disjointed sets of vertices, GTSP is to find the shortest tour that visits exactly one vertex of each set. WTSP is to find the shortest tour that visits arbitrarily required number of vertices of each set, where the required number is pre-determined. The main application is the random stow introduced by Amazon. In our work, we propose two methods to solve the WTSP. The first one is to transform the WTSP to the GTSP, so we can apply GTSP solver to solve WTSP. In addition, we develop a meta-heuristic algorithm called conditional Markov chain search to solve the WTSP directly.

Chair: Hamsa Sridhar Bastani, Wharton School, Philadelphia, PA, 19104, United States

Co-Chair: Arielle Anderer

1 - Estimating Patient Flow Models via Robust Queueing Theory

Chaithanya Bandi, Northwestern University, Evanston, IL, 60208, United States, c-bandi@kellogg.northwestern.edu

In this paper, we consider the statistical study of partially observed queueing systems arising in application areas such as Hospital networks, data centers, and cloud computing systems. Because these services operate under strict performance requirements, a statistical understanding of their performance is of great practical interest. A key challenge in these settings is that the data are incomplete, because recording detailed information about every request to a heavily used system can require unacceptable overhead. We propose an analytically tractable approach for studying inference problems in these queueing systems. Our approach is based on the Robust Queueing framework.

2 - Fairness under Unawareness: Assessing Disparity with Auxiliary Data when the Protected Class is Unobserved

Xiaojie Mao, Cornell University ORIE, Ithaca, NY, United States, xm77@cornell.edu, Angela Zhou, Nathan Kallus

To assess decision disparity in financial and healthcare sectors when protected class (e.g., race) is unobserved, proxy methods were proposed to impute these missing labels from auxiliary data. We prove that disparity measures are generally unidentifiable even with auxiliary data, which explains the bias and instability of previous methods. Instead of giving point estimates, we provide procedures to learn all valid values of common disparity measures that are consistent with the observed data. We illustrate the effectiveness of our method in two real applications with missing race labels: evaluating the racial disparity of mortgage lending decisions, and of personalized dosing of Warfarin.

3 - Robust Policies for Proactive ICU Transfers

Julien Grand Clement, IEOR Columbia University, New York, NY, 11216, United States, jg3728@columbia.edu

Patients admitted to the ICU after a sudden health deterioration have a higher mortality rate than patients who were admitted proactively. We study the impact of proactive transfer policies (based on patient risk scores) on the clinical outcomes. We show that an optimal strategy is threshold and that a strategy robust to parameters misspecifications can be found among threshold policies too. Using data from real hospitals, we estimate the parameter uncertainty in our model and present numerical experiments where the performances of the hospital can deteriorate even for small parameter deviations. As such, we emphasize the impact of data uncertainty when developing robust versus naive strategies.

How Data Analytics Improve Business Decisions and Management

Sponsored: EBusiness

Sponsored Session

Chair: Angela Aerry Choi, Florida State University, Tallahasse, FL, United States

1 - Context Dependent Preferences and Image Based Deep Learning Recommendations

Andrew Heeseung Lee, Korea Advanced Institute of Science and Technology, Seoul, Korea, Republic of, bsh01250@kaist.ac.kr

The preferences of consumers are often determined by the choice of context in which they engage with products. A product looks more attractive when surrounded by less inviting alternatives, but such appeal diminishes when said product is positioned against more captivating options. On the basis of this contrast effect hypothesis, we evaluated and compared the effectiveness of two recommendation schemes, namely, collaborative filtering (CF) and image-based (IB) deep learning. Specifically, we investigated how consumers' preferences are influenced when a list of recommended fashion products is generated by a hybrid recommendation structure.

2 - The Role of the Entrepreneur's Video Pitch in Online Crowdfunding

Jiyong Park, University of North Carolina at Greensboro, Greensboro, NC, United States, jiyong.park@uncg.edu, Jongho Kim, Daegon Cho

Although a video is an essential channel to persuade funders, little is known about the role of video pitches in online crowdfunding. This study examines how a video pitch influences crowdfunding performance. We leverage a range of state-of-the-art machine learning techniques that enable us to not only gauge speech styles but explicitly account for content heterogeneity in both text and video. Using data from over 4,500 crowdfunding projects, we find that an entrepreneur's pitch and its nuanced styles play important yet distinct roles in increasing pledged amounts and social buzz via social media. This study demonstrates an empirical application of machine learning in online content engineering.

3 - "Need for Speed", But How Much Does It Cost? Fee-Speed Relationship on Bitcoin Transactions

Guangzhi Shang, Noyan Ilk, Florida State University, Tallahassee, FL

We study the transaction fee and confirmation speed relationship on Bitcoin. We propose a priority indexing based framework, estimate this framework, and use this framework to recommend transaction fees.

Chair: Vashkar Ghosh, University of North Carolina, Greensboro, Greensboro, NC, 27402, United States

1 - Empirical Investigation of Bullwhip Effect with Sensitivity Analysis in Supply Chain

Shoaib Yousaf, International Islamic University, Islamabad, Pakistan, shoaib.phdtm19@iiu.edu.pk

This paper empirically investigate the bullwhip effect under sensitivity analysis in two tier supply chain in the rice industry of Pakistan. Simulation has been applied with two case studies. The results confirmed that reduction in production delay, increasing the value of time to adjust inventory, reducing the value of time to work in progress also reduces the bullwhip effect. Furthermore, by decreasing the value of alpha increases the damping effect. Moreover, this research will help to reduces the major costs of their products in three ways, i) inventory levels, ii) better utilize their capacity and iii) improve their forecasting techniques.

2 - Quantifying the Bullwhip Effect in NAIJI Production System

Nobuyuki Ueno, Hiroshima University of Economics, Hiroshima, Japan

We present both the model to quantify the demand amplification and the way to dampen it in NAIJI production system between an automobile manufacturer and suppliers. In NAIJI production system, the manufacturer weekly and monthly sends NAIJI (Forecast) in advance of supplier's manufacturing and the supplier makes production plans, but NAIJI is known to be uncertain and changing. We developed the demand model based on NAIJI and the formula for the bullwhip effect ratio depending on only demand fluctuation. And we compared the result by the formula with measurement and the precedent study.

3 - Inter and Intra-firm Bullwhips in a Multi-echelon Pharmaceutical Supply Chain

Ming Jin, University of Oregon, Eugene, OR, United States, mjin2@uoregon.edu, Nicole DeHoratius, Glen M. Schmidt

We investigate the bullwhip effect in a pharmaceutical supply chain using SKU-level data across four echelons: customers, distributors, a manufacturer, and suppliers. We empirically measure intra-firm bullwhips across multiple echelons of the supply chain. The bullwhip measurement based on information flow is larger than that based on material flow. Data aggregation across products or over long time periods tends to mask the bullwhip effect. We find that price variation, replenishment lead time, and inventory are three main factors associated with the bullwhip effect.

4 - Strategic Inventories and Vertical Contracts in Multiechelon Supply Chains

Qing Wu, University of Electronic Science and Technology of China, Chengdu, Sichuan, China, wuq@uestc.edu.cn

Established findings suggest that strategic inventory may alleviate double marginalization and improve the efficiency of a decentralized two-echelon supply chain. However, the role of strategic inventory in multi-echelon supply chains remains largely unexplored. In this paper, we examine the effect of strategic inventory in multi-echelon supply chains.

5 - Impacts of Leadership on CSR Management in Multi-tier Supply Chains

Wanying Wei, Tianjin university, Tianjin, China, weiwanying@tju.edu.cn, Weihua Liu, Tsan-Ming Choi

Considering two different supply chain leaderships: 1) Tier 1 leads Tier 2 supplier and 2) Tier 2 leads Tier 1 supplier, we study when the Tier 0 should entrust the Tier 1 supplier (delegation strategy) or directly motivate the Tier 2 supplier (control strategy) to decrease the CSR violation probability in Tier 2. Contrary to studies intuitively arguing that delegation is more efficient when Tier 1 supplier is in the leading position, we find in some cases, delegation strategy is more likely to ensure a lower violation probability when Tier 2 leads Tier 1.

6 - Pricing Strategies and Asymmetric Information

Vashkar Ghosh, University of North Carolina-Greensboro, Greensboro, NC, United States

We consider information sharing in a supply chain and investigate its effect on different pricing strategies.We develop a model to analyze the preference of each channel member towards sharing information.The analysis examines the effect of competition and information asymmetry on supply chain profits.

Machine Learning and Rough Volatility

Sponsored: Finance

Sponsored Session

Chair: Justin Sirignano, University of Illinois at Urbana-Champaign, Urbana IL, United States

Co-Chair: Alexandra Chronopoulou

1 - A New Model for Stock-Price Trend Analysis and its Exploitation in Trading

James A. Primbs, California State University-Fullerton, Fullerton, CA, United States, B. Ross Barmish

In this work we put forward a new model for stock-price trend analysis which, rather than describing the extent to which a stock price goes up or down, provides a quantification of the duration of trends and the extent to which "efficient" entry points are available for traders. We illustrate how such a model might be used by traders who strategically switch between long and short positions to exploit suitably long trends. Finally, we provide an explicit formula for the expected gain or loss of such a trader over a single trend, and provide numerical examples exploring the possible exploitation of "microtrends" at the stock transaction level.

2 - Personalized Robo-advising

Agostino Capponi, Columbia University, New York, NY, 10027, United States

Automated investment platforms, or robo-advisors, have emerged as an alternative to traditional financial advisors. Their viability depends in a crucial way on the efficiency of the communication exchange between the investor and the machine. We develop a novel robo-advisor algorithm that solves a dynamic version of the mean-variance investment criterion and also adapts over time to changing risk-preferences of the investor it serves. We quantify the trade-off that the investor faces between the cost of updating risk-preferences, i.e. communicating with the machine, and the benefit of obtaining investment advice that is more tailored to her risk profile. We study the regret measures arising from the robo-advisor's imperfect knowledge of the investor's risk profile and analyze their sensitivities to market and human-machine interaction.

3 - Optimal Sampling Schemes in Fractional Volatility Models

Alexandra Chronopoulou, University of Illinois-Urbana-Champaign, Urbana, IL, 61801, United States

The goal of this talk is to propose efficient sampling schemes for sampling fractional (both rough and long memory) stochastic volatility models, when the number and type of observations is constrained due to limited resources. We find that the sampling mechanism depends on the value of the Hurst parameter, H, and that the equidistant sampling scheme is optimal only when H=0.5.

4 - Global Convergence of Stochastic Gradient Hamiltonian Monte Carlo for Non-Convex Stochastic Optimization

Lingjiong Zhu, Florida State University, Tallahassee, FL, 32306, United States

Stochastic gradient Hamiltonian Monte Carlo (SGHMC) is a variant of stochastic gradient with momentum where a controlled and properly scaled Gaussian noise is added to the stochastic gradients to steer the iterates towards a global minimum. Many works reported its empirical success in practice for solving stochastic non-convex optimization problems from machine learning, in particular it has been observed to outperform overdamped Langevin Monte Carlo-based methods such as stochastic gradient Langevin dynamics (SGLD) in many applications. In this work, we provide finite-time performance bounds for the global convergence of SGHMC for solving stochastic non-convex optimization problems with explicit constants. Our results lead to non-asymptotic guarantees for both population and empirical risk minimization problems. For a fixed target accuracy level, on a class of non-convex problems, we obtain iteration complexity bounds for SGHMC that can be tighter than those for SGLD. These results show that acceleration with momentum is possible in the context of non-convex optimization algorithms. This is based on the joint work with Xuefeng Gao (Chinese University of Hong Kong) and Mert Gurbuzbalaban (Rutgers University).

Chair: Jizhou Lu, Central University of Finance and Economics

1 - A Text Analytics Based Review of the Supply Chain and Operations Literature

Thomas Robbins, East Carolina University, Greenville, NC, United States, robbinst@ecu.edu

In this talk we present a review of the academic literature in supply chain and operations management. We have collected summary data that includes the title, authors, keywords, and abstracts for papers published in 18 top tier journals that publish SC&OM research. Using a data set of over 38,000 articles published over the last 25 years we perform a text analytics-based review. We analyze the data to determine the most prevalent methodologies and topic areas addressed. We also use this data to perform a cluster analysis to segment the journal set.

2 - Physical Asset Management (PAM) Based Decision Making Platform in the Utility Sector; the Case of Fluvius

Amir-Behzad Samii, Vlerick Business School, Brussels, Belgium, behzad.samii@vlerick.com, Olga Varganova

Physical Asset Management (PAM) is the systematic and structured process of planning, designing, and controlling the physical assets during their life-cycle to support the delivery of goods and services. We model the total supply chain costs of the physical assets and develop a PAM-based decision-making platform for the Belgian utility provider Fluvius. We showcase the applicability of this platform in evaluating the smart electricity and gas meters implementation projects as well as the proliferation of the renewable energy assets.

3 - Reconfiguration of Manufacturing Supply Chains Considering Outsourcing Decisions and Supply Chain Risks

Qi Tian, Dalian University of Technology, Dalian, China, tianqidlut@163.com

In order to stay responsive to evolving demands and to meet the need for greater product customizations, many manufacturing enterprises are recognizing the need to quickly reconfigure their manufacturing systems and supply chains. This study proposes a graph-based cost model to optimize the configuration of manufacturing supply chain networks to support reconfiguration decisions. We aim to minimize the total cost of the manufacturing enterprise considering operating cost and reconfiguration cost. The graph-based model characterizes the relationship between the similarity of two supply chain networks and the reconfiguration cost. Outsourcing options and risks are also considered.

4 - Evaluating Efficiency and Efficacy for Different Delivery Strategies

Sanam Azadiamin, Ohio University, Athens, OH, United States, sa349416@ohio.edu

Many stores now offer delivery directly to customers' homes. This needs to be done with a low cost while providing high customer satisfaction. This research examines different routing strategies and evaluates how each performs in terms of efficiency and efficacy. The work also examines the impact of waiting for more orders before forming routes, which results in a longer lead time for the customer and therefore, worse efficacy. The results show that the efficiency of the route is primarily dependent on the number of orders in the route and doesn't show significant improvement when the population of orders to be batched is larger.

5 - Information Sharing and Information Quality in Parallel Supply Chains

Jizhou Lu, Assistant Professor, Central University of Finance and Economics, Beijing, China

We consider two parallel supply chains. Each one consists of one manufacturer and one retailer. The demands of two products sold by retailers are interdependent and respectively follow a first order vector autoregressive process. We consider two types of information sharing here: inter-supply chain information sharing and cross-supply chain information sharing. Meanwhile, information errors would happen while information is being shared. We propose an analytical framework to study how the value of information sharing is affected by information errors. We identify the conditions under which the value of information sharing is increased or decreased.

Modern Project Management

Emerging Topic: Project Management & Scheduling

Emerging Topic Session

Chair: Marc E. Posner, Ohio State University, Columbus, OH, 43210-1271, United States

1 - Optimal Hedging in the Stochastic Time Cost Quality Tradeoff Problem

Bruce Pollack-Johnson, Associate Professor of Mathematics and Statistics, Villanova University, Villanova, PA, United States, bruce.pollack-johnson@villanova.edu, Matthew J. Liberatore

We present the Stochastic Time Cost Quality Tradeoff Problem (STCQTP) model to optimally hedge against time and cost uncertainty in project scheduling, incorporating a continuous quality function with stochastic parameters.

2 - Early Termination Compensation under Demand Uncertainty in Public-Private Partnership Projects

Jinbo Song, Dalian University of Technology, Dalian, China, songjinbo@dlut.edu.cn

In the early termination of public-private partnership projects, compensation is considered a core issue that affects the interests of the government and the private sector. To address the early termination that is frequently caused by government default or voluntary buyback, this paper proposes an ex-ante compensation mechanism using the cumulative probability that a given demand could be realized to determine early termination compensation under demand uncertainty. By splitting the compensation into two parts, the base compensation could be the minimum compensation for the private sector, while the additional compensation is considered a reasonable allocation of future booming demand.

3 - Preemptive Resource Leveling

Marc E. Posner, Professor, Ohio State University, Columbus, OH, 43210-1271, United States, posner.1@OSU.edu, Nicholas G. Hall

We examine the resource leveling problem where job splitting is permitted. The complexity of several variants of the problem are examined. Also, we provide bounds on the relative performance of the non-preemptive and the preemptive versions of the problem.

■ SA78

S- Greenwood

Crowdfunding Platforms

Sponsored: New Product Development

Sponsored Session

Chair: Simone Marinesi, Wharton, Philadelphia, PA, 19103, United States

1 - Signaling to the Crowd: Private Quality Information and Rewards-based Crowdfunding

Soudipta Chakraborty, Duke University, Durham, NC, 27708, United States, sc390@duke.edu, Robert Swinney

We consider the problem faced by a creator designing a rewards-based crowdfunding campaign via a platform like Kickstarter. The creator solicits pledges from backers, and if total pledges exceed a pre-determined threshold, the campaign is successful, the creator receives all pledges and each backer receives a reward. Otherwise, the campaign fails, and backers are refunded their pledges. We determine how the creator should design her campaign when backers know less than her about the value of the reward.

2 - Crowdfunding vs. Bank Financing under Market Uncertainty

Fasheng Xu, Washington University in St. Louis, Campus, Saint Louis, MO, 63130, United States, fasheng.xu@wustl.edu, Xiaomeng Guo, Guang Xiao, Fuqiang Zhang

Bank financing is a traditional source of capital for small businesses, whereas crowdfunding has recently emerged as an alternative fund-raising solution to support innovative ideas and entrepreneurial ventures. This paper investigates a firm's optimal funding choice when launching an innovative product to the market with both market uncertainty and word-of-mouth (WoM) communication. We characterize the firm's optimal pricing strategies under the two funding choices (i.e., bank financing and crowdfunding), compare their performances, and investigate the corresponding implications on social welfare.

3 - Crowdfunding: Public Signal for Venture Capital

Jussi Keppo, National University of Singapore, Mochtar Riady, Singapore, 119245, Singapore, keppo@nus.edu.sg, Ming Hu, Yannan Jin

Motivated by the empirical observation of the relationship between crowdfunding and Venture Capital (VC) investments, we study how crowdfunding, as a public information source, affect competing VCs' investment strategies. We show that crowdfunding and competition between VCs raise VC investments. Further, if the downside risk of the startup is severe and if the precision of the crowdsourcing information is high, then the more optimistic VC is more likely to invest before the crowdfunding. Our results are robust in several model extensions.

4 - Designing Crowdfunding Platform Rules to Deter Misconduct

Simone Marinesi, University of Pennsylvania, Philadelphia, PA, 19103, United States, marinesi@wharton.upenn.edu, Elena Belavina, Gerry Tsoukalas

Lacking credible rule enforcement mechanisms to punish misconduct, existing reward-based crowdfunding platforms can leave backers exposed to two risks: entrepreneurs may run away with backers' money (funds misappropriation) and product specifications may be misrepresented (performance opacity). To mitigate these risks, we propose and analyze a variety of designs that involve the use of deferred payments, and possibly also include costly performance verification checks, varying the timing (pre- vs. post-campaign) and enforcement rules (mandatory vs. optional). Overall, we analyze ten different designs and show that eight of them are dominated and only two designs dominate.

Joint Session: Sustainable Growth/MIF: Energy for Increasing Social Good

Emerging Topic: Sustainable Growth

Emerging Topic Session

Chair: Destenie Supreece Nock, University of Massachusetts-Amherst, Amherst, MA, 01035, United States

1 - Fairness in Energy Access Initiatives

Valerie Thomas, Georgia Tech, ISYE, Atlanta, GA, 30332, United States, vthomas@isye.gatech.edu

The UN's Sustainable Development Goals include access to clean and affordable energy. Energy access programs in developing countries have included varying approaches to fairness and to technology. Many electricity production planning models choose the technology options, assume that unmet demand exists, and that providing electricity will result in societal benefits. Demand in developing countries has often failed to meet expectations. An alternative approach emphasizes productive use of electricity. Models contrasting these approaches will be presented. Social metrics used in sustainability and social sciences are introduced.

2 - Valuing System Flexibility: Pumped Hydro Storage in the New England Electricity System

Destenie Supreece Nock, Postdoctoral Researcher, Carnegie Mellon University, Pittsburgh, PA, 01035, United States

Pumped hydro energy storage is one method of enhancing power system flexibility due to its ability to regulate power output from renewables, acting as a supplier and consumer, and enhance overall system sustainability through enhancing the capacity factor of renewables and being a low emission technology. In this paper we determine the value of PHES using multi-criteria decision analysis and the three pillars of sustainability. We rank low carbon generation portfolios under nine-illustrative preference scenarios. We find that using PHES to support renewables proves beneficial for the region, and we present our framework for quantifying the sustainability of flexible power systems.

3 - Using Value-focused Thinking and Multi-criteria Group Decision-making to Evaluate Energy Transition Alternatives

Tim Höfer, RWTH Aachen, Aachen, Germany, Rüdiger von Nitzsch, Reinhard Madlener

We develop a group decision-making process with professional stakeholders and energy experts to evaluate possible energy transition alternatives. The stakeholders are involved in every step of the decision-making process - the development of the alternatives, the definition of the objective system, and the final evaluation of the alternatives. We apply Value Focused Thinking (VFT) to define and structure the objectives of the stakeholders and use Multi-Attribute Utility Theory (MAUT) to evaluate the alternatives. The results show that a majority of the stakeholders prefers the energy transition alternative, which has the highest ambitions to limit climate change.

4 - Least-cost Pathways for The Indian Power Sector

Maxwell L. Brown, National Renewable Energy Laboratory, Arvada, CO, 80002, United States

Increased deployment of variable renewable energy raises new questions related to optimal siting of generation capacity, tradeoffs between generation and transmission, and system flexibility needs. In this analysis, we use the Regional Energy Deployment System (ReEDS) model to evaluate least-cost pathways for India's electric power system over the period 2017-2047. We showcase the impact of different future trends (e.g., storage, transmission) on power sector investments. This work represents the first international application of ReEDS as part of an effort to strengthen institutional capacity within India.

OR/MS Models in Innovation and Entrepreneurship

Sponsored: Technology, Innovation Management & Entrepreneurship

Sponsored Session

Chair: Stefanos Zenios, Stanford University, Stanford, CA, 94305-5015, United States

1 - Anticipating Random Walks: A Dynamic Model of Crowdfunding

Mohamed Mostagir, University of Michigan, Ann Arbor, MI, 48109, United States, Saeed Alaei, Azarakhsh Malekian

This talk introduces a novel stochastic process — anticipating random walks — to analyze backer behavior in crowdfunding. The analysis helps explain why some campaigns fail and some do not and provides guidelines about how sellers should design their campaigns in order to maximize their chances of success.

2 - Does Blockchain Facilitate Responsible Sourcing? Case of Supply Chain of Diamonds

Dmitrii Sumkin, INSEAD, Singapore, 138676, Singapore, dmitry.sumkin@insead.edu, Sameer Hasija, Serguei Netessine

Recently, blockchain was implemented in diamonds supply chain to validate certificates of origin. We examine how it affects responsible production. We model customers valuing both responsible production and reselling opportunity provided by the certificate. We show that with blockchain certificates it is less profitable to segment the market by the reselling opportunities than by responsible production. Thus, blockchain certification can reduce or increase responsibility in supply chains. Moreover, we demonstrate that different certification policies can make the negative effect of blockchain even worse.

3 - Entrepreneurial Search as a Sequential Hypothesis Test with Multiple Controls

ZhenglI Wang, Graduate School of Business, Stanford University, Stanford, CA, United States, Stefanos Zenios

We consider a problem in which an entrepreneur decides whether to launch a given project. The decision maker can choose to acquire different types of signals to learn whether the project is valuable, at different costs. We provide both the Bayesian and the frequentist approaches to the problem under Brownian approximations. We then derive the optimal policy and provide insights on the structure of the policy.

4 - The Indirect Role of Social Comparisons in the Adoption of New Practices in Organisations Using an Evolutionary Game Theory Approach

Antoine Feylessoufi, University of Cambridge, Cambridge, United Kingdom, af545@jbs.cam.ac.uk

We propose an evolutionary game theoretic model of the micro behaviours of individual employees that are faced with the option of adopting a new practice in an organization. We develop insights regarding the potential of an organization to successfully and fully adopt a new management practice or operational technology and show that the interplay between (i) the social comparison effects on individual utilities, as these are dictated by the underlying organizational culture (envious vs. gloating), and (ii) the formal collective rewards instituted by the organization to induce adoption (bonus vs. levy) shape the eventual adoption patterns inside the organisation.

Forestry I: Forest Management

Sponsored: Energy, Natural Res & the Environment/Forestry

Sponsored Session

Chair: Sandor Toth, University of Washington-Seattle, Seattle, WA, 98195-2100, United States

Co-Chair: Cristóbal Pais, M. Sc, UCBerkeley, Berkeley, CA, United States

1 - Sampling Design Optimization for Measuring Forest Carbon

Sandor Toth, University of Washington-Seattle, Seattle, WA, 98195-2100, United States

We seek to optimize spatial sampling design for forest carbon measurements from both remote and ground-based sensors. Expected measurement error is to be minimized subject to budgetary and logistical constraints. To mitigate bias, our proposed integer programming model generates optimal plot inclusion probabilities. The implementation of the probabilistic sampling solutions can lead to budget overruns, however. We demonstrate how to mitigate such scenarios by tuning the parameters of the model for a case study.

2 - Economies of Scale in Forest Cutting Models via 0-1 Quadratic Objectives

Monique Guignard, Professor, Wharton, University of Pennsylvania, Philadelphia, PA, United States, Andres P. Weintraub, Antonio Alonso Ayuso

In plantations, the total cost of cutting two contiguous forest lots in different periods may be reduced if they can be cut in the same period, as economies of scale may then be created by using the same cutting and/or road building equipment. We review such issues as pairs of lots of different maturity, nonoverlapping pairs, and which map information to store to automate model creation.

Policy Intervention to Firms' Sustainability Actions

Sponsored: Energy, Natural Res & the Environment/Environment & Sustainability

Sponsored Session

Chair: Kejia Hu, Vanderbilt University, Nashville, TN, 37215, United States

Co-Chair: Huibin Du, Tianjin University, Tianjin, 300072, China

1 - Warning Against Recurring Risks: An Information Design Approach

Shouqiang Wang, The University of Texas at Dallas, Naveen Jindal School of Management, Richardson, TX, 75080, United States, Shouqiang.Wang@utdallas.edu, Saed Alizamir, Francis E. De Vericourt

Public agencies typically emit warnings to the stake-holders about potential disastrous events. In a repeated setting, they need to incentivize the public to take preventive actions in the current period while managing their credibility in the future. We characterize the optimal warning policy that balance such a tradeoff.

2 - The Unexpected Consequences of Regulation-driven Innovations Evidence from Auto Industry

Kejia Hu, Vanderbilt University, Nashville, TN, 37215, United States, Mark Cohen

We use 10-year vehicle emission dataset to study the pro-social and anti-social innovations under the tightening of emissions standards.

3 - An Agent-based Analysis of the Impact of Carbon Emission Trading on Power Sector: Prospects of China's Low-carbon Electricity

Huibin Du, Tianjin University, Nankai District, Tianjin, 300072, China, duhuibin@tju.edu.cn

The design of emission trading system is still obscure in China. Power companies are pushed to participate in the system, and they are concerned about future investment directions, as they do not understand the impact of such a system. This paper used agent-based modeling to simulate the carbon emission trading system implemented in China's power sector and investigate its impact on the future development of power sector. The results show that emission trading system can promote a virtuous cycle between emission reduction and renewable energy investment. The behavior characteristics of power companies are identified, which can assist the government to design an applicable emission trading system.

4 - Innovation Pressure Through the Supply Chain Network

Kejia Hu, Vanderbilt University, Nashville, TN, 37215, United States

We study how innovation pressure from regulators are spread through the supply chain network and examine how such network effect is changed under different buyer-supplier relationship.

S- Medina

Joint Session ENRE/Elec/Practice Curated: Cyber and Physical Resilience in Power Systems

Sponsored: Energy, Natural Res & the Environment/Electricity Sponsored Session

Chair: Feng Qiu, Argonne National Laboratory, Lemont, IL, 60439, United States

1 - A Resilient and Trustworthy Cloud and Outsourcing Security Framework for Power Grid Applications

Feng Qiu, Argonne National Laboratory, Lemont, IL, 60439, United States, fqiu@anl.gov, Alinson Xavier

Cloud provides a powerful and scalable IT infrastructure for industrial computational needs. As many sectors are moving enterprise applications to cloud, power sector is very slow in this progress. The reason is that, power system applications involve highly sensitive data concerning critical infrastructure security; but cloud is not a trustworthy computational infrastructure due to the "shared responsibility security model". We propose a trustworthy cloud computing framework based on privacy-preserving computation methods. We will use security-constrained unit commitment as an example and discuss the tradeoff between security and computational performance.

2 - Accelerating Bulk Power System Restoration Using Valid Inequalities

Bai Cui, Argonne National Laboratory, 532 Inverrary Ln, Lemont, IL, 60015, United States

The ability to promptly restore power services after blackouts is crucial for power system resilience. However, the process of bulk power system restoration is extremely complex, which involves multiple sequential steps, highly combinatorial operational decisions, and highly nonlinear network constraints. In this presentation, we introduce a mixed-integer linear programming-based formulation for optimal restoration sequence problem using linearized power flow equations. We discuss an approach to strengthen the formulation and improve the computational performance by exploiting a node-based substructure in the formulation.

3 - Quickest Detection of Cascading Failure

Rui Yao, Argonne National Laboratory, Lemont, IL, United States, Rui Zhang

We consider the problem of detecting the cascading failure in power system. We propose a temporal model for the diffusion of the failure. Under this model, the hazard rate of a node increases as the number of failure neighbors increases. Once failure affects a node, the distribution of the measurement changes from pre-change distribution.

Develop HPC Based Algorithms for Energy Applications

Sponsored: Energy, Natural Res & the Environment/Energy Sponsored Session

Chair: Feng Pan, Pacific Northwest National Laboratory

1 - Applying HPC Based HIPPO Software for Future Market Development Evaluation

Yonghong Chen, Midcontinent ISO, Carmel, IN, 46032, United States, ychen@misoenergy.org

This talk discusses how MISO uses HPC based HIPPO software to develop prototypes for future market scenarios and enhancement models. HIPPO includes libraries of formulations and solution approaches for security constrained unit commitment. New market enhancements are included through enhanced resource and system constraint options. It helps MISO to evaluate market impact from different design options and performance impact on market clearing software.

2 - Fast Evaluation of Security Constraints in a Security Constrained Unit Commitment Algorithm

Jesse T. Holzer, Pacific Northwest National Laboratory, Richland, WA, United States, jesse.holzer@pnnl.gov, Yonghong Chen, Feng Pan, Ed Rothberg, Arun Veeramany

We present a new fast security constraint evaluation (SCE) method and show how it facilitates algorithms for security constrained unit commitment (SCUC) problems in a large day ahead electricity market. Our SCE method achieves speedup on the order of 10x to 100x relative to existing commercial methods currently used in this context. This speedup permits the use of SCE as an integrated part of an algorithm for SCUC rather than in alternation with an SCUC algorithm, giving greater flexibility in the design of SCUC algorithms.

3 - Moving the Lower Bound for Unit Commitment MIP Models

Edward Rothberg, Gurobi Optimization, Beaverton, OR, 77027, United States, rothberg@gurobi.com

When considering their size, numerical complexity, and runtime constraints, unit commitment models are among the toughest MIP models that are currently being solved. Solving a MIP of course requires progress in both the lower and upper bound. This talk will discuss some of the approaches we have tried to improve the lower bound more quickly. We'll present computational results for the most effective of these approaches.

4 - On Lower Bounds for MIP-based Unit Commitment Problem

Yanan Yu, University of Florida, Gainesville, FL, 32603, United States, yuyn@ufl.edu, Yongpei Guan

With the development of mixed integer programming (MIP) solvers, MIP-Based Unit Commitment(UC) formulation and algorithm, such as branch-and-bound, have shown promises. To solve a minimization problem and evaluate the quality of a feasible solution in the branch-and-bound algorithm, a lower bound is needed. Improving the lower bound can help shorten the solving time. In this talk, we provide a comprehensive overview of lower bounds for MIP-Based UC formulations. The existed methods are tested on IEEE118 cases and real-world instances. By taking advantage of HPC, we contribute a parallel branching algorithm. The efficiency of the provided algorithm is verified by real-world cases.

5 - Exploiting Almost Symmetry in the Unit Commitment Problem

Jonathan Schrock, University of Tennessee, Knoxville, TN, United States, Jim Ostrowski, Yonghong Chen, Bernard Knueven

Unit commitment (UC) is a central problem in the operation and planning of real-world power systems. The UC problem is to develop an operating schedule for a system of generating units to meet forecasted load while minimizing production costs and satisfying physical and operational constraints. Such units with the same operating parameters and costs are called symmetric. Those that agree on all parameters excluding cost are called almost symmetric. In this work, we utilized these almost symmetries to reformulate the UC problem into a reduced form that can be solved more efficiently. We then applied Benders style cuts iteratively to tighten the model and retrieve a solution to the original UC problem.

6 - A Concurrent Optimizer for Solving Security Constrained Unit Commitment Problem

Feng Pan, Pacific Northwest National Laboratory, Richland, WA, 99352, United States, feng.pan@pnnl.gov, Yonghong Chen, Jesse Holzer, Edward Rothberg, Jie Wan

HIPPO is an ARPA-E funded project aiming to develop efficient algorithmic technologies to solve security constrained unit commitment problem with tenfold increase from the speed of the current solver. The core of the HIPPO software is a concurrent optimizer which manages parallel execution of a suit of algorithms and communication among individual algorithms. In this talk, we will introduce the concurrent optimizer and the underlying solution approaches and demonstrate its performance on a set of MISO market cases which were validated with GE and MISO's production solver.

Balancing Economic and Environmental Goals in Assessing Energy Futures

Contributed Session

Chair: Max Brozynski, University of Texas, Austin, TX, 78704, United States

1 - Electricity Market Impacts of Carbon and Variable Renewable Energy Policies

Todd Levin, Argonne National Laboratory, Lemont, IL, United States

We apply a computationally-efficient generation expansion planning model to a case study of ERCOT. We analyze the market impacts of policies that support VRE investments and carbon reductions. We find that electricity prices vary between policies, even when generation portfolios are comparable. A carbon tax is more system cost-efficient for reducing carbon emissions, while production and investment tax credits are more system cost-efficient for increasing VRE investments. Policies that reduce prices may require additional capacity remuneration mechanisms more than policies that increase prices. Moreover, impacts to consumer payments are not always aligned impacts to system cost.

2 - Utility-scale Photovoltaics and Storage: Economic and Environmental Trade-offs

Edgar Virguez, PhD Candidate, Duke University, Durham, NC, United States, edgar.virguez@duke.edu, Dalia Patino-Echeverri

This study explores the performance of the Duke Energy Progress/Carolinas electric power system under eighty-five configurations combining different capacities of utility-scale photovoltaics (PV) and energy storage. Results indicate that minimum carbon abatement costs are obtained when PV installed capacity is paired with batteries whose power capacity is ~12.5%. For levels of PV penetration (measured as expected annual share of energy) above 17%, higher decarbonization targets are better pursued with increased storage capacity than with more PV. For more ambitious targets (e.g. >30%), carbon dioxide emissions reductions require increases in both PV and storage capacity.

3 - The Performance of NYC's Transportation Policies in the Context of Their 80x50 Targets

Mine Isik, Postdoctoral Researcher, US EPA, Durham, NC, United States, Ozge Kaplan

The demand for mobility propelled by population put the transportation sector at the forefront of city planning. Policy makers confront vital health challenges while designing more sustainable cities and maintaining the mobility demand. The New York City alongside being the most populous city is experiencing a significant increase in travel demand. A community scale, cost optimization linear programming MARKAL model EPANYC6r that focuses on transportation sector, and energy infrastructure for NYC is developed. This study highlights the performance of transportation policy options and alternative technology investment decisions on its 80x50 goals considering CO_2, NO_x and SO_x emissions.

4 - A Game-theoretic Model of Infrastructure-dependent Technology Adoption: Overcoming the Chicken-and-egg Problem

Max T. Brozynski, University of Texas-Austin, Austin, TX, United States, brozynski@utexas.edu

Large technical systems, e.g., transportation, feature infrastructure-dependent technologies that are highly resistant to technology transitions because of lock-in phenomena that are exacerbated by the substantial sunk cost of existing infrastructure. To support an infrastructure-dependent technology transition, a policymaker must therefore overcome the chicken-and-egg problem: does adoption precede infrastructure, or vice-versa? To address this question, we formulate a general game-theoretic model of infrastructure-dependent technology adoption. Our analytical results shed light on the policymaker's and infrastructure provider's optimal strategic decision-making.

Modeling Decarbonization of Energy Systems

General Session

Chair: Ramteen Sioshansi, The Ohio State University, Columbus, OH, 43210-1271, United States

1 - A LP-based Model for Projecting Downscaled Power Plant Emissions from NEMS Model Runs

Benjamin Field Hobbs, Schad Chaired Professor, Johns Hopkins University, Baltimore, MD, 21218, United States, bhobbs@jhu.edu, Shen Wang, Xinrui Zhong

The National Energy Modeling System projects power plant capacity, outputs, and emissions by large regions for 12 time slices per year. However, for fate and transport analyses of pollution impacts, it is necessary to downscale those emissions in time and space. A LP- and geostatistics-based scheme for accomplishing this downscaling through the year 2040 is proposed and illustrated. The downscaling results show that alternative scenarios concerning electric vehicle and natural gas penetration can have signicant impacts on the timing and location of projected emissions.

2 - Strategic Storage Use in a Hydro-thermal Power System with Carbon Constraints

Afzal S. Siddiqui, University College London, Department of Statistical Science, Gower Street, London, WC1E 6BT, United Kingdom, afzal.siddiqui@ucl.ac.uk, Sebastien Debia, Pierre-Olivier Pineau

New York and Québec have a high penetration of variable renewable energy sources (VRES) and hydro production, respectively, along with stringent carbon caps. While cap-and-trade policies have increased VRES generation, they have also enhanced the role of energy storage, viz., by hydro reservoirs. Storage capacity should be deployed in a socially optimal way to smooth out fluctuations in VRES output, but hydro reservoirs may be used strategically as a result of market power. Consequently, incentives for VRES and welfare may be affected by such exertion of market power. We investigate the extent of these distortions and propose policies for their mitigation via a bottom-up equilibrium model.

3 - Using Geologically Stored Co2 and Geothermal Energy to Decarbonize the Electricity System

Jonathan Ogland-Hand, ETH-Zurich, 5363 Amy Lane, Zurich, 43235, Switzerland, Jeffrey Bielicki, Ebony Nelson, Benjamin Adams, Thomas Buscheck, Martin Saar, Ramteen Sioshansi

CO2-Bulk Energy Storage (CO2-BES) uses geologically stored CO_2 to extract geothermal heat in a way that time-shifts electricity production. We used an integrated model of a CO2-BES facility to determine the maximum duration over which electricity could be time-shifted and then used those results to investigate the value that CO2-BES may have in a transmission-constrained electricity system. Our results suggest that a CO2-BES facility can time shift electricity for durations up to multiple weeks and can increase the profit maximizing HVDC transmission capacity that connects a wind farm to a distant load center.

4 - Optimally Mining Heat for Geothermal Energy Production

Jonathan Ogland-Hand, Ohio State University, Columbus, OH, 43235, United States, Jeffrey M. Bielicki, Marcos Miranda, Thomas A. Buscheck, Kayyum Mansoor

Carbon dioxide (CO_2) may be more favorable than native geofluid as a geothermal heat extraction fluid due its higher mobility and the dynamics of a CO_2 plume in the subsurface. We developed and implemented a dynamic program of a natural resource economics approach for optimal heat mining and compared the use of water with the use of CO_2. Of the numerous results that are relevant for decarbonization, we find that CO_2 can be more cost-effective and more sustainably produce geothermal energy while also isolating CO_2 from the atmosphere to help mitigate climate change.

5 - Climate and Water Resource Impacts on Electricity Generation Systems in the United States

Ariel Miara, National Renewable Energy Laboratory, Golden, CO, United States

Power plants that require cooling provide 80% of electricity generation in the U.S. and rely on large volumes of water and sufficiently cool temperatures for optimal operations. This study evaluates the performance of 1,080 plants in the U.S. under future climates. Consideration of engineering interactions with climate, hydrology and environmental regulations reveals the need for regional adaptation strategies. Without placing climate-water impacts in a power systems context, assessments may misgauge the extent of vulnerabilities. Climate-water impacts may affect systems-level reliability, highlighting the need to integrate climate-water constraints into energy planning.

Plenary: Seeking Perfection: Reflections on the Journey

Plenary Session

Introducers: Ramayya Kristnan & Archis Ghate

1 - Seeking Perfection: Reflections on the Journey

Gary S. Kaplan, Virginia Mason, Seattle, WA, United States

This session will review the Virginia Mason journey over 17 years to transform its organization and culture. From the early changes and challenges focused on old paradigms to the adoption of the Toyota Production System (Lean Management) as its management system, this session will highlight early resistance to change, the development of a new strategic plan, adoption of new compacts with physicians, leaders, and board members, and hard wiring improvements in quality and safety for sustainability. The session will include the critical role of leadership and governance and the implications of change in a very dynamic marketplace.

Sunday, 11:00AM - 12:30PM

Data Mining Best General Paper

Sponsored: Data Mining

Sponsored Session

Chair: Ali Dag, Vermillion, SD, 57069, United States

Co-Chair: Changqing Cheng, Binghamton University, Systems Science Industrial Engineering, Binghamton, NY, 13902, United States

Co-Chair: Evangelos Triantaphyllou, Louisiana State University, Division of Computer Science & Engineering, Baton Rouge, LA, 70803, United States

1 - Personalized Dynamic Pricing with Machine Learning: High Dimensional Features and Heterogeneous Elasticity

Gah-Yi Ban, London Business School, Regent's Park, London, NW1 4SA, United Kingdom, N. Bora Keskin

Motivated by online retail applications, we consider a seller who offers personalized prices to individual customers. The seller initially does not know the impact of individual customer characteristics on demand, but can learn about this relationship via sales observations. We construct and analyze near-optimal policies that balance the learn-and-earn tradeoff in this setting.

2 - Data Aggregation and Demand Prediction

Renyu Zhang, New York University, New York, NY, United States, Kevin Jiao, Maxime C. Cohen

Retailers collect large volumes of data to predict future demand for hundreds of products simultaneously. We propose a practical method - referred to as the Data Aggregation with Clustering (DAC) algorithm - that balances the tradeoff between data aggregation and model flexibility. The DAC allows us to predict demand while optimally identifying the features that should be estimated at the (i) item, (ii) cluster, and (iii) aggregated levels. We then show that the DAC has both theoretical and practical advantages.

3 - Probabilistic Structure Learning for EEG/MEG Source Imaging with Hierarchical Graph Prior

Feng Liu, MGH, Harvard Medical School, Massachusetts General Hospital, Boston, MA, United States, Li Wang, Yifei Lou, Ren-Cang Li, Patrick L. Purdon

Brain source imaging is an important method for noninvasively characterizing brain activity using Electroencephalogram (EEG) or Magnetoencephalography (MEG) recordings. Traditional EEG/MEG Source Imaging (ESI) methods usually assume that either source activity at different time points is unrelated, or that similar spatiotemporal patterns exist across an entire study period. The former assumption makes ESI analyses sensitive to noise, while the latter renders ESI analyses unable to account for time-varying patterns of activity. To effectively deal with noise while maintaining flexibility and continuity among brain activation patterns, we propose a novel probabilistic ESI model based on a hierarchical graph prior. Under our method, a spanning tree constraint ensures that activity patterns have spatiotemporal continuity. Comprehensive numerical studies using synthetic data on a real brain model are conducted under different levels of signal-to-noise ratio (SNR) from both sensor and source spaces. We also examine the EEG/MEG data under auditory and visual stimuli, in which our ESI reconstructions are neurologically plausible. Our method also shows accurate result for epilepsy patients. All the results demonstrate significant improvements of the proposed algorithm over the benchmark methods in terms of source localization performance, especially at high noise levels.

4 - Ranking Features to Promote Diversity: An Approach Based on Sparse Distance Correlation

Fairness, Accountability, and Transparency in Machine Learning

Sponsored: Data Mining

Sponsored Session

Chair: Berk Ustun

1 - Fair Classification and Social Welfare

Lily Hu, Harvard University, Cambridge, MA, 02139, United States, lilyhu@g.harvard.edu, Yiling Chen

What is the relationship between fairness as defined by computer scientists and notions of social welfare? We present a welfare-based analysis of classification and fairness regimes. Our main findings center on sensitivity analyses of fairness-constrained risk minimization programs. We characterize the ranges of perturbations to a fairness parameter that yield better, worse, and neutral outcomes in utility for individuals and groups. We show that preferring "more fair" classifiers does not abide by the Pareto Principle—a fundamental axiom of social choice theory and welfare economics.

2 - Actionable Recourse in Linear Classification

Alexander Spangher, Stanford University, Menlo Park, CA, United States, alexander.spangher@gmail.com

Classification models are often used to make decisions that affect humans: whether to approve a loan, extend a job offer, or provide insurance. In such applications, individuals should have the ability to change the decision of the model. When a person is denied a loan by a credit scoring model, for example, they should know what changes to make to gain approval. Otherwise, this person will be denied the loan so long as the model is deployed, and, more importantly, will lack agency over a decision that affects their livelihood. We present a new way to audit linear classification models in terms of "recourse": the ability of a person to change the decision of the model through actionable input variables.

3 - Assessing Disparate Impact of Personalized Interventions: Identifiability and Bounds

Angela Zhou, Cornell University ORIE, Ithaca, NY, 14853, United States, Nathan Kallus

Personalized interventions in social services, education, and healthcare leverage individual-level causal effect predictions in order to prioritize program interventions for the individuals most likely to benefit. Actually auditing their disparate impacts per metrics such as true positive rates, is impossible since ground truths are unknown; nonetheless we can point-identify these quantities under the additional assumption of monotone treatment response and provide a sensitivity analysis for this assumption under violations of monotonicity of varying strengths. We illustrate auditing personalized interventions with ROC and xROC curves in a case study of a French job training dataset.

4 - Predictive Multiplicity in Classification

Charles Marx, Haverford College, Haverford, PA, United States, Flavio du Pin Calmon, Berk Ustun

Machine learning problems exhibit "multiplicity" when there exist several "good" models with near-optimal performance. In this talk, we discuss a specific kind of multiplicity — predictive multiplicity — which describes the existence of good models with conflicting predictions. We describe how predictive multiplicity arises in practice, and how it affects fairness and explain ability in human-facing applications such as recidivism prediction. We present formal measures of predictive multiplicity along with integer programming tools to compute these measures for linear classification problems.

Data Analytics in Complex Systems – Applications in Manufacturing

Sponsored: Data Mining

Sponsored Session

Chair: Cheng-Bang Chen

1 - Characterization of Fiber Orientation and Curvature Tensors in Carbon Fiber Reinforced Polymer Composite using Micro X-ray Computed Tomography

Shenli Pei, The Pennsylvania State University, State College, PA, United States, Kaifeng Wang, Jingjing Li

This study characterizes fiber orientation tensor and curvature tensor in injection-molded short- and continuous-carbon fiber reinforced polymer composites. The tensors are calculated from individual fibers extracted from 3D micro X-ray computed tomography images representing materials' interior microstructure. We propose a new fiber extraction algorithm, which consists of local 3D template matching and fiber orientation tracking for image segmentation and fiber reconstruction, respectively. The proposed algorithm is suitable for both short and continuous fibers, especially for regions with congested fibers.

2 - Heterogeneous Recurrence Analysis of Spatial Data with Applications in Manufacturing

Cheng-Bang Chen, The Pennsylvania State University, State College, PA, 16801, United States, czc184@psu.edu, Hui Yang, Soundar Kumara

To delineate the recurrence dynamics of the spatial data, prior efforts developed a hyper-dimensional recurrence plot or utilized the weighted network structure to characterize the spatial recurrence patterns. However, these works treated all recurrences homogeneously that rich information embedded on the heterogeneous states are not fully explored in the spatial domain. We propose a novel approach utilizing the space-filling curve and fractal representation to quantify the heterogeneous recurrences of the spatial data. Experimental results show our approach yields superior performance in the extraction of salient features to characterize recurrence dynamics in spatial systems.

3 - Predictive Analytics in Automobile Manufacturing with Bag-of-Words and Multivariate Time Series Classification

Shenghan Guo, Rutgers University, Piscataway, NJ, 08854, United States, sg888@scarletmail.rutgers.edu

In advanced manufacturing, data are collected from multiple sensors during the manufacturing process, resulting in multivariate time series (MTS) data. Fault prediction for manufacturing process based on MTS is challenging due to the high dimensionality and potential dependency among attributes. In addition, patterns that are highly relevant to fault occurrence may be hidden behind the complexity of MTS. Bag-of-Words models extract features by converting numerical observations into sets of words (features). Pattern recognition and dimensionality reduction are thus achieved by feature selection. MTS classification is then applied to the selected features for predicting failure events.

4 - A Deep Learning Approach for Sensor-based Monitoring of Transient Processes: A Study Case for Characterizations of Machining Natural Fiber Reinforced Plastics

Zimo Wang, Texas A&M University, College Station, TX, 77840, United States

We investigated a long short-term memory (LSTM) recurrent neural network to relate the waveform features of transient acoustic emission (AE) sensor signals to different process conditions and the underlying material removal mechanisms during machining natural fiber reinforced plastics (NFRP). The developed model is tested on the AE data gathered from earlier conducted orthogonal cutting experiments on NRFPs samples with various cutting speeds and fiber orientations. Results from this experimental study suggest that the employed recurrent neural network can correctly predict (over 88% accuracy) the cutting conditions based on the extracted temporal-spectral features of AE signals.

Statistical Learning for Complex Data

Sponsored: Data Mining

Sponsored Session

Chair: Qiong Zhang

Co-Chair: Christopher McMahan, Clemson University, Clemson, SC, United States

1 - An Additive Regression Model for Group Testing Data

Christopher McMahan, Clemson University, Clemson, SC, United States, mcmaha2@clemson.edu, Yan Liu, Joshua Tebbs, Christopher Bilder

Group testing has proven to be a cost-effective alternative to one-at-a-time testing. Several authors have developed regression methods to analyze group testing data but generally proceed under the assumption that covariate effects are linear. To avoid the potential pitfall of this assumption, we propose a Bayesian generalized additive model to describe the individual-level probability of disease with potentially misclassified group testing data. This model can be used to analyze data arising from any group testing protocol with the goal of estimating multiple unknown smooth functions of covariates, standard linear effects for other covariates, and even assay accuracy probabilities.

2 - Multi-resolution Functional ANOVA for Large-scale, Many-input Computer Experiments

Chih-Li Sung, Michigan State University, East Lansing, MI, 48824, United States, sungchih@msu.edu

The Gaussian process is a standard tool for building emulators for both deterministic and stochastic computer experiments. However, application of Gaussian process models is greatly limited in practice, particularly for large-scale and many-input computer experiments that have become typical. In this talk, a multi-resolution functional ANOVA model will be introduced as a computationally feasible emulation alternative. More generally, this model can be used for large-scale and many-input non-linear regression problems.

3 - Modeling of System Internal State Degradation from Sensor Monitoring Data and Engineering Physics

Mohammadmahdi Hajiha, University of Arkansas, Fayetteville, AR, 72701, United States, mhajiha@email.uark.edu, Xiao Liu

Based on the thermodynamic law that governs the relationship between system internal states, operating conditions and cooling efficiency, a physics-based statistical approach for modeling the cooling efficiency is proposed. The model also takes into account the statistical dependence among system state variables and captures the complex dependence structure by the Archimedean family of copulas with its generator function approximated by cubic B-splines.

Recent Advances of Practical Data Mining Techniques in Transportation Planning with Emphasis on Supply Chain Networks Supported by Machine Learning

Sponsored: Data Mining

Sponsored Session

Chair: Muhannad H. Ramahi, TTX Company, Chicago, IL, United States

1 - Data Mining to Improve Transit Performance and Better Inform Transit Riders

Brian Mayer, Research Associate, Virginia Polytechnic Institute and State University, Blacksburg, VA, 24060, United States, bmayer@cs.vt.edu, Nikhil Muralidhar, Naren Ramakrishnan

It is projected that by the year 2030, 6 out of 10 people will live in a city and transportation is a key issue concerning urban populations. In the United States the average commute time is 52 minutes and the average urban commuter spends 42 hours sitting in traffic each year. The Washington Metropolitan Area Transit Authority is working with the NSF-sponsored Urban Computing Program at Virginia Tech to use data mining to solve real-world problems enabling WMATA to improve performance and better inform riders. The team has used passenger tap-in/out, train movement, & bus location data to cluster stations/users, make predictions of future demand & performance, and identify delay patterns.

2 - Rail Routing and Travel Times in a Congested North American Network

Andrzej Zuranski, Princeton Consultants Inc., Princeton, NJ, United States, azuranski@princeton.com

A study is performed on measuring travel times for a North American rail network using a one-year data sample for a fleet of automotive railcars. We present a method of route segmentation based on railcar location reports when missing data and out-of-time data is common using a directed graph. We then study historical travel times on each viable route segment and its dependence on local railcar congestion using a handful of data mining techniques based on temporal or global correlations. Finally, an ETA model is constructed, and its precision is evaluated.

3 - A Comparative Study between Machine Learning and Classical Methods in Forecasting Railroad Operational Metrics

Muhannad H. Ramahi, TT X. Company, Chicago, IL, 60606, United States, Muhannad.Ramahi@TTX.com

A comparative study between machine Learning and Classical Methods in Forecasting Railroad Operational Metrics We present a study/results of exploring a new technique for forecasting railroad operational metric(s) such as cycle time and railcars network mileage. The goal is to explore the new emerging techniques of machine learning against classical methods in predicting cycle time and railcar mileage for various fleets. Cycle time is an essential part of the business planning process that partly determines how many railcars are potentially needed for satisfying the network demand. Moreover, mileage prediction is critical in deciding how equipment maintenance is planned and budgeted.

4 - Big Data for Smart Rail

Kristina Chambers, Director Operations Strategy and Analytics, TTX. Company, Chicago, IL, 60606, United States, Kristina.Chambers@TTX.com

TTX Company is applying innovative data science solutions to railcar maintenance for their fleet of 220k railcars. They are developing machine learning models and advanced analytics techniques to tackle tough business challenges, automate processes and drive business value across the organization. This presentation will provide an introductory overview of machine learning and provide a foundational context for how the data science work at TTX has helped them evolve their business processes and enhance decision making.

Joint Session DM/Practice Curated: Biases in Data Mining, the Achilles' Heel of Intelligent Machines

Sponsored: Data Mining

Sponsored Session

Chair: Bridget Huang, APKUDO

1 - Designing Bias-free, Generic Number Guessing Games that Mimic the Stock Market and Eliminate Non-randomness

Vincent Granville, Co-founder, Data Science Central, Issaquah, WA, United States, vincentg@datasciencecentral.com

We discuss a generic number guessing game, mimicking stock trading or a lottery, depending on the model parameters. A public algorithm is available to compute the winning numbers in advance, based on chaotic but ergodic sequences. The gain and losses are known in advance and pre-recorded in public ROI tables. The player can design her own ROI table, with the expected average return set to some pre-specified level (typically 0% for a fair game) and pre-specified maximum cap for the volatility, in order for the operator to control cash float. Biases can be introduced in the system, accidentally or on purpose. We discuss these types of biases, and how to address them.

2 - Democratizing Data Science

Brian Wright, Co-Director, Data Science Graduate Programs GW, George Washington University, 1556 Westmoreland St., Washington, DC, 22101, United States, bwright.wright6@gmail.com

The expansion of AI into everyday life brings with it the unanticipated challenge of confronting decisions or recommendations that could be considered bias or even unethical. Technical approaches to combat algorithmic bias have been advancing in recent years and show great promise, however, these solutions can only partly address the problem. Research shows that increases in general knowledge related to AI systems actually reduces trust. I'll discuss how this distrust could be healthy, that the nature of the field of data science works in our favor and ways that we can facilitate broader awareness to elicit increased discourse and allow for a "healthy distrust" of AI.

3 - Handling Classification Bias in Tagging Medical IoT Devices with Token Data

Richard Xie

Please check the mobile app for this abstract.

4 - Privacy Protection vs. Prevention of Biases in Telecom Industry Data Virgin Territories Exploration

Hongyi Bridget Huang, APKUDO, Baltimore, MD, United States, huang1225@hotmail.com

In the era of customized services, no one expects it haunts the public with data privacy invasion. With regulations like GDPR, the public pay attention to their privacy, which increases the tendency of data missing. Considering the real-world data is not perfect, will the new trend jeopardizes the data quality by introducing more biases? The telecom industry Exchange Risk Index optimizes the devices exchange process. It gives the utility to estimate the performance of any issue. It also enables prioritizing the concerned issues and predicting the future risk performance. Exchange consists of individual behaviors. Each data point is critical. How to adjust the data operation strategies to the new norm?

5 - A New Fairness Improvement Approach in Incentive Structure Optimization for Uber Vehicle Solution

Le Li, Data Science Manager, Uber, Seattle, WA, United States, Shitao Wang

Uber Vehicle Solution program is an important global force in Uber ride-sharing business, and it provides end to end vehicle services to drivers who are willing to drive for Uber but do not have vehicle access. Vehicle solution mainly operates in vehicle-constrained markets. Increasing vehicle utilization is one of the key initiatives to drive supply in those areas. Comparing with traditional driver-based incentive, the vehicle-based incentive aims to increase vehicle sharing and drives vehicle-based utilization higher. The vehicle-based incentive is proved to be the most economical way to increase vehicle utilization, which improves earnings per vehicle - with little diminishing return.

2 - Dynamic Machine Learning Models to Improve Patient Care in PERIOP

Kevin Yang, General Electric Healthcare, Hoffman Estates, IL, United States, Kevin.Yang@ge.com

In the industry of healthcare, quality and efficiency of services are always the focus of attention of service providers and patients. There are various reasons that a delay occurs during the pipeline of a surgical operation. This presentation illustrates a deployment of machine learning methods to predict the possibility that a delay will happen during the workflow. Therefore, the service providers will have opportunities to improve their efficiency and satisfy their patients ultimately.

3 - A Multi-layer Prescriptive Analytic for Efficient Workforce Deployment and Planning for Hospital Machine Maintenance and Repairs

Thanos Aristotelis, General Electric Global Research, Niskayuna, NY, United States, a.thanos@ge.com

GE Healthcare manages several thousand Field Engineers (FEs) over a 5000-hospital customer base, serving approximately 70,000 devices under specific contractual service level agreements. The FEs are responsible to provide phone support, perform preventative maintenance and conduct on-site repair for unexpected machine failure. The customers-hospitals depend on the timely and efficient repair and maintenance of those devices to provide in turn high quality healthcare services. To achieve this goal we have designed and implemented a multi-layer prescriptive analytic that targets to provide decision support on hiring, training, assigning shifts and scheduling the repairs.

Joint Session AI ML/ICS: Machine Learning Meets Discrete Optimization

Emerging Topic: Artificial Intelligence & Machine Learning

Emerging Topic Session

Chair: Thiago Serra, Bucknell University, Mitsubishi Electric Research Labs, Lewisburg, PA, 02139, United States

1 - A Sample Size-Efficient Polyhedral Encoding and Algorithm for Deep Neural Network Training Problems

Gonzalo Muñoz, Polytechnique Montreal, 2920 Chemin de la Tour, Montreal, QC, H3T 1N8, Canada, gonzalo.munoz@polymtl.ca, Daniel Bienstock, Sebastian Pokutta

Deep Learning has received much attention lately, however, results regarding the computational complexity of training deep neural networks have only recently been obtained. Moreover, all current training algorithms for DNNs with optimality guarantees possess a poor dependency on the sample size, which is typically the largest parameter. In this work, we show that the training problems of large classes of deep neural networks with various architectures admit a polyhedral representation whose size is linear in the sample size. This provides the first theoretical training algorithm with provable worst-case optimality guarantees whose running time is polynomial in the size of the sample.

2 - Optimizing Over Trained Neural Networks

Christian Tjandraatmadja, Google Research, Cambridge, MA, United States, Ross Anderson, Joey Huchette, Will Ma, Juan Pablo Vielma

We present an overview of tf.opt, a MIP-based solver for optimization models embedded with neural networks. Its goal is to find decisions x that optimize f(x) under constraints, where f(x) is given by a trained neural network with a piecewise linear architecture. This problem appears in a variety of areas, such as deep reinforcement learning, sequence design, and neural network verification. Our solver inherits two advantages from MIP: optimality guarantees, useful for verifying neural network properties, and mixed-integer linear constraints, which pave the way to large combinatorial action spaces in deep reinforcement learning. We discuss these applications and the techniques within tf.opt.

3 - Strong Mixed-integer Programming Formulations for Trained Neural Networks

Joey Huchette, Rice University, Houston, TX, 02143, United States, Ross Anderson, Will Ma, Christian Tjandraatmadja, Juan Pablo Vielma

We present strong mixed-integer programming (MIP) formulations for high-dimensional piecewise linear functions that correspond to trained neural networks. These formulations can be used for a number of important tasks, including robustness verification, or "predict, then optimize" decision problems with machine learning models embedded inside. We derive MIP formulations a number of the most popular nonlinear operations (e.g. ReLU and max pooling) that are strictly stronger than other approaches from the literature. We corroborate this computationally, showing that our formulations are able to offer substantial improvements in solve time on image classification verification problems.

4 - Exact and Approximate Transformations of Deep Neural Networks

Thiago Serra, Bucknell University, Lewisburg, PA, 02139, United States, Abhinav Kumar, Srikumar Ramalingam

We study the possibility of transforming a deep neural network to another network with a different number of units or layers, which can be equivalent or an approximation. First, we show that certain rectified linear units (ReLUs) can be safely removed from a network if they are always active or inactive for any valid input. Second, we show that any feed-forward ReLU network can be approximated to arbitrary precision by a 2-hidden layer shallow network with a fixed number of units associated with the linear regions of the original network. Based on experiments with ReLU networks on the MNIST dataset, we found that networks trained with L1-regularization can be effectively compressed due to weight sparsity.

Sponsored Session

Chair: Junming Liu, Rutgers Business School, Newark, NJ, 07102, United States

1 - Enhancing Recommender System for Taxi Drivers with Business Effective Strategies

Mingfei Teng, Rutgers Business School, Newark, NJ, 07102, United States, mingfei.teng@rutgers.edu

We propose an enhanced recommender system aiming to maximize the expected profit of the taxi drivers. Specifically the system estimates the pickup probability for each road segment. Followed by the estimation, it makes an optimization-based decision whether to take the best route given by our route searching strategy or waiting at a specific virtual station which is identified by the virtual station discovery procedures based on taxis' trajectory data. Finally, we carry out extensive experiments on a real-world data set and the experimental results clearly validate the effectiveness of the proposed system.

2 - Operational Values of AI-powered Demand Forecasting for Fast Fashion Products

Jingci Ming, Rutgers University Business School, Newark, NJ, United States, jingci.ming@rutgers.edu

The store-level product demand forecasting is of great importance for the daily operations of fast-fashion retailers. We propose a demand forecasting model with Seq2Seq concerning specific information including store environmental information and life cycle of categories of SKUs. We develop our model with the collaboration with a leading fast-fashion company. By comparing with other baseline models we significantly improve the prediction accuracy which contributes to the daily inventory control.

3 - An Iterative Algorithm for Multi-level E-logistics Distribution Center Network Design

Jingyuan Yang, Assistant Professor, George Mason University, Fairfax, VA, 22030, United States, jyang53@gmu.edu, Junming Liu

The multi-level distribution center (MLDC) network, aiming to provide a fast and reliable logistic service for product shipment and delivery, is becoming critical for online retailers. The location selection of this MLDCs for fast delivery and low logistics cost remains a challenging task due to two problems: a) how to accurately predict the customer demand distribution in a new DC network; b) how to effectively solve the large-scale MLDC site location selection problem given the sales distributions. We propose an iterative hierarchical optimization strategy for multi-level inter-connected DC network site selection.

4 - An Intelligent Production-distribution System for Perishable Products

Junming Liu, City University of Hong Kong, Hong Kong, 07102, Hong Kong, junmiliu@cityu.edu.hk, Yijun Wang

We develop a data-driven intelligent production-distribution system for perishable product retailers, aiming to minimize the long-term profit loss due to the stockouts and overstock. By collaborating with a leading perishable product retailer, we combine the detailed internal supply chain data and environmental factors. The system consists of two modules: an L-day ahead sales demand forecasting model based on a seq2seq deep learning model with store aggregation and environmental semantics, and 1-day ahead multi-product redistribution. We validate the system performance by comparing the profit loss with other baselines and the current system in the perishable product industry.

Experts, Opinions, and Forecasts

General Session

Chair: Jason R.W. Merrick, Virginia Commonwealth University, Richmond, VA, 23284, United States

Co-Chair: Yael Grushka-Cockayne, Harvard Business School, Boston, MA, 02163, United States

1 - Using Prediction Interval Skewness to Improve Forecast Accuracy

Yael Grushka-Cockayne, Harvard Business School, Boston, MA, United States, ygrushkacockayne@hbs.edu, Victor Jose, Jacob Rittich, Jack Soll

We examine how accuracy of the aggregate forecast can be improved when prediction intervals are considered. We show how implied skewness from the three elicited points can be used to combine forecasts. We propose an aggregation method that incorporate skewness to asymmetrically trim forecasts and study properties of this method on two data sets.

2 - Expert Selection Within a Single Judgment Problem

Asa Palley, Indiana University, Bloomington, IN, 47405, United States, Ville Satopaa, Jack Soll

Averaging point estimates from a select set of judges can provide a more accurate consensus estimate. We develop methodology to identify a high-performing set of judges within a single estimation task, without relying on past performance data. Judges' predictions of others are used as part of a customized criterion to identify this select crowd. The procedure identifies a set of judges who collectively hold a list of point estimates which happen to be accurate when averaged. In theory, our proposed aggregation procedure can extract the most accurate information from the crowd and provide a consensus estimate with greater accuracy than previously proposed methods.

3 - Forecast Combination with Multiple Models and Expert Correlations

Jason R. W. Merrick, Virginia Commonwealth University, Richmond, VA, 23284, United States, David Soule, Yael Grushka-Cockayne

A simple average of forecasts has been found to be robust despite theoretically superior combination methods. This is known as the forecast combination puzzle. We study the role of number of experts and expert correlation levels on the distribution of estimated weights and propose a new combination heuristic which reduces the impact of correlation estimation errors. This heuristic is shown to outperform a simple average on economic and experimental data.

1 - Pricing the Cloud: A QoS-based Decentralized Auction Platform

Yang Lu, PhD, Old Dominion University, Norfolk, VA, 29466, United States, ziiyuu@gmail.com

Cloud computing, providing computing resources as services, will have a major impact on the IT industry. How to price and allocate cloud resources to meet users' requirements is an important problem in both IT and business disciplines. Inspired from blockchain and economics, this study proposes a hybrid decentralized trading platform based on cloud QoS (Quality of Service). In this approach, cloud consumers place a bid on the computing resources based on the QoS preferences. An integration of QoS and blockchain technologies, enabling each user to invest and manage cloud resources.

2 - What YouTube Videos Really Tell You: Identity Economics Perspective

Jae Hoon Choi, University of Wisconsin Green Bay, Green Bay, WI, United States

Economics is not only about money, today. Noneconomic motives need to be studied as well. People behave based on the beliefs about who they are, and how they are supposed to behave, in every social context. Economic outcomes are established not only by pecuniary motives, but also by people's identities. YouTube is one of the most widely used platforms which allows users to share user-generated videos. It also allows users to add comments on those videos. This paper investigates a framework for incorporating social identities into standard economics models using YouTube content. This paper examines the effect of social identities, focusing on gender identity and ethnic identity, on economic behaviors.

3 - Comment Symbols: How Do You Deal with Them?

Tung Cu, Northeastern Illinois University, Chicago, IL, 17815, United States, Charletta F. Gutierrez

The study investigates how people use symbols embedded in comments as a community language to express their idea, attitude and perception to a certain topic. To this end, a research method is conducted to survey online members of common social media networking sites. The results show that while textual comments might expose user's sentiment, symbols not only exaggerate or reverse the comment meaning, but also reflect a new kind of linguistic gesture in online settings. The study offers some discussions and recommendations for business managers who want to better understand their customers.

4 - Modeling and Visualizing the Effects of Educational Advertising on Disengaged Hispanic Americans

Olivia Hernandez, Ohio State University, Columbus, OH, United States

Voter turnout among Hispanic Americans is low and falling. We study knowledge levels about major public policy facts among Hispanics and the empirical effects of educational advertising campaigns. Several visualizations are provided that indicate the scope of related challenges and the promise of outreach efforts for improving knowledge and attitudes.

5 - Investigation of Cookie Vulnerabilties

Marjani Peterson, Hampton University, Hampton, VA, 23669, United States, marjani.peterson@my.hamptonu.edu, Chutima Boonthum-Denecke

Cookies have emerged as one of the most convenient solutions to keep track of browsers. They continue to raise both security and privacy concerns due to their continuous evolution. There is limited support for confidentiality, integrity, and authentication in the way cookies are used. In this respect, the possibilities for misusing cookies are very real and are being exploited. Commonly used browsers have the ability to enable or disable cookies, or prompt the client to accept the cookies, or not. This paper will discuss the pros and cons of cookies as well as preferences of users based on survey results. This paper will discuss cookie vulnerabilities, ways to exploit them, and ways to mitigate them.

Information, Learning and Dynamic Resource Allocation

Sponsored: Applied Probability

Sponsored Session

Chair: Kuang Xu, Stanford Graduate School of Business, Stanford, CA, 94305, United States

1 - Kingman's Transform Method for Heavy-traffic Queues

Johan van Leeuwaarden, Eindhoven University of Technology, Eindhoven, Netherlands, j.s.h.v.leeuwaarden@TUE.nl

Heavy traffic limit theory deals with queues that operate close to criticality and face severe wait. Let W denote the stationary waiting time in the GI/G/1 queue. Kingman (1961) showed that an appropriately scaled W converges in distribution to an exponential random variable, as the queue approaches criticality. The original 1961 proof of this famous result uses the transform method, showing convergence of transforms, and hence weak convergence of the associated random variables. We apply and extend this transform method to obtain convergence of moments and refined approximations. We also demonstrate how the transform method can be applied to other heavy-traffic regimes and other queueing models.

2 - On the Learning Benefits of Resource Flexibility

Mihalis Markakis, IESE Business School, Avenida Pearson, 21, North Campus, T-402, Barcelona, 08034, Spain

Resource flexibility is known to provide firms facing demand uncertainty with such benefits as risk pooling, revenue-maximization optionality, and operational hedging. In this article we uncover a heretofore unknown benefit: we establish that resource flexibility mitigates censoring of sales data, and thereby facilitates learning the true demand under a variety of practical settings and demand distributions. Further, we quantify these learning benefits of flexibility and find them to be of the same order of magnitude as the extensively studied risk pooling benefits of flexibility.

3 - Deep Exploration in Reinforcement Learning via Randomized Value Functions

Daniel Russo, Columbia University, Kellogg School of Management, New York, NY, 60208, United States

We propose the use of randomized value functions to guide systematic exploration in reinforcement learning. This offers an elegant means for synthesizing statistically and computationally efficient exploration with common RL algorithms like temporal-difference learning, which produce parameterized value function estimates. We present several RL algorithms that leverage randomized value functions and demonstrate their efficacy through computational studies. I'll also discuss a new worst-case regret bound for these methods that establishes statistical efficiency with a tabular representation.

4 - Experimenting in Equilibrium

Stefan Wager, Stanford GSB, 655 Knight Way, Stanford, CA, 94305, United States

We study experimental design in large-scale stochastic systems with substantial uncertainty and structured cross-unit interference. We consider the problem of a platform that seeks to optimize supply-side payments p in a centralized marketplace where different suppliers interact via their effects on the overall supply-demand equilibrium and propose a class of local experimentation schemes that can be used to optimize these payments without perturbing the overall market equilibrium.

1 - Mean Field Equilibrium: Uniqueness, Existence, and Comparative Statics

Bar Light, Stanford, Stanford, Stanford, CA, United States, Gabriel Weintraub

The standard solution concept for stochastic games is Markov perfect equilibrium (MPE); however, its computation becomes intractable as the number of players increases. Instead, we consider mean field equilibrium (MFE) that has been popularized in the recent literature. MFE takes advantage of averaging effects in models with a large number of agents. We make three main contributions. First, our main result in the paper provides conditions that ensure the uniqueness of an MFE. Second, we generalize previous MFE existence results. Third, we provide general comparative statics results. We apply our results to dynamic oligopoly models commonly used in previous work.

2 - Near Optimal Control of a Ride-hailing Platform via Mirror Backpressure

Pengyu Qian, Columbia University-Graduate School of Business, Columbia Business School, New York, NY, 10027, United States, PQian20@gsb.columbia.edu, Yash Kanoria

Ride-hailing platforms need to match supply and demand so as to maximize payoff under the geographical flow constraints. We consider two platform control settings: joint entry-assignment (JEA) and joint pricing-assignment (JPA). We introduce a novel family of Mirror Backpressure (MBP) policies which are simple, practical, and do not require knowledge of the demand arrival rates. MBP generalizes Backpressure policy such that it executes mirror descent. MBP loses at most $O(K/T + 1/K)$ fraction of the achievable payoff in JEA and $O(\sqrt{(K/T + 1/K)})$ fraction in JPA, where K is the number of vehicles and T is the horizon. Simulation results in a realistic environment support our theoretical findings.

3 - Matching Supply and Demand with Mismatch-Sensitive Players

Mingliu Chen, Duke University, Durham, NC, 27560, United States, mingliu.chen@duke.edu

We study a matching problem using a novel method to characterize the mismatch. In particular, players' preferences are uniformly distributed on a circle so the mismatch between two players is characterized by the one-dimensional circular angle between them. This framework allows us to capture matching processes in applications ranging from ride sharing to job hunting. We provide an analytical framework for analyzing the matching model based on a limiting regime where overall customer arrival rates are high, and players demonstrate low tolerance towards mismatch. Our analysis reveals meaningful insights on market and matching design.

4 - Scrip Economies are Fair and Efficient

Artur Gorokh, Cornell University, Ithaca, NY, United States

We consider the problem of allocating multiple items dynamically between several agents without money, where the preferences of participants are fractionally subadditive (XOR), random and independent both in time and across agents. We investigate the properties of a particular simple mechanism: endowing participants with budgets of artificial currency and repeatedly running simultaneous first price auctions. In particular, we show that this mechanism can be viewed as approximately implementing Kalai-Smorodinsky bargaining outcome, as maxmin value of each agent is a 1/2 approximation of the ideal point of each agent.

Pricing Strategy and Games

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Li Chen, Cornell University, Ithaca, NY, 14853, United States

Co-Chair: Yao Cui, Cornell University, Ithaca, NY, 14853, United States

1 - Bundle Pricing of Congested Services

Chenguang (Allen) Wu, Hong Kong University of Science and Technology, HongKong University of Science and Technology, Clear Water Bay, 60208, Hong Kong, allenwu@ust.hk, Luyi Yang

Bundle pricing is commonly adopted by service firms managing multiple congestion-prone service facilities. Under bundle pricing, the firm charges a single price for all the services as a whole, and customers either purchase the bundle or do not purchase at all. This scheme is in contrast to a la carte pricing, under which the firm sets a separate price for each service, and customers can choose which service to purchase, if any. We explain when and how the prescriptive guidelines from the existing theory of bundling can be reversed in congested service settings.

2 - The Effect of Service Capacity on Price Competition and Customer Retention

Junhyun Bae, Cornell University, Ithaca, NY, 14850, United States, jb2258@cornell.edu, Li Chen, Yao Cui

We consider price competition between two firms who face a service capacity constraint in a market with experience-based customer switching cost. In our model, customers' purchase choices depend not only on price but also on service experience. We find that under-capacity mitigates price competition because customers are less likely to be locked in on either side. We also show that price decisions for both firms can be randomized when their capacity covers slightly less than the full market or slightly more than the full market. Our paper could explain a business phenomenon of active price promotion strategies in practice through the lens of operational/marketing frameworks combined.

3 - Not Every Game is Created Equal: The Impact of Variable Pricing on NFL Ticket Markets

Ovunc Yilmaz, University of Notre Dame, South Bend, IN, 46617, United States, oyilmaz@nd.edu, Alper Arslan, Necati Tereyagoglu

Although variable pricing is recommended to event organizers to respond to changing popularity across their events, the evidence documenting its impact on capacity utilization is much less present in the empirical revenue management literature. In this study, we study the effect of adopting variable pricing strategies on primary market sales using Difference in Differences approach on quasi-experimental data from the NFL. We elaborate on the mechanism behind the benefits of variable pricing by checking its implications on the resale market prices and volume.

4 - Bonus Competition in the Gig Economy

Xiaoyan Liu, Cornell University, Ithaca, NY, 14853, United States, Yao Cui, Li Chen

Service platforms in the gig economy commonly offer bonuses to independent service providers contingent on consistent participation. This paper studies the driving forces and implications of this bonus strategy. We analyze a model of two-sided platform competition in multi-periods. We find that platforms offer bonuses (i) when providers' willingness to participate is high and preference stickiness is low; (ii) when providers' willingness to participate is low. Platforms' bonuses are driven by their poaching incentives in case (i) and market expansion incentives in case (ii). Platforms will reduce bonuses under coordination, which improves platform profits and may not hurt social welfare.

5 - Optimal Design of the Platforms: Consumer Privacy Considerations

Ruslan Momot, Assistant Professor, HEC Paris, 78350, France, momot@hec.fr, Itay P. Fainmesser, Andrea Galeotti

We study an optimal design of a platform, users of which are concerned about their privacy. We build a stylized game-theoretic model in which users (i) experience direct utility from using the platform but also (ii) are susceptible to misuse of the information they reveal to the platform. The platform optimally chooses the information storage strategy and security level against user data leakage/misuse. We characterize optimal designs for the platforms of different types and derive corresponding levels of user activity and privacy.

Responsible Research in OM

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Christopher S Tang, University of California-Los Angeles, Los Angeles, CA, 90095-1481, United States

1 - Gender-based Operational Issues Arising from On-demand Ride-hailing Platforms: Safety Concerns, Service Systems, and Pricing and Wage Policy

Yulan Wang, Hong Kong Polytechnic University, Hong Kong, yulan.wang@polyu.edu.hk, Pengfei Guo, Christopher S. Tang, Yanli Tang

Motivated by the recent development of women only ride-hailing platforms that aim to address the safety concerns raised by female riders and drivers, we examine whether a platform such as Didi should offer gender-specific services instead of the current gender-neutral services. We make an initial attempt to examine if and when gender-specific services can enable the platform to address female safety concerns and improve its profitability. We pinpoint that a key obstacle for the platform to move to the dedicated system is the limited female labor size. The equal policy under which the platform has to impose the same price and wage on both the female and male subsystems further burdens the platform.

2 - Improving Rehab Bus Services in Hong Kong

Lucas P. Veelenturf, Eindhoven University of Technology, Eindhoven, Netherlands, l.p.veelenturf@tue.nl, Christopher S. Tang

Armed with 164 mini-buses, Rehabus offers a non-profit public service in Hong Kong that is affordable and welcome by persons with disabilities (PWDs) for their daily commuting trips to work or school. Currently, the demand far exceeds the supply. Some PWDs have been on the waiting list for years. In this research we investigate how Rehabus can serve more passengers without increasing the number of buses and drivers and without increasing the waiting and travel time of passengers too much. Several complicated real-life operational constraints which needs to be considered make this a challenging task, e.g. the capacity of the bus is twofold (wheelchair and regular places) and even flexible.

3 - Environmental Violations in China: Evaluation of Long-term Impact and Prediction of Future Violations

Chris K. Y. Lo, Hong Kong Polytechnic University, Hong Kong, Hong Kong, kwan.yu.lo@polyu.edu.hk, Christopher S. Tang, Paul Zhou

We take a business analytic approach to examine ways to reduce irresponsible environmental violations of Chinese manufacturers. First, we perform a descriptive analysis to examine the long-term impact of 1542 environmental incidents on a firm's Returns on Assets and other operational performance indicators and we found significant negative impacts in consecutive years "only after" the violations were exposed. We then develop a prediction model that exposes over 71% of the violations by inspecting only 21.5% of the firms with top 80 percentile in risk scores. We finally present a prescriptive inspection mechanism to promote responsible operations in global supply chain.

4 - Improving Consumer Welfare and Manufacturer Profit via Government Subsidy Programs: Subsidizing Consumers or Manufacturers?

Joey Jiayi Yu, PhD, Tsinghua University, Beijing, China, University of California, Berkeley, Berkeley, CA, United States

Most consumers in rural areas of many developing countries cannot afford to purchase certain livelihood improvement products such as home appliances. To improve consumer welfare and manufacturer profit, many governments launch different types of subsidy programs that offer subsidies to consumers, manufacturers, or both. Motivated by a subsidy program developed by the Chinese government in 2007, we present a parsimonious model to determine the optimal subsidy program in different settings so as to gain a better understanding about the conditions under which it is optimal for the government to subsidize consumers only, manufacturers only, or both.

1 - Assortment Optimization for Online Marketplaces

Antoine Desir, INSEAD, Paris, 75011, France, antoine.desir@insead.edu, Santiago Balseiro

We consider the assortment optimization problem faced by a platform (such as Amazon or Google Shopping) connecting sellers and consumers when sellers have private information about the products they sell. We design tractable mechanisms for the platform that truthfully elicit the sellers' private information while taking into account the externalities among displayed sellers in the assortment. In doing so, our work combines ideas from mechanism design with interdependent values and assortment optimization.

2 - Information Acquisition Costs in Matching Markets

Irene Lo, Stanford University, Palo Alto, CA, 94306, United States

The design of centralized matching markets often assumes that agents know their preferences. We provide a model of many-to-one matching in college admissions that formally accounts for information acquisition costs in preference formation and captures students' disutility from providing full preferences ex ante. Our main finding is that standard matching mechanisms are susceptible to reaching information deadlocks, where no information is acquired because every agent needs more information to know how to get information. Instead we emphasize the importance of additional sources of aggregate market information and provide simple mechanisms that implement approximately optimal outcomes.

3 - Dynamic Pricing with Unknown Non-parametric Demand and Limited Price Changes

Divya Singhvi, Massachusetts Institute of Technology, Cambridge, MA, United States, Georgia Perakis

We consider a dynamic pricing problem where the retailer has no knowledge of the demand curve and there is a cost on price experimentation. The retailer seeks to efficiently learn the demand curve and keep the cost of price experimentation low. We propose an optimistic-pessimistic approach for price experimenting and learning which is simple and mimics industry practice. We provide revenue regret and price change bounds that are near optimal. We also perform numerical simulations to show considerable improvements over other pricing methods.

4 - Optimizing Services in Retail Networks

Amandeep Singh, The Wharton School, Philadelphia, PA, 19104, United States, amansin@wharton.upenn.edu, Kenneth Moon, Gad Allon

We study how retail stores' multi-dimensioned service levels affect consumers' buying behavior in spatial markets. To this end, we propose the Double Block-Lasso BLP estimator under mild assumptions of structural stability and sparsity. Using the estimated influence structure, we highlight service quality interventions impacting consumers' buying patterns.

Advances in Service Operations

Sponsored: Manufacturing & Service Oper. Mgmt/Service Operations

Sponsored Session

Chair: Tarek Abdallah, Northwestern University

1 - Demand Visibility and Capacity Pooling Given Commitments

Pol Boada-Collado, Northwestern University, Evanston, IL, United States, boada.pol@u.northwestern.edu, Sunil Chopra, Karen Smilowitz

We study the value of limited demand visibility and capacity pooling, two hedging mechanisms against demand uncertainty, for signing capacity contracts with temporal commitment. Previous studies show that, without commitment, the two mechanisms are substitutes. We show that the commitment imposed across periods leads to new dynamics in which demand visibility and capacity pooling act as both substitutes and complements.

2 - Mechanism Design with Approximate Incentive Compatibility

Francisco Castro, Columbia University, Columbia School of Business, New York, NY, 10027, United States, Santiago Balseiro, Omar Besbes

We study the problem of selling an item to a buyer who might not accurately assess her utility from a transaction, and thus may make only near-optimal decisions. We consider the standard Myerson setting and, to capture that the buyer is not a perfect optimizer, we allow the incentive compatibility constraints to be satisfied up to . We establish a link between reporting strategies and a set of delayed differential equations that enable us to characterize the structure of the optimal selling mechanism. Our characterization features an unexpected phase transition. For =0, it is a posted price mechanism. However, for small , it requires randomization—a departure from the classic bang-bang solution.

3 - Demand Estimation under the Multinomial Logit Model from Sales Transaction Data

Tarek Abdallah, Northwestern University, Kellogg School of Management, Evanston, IL, 60614, United States, tarek.abdallah@kellogg.northwestern.edu, Gustavo J. Vulcano

We propose a method for computing maximum likelihood estimates for a multinomial logit model of demand from (incomplete) transactional data. The model is non-identifiable in general, but we characterize conditions under which this feature is overcome. The conditions rely on building a directed graph based on the input data and checking if it is strongly connected. We also discuss conditions under which the estimates are consistent. Our estimation proposal is based on a Maximize-Minorize (MM) algorithm that inherits the strongest convergence properties of this type of framework.

4 - Fitting Large-scale Mixture of Logit Models: A Convex Optimization Approach

Ashwin Venkataraman, UT Dallas, Dallas, TX, 02139, United States, Srikanth Jagabathula, Lakshminarayanan Subramanian

A key challenge in estimating mixture models is that the mixing distribution is often unknown and imposing apriori parametric assumptions can lead to model misspecification issues. We propose a new methodology for nonparametric estimation of the mixing distribution. We formulate the likelihood-based estimation problem as a constrained convex program and our key contribution is applying the conditional gradient (aka Frank-Wolfe) algorithm to solve this convex program, showing that it iteratively generates the support of the mixing distribution. We show that our estimator is robust to different ground-truth mixing distributions and outperforms the EM benchmark in two case studies on real data.

1 - Electricity Pricing with Limited Consumer Response

Fariba F. Mamaghani, University of Texas at Dallas, Dallas, TX, United States, fxf150430@utdallas.edu, Saed Alizamir, Shouqiang Wang

We construct a demand model to describe how rationally inattentive consumers make consumption decisions in response to their ambient environment for a given price and how firms take advantage of it to optimize their profit. Subsequently, we investigate implication of monopolistic firm's pricing decision on social welfare and system reliability.

2 - Managing EV Charging Stations

Li Chen, National University of Singapore, Singapore, chen_l@u.nus.edu, Long He, Yangfang Zhou

We consider the charging of electrical vehicles in a charging station with uncertain arrival and departure times and charging quantity to minimize the total expected costs. We formulate the problem as a steady-state stochastic program (SP) incorporating these uncertainties with an electricity tariff including demand charge. To solve the large-scale SP, we develop exponential cone program approximations (ECP-U and ECP-C respectively for uncapacitated and capacitated charging station). We provide a theoretical performance guarantee for ECP-U and show better numerical performance of ECP-C compared with other approaches on real data set and offer managerial insights via sensitivity analysis.

3 - Collaborative Vehicle-to-grid Operations in Electricity Regulation Markets

Ho-Yin Mak, University of Oxford, Park End Street, Oxford, OX1 1HP, United Kingdom, ho-yin.mak@sbs.ox.ac.uk

We study the problem of electric vehicles (EVs) providing regulation services to the grid, coordinated by a vehicle-to-grid platform. We model the platform's problem as a bilevel program: At the upper level, the platform varies price incentives to procure capacity from EVs and determines capacity bids in the regulation market; At the lower level, individual drivers optimize travel and charging schedules in response to pricing incentives. To account for uncertainties and heterogeneity in regulation market prices and travel patterns, we make use of distributionally-robust optimization techniques to obtain a tractable convex optimization formulation for the problem.

4 - Net-metered Distributed Renewable Energy: A Peril for Utilities?

Nur Sunar, UNC, Chapel Hill, NC, 27517, United States, nur_sunar@kenan-flagler.unc.edu, Jayashankar M. Swaminathan

Electricity end-users have been increasingly generating their own electricity via rooftop solar panels. Our paper studies the implications of such "distributed renewable energy" for utility profits under net metering that has sparked heated debates in practice. Our analysis shows that in contrast to the common belief in practice, the presence of net-metered distributed renewable energy can result in strictly larger expected profit for utilities when wholesale market dynamics are factored in. Using data for distributed solar energy in California and the CAISO's wholesale electricity market, we demonstrate that our results are valid when the parameters are set to realistic values.

1 - Supply Chain Coordination and Transparency for On-time Delivery

Elisabeth Paulson, MIT, 1164 Smithfield Street, Cambridge, MA, 16801, United States, epaulson@mit.edu

This work explores how supply chain visibility and coordination can be used to increase on-time delivery of perishable gods from suppliers to retailers. We consider a supply chain consisting of two independent retailers who source substitutable items from two suppliers. The suppliers strategically choose order fulfillment schedules, which may consist of early/late deliveries. We find that a coordinated setting—where the suppliers cooperate to fulfill orders or share complete information with the retailers—can improve on-time delivery significantly while decreasing suppliers' costs. A more realistic setting with partial visibility can achieve most of the gains of the coordinated setting.

2 - Artificial Shortage in Agricultural Supply Chains

Yanchong Zheng, Massachusetts Institute of Technology, Sloan School of Management, Cambridge, MA, 02139, United States, Retsef Levi, Somya Singhvi

Artificial shortages that lead to exorbitant increase in retail prices of essential commodities despite inventory availability is a matter of great concern for the governments, who employ a range of strategies to mitigate this phenomenon and its impact. This work develops analytical models to capture the dynamics of artificial shortages and impact of government interventions on consumer behavior and market prices. We validate our models using retail price data from India and highlight that to be effective, interventions need to be carefully designed while taking potential strategic responses of other players into account.

3 - Increasing Farmers' Income in Agricultural Markets: Evidence from a Field Implementation

Somya Singhvi, MIT, Cambridge, MA, 02139, United States, ssinghvi@mit.edu, Retsef Levi, Yanchong Zheng, Manoj Rajan

Lack of competition in agricultural markets has led to poor outcomes for farmers in many developing countries. In this work, we collaborate with the state government of Karnataka to implement an updated two-stage auction on their Unified Market Platform (UMP). The design was launched in February 2019, and more than 9000 lots worth $6 million USD have been traded through the new design so far. Using a Difference-in-Differences approach, we estimate significant positive gains from the new design. A combination of field surveys and an analytical behavioral model allow us to test and validate various behavioral factors that may help explain the results.

4 - Supply Chain Analytics Guiding Food Inspections

Nicholas J. Renegar, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, renegar@mit.edu

In this talk, we describe how analytics can provide major regulatory insights regarding supply chain sources of adulteration, risk-based regulatory resource allocation and regulatory enforcement. The work is based on unique integrated database of publically available CFDA food inspections results, as well as additional publically available databases. It leverages text analytics, machine learning, supply chain analysis and technical analysis of adulterants.

Commodity and Energy Risk

Sponsored: Manufacturing & Service Oper. Mgmt/iFORM

Sponsored Session

Chair: Nicola Secomandi, Carnegie Mellon University, Pittsburgh, PA, 15213, United States

1 - Strategic Forward Trading and Technology

Heikki Peura, Imperial College Business School, South Kensington Campus, London, SW7 2AZ, United Kingdom, Derek W. Bunn

Additional wind power is expected to reduce power prices by displacing incumbent gas generators by virtue of its lower production costs. We revisit this so-called merit-order effect of renewables, accounting for operational factors such as wind intermittency. Analysing a spot-forward market with imperfect competition, we find that intermittency may cause producers to behave less aggressively in forward trading for fear of unfavorable spot-market positions. Equilibrium prices may then paradoxically increase with more wind power, even though both renewables and forward trading are separately viewed as pro-competitive.

2 - An Alternating Direction Method of Multipliers Approach to Pathwise Optimization in Merchant Energy Production

Bo Yang, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, Selvaprabu Nadarajah, Nicola Secomandi

Pathwise optimization (PO) is an approximate dynamic programming approach that has been successfully applied to intractable Markov decision processes that arise in merchant energy production and related optimal stopping contexts. The difficulty of solving its underlying large-scale linear program currently limits its practical applicability. We address this issue by developing an alternating direction method of multipliers algorithm with improved computational complexity relative to a state of the art method. Our technique increases by a factor of 1.5 the size of instances that PO can handle.

3 - Estimating Dynamic Conditional Spread Densities to Optimize Daily Storage Trading of Electricity

Derek Bunn, London Business School, London, United Kingdom, Ekaterina Abramova

This paper formulates dynamic density functions, based upon skewed-t and similar representations, to model and forecast electricity price spreads between different hours of the day. This supports an optimal day ahead storage and discharge schedule, facilitating a trading strategy for a merchant arbitrage facility. The four latent moments of the density functions are dynamic and conditional upon exogenous drivers, permitting the mean, variance, skewness and kurtosis of the densities to respond hourly to weather and demand forecasts. Analytical properties allow the calculation of risk associated with the spread arbitrages.

4 - Optimization of Option Exercise Policies in Incomplete Markets with Quadratic Hedging

Nicola Secomandi, Carnegie Mellon University, Tepper School of Business, Pittsburgh, PA, 15213, United States

Quadratic hedging is a practically appealing approach for approximately replicating the random payoffs of European options in incomplete markets. This work extends this methodology to the case of Bermudan options, for which an exercise policy needs to be optimized. The resulting optimal option exercise policies are in general time inconsistent. Time consistent option exercise policies can be optimized recursively. The proposed approach is relevant to both financial and real options.

Structuring Decisions for Analysis and Evaluation

Sponsored: Decision Analysis

Sponsored Session

Chair: Ralph L. Keeney, Duke University, San Francisco, CA, 94111, United States

1 - Structuring Decisions using Mental Models

James S. Dyer, The University of Texas at Austin, Austin, TX, United States, Saurabh Bansal

Management decisions are often based on the consideration of a number of factors or attributes that seem relevant to the decision. A manager may subjectively consider these factors and then make a decision based on a cognitive understanding of these factors that we call a mental model. We discuss how a more formal approach to decision making based on formally recognizing these mental models and making them explicit can improve decision making.

2 - Partitioning the Value of Countermeasure Deployment: Estimating the Expected Value of Deterrence

Richard S. John, Professor, University of Southern California, Dept of Psychology MC 1061, Los Angeles, CA, 90089-1061, United States, richardj@usc.edu, Nicholas Scurich

I describe a methodology for adapting Defender-Attacker Decision Trees (DADTs) to partition the value of adversary countermeasures into three components: Threat reduction (deterrence), vulnerability reduction, and consequence mitigation. The Expected Value of Imperfect Control (EVIC) can be partitioned into three non-additive components: Expected Value of Imperfect Deterrence (EVID), Expected Value of Vulnerability Reduction (EVVR), and Expected Value of Consequence Mitigation (EVCM). I provide an example DT and calculation for deploying dogs at airport passenger screening checkpoints that illustrates overlap among the three components and the problem of double counting.

3 - The Relative Benefits of Pursuing Decision Opportunities and Decision Problems

Johannes Ulrich Siebert, Profersson, Management Center Innsbruck, Universitaetsstr 15, Innsbruck, 6020, Austria, Christian Hannes, Rüdiger von Nitzsch

Decision situations are usually called and faced as decision problems. Most of the decision-theoretic methods contribute to solving these “problems”. Keeney argues that decision makers who are “solving problems” only restore the situation to how it was before and suggests proactively creating decision opportunities to improve the quality of life. In our study, we analyzed individual decision situations and gathered empirical evidence about the relative consequences of addressing decision problem and decision opportunities.

4 - Constructing a Decision Frame for Analysis and Evaluation

Ralph L. Keeney, Duke University, Durham, NC, United States, KeeneyR@aol.com

Constructing a decision frame provides an unambiguous and complete description of the decision to be made. It begins with a statement of the decision, which provides a guideline for identifying the relevant objectives to be achieved and a full set of alternatives for this decision. Procedures are described to efficiently and thoroughly create the objectives and alternatives that are the foundation for analysis and evaluation.

Junior Researcher Best Paper Award

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Serpil Sayin, Koc University, Istanbul, 34450, Turkey

1 - Quadratic Scalarization for Decomposed Multiobjective Optimization

Brian Dandurand, Argonne National Laboratory, Lemont, IL, 60439, United States, Margaret M. Wiecek

For nonconvex multiobjective optimization problems (MOPs), linear scalarization methods can fail to support the entire Pareto efficient set. A quadratic scalarization method (QSM) is developed as a solution approach which preserves decomposable structures of the MOP and avoids introducing a high degree of nonlinearity and additional nonsmoothness. Under mild assumptions, necessary and sufficient conditions for QSM-generated solutions to be local weakly and properly efficient for an MOP are developed. QSM is shown to correspond with the relaxed, reformulated weighted-Chebyshev method as a special case. An example is provided for demonstrating the application of QSM to a nonconvex MOP.

2 - Heuristics for Prioritizing Pair-wise Elicitation Questions with Additive Multi-attribute Value Models

Milosz Kadzinski, Poznan University of Technology, Poznan, 60-965, Poland

Indirect techniques that employ pair-wise questions are commonly used for lowering the Decision Maker’s effort related to the elicitation of additive value models. We develop heuristics for prioritizing such questions based on the outcomes of robustness analysis with the aim of minimizing the number of answers required for ranking the alternatives. Extensive numerical experiments allow us to identify a subset of heuristics that score well on different metrics in a variety of problem settings. This conclusion was validated in a real-world experiment where 101 subjects answered pair-wise questions to rank 10 mobile phone packages evaluated in terms of 4 criteria.

3 - Trade-off Preservation in Inverse Multi-objective Convex Optimization

Taewoo Lee, University of Houston, Houston, TX, 77204-4008, United States

Given an input solution that may not be Pareto optimal, we present a new inverse optimization methodology for multi-objective convex optimization that determines a weight vector producing a weakly Pareto optimal solution that preserves the decision maker’s trade-off intention encoded in the input solution. We introduce a notion of trade-off preservation, which we use as a measure of similarity for approximating the input solution and show its connection with minimizing an optimality gap. We also show that our model encompasses many of the existing inverse optimization models. We demonstrate the proposed method in cancer therapy applications.

CC- Room 401

Joint Session Interface of M&O/Practice Curated: Game Theory for Marketing-Operations Interface II

Emerging Topic: Interface of Marketing & Operations

Emerging Topic Session

Chair: Tinglong Dai, Johns Hopkins University, Baltimore, MD, 21202, United States

1 - Wage Transparency and Social Comparison in Salesforce Compensation

Xiaoyang Long, University of Wisconsin-Madison, Wisconsin School of Business, Madison, WI, 53706, United States, xiaoyang.long@wisc.edu, Javad Nasiry

When wages are transparent, sales agents may compare their pay with that of their peers and experience positive or negative feelings if those peers are paid (respectively) less or more. We investigate the implications of such social comparisons on sales agents' effort decisions and their incentives to help or collaborate with each other. We then characterize the firm's optimal salesforce compensation scheme and the conditions under which wage transparency benefits the firm.

2 - Dynamic Salesforce Incentives with Inventory Considerations

Olivier J. Rubel, UC Davis Graduate School of Management, Davis, CA, 95616, United States

We propose a dynamic principal-agent model where the agent sells a product, while the principal manages its rate of production, its price, as well as the agent's compensation plan. We characterize the optimal strategies that dynamically stabilize the firm's operations.

3 - Assign the Right Person or Train Them to Do the Right Task: A Model of Key Account Manager

Ying Yang, University of Iowa, Iowa City, IA, United States, ying-yang@uiowa.edu

By an information-theoretic model of the Key Account Manager (KAM), we found out that the success of key account selling depends on two important responsibilities of the key account manager: assigning the right specialist and training them to do the right task. Both are necessary conditions for a happy customer and thus a sale. Interestingly, the interaction between the team members' incentives causes the KAM to double reverse strategic choices between exceptional assigning and training. When there is a conflict of interest between the team and the firm, a managerial recommendation to the firm is to mitigate the conflict by compensating the specialists rather than the KAM.

4 - Service Design under Acclimation and Non-homogeneous Memory Decay

Tinglong Dai, Johns Hopkins University, Baltimore, MD, 21202, United States, dai@jhu.edu, Yifu Li, Xiangtong Qi

We study the optimal sequencing and selection of activities a service package comprises to creating memorable, delightful customer experiences. Prior theoretic literature, however, suggests that the peak activity should be scheduled either at the beginning or the end, contradicting empirical evidence of "interior peaks." Our paper bridges the gap in the literature and lends theoretic support to empirical findings. We also analyze the problem of activity selection and show it can be optimal to choose a portfolio of activities with either the highest or lowest utility values, but not those with medium utility values.

Best Service Science Paper I

Sponsored: Service Science

Sponsored Session

Chair: Ming-Hui Huang, National Taiwan University, Taipei, 10617, Taiwan

1 - Multi-objective Optimization for Political Districting: A Scalable Multilevel Approach

Sheldon H. Jacobson, University of Illinois, Dept. of Computer Science, Urbana, IL, 61801-2302, United States, shj@illinois.edu, Rahul Swamy, Douglas M. King

The notion of fairness in political districting has been an important topic of subjective debate, with district maps having consequences to multiple stakeholders. This paper introduces optimization models for districting with political fairness criteria. The criteria considered are based on fundamental fairness principles such as vote-seat proportionality (efficiency gap), partisan (a)symmetry, and competitiveness. The results demonstrate that district plans constituting the Pareto-front are equitable, symmetric, competitive, and compact, and that a multi-objective approach is integral to paving the way towards a holistic districting process that addresses all the stakeholders.

2 - Service Design of Non-profits that Serve Distressed Individuals

Priyank Arora, University of Massachusetts-Amherst, Amherst, MA, United States, parora@isenberg.umass.edu, Morvarid Rahmani, Karthik Ramachandran

Non-profit organizations that serve distressed individuals are driven to not only offer a variety of services, but also engage in advisory activities to minimize mismatches between services clients receive and their true needs. We study the portfolio and service design problem for resource-constrained NPOs that aim to maximize their impact.

3 - When Transparency Fails: Bias and Financial Incentives in Ridesharing Platforms

Christopher Dalton Parker, Pennsylvania State University, University Park, PA, United States, Jorge Mejia

Previous research documents racial/gender biases by drivers for ridesharing platforms. Firms removed riders' names and pictures from the ride request presented to drivers in an attempt to reduce this bias. Our primary research question is whether this change has indeed removed the biases. We investigate this through a large field experiment on a major ridesharing platform in Washington, DC. Racial and LGBT biases are persistent, while we find no evidence of gender biases. Peak times moderate (through increased pay) rather than exacerbate (by allowing drivers to be more selective) these biases for non-caucasian riders. We do not find a similar moderating effect for supporters of the LGBT community.

4 - Detecting Customer Trends for Optimal Promotion Targeting

Lennart Baardman, University of Michigan, Ann Arbor, MI, United States, baardman@umich.edu, Setareh Borjian Boroujeni, Tamar Cohen-Hillel, Kiran V. Panchamgam, Georgia Perakis

Detecting trends in fashion can help retailers determine effective personalized promotion plans more easily. Social media data is valuable in understanding these trends, but it is often unavailable. We introduce a personalized demand model that captures customer trends from transaction data instead. We base our efficient estimation method on instrumental variables, which allows us to draw causal inference on the effects that targeted promotions have. The promotion targeting problem is NP-hard to solve, so we develop an efficient and provably-good greedy approach. Finally, with real fashion retail data, we estimate our customer trend model and test the promotion targeting algorithm.

5 - Heuristic Thinking in Patient Care

Diwas S. KC, Emory University, Goizueta Business School, Atlanta, GA, 30322, United States

We study heuristic thinking in the patient discharge decision at acute care hospitals. Determining a patient's suitability for discharge is cognitively taxing. We postulate that bounded rationality leads the care provider to substitute clinical readiness for discharge - a more cognitively complex attribute, with a more easily accessible heuristic.

6 - The Spillover Effects of Employee-customer Interactions: Field Evidence from an Online Education Platform

Dennis Zhang, Washington University in St Louis, St Louis, MO, 63130, United States, denniszhang@wustl.edu, Hengchen Dai

Maintaining productivity and service quality across employee-customer interactions has important implications for business. How does a single employee-customer interaction, particularly an interaction in which the customer underappreciates the employee's effort and time, influence the employee's effort provision the next time she interacts with a different customer? We address this question using a large-scale dataset recording interactions between teachers and their students on an online education platform.

Service Customer

Contributed Session

Chair: Jiangning He, Shanghai University of Finance and Economics

1 - Service Commitment and Customers Response: An Empirical Study on Effects of Delivery Lead Time Commitment on Online Ratings

Ho Cheung Brian Lee, University of Massachusetts-Lowell, Lowell, MA, United States, brian_lee@uml.edu, Nichalin S. Summerfield, Amit Deokar, Ali Ahmed

Service commitment is a commonly used operational strategy to attract customers. While the literature has reported the advantages of service commitment, its impact on the online word of mouth of a firm remains unexplored. We examine how the online rating behavior may be influenced by the delivery lead time and promised delivery date for online orders. This study shows that the service commitment reduces the customers' rating participation propensity and online customer ratings as they may be affected by the changes in customers's pre-purchase expectation.

2 - A Consumer Perspective on Blockchain Technology in Shared Mobility Services

Christopher Grossmann, EBS Universitaet fuer Wirtschaft und Recht, Wiesbaden, Germany, christopher.grossmann@ebs.edu, Katrin Merfeld

While traditionally OEMs relied on permanent vehicle acquisition, peer-to-peer sharing services now empower consumers to offer mobility as a service. However, many consumers are still reluctant to use shared services, and respective insights remain scarce. One approach to overcome those hurdles is the implementation of blockchain technology. Still, it is questionable whether in shared mobility services the technology creates consumer-perceived value. This paper provides an overview of the literature, business cases, and applies the means-end chain approach to qualitatively elicit consumers' motivational structures towards blockchain technology in peer-to-peer sharing.

3 - Mining Consumer Involvement to Improve Mobile App Recommendation

Jiangning He, Assistant Professor, Shanghai University of Finance and Economics, Shanghai, China, he.jiangning@sufe.edu.cn, Fang Xiao, Hongyan Liu

Given the ubiquitous role of mobile apps in people's lives as well as the sheer size of the mobile app market, developing effective mobile app recommendation methods is critical for both mobile app users and platforms. Premised in involvement theory, we propose a novel mobile app recommendation method that integrates both download and browsing behaviors to learn users' overall interests in and involvement with apps, in contrast to existing methods that rely on download behaviors but neglect browsing behaviors. Our experimental results based on a real large mobile app dataset demonstrate the superior performance of our method over several state-of-the-art mobile app recommendation methods.

4 - Reevaluating Order Fulfillment Plans in Real Time in an Online Retail Environment

Matthew Petering, University of Wisconsin-Milwaukee, Milwaukee, WI, United States, mattpete@uwm.edu, Amir Kalantari

We use discrete event simulation and optimization to compare options for automatically assigning and reassigning the orders placed with an online retailer to the retailer's fulfillment centers. We show that online retailers can significantly reduce total shipping costs by intelligently reevaluating their order fulfillment plans.

Operational Issues in Service Economy

Sponsored: Service Science

Sponsored Session

Chair: Rakesh Reddy Mallipeddi, Texas A&M University, College Station, TX, 77843-4217, United States

1 - Safety Stock Allocation in Online Retailing Network under Demand Uncertainty and Lost Sales

Mayukh Majumdar, Texas A&M University, College Station, TX, United States, Chelliah Sriskandarajah, Anupam Agrawal

It is a challenge for online retailers to balance the trade-off between expensive transshipment and safety stocks to fulfill customer demand on time. We examine the allocation of safety stocks in a large online retailing network consisting of several fulfillment centers with an objective to minimize the total cost composed of transportation, inventory holding, and lost sales. We formulate a stochastic optimization model under a periodic-review inventory system with demand uncertainty and analyze a large and complex network. This work generates valuable insights and provides an easy-to-implement procedure to allocate safety stocks.

2 - The Impact of Collaboration in Cross-docking Supply Chains

Seulchan Lee, Mays Business School, College Station, TX, United States, slee@mays.tamu.edu, Alexandar Angelus, Chelliah Sriskandarajah

The recent increase in the shipment frequency with small load sizes in distribution logistics has motivated many logistics service providers to collaborate with their partners. An increasing number of supply chain networks with cross-docking function explores opportunities to enhance collaboration at successive stages (i.e., vertical collaborations), or at the same stage within the distribution channels (i.e., horizontal collaborations). We provide an optimization framework and analyze the properties of optimization models in order to derive implications of vertical and horizontal collaborations in scheduling inbound and outbound shipments in the three-stage supply chain.

3 - Dynamics in Ethical Decision Making

Xingzhi Jia, Mays Business School, Wehner Building, College Station, TX, 77843, United States, xjia@mays.tamu.edu, Xenophon Koufteros

We investigate ethical decision-making and examine the dynamics between consecutive decisions that invoke ethical considerations in supply management. Instead of focusing on individual instances of ethical decision-making, we investigate an individual's ethical decision-making behaviors in the long term (10 decisions over 10 weeks) via a stochastic process methodology.

4 - Capacity Planning for Ambulatory Surgery Centers: A Bottom-up Strategy Based on Optimization Combined with Data Analytics

Seokjun Youn, The University of Arizona, Tucson, AZ, 77840-4217, United States, syoun@email.arizona.edu, Harry Neil Geismar, Chelliah Sriskandarajah, Vikram Tiwari

Timely capacity adjustment is essential for the surgery center planners, but the related research is limited. In contrast to the traditional top-down approach to capacity planning, our approach proposes a bottom-up strategy based on optimization methods combined with analytics that are informed by operational-level archival patient flow data. We develop mathematical formulations and algorithms based on scheduling theory to derive the most cost-efficient capacity solution for the multi-stage structure of surgery centers. In the computational study, we further show how uncertain business parameters can affect capacity planning decisions.

Advances in Auction Design

Sponsored: Auction and Market Design

Sponsored Session

Chair: Benjamin Lubin, Boston University, Boston, MA, 02215, United States

Co-Chair: Sven Seuken, University of Zurich, Zurich, 8050, Switzerland

1 - Cloud Pricing: The Spot Market Strikes Back

Ludwig Dierks, University of Zurich, Binzmÿhlestrasse 14, Zurich, Switzerland, Sven Seuken

Cloud computing providers must constantly hold many idle compute instances available. A natural idea to increase profits is to sell these idle instances on a secondary market, for example, via a preemptible spot market. However, this ignores possible ``market cannibalization” effects that may occur in equilibrium as well as the additional costs the provider experiences due to preemptions. To study the viability of secondary markets, we combine queuing theory and game theory. Our main result is an easy-to-check condition under which a provider can achieve a profit increase and create a Pareto improvement for the users by offering a spot market (using idle resources) alongside a fixed-price market.

2 - Testing Dynamic Incentive Compatibility in Display Ad Auctions

Sébastien Lahaie, Google Research, New York, NY, United States, Yuan Deng

This paper develops statistical tests that a bidder in a display ad auction can use to confirm whether the underlying auction mechanism is dynamically incentive compatible (IC), so that truthful bidding in each individual auction and across time is an optimal strategy. We characterize dynamic mechanisms that are dynamic-IC for all possible time-discounting factors according to two intuitive conditions, which motivate two separate tests: the mechanism should be IC at each stage, and expected present utility should be independent of past bids. We evaluate the tests on display ad data from a major ad exchange.

3 - Deep Learning-powered Iterative Combinatorial Auctions

Jakob Weissteiner, University of Zurich, Zurich, Switzerland, Stefania Ionescu, Nils Olberg, Sven Seuken

We study the design of machine learning-powered iterative combinatorial auctions (ICAs). We build on Brero et al., who have successfully integrated support vector regression (SVRs) into the preference elicitation algorithm of an ICA. However, with expressive kernels, the winner determination problem (WDP) cannot be solved for large domains. We address this shortcoming by using deep neural networks (DNNs) instead of SVRs. We show that the resulting maximization step of DNNs with ReLu activations can be reformulated into a MILP and solved efficiently. First simulation results indicate that even small DNNs outperform SVRs with expressive kernels.

4 - Parametric Mechanism Design under Uncertainty

Enrique Areyan, Brown Univeristy, Providence, RI, United States, enrique_areyanviqueira@brown.edu

We introduce a methodology for the design of multiagent systems inhabited by strategic agents. We assume agents play approximate equilibria, which we estimate using the probably approximately correct learning framework. Under this assumption, we learn approximately optimal mechanism parameters. We do this theoretically, assuming a finite design space, and heuristically, using Bayesian optimization (BO). Our BO algorithm incorporates noise associated with modern concentration inequalities, such as Hoeffding's, into the underlying Gaussian process. We show experimentally that our search techniques outperform standard baselines in a stylized but rich model of advertisement exchanges.

5 - Online Learning for Measuring Incentive Compatibility in Ad Auctions

Zhe Feng, Harvard University, Cambridge, MA, 02138, United States, zhe_feng@g.harvard.edu, Okke Schrijvers, Eric Sodomka

In this paper we investigate the problem of measuring end-to-end Incentive Compatibility (IC) regret given black-box access to an auction mechanism. Our goal is to 1) compute an estimate for IC regret in an auction, 2) provide a measure of certainty around the estimate of IC regret, and 3) minimize the time it takes to arrive at an accurate estimate. We consider two main problems: In the advertiser problem the goal is to measure IC regret for some known valuation v, while in demand-side platform (DSP) problem we wish to determine the worst-case IC regret over all possible valuations. The problems are naturally phrased in an online learning model and we design Regret−UCB algorithms for both problems.

Health Care, Modeling and Optimization II

Contributed Session

Chair: Iqra Ejaz, Texas A&M University, College Station, TX, 77843, United States

1 - Optimizing the Continuum of HIV Care in Vancouver, Canada

Alexander R. Rutherford, Simon Fraser University, Burnaby, BC, Canada, arruther@sfu.ca, Benny Wai, Sarah Kok, Reka Gustafson, Rolando Barrios, Krisztina Vasarhelyi

A combined systems dynamics and compartmental epidemiological model was developed for the continuum of HIV care in Vancouver, Canada, as part of a long-term collaboration to improve quality of care and reduce new infections under health care cost constraints. The model captures testing, treatment, engagement in care, and retention in care for men who have sex with men, injection drug users, sex workers, and the general population. Model optimizations were performed to identify strategies for reducing HIV incidence, morbidity, and mortality. Key recommendations include expanding routine HIV testing in acute care settings and focusing intensive case management to injection drug users.

2 - Preferred Post-acute Provider Network: An Approach to Improve Care Coordination in Healthcare Continuum

Ineen Sultana, Texas A&M University, College Station, TX, United States, ineensultana@tamu.edu, Lewis Ntaimo, Mark Lawley

Post-acute care (PAC) provides treatment for critical patients following hospital discharge to further improve patient outcomes. To ensure availability of PAC, an effective care coordination from acute care facilities (ACF) to PAC facilities is a long due necessity. Building a Preferred Post-Acute Network (PPN), which involves a contract agreement between ACF and PAC, can strengthen this care coordination. The aim of this study is to develop strategic agreement decisions and resource adjustment planning to form a PPN. In this study, a two-stage stochastic mixed integer model is proposed to optimize the decision features of PPN formation considering uncertainty in resources and patient demand.

3 - Sepsis Patient Hospitalizations from Home Health Care – Risk Models, Early Identification and Care

Jakka Sairamesh, CEO and President, CapsicoHealth, Inc, San Francisco, CA, United States, ramesh@capsicohealth.com, William Stein-III, Laurent Hasson, Arun Villivalam

Sepsis care costs CMS (Center for Medicare and Medicaid) 14 Billion per year for Medicare patients. Over 1 in 10 Sepsis patients are hospitalized yearly, and over 24.5% hospitalized from home health care within the first 30-days of home care. Our studies have shown 20% hospitalization rates within the first 7-days of home health care when considering all Sepsis hospitalizations from home care. Our data includes several million Medicare claims from 2016-Q1 to 2018-Q1. Our risk prediction models show a ROC of 0.81. Factors include comorbidities, age, previous hospitalizations and utilization. Early identification will help reduce 7-day hospitalizations during the early phase of home health care.

4 - A Decomposition Method for the Dynamic Home Health Care Routing and Scheduling Problem

Florian Grenouilleau, PhD Candidate, Ecole Polytechnique de Montreal, Montreal, QC, Canada, florian.grenouilleau@cirrelt.net, Nadia Lahrichi, Louis-Martin Rousseau

Due to the aging of the population, the demand in home health care services have greatly increased during the past decade. In order to manage this demand, an improvement of the resources utilization is necessary. In this work, we are interested in the dynamic home health care routing and scheduling problem. The objective here is to develop a decomposition method based on scenarios in order to dynamically accept and schedule new patients in the system while conserving a high quality of service for existing patients.

5 - A Multilevel Cost-saving Modeling of Accountable Care Organizations

Jiajia Qu, University at Buffalo, SUNY, Buffalo, NY, United States, Jiajiaqu@buffalo.edu, Meiling Jiang, Raj Sharman, Sanjukta Smith, Pamella Howell, Chet Fox

This paper proposed a decision-making modeling of Accountable Care Organizations, a new system of care and payment to tie the high-quality care to the reimbursement for providers. The primary goal is to help ACOs to structure incentive and intervention scheme to achieve their long-term sustainability from shared savings. With a multi-level nonlinear programming model capturing the interplay among multiple tiers, we develop several in-depth insights. First, we show the optimal intervention effort for physicians to intervene to mold patient behavior, to achieve highest the physician's surplus. Second, we discuss the optimal incentivize schemes to help ACO achieve cost-efficient.

6 - Effects of Nested Interruptions Experienced by Intensive Care Nurses on System Stability

Iqra Ejaz, Texas A&M University, College Station, TX, United States, Natarajan Gautam, Farzan Sasangohar, Mark Lawley

We develop an analytical model for nested interruptions experienced by intensive care nurses. Stability conditions and performance measures are derived for the system.

Tutorial: The Fulfillment-Optimization Problem

Emerging Topic: Tutorials

Emerging Topic Session

1 - The Fulfillment-Optimization Problem

Vivek Farias, MIT, Cambridge, MA, 02142, United States, Jason Acimovic

This tutorial studies the fulfillment-optimization problem, a key optimization problem facing retailers who fulfill online customer orders using inventory that might be distributed across multiple supply nodes, which for omni-channel retailers may include the entire store network in addition to distribution centers. This tutorial formulates and studies the fulfillment optimization problem as an online optimization problem. The first approach we study to solving this problem is similar in spirit to LP-based bid price approaches to network revenue management. The second approach relies on an algorithm based on the primal-dual schema. The approaches are complementary; the first is suitable in a regime where the demand for products is relatively predictable, whereas the latter is applicable to settings where such predictability is not available. In both cases we describe the practical impact of these solutions at real-world retailers. Finally, we discuss outstanding unsolved problems in the area that we believe can have significant impact on practice.

Co-Chair: James P. Howard, Johns Hopkins Applied Physics Laboratory, Columbia, MD, 21045, United States

1 - Analytical Modeling of Stochastic Systems

Roger Chapman Burk, Associate Professor, United States Military Academy, Department of Systems Engineering, Bldg., West Point, NY, 10996-1779, United States, roger.burk@westpoint.edu

This presentation to promotes the modeling with analytical models rather than discrete event simulation (DES). DES has many advantages, but it also requires multiple runs and statistical treatment of their result and its model tend to grow in detail and complexity. Analytical models give quick answers, but they require a mathematical structure, and they are more abstract and harder to explain. Despite this balance, simulation is more widely used than analytical models in the practice of military operations research. A brief review of DES and analytical modeling is given, including the particular advantages and disadvantages of each. This is followed by a direct comparison and examples.

2 - Multiattribute Decision Modeling in Defense Applications

Roger Chapman Burk, Associate Professor, United States Military Academy, Department of Systems Engineering, Bldg., West Point, NY, 10996-1779, United States, roger.burk@westpoint.edu

The role of decision analysis (DA) within military operations research (OR) is discussed. A technically sound and easy-to-apply approach for multiattribute problems is presented, based on an additive value model. This includes developing a value hierarchy, identification of measures of value and of single-attribute value functions, and elicitation of attribute swing weights. Cost issues are addressed, as are issues of multiple stakeholders. The ramifications of decisions under uncertainty are then considered. The emphasis is on practical methods that are technically sound but understandable by clients without special training in OR or DA, and on clear methods of presentation of results.

3 - Modern Methods for Characterization of Social Networks through Network Models

Christine Schubert Kabban, Air Force Institute of Technology, Wright Patterson AFB, OH, United States, Fairul Mohd-Zaid, Richard F. Deckro

Social Network Analysis is widely used by intelligence and operational communities to analyze relationships and monitor a network of interest. However, the social network must first be characterized to be effectively modeled. This work exhibits the use of statistical approaches to characterize social networks into specific network structures with quantifiable properties. We demonstrate such an approach for common network models and motivate future directions in this research area. Ideally, by capturing all the facets of a social network, a better understanding and representation of the network can be created for analysis and monitoring.

JuMP for Stochastic Optimization

Sponsored: Optimization/Computational Optimization and Software

Sponsored Session

Chair: Joaquim Garcia, PSR & PUC-Rio, Brazil

1 - Recent Developments in SDDP.jl

Oscar Dowson, Northwestern University, Evanston, IL, United States

In this talk we discuss recent improvements to SDDP.jl, an open-source multistage stochastic programming solver implemented in the Julia language. These include an update to Julia 1.0 and JuMP 0.19, as well as the ability to solve infinite-horizon multistage stochastic programs.

2 - Solving Multistage Stochastic Optimization Problems using JuMP

Thuener A. Silva, PUC-Rio LAMPS, Rio de Janeiro, 22451-900, Brazil, thuener@esp.puc-rio.br

JuMP and Julia ecosystem allows for great flexibility in research applications on optimization. Problems previously solved in a simplified way can now be easily constructed and solved using JuMP and the derived frameworks. This is the case for Multistage stochastic problems, which are very complicated to solve due to the increase in dimensionality. This allows us to focus our research more on modeling problems than solving those problems. Thus, several applications, for example, in energy, finance and corporate finance can now be modeled more accurately, taking into account realistic assumptions.

3 - Large Scale Stochastic Optimization in Power Systems with Julia and JuMP

Joaquim Masset Lacombe Dias Garcia, PSR Inc, Botafogo, Rio de Janeiro, 22250-040, Brazil, joaquimgarcia@psr-inc.com Joaquim Masset Lacombe Dias Garcia, PUC-Rio, Rio de Janeiro, Brazil, joaquimgarcia@psr-inc.com

Stochastic programming is a key tool for modern power systems simulation, operation and expansion. The large scale of these systems make problems of interest extremely large, tailored solutions are necessary to solve such problems. We will show how the Julia language and the Mathematical Modeling package JuMP were used to apply optimization algorithms to such problems. We highlight the nice performance, simplicity, interoperability and parallel programming features of Julia. JuMP will be shown to be a great asset because of its simplicity, efficiency and flexibility. Case study will detail the application of such tool in real power systems.

4 - A Scenario Based Single Vehicle Routing Problem with Stochastic Demands: Flow Models

Marcus V. Poggi, PUC-Rio, Rua M. S. Vicente 225, Rio de Janiero, 22591-900, Brazil, Georges Spyrides, Thibaut Vidal

We consider the problem of routing a single vehicle with capacity Q to collect demands from a set C of customers. Demands ds from a set S of scenarios are uncovered at arrival. The objective is to minimize expected routing distance. Two recourse policies are considered when vehicle capacity is exceeded: go to the depot and back to the current customer and go to the depot and re-route optimally the remaining customers. We propose flow models that assume at most a single failure in the route. The resulting two level stochastic programs are implemented and run with JuMP using Gurobi.

Chair: Hugh Medal

1 - Complex Decision Making in Experimental Materials Science

Soojung Baek, University at Buffalo, Buffalo, NY, United States, soojungb@buffalo.edu, Kristofer Reyes

The Materials Science community has increasingly turned to Bayesian Optimization (BO) to assist in the search for Materials design parameters that optimize material properties. In many settings, the experimentation process imposes constraints that BO does not adequately model, resulting in process inefficiencies. We outline such constraints and illustrate more fluent modeling of experimental state using Markov Decision Processes. We show, through numerous examples, how this modeling, along with the Monte Carlo Tree Search (MCTS) leads to better informed decisions in experimental material science.

2 - Bayesian Optimization for Peptide Design

Peter Frazier, Cornell University, School of Operations Research, and Information Engineering, Ithaca, NY, 14853, United States, pf98@cornell.edu, Lorillee Tallorin, Jialei Wang, Woojoo E. Kim, Swagat Sahu, Nicolas Kosa, Pu Yang, Matthew Thompson, Michael K. Gilson, Michael D. Burkart, Nathan C. Gianneschi

We describe an application of Bayesian optimization in biomaterials. Our goal is to design a peptide to which an enzyme can attach other chemical groups. This allows us to modify, control, and image proteins in which we embed these peptides. Peptides can be tested in a batch in a month-long experiment. We develop a novel algorithm, Peptide Optimization with Optimal Learning (POOL), for recommending batches of peptides that maximize the probability of achieving our design goal. Guided by POOL and using a sequence of month-long laboratory experiments, biochemists at UCSD were able to discover novel short peptides achieving our design goal. This work was recently published in Nature Communications.

3 - Efficient Global Optimization Integrated Stochastic Programming Framework for Reliability-based Design Optimization

Tanveer Hossain Bhuiyan, University of Tennessee, Knoxville, Knoxville, TN, United States, tbhuiyan@vols.utk.edu, Hugh Medal

This paper studies a reliability-based design optimization problem where the product design variables affect the probability distribution of the quality of different components of the product. We model this problem as a stochastic program with endogenous uncertainty where the first-stage selects the design variables for individual components and the second-stage uses a black-box function to evaluate the reliability for the entire system given a realization of the component states. To solve this problem, we use an efficient global optimization approach, exploiting the fact that the relationship between design variables and the probability distribution of component quality is known.

Discrete Optimization Meets Machine Learning

Sponsored: Optimization/Integer and Discrete Optimization

Sponsored Session

Chair: Aleksandr M. Kazachkov, QC, H3T1J4, Canada

Co-Chair: Gonzalo Munoz, Montreal, QC, H3T 1N8, Canada

1 - Reward-driven Branching Policies

Giulia Zarpellon, Polytechnique Montreal, Montreal, QC, H3T 1J4, Canada, Jason Jo, Andrea Lodi, Yoshua Bengio

To efficiently solve Mixed-Integer Programming (MIP) problems, solvers trade-off between several aspects of the resolution process, all fundamentally linked to the way the B&B tree is explored and hence to the crucial decision of variable branching. Building on the idea that MIPs share rationales behind what drives a successful search, we identify desirable behaviours within the B&B evolution and translate these properties into reward functions to train branching policies in a reinforcement learning fashion. We compare such reward-driven branching policies to state-of-the-art branching rules and investigate their ability to ultimately being able to solve (never seen) MIP instances.

2 - Boolean Decision Rules via Column Generation

Sanjeeb Dash, IBM Research, Yorktown Heights, NY, 10598, United States, sanjeebd@us.ibm.com, Oktay Gunluk, Dennis Wei

In many machine learning applications, interpretable classification models, such as decision trees, are preferred over more accurate but less interpretable models such as random forests. In this talk, we consider boolean decision rule sets as interpretable models for binary classification. We discuss an integer programming formulation for such models that trades off classification accuracy against rule simplicity, and obtain high-quality classifiers using column generation techniques. Our algorithm dominates some recent alternatives in the accuracy-simplicity trade-off in 8 out of 16 datasets, and produced the winning entry in the 2018 FICO explainable machine learning challenge.

3 - Learning to Branch with Graph Convolutional Neural Networks

Maxime Gasse, Post-doctoral Student, Polytechnique Montréal, Montréal, QC, H3T 1J4, Canada

Combinatorial optimization problems are typically tackled by the branch-and-bound paradigm. We propose a new graph convolutional neural network model for learning branch-and-bound variable selection policies, which exploits the natural variable-constraint bipartite graph representation of mixed-integer linear programs. We train our model via imitation learning on a diversified variant of the strong branching expert rule and demonstrate on a series of synthetic problems that our approach produces policies which can improve upon expert-designed branching rules, and also generalize to instances significantly larger than seen during training.

4 - Learning Optimized Risk Scores

Berk Ustun, Harvard University, Cambridge, MA, United States, berk@seas.harvard.edu, Cynthia Rudin

Risk scores are simple models that let users quickly assess risk by adding and subtracting a few small numbers. These models are widely used in medicine and criminal justice, but difficult to learn from data because they must be calibrated, use small integer coefficients, and obey diverse constraints. We present a new method to learn risk scores from data by solving a discrete optimization problem. We formulate the risk score problem as a MINLP, and present a cutting-plane algorithm to efficiently recover its optimal solution by solving a MIP. We discuss the benefits of our approach by creating risk scores for real world problems.

1 - Free Rides in Dockless Electric Vehicle Sharing Systems

Bobby Nyotta, UCLA Anderson School of Management, Los Angeles, CA, United States, bobby.nyotta.1@anderson.ucla.edu, Fernanda Bravo, Jacob Feldman

We study the effectiveness of free rides as a mechanism to incentivize customer behavior in an electric vehicle sharing system (EVSS) with "dockless" or "free-floating" parking. First, we develop an infinite-horizon dynamic program, and then we build on this formulation to construct a mixed-integer program that determines when to offer based on an intuitive, battery-threshold rule. In a discrete-event simulation model using real EVSS data, we compare the performance of this simple policy and more general discount policies against a Fine-Based policy. Our numerical study shows the free-ride policies dominate on customer utility, but the performance on other dimensions can vary considerably.

2 - Intraday Scheduling with Patient Re-entry and Variability in Patient Behaviours

Minglong Zhou, NUS, Singapore, Singapore, Gar Goei Loke, Chaithanya Bandi, Zi Qiang Glen Liau, Wilson Wang

We consider an intraday scheduling problem where the planner schedules appointment starting times given a sequence of patient appointments. A key feature in our problem is the feedback loop. During a consultation, a patient may be required to go for additional tests, such as X-rays, in different servers. The patient will then go back to the same consultation doctor for a repeated consultation within that day once additional tests are completed. We propose a tractable satisficing framework that satisfices operational constraints and service quality indicators as much as possible. This framework has a strong modelling power and can be applied to realistic job-shop problems in general.

3 - Adaptive Distribution Decision Rule in Resource Allocation Problems

Gar Goei Loke,National University of Singapore, Singapore, Singapore Yun Fong Lim, Peng Wang

In this paper, we consider the resource allocation problem, where the planner can decide upon the resource availability, while attempting to adaptively match the uncertain demand to different supply nodes over a multi-period horizon. Such formulations can be observed in problems such as ride-share fleet re-positioning, and patient management in healthcare. We introduce an adaptive distribution decision rule, which decides on the proportion of jobs awaiting dispatch to each of the possible resource supply pools. Our model has a convex reformulation that can be solved efficiently. We illustrate our model on a maintenance job allocation problem with real world data.

4 - Value of Centralization in Ride-sharing Platforms

Neha Sharma, Kellogg School of Management, Evanston, IL, United States, neha.sharma@kellogg.northwestern.edu, Chaithanya Bandi

We model a platform that matches riders and drivers present on multiple nodes of network. We study the value of centralization (VoC) of the supply for such a ride sharing platform. Since transportation systems are dependent on the road layout of the cities, we study the impact of topology of the network on the VoC. We specifically consider two common urban road layouts: tree and radial network. Further, we investigate how network characteristics like the number of providers, capacity and Gini coefficient impact the VoC for the ride sharing platform.

Sponsored Session

Chair: Ming Zhao, Houston, TX, 77204, United States

1 - Spatial Homogeneity Pursuit of Regression Coefficients for Large Datasets

Huiyan Sang, Associate Professor, Texas A&M University, College Station, TX, United States, huiyan@stat.tamu.edu

Spatial data arises from the research of diverse disciplines. In this talk, we consider a varying coefficient regression model to study the clustered relationship between responses and covariates. In particular, tree-based regularization methods will be developed to encourage spatial homogeneity between regression coefficients at neighboring locations. We will design efficient penalized optimizations to implement the proposed models. We also study the theoretical properties concerning the behavior of the regularization methods. Finally, the performance of the proposed methods is tested with simulation studies and applied to real-life applications.

2 - A Structure Exploiting Branch-and-bound Algorithm for Mixed-integer Model Predictive Control

Pedro Hespanhol, UC Berkeley, San Francisco, CA, 94103, United States, pedrohespanhol@berkeley.edu, Rien Quirynen, Stefano Di Cairano

Mixed-integer model predictive control (MI-MPC) requires solving a mixed-integer quadratic program (MIQP) at each sampling instant under strict timing constraints, where some state/control variables can only assume a discrete set of values. We use the problem structure of MI-MPC in order to provide a branch-and-bound algorithm that can exploit the block-sparse optimal control structure of the problem, and which can also be warm started by propagating information from branch-and-bound trees and solution paths at previous time steps. We illustrate the computational performance of the proposed algorithm and compare against current state-of-the-art solvers for multiple MPC case studies.

3 - Efficient Stochastic Algorithms for Solving Two-player Games

Aaron Sidford, Stanford University, Stanford, CA, United States

In this talk I will present several results on designing more efficient algorithms for solving a variety of structured two-player games. In particular, I will discuss how to design more time and sample-efficient algorithms for solving both bilinear saddle point problems and zero-sum two-player stochastic games (the two-player generalization of MDPs). This talk will feature a variety of tools in sampling, variance-reduction, and iterative method design of hopefully broader utility in building robust optimization procedures.

4 - How Good Are Default Investment Policies in Defined Contribution Plans?

Bernardo Kulnig Pagnoncelli, Universidad Adolfo Ibanez, Diagonal Las Torres Santiago, 7910000, Chile, bernardo.pagnoncelli@uai.cl, David Morton, Daniel Duque

Defined contribution (DC) pension plans have been gaining ground in the last 10-20 years as the preferred system for many countries and agencies, both private and public. The central question for DC plans is how to invest the money in order to reach the participant's retirement goals. Given the financial illiteracy of the general population, it is common to offer a default policy for members who do not actively make investment choices. Using data from the Chilean system, we propose an investment model using stochastic dynamic programming and compare the results with the default policy under a wide variety of objectives.

Special Session: A Unified Framework for Optimization under Uncertainty

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Warren B. Powell, Princeton University, Princeton, NJ, 08544, United States

1 - Part 1: The Unified Modeling Framework with Applications

Warren B. Powell, Princeton University, Dept of Operations Research and Financial Engr., Princeton, NJ, 08544, United States, powell@princeton.edu

The first stop in solving any sequential decision problem under uncertainty is modeling. We offer a unified modeling framework that consists of five components: state variables, decision variables, new information, the transition function and the objective function, where the objective function is always optimizing over policies. We illustrate this framework in a variety of applications from pure learning problems (also known as bandit problems), to stochastic search, to a range of applications in energy, transportation, health and e-commerce. Key elements involve proper modeling of state variables, modeling different types of uncertainty, and the handling of policies.

2 - Part 2: Modeling Uncertainty and Adaptive Learning

Warren B. Powell, Princeton University, Dept of Operations Research and Financial Engr., Princeton, NJ, 08544, United States, powell@princeton.edu, Saeed Ghadimi, Hugo P. Simao

The next step in the modeling process is identifying and modeling different forms of uncertainty. This is the most overlooked dimension of stochastic optimization, yet is arguably the most important. I will illustrate the different ways that uncertainty can enter a model, and strategies that I have found useful in my own work for modeling uncertainty. I will then identify five classes of adaptive learning problems that arise in stochastic optimization, and review some methods that we have found useful in our own work.

3 - Part 3: Designing Policies I: The Policy Search Class

Warren B. Powell, Princeton University, Dept of Operations Research and Financial Engr., Princeton, NJ, 08544, United States, powell@princeton.edu

There are two fundamental approaches for designing policies: the policy search class, which searches over parameterized classes of policies to find those that work well over time, and the lookahead class, where policies are designed by approximating the impact of a decision on the future. In this part of the talk, I will focus on two strategies in the policy search class: policy function approximations (PFAs) and cost function approximations (CFAs). These are the approaches most widely used in practice because they are the simplest, but the price of simplicity is tunable parameters, a topic I will address.

4 - Part 4: Designing Policies II: The Lookahead Class

Warren B. Powell, Princeton University, Dept of Operations Research and Financial Engr., Princeton, NJ, 08544, United States, powell@princeton.edu

The lookahead class has attracted the most interest from the research community using names such as stochastic programming, dynamic programming and ``model predictive control" (rolling horizon procedures). I will introduce the idea of a lookahead model, and review five ways to approximate these. I will then cover topics such as approximate dynamic programming/reinforcement learning, Monte Carlo tree search, and stochastic programming (briefly). I will close by discussing hybrid strategies such as a parameterized deterministic lookahead that combines the principles of lookahead and policy search (a powerful idea that is widely used in practice).

Chair: Xuesong Zhou, Arizona State University, Tempe, AZ, 85281, United States

Co-Chair: Andrea Leticia Arias, BNSF Railway, Fort Worth, TX, 76244, United States

1 - Railway Applications Section Problem Solving Competition

Andrea Leticia Arias, BNSF Railway, 3945 shiver road, Fort Worth, TX, 76244, United States

This session is reserved for the finalists of the 2019 RAS Problem Solving Competition: "Integrated Train Blocking and Shipment Path Optimization". The presenters and their abstracts will be determined the Judging Committee by late September. More information about the competition is available at https://connect.informs.org/railway-applications/awards/problem-solving-competition

2 - A New Mixed Integer Programming Model for the Integrated Train Blocking and Shipment Path Optimization Problem

Vahid Famildardashti, Cirrelt, Montreal, QC, H3W1W6, Canada, Mohammad Reisi-Nafchi, Pouria Arsalani

An arc-based Mix Integer Programming (MIP) model is presented to solve the Integrated Train Blocking and Shipment Path optimization problem. No linear MIP model has been presented for this problem in the literature. We developed a linear MIP model for this problem and reported and analyzed the computational results. Three different problem instances provided by RAS2019 for this problem were solved using GUROBI optimizer.

3 - Integrated Train Blocking and Shipment Path Optimization (TBSP)

Tsung-Han Wang, National Cheng Kung University, Hsinchu City, Taiwan, Yen-Tzu Yueh, Yen-Wei Chen

Viewing each OD shipment as a commodity, this problem becomes a special min-cost OD multicommodity network design problem, where the bundle constraints consider two more types of node capacities. Starting with good initial multicommodity flows, our two integer programs cover all constraints with good efficiency and effectiveness. The innovative inverse shortest path heuristic helps good estimation on the dual variables of bundle constraints. A column generation scheme is also proposed.

4 - Integrated Train Blocking and Shipment Path Optimization

Karen Angulo Diaz, Universidad de los Andes, Bogotá, 110111, Colombia, Oscar Guaje Acosta, Daniel Suarez Bayona

We propose a methodology that solves the TBSPP based on three stages. First, we propose a novel formulation based on a multi-commodity network flow problem to generate an initial set of routes. Second, we greedily augment the set of routes seeking diversity in the available routes. Finally, we solve an MIP that enforces feasibility using the set of available routes. We achieve good solutions in acceptable computational time.

1 - An Asymptotically Superlinear Convergent Semismooth Newton Augmented Lagrangian Method for LP

Xudong Li, Fudan University, Shanghai, China, lixudong@fudan.edu.cn, Defeng Sun, Kim-Chuan Toh

Powerful interior-point methods (IPM) based commercial solvers have been hugely successful in solving large-scale linear programming problems. Unfortunately, the natural remedy, although can avoid the explicit computation of the coefficient matrix and its factorization, are not practically viable due to the inherent extreme ill-conditioning of the large scale normal equation arising in each interior-point iteration. To provide a better alternative choice for solving large scale LPs with dense data, we propose a semismooth Newton based inexact proximal augmented Lagrangian method.

2 - Consistency of Stationary Solutions of Coupled Nonconvex Nonsmooth Empirical Risk Minimization

Zhengling Qi, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, Ying Cui, Yufeng Liu, Jong-Shi Pang

This paper establishes the statistical consistency of stationary solutions of a class of coupled nonconvex and nonsmooth empirical risk minimization problems, whose optimal solutions are computationally elusive in general. The considered model covers a broad range of emerging applications in machine learning such as two-hidden-layer neural networks. Our derived results show that the sharpness of stationary solutions (directionally stationary points) at the empirical level is preserved at the population level, which demonstrates the necessity of computing sharp stationary solutions in practice.

3 - Power k-Means Clustering: Majorization-Minimization Avoids Local Minima

Jason Xu, Assistant Professor, Duke University, Durham, NC, United States, Kenneth Lange

We propose an alternative to Lloyd's classic clustering algorithm that retains its simplicity but mitigates its tendency to get trapped in local minima. Our method embeds the k-means objective in a family of similar, better behaved problems with fewer local minima. The previously discovered k-harmonic means algorithm coincides with one point along this continuum. Power k-means anneals its way toward the solution by way of majorization-minimization (MM), sharing the appealing descent property and low O(nkd) complexity of Lloyd's algorithm. We demonstrate its merits in simulated and real data examples.

Algorithmic Foundations for Large-Scale Machine Learning

Sponsored: Optimization/Linear and Conic Optimization

Sponsored Session

Chair: Xudong Li

1 - Reinforcement Leaning in Feature Space: Matrix Bandit and Regret Bound

Lin Yang, Princeton, Princeton, NJ, United States

We study the regret-minimization problem of reinforcement learning for an episodic Markov decision process. We propose an algorithm that leverages the linear bandit and dynamic programming to learn a low-dimensional representation of the transition matrix as well as to do exploration that balances exploitation. We show that our algorithm achieves a regret bound ${O}\big(d^2\sqrt{H^3T\log T}\big)$, where d is the dimension of the features. To the best of our knowledge, for reinforcement learning with linearly additive features, this is the first regret bound that is simultaneously near-optimal in time, polynomial in the planning horizon and the feature dimension.

2 - High Dimensional Tensor Regression Analysis

Anru Zhang, University of Wisconsin-Madison, Madison, WI, 53562, United States, anruzhang@stat.wisc.edu

The past decade has seen a large body of work on high-dimensional tenors that arise in numerous applications and are applied to many statistical problems. The tensor often comes with natural low-rank or sparsity structure. How to exploit such structure for tensors poses new statistical and computational challenges.In this talk, we introduce a novel procedure for low-rank tensor regression to address these challenges. We show that our method is sharply minimax optimal under low-rank Tucker assumptions. Further, we show the proposed procedure achieves comparable mean-squared error performance to existing state-of-the-art methods whilst having substantial storage and run-time advantages.

3 - High-dimensional Principal Component Analysis with Heterogeneous Missingness

Ziwei Zhu, University of Cambridge, Cambridge, United Kingdom

I will focus on the effect of missing data in PCA. Under a homogeneous missingness mechanism, the leading eigenspaces of a Hadamard reweighted sample covariance matrix are shown to achieve the minimax optimal rate up to logarithmic factors. Under the incoherence assumption, we can embrace much more flexible missingness mechanisms. We derive the statistical rate of the Hadamard-reweighting-based estimator under arbitrary deterministic observation regime. We then feed this estimator to a new tuning-free iterative algorithm called primePCA. We show that under the noiseless setting, primePCA achieves exact recovery of the true leading eigenspaces with geometric convergence.

4 - On the Equivalence of Inexact Proximal ALM and ADMM for a Class of Convex Composite Programming

Xudong Li, Fudan University, Shanghai, China, lixudongkeer@gmail.com

In this talk, we show that for a class of linearly constrained convex composite optimization problems, an (inexact) symmetric Gauss-Seidel based majorized multi-block proximal alternating direction method of multipliers (ADMM) is equivalent to an inexact proximal augmented Lagrangian method (ALM). This equivalence not only provides new perspectives for understanding some ADMM-type algorithms but also supplies meaningful guidelines on implementing them to achieve better computational efficiency.

1 - Optimal Deployment of Charging Lanes and Charging Stations for Electric Vehicles in Transportation Networks

Xiasen Wang, University of Washington, Seattle, WA, United States, wxiasen@gmail.com

With the rapid development of charging-while-driving technology, the deployments of charging lanes and direct current fast chargers (DCFC) inevitably affect the charging and route choices decisions of battery electric vehicle (BEV) drivers. This study builds a two-level optimization framework to solve the deployment problem of the two different charging facilities and the traffic assignment problem simultaneously. We first build a user equilibrium model to assign the traffic on the road network given the location of the two charging methods. we further formulate the deployment plan as a mathematical program.

2 - Extreme-point Tabu Search Heuristics for Fixed-charge Generalized Network Problems

Angelika Leskovskaya, Visiting Professor of Practice, Southern Methodist University, Dallas, TX, United States, aleskovs@smu.edu, Richard Barr

While researchers have studied generalized network flow problems extensively, the powerful addition of fixed charges on arcs has received scant attention. The proposed network-simplex-based algorithm efficiently exploits the quasi-tree basis structure, utilizes a candidate list, a tabu search, and a diversification phase to solve FCGT problems. Computational testings demonstrate heuristic's effectiveness in terms of speed and quality of solutions. Comparisons with a state-of-the-art solver, CPLEX, show that the extreme-point tabu search algorithm runs, on average, five orders of magnitude faster and produces solution values within 2.2% of the optimal solution reported by CPLEX.

3 - A Comprehensive Collaborative Agreement for Cost-effective Vessel Scheduling in Liner Shipping

Maxim A. Dulebenets, Florida A&M University-Florida State University, Tallahassee, FL, 32311, United States, mdlbnets@gmail.com, Junayed Pasha, Masoud Kavoosi, Olumide Abioye

Without effective vessel schedules liner shipping companies may incur substantial monetary losses. This study proposes a new collaborative agreement for vessel scheduling, based on which the liner shipping company is offered multiple vessel arrival time windows, start and end times for each time window, and multiple handling rates during each time window by the marine container terminal operator to at each port of the liner shipping route. The proposed collaborative agreement is evaluated against the ones, which were previously presented in the liner shipping literature.

4 - A Medical Device Network Design Model

Tan C. Miller, Director of Global Supply Chain Management Program, Rider University, Morris Plains, NJ, United States, tanjean@verizon.net, Renato E. de Matta, Emmanuel Peters

We propose and develop new methodologies utilizing mathematical optimization and simulation models to jointly improve the design of the physical networks, and to enhance the inventory management practices of the medical device industry.

Chair: Yongjia Song, Clemson University, Clemson, SC, 29634, United States

1 - Enhanced Balancing of Bias-variance Tradeoff in Stochastic Simulation

Henry Lam, Columbia University, New York, NY, 10027, United States, henry.lam@columbia.edu

Biased stochastic estimators, such as finite-differences for noisy gradient estimation, often contain tuning parameters that balance impacts from the bias and the variance. While the optimal order of these parameters in terms of the simulation budget can be readily established, the precise best values depend on model characteristics that are typically unknown in advance. We investigate a minimax risk framework to construct new estimators by combining simulation runs on sequences of tuning parameter values, such that the estimators consistently outperform a given tuning parameter choice in the conventional approach, regardless of the unknown model characteristics.

2 - ASTRO for Derivative-based Smooth Stochastic Optimization

Daniel Vasquez, Purdue University, West Lafayette, IN, United States, dvasque@purdue.edu

Trust-region algorithms have proven to be a stable and efficient class of algorithms to solve optimization problems having smooth objective functions. We present Adaptive Sampling Trust-Region Optimization (ASTRO) for derivative-based stochastic optimization settings, where the objective function and it's gradient are observed with stochastic error, e.g., using a dataset or Monte Carlo. We detail ASTRO, clarify its achieved complexity rates especially in relation with two other stochastic trust-region algorithms, and present extensive numerical results.

3 - Distributionally Robust Stochastic Dual Dynamic Programming

Daniel Duque Villarreal, Northwestern University, Evanston, IL, United States, danielduque@u.northwestern.edu, David Morton

We consider a multi-stage stochastic linear program that lends itself to solution by stochastic dual dynamic programming (SDDP). In this context, we consider a distributionally robust variant of the model with a finite number of realizations in each stage, and distributional robustness is with respect to the probability mass function governing candidate realizations. We describe a computationally tractable variant of SDDP to handle this model using the Wasserstein distance to characterize distributional uncertainty.

4 - Joint Chance-constrained Programs and Intersection of Mixing Sets Through a Submodularity Lens

Dabeen Lee, Institute for Basic Science, Daejeon, Korea, Republic of, Fatma Kilinc-Karzan, Simge Kucukyavuz

Intersection of mixing sets with common binary variables arise when modeling joint linear chance-constrained programs with random right-hand sides and finite sample space. In this talk, we first establish a strong and previously unrecognized connection of mixing sets to submodularity. This viewpoint enables us to unify and extend existing results on polyhedral structures of mixing sets. Then we study the intersection of mixing sets with common binary variables and also linking constraint lower bounding a linear function of the continuous variables. We propose a new class of valid inequalities and characterize when this new class along with the mixing inequalities are sufficient to describe the convex hull.

1 - Optimizing the Response for Arctic Mass Rescue Events

Mustafa Can Camur, Rensselaer Polytechnic Institute, Troy, NY, 12180, United States, Thomas C. Sharkey, Martha Grabowski, Clare Dorsey

We study a mass rescue model containing dynamic logistics decisions for a large-scale maritime evacuation in the Arctic. An integer linear programming model is proposed with the objectives of minimizing the impact of the event on the evacuees and the average evacuation time. We capture the unique aspects of this environment, including the fact that evacuees will flow from the ship through small Arctic communities while support resources will flow from southern Alaska to support them. We discuss experimental results and the impact of decomposition algorithms on runtimes.

2 - Cost Effective Regional Evacuation Network Design Problem under Uncertainty

Nadere Mansouri, Southern Methodist University, Dallas, TX, 75231, United States, Halit Uster

We pose and analyze a strategic evacuation network design problem which determines open shelter locations and evacuee routes (road segments) under uncertainty in the number of people evacuating the sources. We propose a chance-constrained stochastic programming model and present an efficient Benders Decomposition based approach for its solution. We also apply our methodology to solve test instances developed based on real data from Central Texas.

3 - Routing Plans in the Wake of Hurricanes: Practitioner Guided Scenarios

Andrew Alseth, University of Arkansas, Fayetteville, AR, United States, awalseth@email.uark.edu, Ashlea Bennett Milburn

Despite the growing availability of real-time data on road networks, road network availability during and after disasters changes rapidly. This affects the ability to bring supplies to points of distribution (PODs) and other time-sensitive tasks. We investigate the application of the Canadian Traveler's Problem (CTP) to model scenarios developed from interviews of emergency managers and logisticians in government, private companies, and non-profit agencies. Several routing strategies are compared for agents acting in a network with stochastic edge status.

4 - A Multi-vehicle Covering Tour Problem with Speed Optimization

Joshua T. Margolis, PhD Candidate, Clemson University, Clemson, SC, 29631, United States, jtmargo@clemson.edu, Yongjia Song, Scott J. Mason

The multi-vehicle covering tour problem with time windows (MCTPTW) aims to construct a set of maximal coverage routes for a fleet of vehicles that observe a secondary set of sites given a fixed time schedule, coverage requirements, and energy restrictions. The problem is formulated as a mixed-integer second-order cone program and is an extension of both the multi-covering tour problem and the vehicle routing problem with time windows under energy constraints. We study a special case of the proposed model and develop a label correcting algorithm to solve its Lagrangian relaxation problem, which exploits the combinatorial structure exhibited by an optimal solution to the Lagrangian relaxation.

1 - Plug-and-play: Use Trained Networks in Optimization with Provable Convergence

Wotao Yin, University of California, Los Angeles, Los Angeles, CA, United States, Ernest Kang Ryu, Jialin Liu, Sicheng Wang, Xiaohan Chen, Zhangyang Wang

Plug-and-play (PnP) is an optimization framework that integrates pre-trained deep networks into ADMM and other proximal optimization algorithms. An advantage of PnP is that one can use pre-trained networks when there is not sufficient data for end-to-end training. Although PnP has exhibited great empirical results, theoretical analysis addressing even the basic question of convergence has been insufficient. We establish convergence of PnP-FBS and PnP-ADMM. Finally, we present experimental results that validate the theory.

2 - Algorithmic Development for Computing B-stationary Points of a Class of Nonsmooth DC Programs

Zhaosong Lu, Simon Fraser University, Burnaby, BC V5A 1S6, BC, Canada, zhaosong_lu@sfu.ca

In this talk we first consider a class of unconstrained nonsmooth DC programs in which the concave summand of the objective is an infimum of possibly infinitely many smooth concave functions. We propose some algorithms by using nonmonotone linear search and extrapolation techniques for possible acceleration for them, and analyze their global convergence, sequence convergence and also iteration complexity. We then consider a class of DC constrained nonsmooth DC programs. We propose a penalty method for solving them and show that it converges to a B-stationary point under much weaker assumptions than those imposed in the literature. This is joint work with Zhe Sun and Zirui Zhou.

3 - Multi-composite Nonconvex Optimization for Training Deep Neural Networks

Ziyu He, University of Southern California, Los Angeles, CA, United States, ziyuhe@usc.edu, Ying Cui, Jong-Shi Pang

We present a novel deterministic algorithmic framework that enables the computation of a directional stationary solution of the empirical deep neural network training problem. The proposed approach combines the methods of exact penalization, majorization-minimization, gradient projection with enhancements, and the dual semismooth Newton method, each for a particular purpose in an overall computational scheme. Numerical results from a MATLAB implementation demonstrate the effectiveness of the framework for solving reasonably sized networks with a modest number of training samples.

4 - Bounds on the Stationary Solutions of Sparse SAA Problems

Miju Ahn, Southern Methodist University, Dallas, TX, 75205, United States, mijuahn@gmail.com

In many applications, predictive modeling with nonconvex sparsity functions is practiced to minimize the empirical prediction error through sample average approximation. We study the properties of the stationary solutions of such problems. We derive bounds for the distance between the stationary solutions and a vector that is possibly the ground truth, and the model predictions produced by them. Furthermore, the inclusion relationships between their support sets of nonzero valued indices are studied. Some of the results are generalization of the existing theory shown for the specialized problem of L1-norm regularized least squares minimization for linear regression.

1 - Data Driven Approach for Calibrating BPR Function as a Queueing Model

Qixiu Cheng, Southeast University, Nanjing, 210096, China, qixiu.cheng@seu.edu.cn, Xuesong Zhou, Zhiyuan Liu

Emerging urban transportation applications need to address a wide range of challenges, including highly dynamic traffic conditions and complex demand-supply interaction. This talk aims to establish analytical equivalence between the BPR travel time function and deterministic queuing models, in order to develop a theoretically rigorous and data driven approach for large-scale traffic system calibration.

2 - Extracting Trips from Multi-Sourced Data for Mobility Pattern Analysis: An App-Based Data Example

Feilong Wang, Department of Civil and Environmental Engineering, University of Washington, Seattle, WA, United States

Passively-generated data need to be processed to extract trips. Most existing methods rely on data generated via a single positioning technology such as GPS or triangulation through cellular towers (single-sourced data), and methods to extract trips from data generated via multiple positioning technologies (or, multi-sourced data) are absent. Generated using multiple technologies (e.g., GPS, cellular network- and WiFi-based), multi-sourced data contain high variances in their temporal and spatial properties. Consequently, methods for single-sourced data are not applicable to multi-sourced data. Here, a DCI framework is proposed and tested.

3 - Identifying Network Characteristics of Bike-sharing System and Station Usage: Chicago Divvy Bike Case Study

Yuhan Zhou, Northwestern University, Evanston, IL, United States, yuhanzhou2020@u.northwestern.edu, Ying Chen, Hani S. Mahmassani

Divvy bike in Chicago is the second largest bike sharing system in the US. In this study, longitudinal data from 2014 to 2018 is used to investigate properties of bike-sharing trips and station usage, as well as how these attributes change as Divvy bike system are expanding from 300 stations to more than 600 stations. Network analysis metrics are adapted to exhibit connectivity among bike stations and identify patterns of bike-sharing activities in Chicago.

4 - A Methodological Framework for Data-Driven Performance Evaluation of Subway Operations Using Mobile Data

Abdullah Kurkcu, Research Associate, New York University, Brooklyn, NY, United States, ak4728@nyu.edu, Kaan Ozbay, Hisashi Kanamori, Daichi Ayado

For NYCT's subway operations to be operated efficiently and resiliently, it is important to have visibility into how the population interfaces with the system. Unfortunately, this information would not be readily available if NYCT relies only on existing datasets. One additional data source is the WiFi association data collected by TransitWireless. The communications company owns and operates 160 miles of fiber across 282 underground subway stations. They collected data on approximately 120 million passengers in the last year, which constitutes 7% of total annual passengers. With this sample size, much can be inferred about transit operations that can be put into practice fairly quickly.

1 - Dynamic Optimal Approach for An Electric Taxi Fleet's Charging and Order-service Schemes

Kaize Yu, University of Electrolic Sicence and Technology of China, Chengdu, China, 845557030@qq.com, Pengyu Yan

This paper addresses a charging and order-service scheme problem for an electric Taxi (ET) fleet operated by an e-hailing platform. The long charging time significantly affects the fill rate of orders and the incomes of the fleet. The platform as a centralized manager needs to determine the charging and order-service scheme of all ETs for each period based on the real-time information of a charging station, the remained powers of ETs and the coming orders. The problem is formulated as a multiple-period stochastic programming model to maximize the total revenue and a rolling horizon approach is proposed. The experimental results demonstrate the effectiveness of the proposed dynamic decision approach.

2 - Integrated Planning of Charging Stations and PV Power Plants with Time-dependent Pricing for Electric Vehicles

Zhixiong Luo, Tsinghua University, Beijing, China, luozx18@mails.tsinghua.edu.cn, Fang He, Xi Lin, Yanni Yang, Meng Li

This study jointly designs charging stations and photovoltaic (PV) power plants with time-dependent electricity price to better manage the coupling of network traffic and power flow carried by electric vehicles (EV). We first propose an extend label-setting algorithm to solve the routing choice of EV drivers. Then a variational inequality and a mixed integer second order cone programming are formulated to respectively model the EV traffic equilibrium and the optimal power flow. Based on the above models, we formulate a bi-level model and solve it by a surrogate-based optimization (SBO) algorithm. Numerical studies show the efficiency of the SBO algorithm and the benefits of jointly planning.

3 - The Urban Recharging Infrastructure Design Problem with Electric Taxi Demand Prediction Using Convolutional Neural Network

Seong Wook Hwang, Assistant Professor, Hongik University, Sejong-si, Korea, Republic of, swhwang@hongik.ac.kr, Sunghoon Lim

In this study we first design a convolutional long short-term memory model that predicts taxi drop-off and pick-up demands for time periods in urban areas. Then, based on the predicted taxi demand in drop-off and pick-up hotspots, a mathematical model is proposed to optimize the location of recharging stations so as to minimize the locating cost of stations and delay cost for recharging service.

4 - Capacitated Optimization Problems for Taxi vs. Uber Platforms with Gasoline vs. Electric Fleets

Sang Jin Kweon, Ulsan National Institute of Science and Technology, Ulsan, Korea, Republic of

Taxi platforms are interested in deploying electric fleets for operational benefits compared to gasoline fleets. At the same time, Uber and any other Uber-like online mobile platforms are emerging to match riders with drivers. They are also excited to deploy electric fleets for ride service. While electric fleets are less expensive to operate, they are more expensive to acquire, and besides, they have less capacity than gasoline fleets in terms of ride service due to long time to charge their batteries. In this talk, we study which platform is more favorable to deploy electric vehicles.

5 - Hailing Rides Using On-demand Mobility Platforms: What Motivates Consumers to Choose Pooling?

Sergey Naumov, Assistant Professor, Penn State Smeal College of Business, State College, PA, United States, snaumov@sloan.mit.edu, David Keith

Carpooling, in which multiple passengers share a single vehicle, provides opportunities to reduce negative externalities of driving. While historically, pooling has been unpopular in the U.S., partly due to the inconvenience of finding fellow commuters, recently, it has been of renewed interest, because ride-hailing platforms automate rider matching and offer pooled rides at relatively low prices. As automated vehicles are expected to further reduce trip costs, will people pool even more? We estimate consumer preferences and show that counter-intuitively the share of pooled rides will shrink, rather than increase, with lower driving costs, but a significant income effect exists.

Freight Transportation Resilience and Economic Impacts

Sponsored: Transportation Science & Logistics/Freight Transportation & Logistics

Sponsored Session

Chair: Mohamad Darayi, Pennsylvania State University-Great Valley, Malvern, PA, 19355, United States

1 - Planning for Recovery under Uncertainty in a Multi-modal Freight Transportation Network

Majid Eskandarpour, Ecole des Mines de Nantes, Nantes, France

Freight transportation network recovery is mainly affected by bad weather conditions and involved uncertainties in transfer time of work crew and equipment, and the required time to recover a network component. This work proposes a stochastic MILP model and a simulation-based optimization algorithm to find the best routes to transfer the crew for network restoration in uncertain conditions in order to minimize the economic loss.

2 - A Systematic Framework to Analyze Freight Transportation Resilience Considering Economic Impacts

Mohamad Darayi, Pennsylvania State University-Great Valley, Engineering Division, Malvern, PA, 19355, United States

Freight transportation infrastructure, including ports, intermodal stations, interstate highways, and railways, plays an important role in the economic vitality of states, regions, and the broader country. This work proposes a systematic framework to analyze freight transportation resilience by (i) evaluating vulnerability of the interdependent system of freight infrastructure and economic sectors, (ii) seeking strategies to allocate a limited budget to harden the system, and (iii) assessing value of information in decision making under uncertainty.

3 - Investing in Freight Transportation Infrastructure Resilience Considering Economic Impacts

Devendra Prakash Jaiswal, Pennsylvania State University-Great Valley, Malvern, PA, United States, dxj323@psu.edu, Mohamad Darayi

The functionality of a multi-modal freight transportation network is threatened by disruptive events that can disable the capacity of the network to enable flows of commodities in portions of nodes and links. This research proposes a simulation-based optimization model to devise budget allocation under uncertainty to enhance the network resilience via network hardening and/or network completion strategies.

4 - Restoration Routing Problem with Path Selection

Nazanin Morshedlou, Mississippi State University, Starkville, MS, United States, nazanin.morshedlou@ou.edu, Kash Barker

We introduce two mixed integers (MIP) restoration problems that schedule a set of disrupted components to each restoration crew. The model interconnects a routing network with the restoration problems through which restoration crews are dispatched, from depots, towards disrupted components. To approach the formulation to reality, we propose a path selection algorithm to stochastically choose shortest paths between each pair of disrupted locations. However, the shortest path between each pair of locations changes due to the nonconvex behavior of commuters and restoration schedule. The proposed model tries to incorporate the stochastic shortest path selection problem into the model.

5 - A Novel Hurricane Classification Method to Quantify Economic Impacts of Hurricanes

Vera Wendler-Bosco, University of Oklahoma, Norman, OK, United States, Charles D. Nicholson

The Saffir-Simpson Hurricane Scale (SSHS) is the most commonly used classification method for hurricanes. Even though widely used and well-established, the SSHS presents a clear shortcoming: it is not able to convey the economic impacts of hurricanes to the affected region. A high SSHS classification scale does not necessarily means a highly destructive and costly hurricane. Similarly, a hurricane with a low SSHS classification does not necessarily mean a weak hurricane. A novel hurricane classification method was developed, focusing on the potential monetary damage that a hurricane can cause when reaching the coast.

Joint Session TSL/URB/Practice Curated: Data Analytics in Transportation Operations

Sponsored: Transportation Science & Logistics/Urban Transportation

Sponsored Session

Chair: Isil Koyuncu, The University of Alabama, Tuscaloosa, AL, 35487, United States

Co-Chair: Sevgi Erdogan, University of Maryland, Silver Spring, MD, 20910, United States

1 - Using Analytics to Assess Travel Reliability in Public Transportation Networks

Michael Redmond, University of Iowa, Iowa City, IA, 52246, United States, michael-a-redmond@uiowa.edu, Ann Melissa Campbell, Jan Fabian Ehmke

Urban travel planning applications are increasing in popularity as travelers look to utilize technology when planning their trips. However, the research and applications in this area often only consider deterministic and scheduled travel time through the network. This presentation will focus on using stochastic travel time distributions on the edges of public transportation networks to give travelers reliability of their itineraries. This research helps capture how transfers and variance in travel time affect the reliability of an itinerary. The presentation will also explore the concept of a backup itinerary in case a transfer is missed.

2 - What Can We Learn About Health Care in Alabama from Analysis of Emergency Medical Services Data?

Abhay Lidbe, University of Alabama, Tuscaloosa, AL, United States, adlidbe@ua.edu, Margaret McNamara, Thomas English, Todd Smith, Nathan Culmer

Maintaining profitability for most rural hospitals has threatened their existence when the county residents bypass local county hospitals and choose distant hospitals. This study investigates variations in EMS response times focusing on the various travel time components (e.g., travel to scene, travel between scene and destination facility, wall time, etc.) resulting from such patients' choices. It is proposed that the study could be used to identify opportunities for optimization of EMS response times in both rural and urban areas.

3 - Data-driven Origin-destination Matrix Estimation in Large-scale Integrated Public Transport Systems

Jorge Huertas, Universidad de los Andes, Bogota, Colombia, huertas.ja@uniandes.edu.co, Palacio Alejandro, Marcelo Botero, Lisseth D. Grosso, Carolina Osorio, Andres L. Medaglia, Sergio Cabrales

The OD matrix estimation problem lies at the core of decision making for transport operators worldwide. The OD matrix describes the spatial and temporal distribution of demand and is fundamental to update bus routes and schedules. Bogotá's integrated public transport system consists of a Bus-Rapid Transit system articulated with a bus system. Solely the bus component comprises over 7400 bus stops, 275 services, and 1.6 million trips, we propose a low cost and efficient estimation method for calculating an OD matrix for the bus system incorporating information from smart cards, bus geolocation data, and mobility surveys, among other sources.

4 - No One is Left Behind: Modeling Access to Evacuation Shelters for Low-income Residents

Sevgi Erdogan, Assistant Research Professor, University of Maryland, College Park, MD, 20910, United States, serdogan@umd.edu, Mohammad M. Nejad, Cinzia Cirillo

Natural or man-made hazards that require evacuation put already vulnerable populations in a more precarious situation. Low income residents without vehicles need alternative transportation means to reach shelters. Data from the American Community Survey, US Census, Internal Revenue Services and the National Household Travel Survey are used to generate synthetic population for Anne Arundel County, MD using the copula concept. Geographic locations of low-income residents are identified within each sub-area of the county and their car ownership is estimated with Binomial Logit model. A facility location model is formulated to identify the best shelter for each geographic sub-area.

5 - Exploiting Conventional Vehicles in Green Vehicle Routing

Isil Koyuncu, University of Alabama, Alston Hall 300, Tuscaloosa, AL, 35487, United States, ikoyuncu@crimson.ua.edu, Mesut Yavuz

This talk addresses a family of green vehicle routing problems that incorporates several key modeling aspects such as refueling at customer and non-customer locations. Conventional vehicles, i.e., gasoline or diesel vehicles, are exploited in the heterogeneous green vehicle routing context.

CC- Room 619

Drones for Smart Logistics

Sponsored: Transportation Science & Logistics/Facility Logistics

Sponsored Session

Chair: Mehdi Behroozi, PhD, Northeastern University, Boston, MA, United States

Co-Chair: Mohammad Moshref Javadi, PhD., MIT, Cambridge, MA, United States

1 - A Vehicle Routing Visualization Toolkit for Drones

Chase Murray, University at Buffalo, Dept of Industrial & Systems Engineering, Amherst, NY, 14260-2050, United States, cmurray3@buffalo.edu, Lan Peng

This talk introduces VeRoViz, an open-source vehicle routing visualization package for Python. VeRoViz aims to simplify the process of creating test problems, generating distance matrices, and visualizing the solutions to vehicle routing problems. It consists of a large (and growing) collection of functions. While some of these functions are wrappers for existing APIs, many of the functions represent new capabilities. We discuss the key features of VeRoViz, explain the overall system architecture, and provide some examples that showcase its utility for for drone routing problems.

2 - Same-day Delivery with Deterministic Release Dates and Drones Resupply

Juan C. Pina, Pontificia Universidad Catolica Valparaiso, Valparaiso, Chile, Daniel F. Silva, Alice E. Smith

For several years researchers have studied using drones for last-mile parcel delivery. However, an area that is often neglected, but a natural fit for drone operations is same-day delivery services, where waiting times are key to customer satisfaction. We propose the use of drones to resupply dispatch vehicles while they are en route, assuming order-release times are known at the beginning of the day. We present a MILP formulation that minimizes distribution costs and customer waiting times. We also show a heuristic to find satisfactory solutions in computationally reasonable times.

3 - Several New Results for the Traveling Salesman Problems with Drone

Minh Hoàng Hà, ORLab, VNU University of Engineering and Technology, Hanoi, Viet Nam, minhhoangha.vth@gmail.com

In this presentation, we will discuss the traveling salesman problems with drone in which at a customer location, a truck can launch a drone to service customers, then continue to visit other customers before retrieving the drone at another customer location. Two problems are considered. The first one deals with the case where drone can service only one customer during a flight while in the second one, it can perform multiple deliveries after being launched. We will introduce a new hybrid genetic algorithm for the former. A mixed integer linear programming formulation and a metaheuristic based on Iterated Local Search are presented for the latter.

4 - A Stochastic Multi-criteria Team Orienteering Problem of UAVs Considering Time Window and Charging Stations

Mohammad Dehghanimohammadabadi, Northeastern University, Boston, MA, United States, m.dehghani@neu.edu, Yuanye Ma

Unmanned Aerial Vehicles (UAVs) are a proper transportation option that can directly fly from one node to another without any traffic congestion and extend their flying range by making use of the charging stations. However, the flying range of the UAVs is limited due to battery constraints. A huge additional cost will occur if a UAV runs out-of-charge on the way to its next destination. This paper focuses on an innovated version of Team Orienteering Problem with Time Windows (TOPTW) in which a set of nodes with stochastic rewards need to be visited by a set of homogeneous UAVs. A simheuristic approach is used to solve the problem and maximize the total expected rewards as well as the total coverage area.

5 - Integrated Truck-Drone Vehicle Routing Problem

Patchara Kitjacharoenchai, PhD Candidate, Purdue University, West Lafayette, IN, 47906, United States, pkitjach@purdue.edu, Seokcheon Lee

This research integrates the truck routing problem, drone routing problem and synchronized truck-drone routing problem all together as a single distribution system. The proposed model is a variant of Heterogeneous Fleet Vehicle Routing Problem (HFVRP) with different capacity and traveling range for three types of vehicles: truck, drone, and synchronized truck-drone vehicle. It determinesthe optimal routes of both trucks and drones which minimize the total arrival time of both trucks and drones at the depot after completing the deliveries. The problem can be solved by the formulated mixed integer programming (MIP) for the small size problem.

AAS Best Student Presentation Competition II

Sponsored: Aviation Applications

Sponsored Session

Chair: Heng Chen, University of Nebraska-Lincoln, Lincoln, NE, 68588, United States

1 - Frequency Approximations for Two-Stage Location Price Competition

Reed Harder, Dartmouth, Hanover, NH, 03755, United States

In many critical industries, competing firms allocate resources across their networks by deciding service locations and pricing these services. For example, airlines competitively schedule and price flights across many origin-destination pairs. Solving for exact equilibrium service locations and prices can quickly become intractable. However, questions of practical interest are often more concerned with aggregate quantities of service within a market than exact service location decisions. With considerations in mind, we evaluate the effectiveness of approximating location decisions with service frequency decisions in firm profit functions.

2 - A Delayed Column Generation Approach for Solving a Cargo Crew Scheduling Problem

Junhong Guo, University of Michigan-IOE, Ann Arbor, MI, 48109-2117, United States

We develop efficient models and algorithms to construct monthly crew schedules for a cargo airline, where crew pairings are allowed to contain a break in the middle. These pairings should be of appropriate length and workload so as to cover as many flights scheduled in the planning horizon as possible. Allowing a break in the middle can greatly increase the flight coverage, but at tremendous computational cost, as the underlying network becomes extremely dense. We propose a heuristic and an exact algorithm, embedded in a delayed column generation procedure, to address this issue.

3 - Network Revenue Management under a Spiked Multinomial Logit Choice Model

Yufeng Cao, Georgia Tech, Atlanta, GA, 30080, United States, yufeng.cao@gatech.edu

Airlines have long noticed that the cheapest available fare class attracts a disproportionate fraction of demand. Incorporating this phenomenon, we study a network revenue management problem under a spiked multinomial logit (spiked-MNL) choice model, where an airline dynamically adjusts its assortment offered to customers. We formulate the problem as a stochastic dynamic program and study the structure of its optimal policy. We propose a tractable deterministic approximation and show how its solution can be used to construct booking limit heuristics that are near-optimal.

Data-Driven Assortment and Price Optimization

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Sajad Modaresi, UNC Chapel Hill, Kenan-Flagler Business School, Chapel Hill, NC, 27514, United States

1 - Demand Learning and Dynamic Pricing for Varying Assortments

Kris J. Ferreira, Harvard Business School, Boston, MA, 02163, United States, kferreira@hbs.edu, Emily Mower

We develop a multi-product, attribute-based demand learning and dynamic pricing algorithm that efficiently learns customer demand to maximize revenue when a small number of price changes are allowed and when products may change over time. Our algorithm follows a learn-then-earn approach, using a novel adaptation of conjoint analysis in the learning phase. We validate the effectiveness of our algorithm through a three-month field experiment with an e-commerce company, where we change the price of products with daily assortment changes. Relative to a control group, our algorithm led to an 8.8% increase in average daily revenue.

2 - Markdown Optimization with Infinite Inventory

Su Jia, CMU Tepper, Pittsburgh, PA, 15232, United States, Andrew A. Li, Ramamoorthi Ravi

We study a single-product setting where the objective is to adaptively reduce the price over a finite sales horizon to maximize revenues. We assume that the expected revenue is unimodal over price so the challenge is to find the revenue maximizing price with an optimal combination of markdown exploration and exploitation. We show that a natural algorithm, which reduces the price at a suitable speed until it is confident that it has passed the optimal price, achieves near-optimal regret. Our tight regret bounds highlight the additional complexity of the markdown constraint in these price exploration problems and are asymptotically higher than corresponding bounds without this constraint.

3 - The Value of Personalized Pricing

Michael L. Hamilton, Columbia University, New York, NY, United States, mh3461@columbia.edu, Adam Elmachtoub, Vishal Gupta

Increased access to customer information has fueled interest in personalized pricing strategies, i.e., strategies that predict a customer's valuation for a product and then offer them a customized price. While the appeal of personalized pricing is clear, it may also incur costs in the form of market research, investment in information technology, and branding risks. In light of these tradeoffs, in this work, we study the value of personalized pricing over simpler pricing strategies and provide various closed-form upper and lower bounds on the ratio that depend on simple statistics and shape properties of the valuation distribution.

4 - Attribute-based Modeling of Product Recommendations

Sajad Modaresi, UNC Chapel Hill, Kenan-Flagler Business School, Chapel Hill, NC, 27514, United States, Sajad_Modaresi@kenan-flagler.unc.edu, Denis R. Saure, Fernando Bernstein

We study efficient real-time data collection approaches for an online retailer that dynamically personalizes assortments based on customers' attributes. We propose policies that leverage transaction data of customers with similar attributes to expedite the learning process and maximize revenue. We test the performance using a dataset from a Chilean retailer.

Innovations in E-commerce and Pricing

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Adam Elmachtoub, Columbia University, New York, NY, 10027, United States

1 - Incentivized Actions in Freemium Games

Lifei Sheng, University of Houston Clear Lake, Houston, TX, United States, sheng@uhcl.edu, Christopher Ryan, Mahesh Nagarajan

We study a common strategy of mobile game companies offering users "virtual" benefits to take actions in-game that earn the company revenue from third parties. Examples of "incentivized actions" include paying users in "gold coins" to watch video advertising. We explore the costs and benefits of offering incentivized actions as users progress in their engagement with the game. We find conditions for when it is optimal to follow a threshold policy of offering incentivized actions to low engaged users and then remove them once a user is sufficiently engaged. And we test such policy with real data. Finally, we provide insights into what types of games benefit most from offering incentivized actions.

2 - Loot Box Pricing and Design

Xiao Lei, Columbia University, New York, NY, 10027, United States, xl2625@columbia.edu, Ningyuan Chen, Adam Elmachtoub, Michael Hamilton

Online games garner annual revenues in the billions, more than half of which is from purchases of virtual items to be used by the player in the game. One popular way to sell in-game items are via loot boxes, which are random bundles of virtual items, the contents of which are revealed after purchase. We consider how to design loot boxes selling strategies, and compare them with bundle selling and separate selling. We show that in an asymptotic regime, carefully designed loot box strategies can garner as much revenue as bundle selling while inheriting many nice properties of separate selling. Our result and discussion give insights to customers, sellers and regulators.

3 - Optimal Pricing Policy for Service Systems with Reusable Resources and Strategic Customers

Yiwei Chen, University of Cincinnati, Cincinnati, OH, United States, Cong Shi

We consider a firm who uses a finite number of reusable resources to serve customers who are heterogeneous in their arrival times, service start and end times. The firm dynamically adjusts the service prices. Customers are forward-looking who strategize their times to request the services. We present a simple fixed price policy that the firm charges customers a flat rate of the resource usage per unit of time. We show that this policy is asymptotically optimal.

4 - Static Pricing: Universal Guarantees for Reusable Resources

Adam Elmachtoub, Columbia University, New York, NY, 10027, United States, Omar Besbes, Yunjie Sun

We consider a fundamental pricing model in which a fixed number of units of a reusable resource are used to serve customers. Our model represents various markets for reusable resources such as cloud computing, shared vehicles, rotable spare parts, and hotel rooms. We analyze this pricing problem when the firm attempts to maximize a weighted combination of three central metrics: profit, market share, and service level. While an optimal policy is fully dynamic, we prove that a static pricing policy simultaneously guarantees 78.9% of the profit, market share, and service level from the optimal policy. Notably this result holds for any service rate and number of units the firm operates.

Mechanisms and Market Equilibria

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Nicolas Stier-Moses, Facebook, Menlo Park, CA, 94025, United States

1 - Budget Management Strategies in Repeated Auctions

Anthony Kim, Columbia University, New York, NY, 10027, United States, aek2185@columbia.edu, Vahab Mirrokni, Santiago Balseiro, Mohammad Mahdian

One of the most important features advertising platforms often provide is budget management, which allows advertisers to control their cumulative expenditures. We study the "system equilibria" of a range of budget management strategies in terms of the seller's profit, buyers' utility and overall welfare. We show these methods admit a system equilibrium in a rather general asymmetric setting, analyze their stability properties, and prove dominance relations between them when buyers are symmetric. We also empirically compare the system equilibria of these strategies using real ad auction data.

2 - Competitive Equilibria and Trading Networks

Ozan Candogan, University of Chicago, Booth School of Business, Chicago, IL, 27708, United States, ozan.candogan@chicagobooth.edu, Markos Epitropou, Rakesh Vinay Vohra

Under full substitutability of preferences, we formulate the problem of finding a competitive equilibrium in trading networks as a generalized submodular flow problem. Our formulation enables us to perform comparative statics with respect to the number of buyers, sellers, and trades. For instance, we establish that if a new buyer is added to the economy, at an equilibrium the prices of all existing trades (including those that are not adjacent) increase. More generally, we identify certain "bridge" trades, whose addition to the network yields monotone changes in surpluses of downstream agents.

3 - Computing Large Market Equilibria Using Abstractions

Christian Kroer, Professor, Columbia University, Computer Science New York, NY, 15213, United States, christian.kroer@columbia.edu Christian Kroer, Professor, Facebook, New York, NY, United States, christian.kroer@columbia.edu, Alexander Peysakovich, Eric Sodomka, Nicolas Stier-Moses

Computing market equilibria is an important problem for market design. However, these equilibria require large amounts of information and computation. We consider ameliorating these issues by abstraction: an equilibrium is computed in a coarsened market, and then lifted to the original market. We show that several objectives have optimality bounds under this approach. We then study two practical abstraction methods: 1) filling in unknown valuations using matrix completion, 2) reducing the problem size by using representative buyers/items. We find that in real data allocations that are relatively close to equilibria can be computed from coarse abstractions.

4 - Tractable Equilibria in Sponsored Search with Endogenous Budgets

Dragos Florin Ciocan, INSEAD, Fontainebleau, France, Krishnamurthy Iyer

We consider an ad network's problem of allocating the auction for each individual impression to an optimal subset of advertisers, with the goal of revenue maximization. This is a variant of bipartite matching, except that advertisers may strategize by choosing their bidding profiles and their total budget. Under a linear budget cost of r, we show there exists an approximate equilibrium, where bidders bid their valuations shaded by a factor of 1+r, and set budgets slightly above their expected spending. Furthermore, in this approximate equilibrium, the optimal allocation for the ad network, as determined from an LP, is greedy with high probability.

Pricing and Revenue Management in Retail Operations

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Mehmet Sekip Altug, George Mason University, Washington, DC, 20052, United States

1 - The Equivalence of Restocking Fees and Rebates for Product Returns

Rachel Rong Chen, University of California-Davis, 3208 Gallagher Hall, One Shields Avenue, Davis, CA, 95616, United States, rachen@ucdavis.edu, Eitan Gerstner, Paolo Roma

Sellers experience excessive purchase cancellations in the form of product returns and seat cancellation of services such as hotels, cuisines and restaurants. Purchase cancellations result in lost sales, overproduction of goods and services, inflated shipping and handling costs, and damages to the environment. Are there policies that could help mitigate these damages? In this paper, we show that the restocking fee policy is equivalent to the rebate policy at reducing product returns.

2 - Endogenous Consumer Search under Asymmetric Product Familiarity

Michael Galbreth, University of Tennessee, Haslam College of Business, Knoxville, TN, 37996, United States, galbreth@utk.edu, Bikram Ghosh

When a consumer is familiar with one product but not its competitor, she is faced with a decision: buy what she knows, or engage in search to learn more. When search is costly, competing firms may attempt to encourage or discourage search by adjusting prices. We consider how these competitive dynamics are affected by marginal changes in the relative familiarity of competing products. An increase in familiarity for one product gives a firm pricing power, but it also gives its competitor a stronger incentive to decrease price to encourage search. We analytically investigate these opposing effects and discuss several directions for future research into competition under asymmetric product familiarity.

3 - Competitive Demand Learning and Pricing in Online Marketplaces

Arcan Nalca, Smith School of Business / Queen's University, Goodes Hall Queen's University, Kingston, ON, K7L 3N6, Canada, arcan.nalca@queensu.ca, Taner Bilgic, Mehmet Gumus

A pure online marketplace is an e-commerce site where independent sellers sell their products and transactions are managed by a marketplace platform. We focus on 3 characteristics of pure online marketplaces: 1) the demand-price relationship is unknown and has to be learned from sales data, 2) the platform observes sales transactions of all sellers while the sellers observe only their own sales, 3) platform allows sellers to exercise full control on their prices, and it only charges a commission to accumulate earnings for the platform. We evaluate alternative information sharing arrangements and contractual arrangements in platform-to-seller relationships in the presence of demand learning.

4 - Optimal Dynamic Allocation of Sales and Rental Inventory at a Retailer

Oben Ceryan, City, University of London, Cass Business School, London, EC1 Y. 8TZ, United Kingdom, Oben.Ceryan@city.ac.uk, Mehmet Sekip Altug

We consider a retailer that primarily rents and sells on the side over a given horizon. In every period, the retailer faces uncertain demand that splits between renters and buyers based on their utility. We characterize the optimal dynamic rental allocation policy and study its properties. We propose an implementable heuristic. We then extend our results to a retailer that primarily sells and rents on the side and study the duopoly case to characterize the emerging equilibrium. We derive the conditions that lead to "pure sales", "pure rental" and "mixed" equilibrium.

Theoretical Aspects of Pricing Mechanisms

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Manolis Pountourakis, University of Texas at Austin

1 - Optimal Auctions vs Anonymous Pricing

Emmanouil Pountourakis, UT Austin, Austin, TX, 78712, United States, Saeed Alaei, Jason Hartline, Rad Niazadeh, Yang Yuan

For selling a single item to agents with independent but non-identically distributed values, the revenue optimal auction is complex. With respect to it, Hartline and Roughgarden (2009) showed that the approximation factor of the second-price auction with an anonymous reserve is between two and four. We consider the more demanding problem of approximating the revenue of the ex ante relaxation of the auction problem by posting an anonymous price (while supplies last) and prove that their worst-case ratio is e. As a corollary, the upper-bound of anonymous pricing or anonymous reserves versus the optimal auction improves from four to e.

2 - Dynamic Procurement Auction

Ali Khodabakhsh, University of Texas at Austin, Austin, TX, 78703, United States, ali.kh@utexas.edu, Emmanouil Pountourakis, Evdokia Velinova Nikolova

In this talk we will talk about procurement auctions in a dynamic setting, in which the set of participating agents varies based on their previous assignments. This is motivated by electricity markets where the system operator wants to assign electricity generation to the available generators while satisfying the demand. In such a market, if a generator is not assigned frequent enough, they may not participate in the future rounds, which can increase the prices due to lack of competition.

3 - Sample Complexity for Non-truthful Mechanisms

Sam Taggart, Oberlin College, Oberlin, OH, United States, Jason Hartline

This paper considers the design of non-truthful mechanisms from samples. We identify a parameterized family of mechanisms with strategically simple winner-pays-bid, all-pay, and truthful payment formats. In general (not necessarily downward-closed) single-parameter feasibility environments we prove that the family has low representation and generalization error. Specifically, polynomially many bid samples suffice to identify and run a mechanism that is epsilon-close in Bayes-Nash equilibrium revenue or welfare to that of the optimal truthful mechanism.

4 - Returns on Privacy: Phase Transitions in Repeated Sales

Ezra Goss, Georgia Institute of Technology, Atlanta, GA, United States, ezragoss@gmail.com, Rachel Cummings, Yuan Cui, Samuel Taggart

We analyze a repeated pricing game between a buyer and seller in the presence of privacy and the absence of commitment power. Past work has shown that in the absence of privacy, equilibrium can fail to exist. Meanwhile, for full privacy, the standard results for single-shot games apply. We ask: what happens in the middle? We show that the results for extremely low and high levels of privacy are robust: equilibrium still does not exist with nominal but positive privacy, and full privacy can be significantly relaxed while preserving equilibrium. As a corollary, we obtain that the transition from nonexistence to the presence of equilibrium takes place at an intermediate level of privacy.

Humanitarian Analytics

Sponsored: Public Sector OR

Sponsored Session

Chair: Elisa Frances Long, UCLA Anderson School of Management, Los Angeles, CA, 90024, United States

1 - Hurricanes, Power Outages, and Utility Response

Elnaz Kabir, University of Michigan, Ann, MI, United States, Seth Guikema, Chengwei Zhai

Hurricanes cause substantial damage to power systems, leading to widespread, prolonged power outages. Utilities then have a significant logistical challenge to restore power across a large service territory under challenging conditions. Modeling is beginning to support this work in practice, with predictive models of the degree of damage and the duration of outages developed through research projects now being used in practice. This talk will giver an overview of this research and focus in particularly on how these models are transitioned from research to practice.

2 - Product Availability, Consumer Stockpiling, and Hurricane Events

Xiaodan Pan, Concordia University, Montreal, QC, H3H 0A1, Canada, xiaodan.pan@concordia.ca, Martin E. Dresner, Benny Mantin, Jun Zhang

The provision of essential supplies is a key service provided by retailers when demand spikes due to consumer stockpiling during environmental emergencies. We study consumer stockpiling behavior prior to the onset of hurricane landfalls, with a focus on the impact of this behavior on in-store product availability for various formats of retail store outlets. Our study points to the need for retailers to carefully monitor factors affecting consumer stockpiling behavior during the hurricane season that will allow them to better preposition inventories and fulfill consumer demand.

3 - Tracking Misinformation on Social Media: a Machine Learning Approach

Kyle J. Hunt, Student and Research Assistant, University at Buffalo, Buffalo, NY, 14221, United States, kylehunt@buffalo.edu, Puneet Agarwal, Jun Zhuang

A prodigious gap in research exists in studying the tracking of misinformation on social media platforms in times of disasters and other crisis events. Such studies would offer organizations and agencies new tools and ideologies to track identified misinformation on platforms such as Twitter and make informed decisions on whether or not to use their resources in order to debunk the false information. In this work, we fill the research gap by training eight different machine learning algorithms to predict the veracity of misinformation-related tweets that are spread during crisis events. The tweets are tracked in real-time based on the veracity of their content as either true, false, or neutral.

4 - Political Storms: Tracking Hurricane Evacuation Behavior using Smartphone Data

Elisa Long, UCLA Anderson School of Management, 110 Westwood Plaza, Gold Hall B-508, Los Angeles, CA, 90024, United States, elisa.long@anderson.ucla.edu, Keith Chen, Ryne Rohla

The 2017 hurricane season devastated the U.S. gulf coastline but, despite extensive warnings, most residents did not evacuate before the storms hit. Using a GPS dataset for 2.7 million smartphone users in Florida and Texas, along with census and precinct voting data, we empirically examine demographic predictors of hurricane evacuations. A strong predictor was the 2016 Democrat/Republican President vote share, but only after conservative media skepticism of hurricane warnings emerged in 2017. Using spatial regression discontinuity, we confirm the causal impact of hurricane alerts by comparing evacuation rates for residents on opposite sides of county boundaries receiving different alerts.

Joint Session Policy/HAS: Pricing Models in Pharmaceutical and Healthcare Markets

Emerging Topic: Policy & Government

Emerging Topic Session

Chair: Turgay Ayer, Georgia Institute of Technology, Atlanta, GA, 30332, United States

Co-Chair: Zhaowei She, Georgia Institute of Technology, Atlanta, GA, 30067, United States

1 - Outcome-based Reimbursement: The Solution to High Drug Spending?

Liang Xu, Pennsylvania State University, State College, PA, 16801, United States, lzx103@psu.edu, Hui Zhao, Hongmin Li

To induce insurer coverage of expensive new drugs, manufacturers have proposed the outcome-based reimbursement (OBR) scheme, under which the insurer will receive a rebate if the realized drug effectiveness does not reach the expected level. We investigate the impact of OBR on the insurer, manufacturer and patients, by developing a Stackelberg game framework to capture the optimal design of the OBR scheme. We apply data on 15 drugs treating hyperlipidemia, a common disease, and provide calibrated answers to the above questions for these drugs. Our results show that, while OBR reduces insurer's risk, it does not lower insurer's spending due to the manufacturer's inflated price.

2 - Outcomes-based vs. Traditional Pharmaceutical Contracts

Andrew ElHabr, Georgia Institute of Technology, Atlanta, GA, United States, andrewelhabr@gatech.edu, Can Zhang, Turgay Ayer

We study under what market conditions and drug characteristics payers and pharmaceutical manufacturers are better off engaging in an outcomes-based contract, an agreement that links payments for drugs to drug effectiveness, over a traditional contract. Our findings include that moderately cheap and effective drugs can be good candidates for outcomes-based contracts. We also find that an agreement on preferred drug formulary placement in exchange for lower per-unit drug price can be beneficial to all stakeholders.

3 - Financing Hepatitis C Treatment Through the Netflix Model

Zhaowei She, Georgia Institute of Technology, Atlanta, GA, 30067, United States, zhaowei@gatech.edu, Yueran Zhuo, Jagpreet Chhatwal, Turgay Ayer

Several state governments (e.g. Louisiana and Washington) recently entered into Netflix-Style contracts with their pharmaceutical partners (e.g. Gilead and AbbVie), where the state agency makes a fixed lump sum payment to its pharmaceutical partner in exchange for unlimited access of Hepatitis C drugs for its Medicaid patients. We analyze these emerging Netflix-Style payment models for pharmaceutical treatments from a mechanism design perspective, and characterize conditions under which these contracts would improve the efficiency of pharmaceutical market.

4 - A Study of Prospectively-paid, Performance-based Incentive Payments in Healthcare

Zheng Han, University of Kansas, Lawrence, KS, 66045, United States, Mazhar Arikan, Suman Mallik

We study decision problems of a healthcare practice under Comprehensive Primary Care Plus (CPC+) payment scheme, which aims to strengthen primary care by providing practices additional financial resources and flexibility to make investments and improve quality of care. We develop insights on the resulting quality of care, using fee-for-service (FFS) payment scheme as a benchmark.

11:00-11:45 The AnyLogic Company / 11:45-12:30 Palisade

Vendor Tutorial

1 - Simulation Models as Virtual Environments to Train and Test AI for Business Applications

Arash Mahdavi, Anylogic Company, Chicago, IL, United States

In this tutorial, we will discuss how you can leverage unique features of AnyLogic simulation software and AnyLogic Cloud to solve your business challenges or perform scientific research. We demonstrate application of simulation in various domains and demonstrate state-of-the-art technologies that can take your simulation models to the next level in terms of sophistication and usefulness.

2 - Quantitative Risk Analysis in Excel with @RISK

José Raúl Castro, Palisade Trainer/Consultant, Palisade Corporation, Ithica, NY, United States

This tutorial will guide you in the use of @RISK for analyzing historical data and making better decisions in an uncertain business environment. @RISK is part of Palisade's Decision Tools Suite and runs as an add-in for MS Excel. It provides all the features you need to quantify and understand risks with the support of Monte Carlo Simulation, including graphical capabilities and quick reports to help you present results to a non-technical audience.

Big Data Science: Classical Origins and New Frontiers

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Ran Jin, Virginia Tech, Blacksburg, VA, 24061, United States

Co-Chair: Lulu Kang, Illinois Institute of Technology, Chicago, IL, 60616, United States

1 - Information Quality, the New Challenge in the Data Science Age

Ron Kenett, KPA, Israel, ron@kpa-group.com

The quality of information generated in data-driven analytics is of central importance in modern data science. The talk will present a framework for evaluating, analyzing, and improving the quality of information called InfoQ. InfoQ consists of four components (goal, data, analysis and utility) and eight dimensions. The talk will also present recent initiatives to define data readiness level (DRL) as a basis for generating InfoQ.

2 - Data Science and Informs

Yu Ding, Texas A&M University, Dept. Industrial & Systems Engineering, College Station, TX, 77843-3131, United States, yuding@tamu.edu

During 2018's NSF Big Data PI meeting, Dr. Michael Franklin gave a keynote speech talking about what data science is and whether data science is a new discipline. This speaker wants to continue this conversation but with more focus on data science's interaction and relevance to INFORMS communities

3 - Statistical Process Control in the Big Data Era

Peihua Qiu, University of Florida, Gainesville, FL, 32610, United States, pqiu@ufl.edu

"Big data" is a buzzword these days due to an enormous amount of data-rich applications in different industries and research projects. In practice, big data often take the form of data streams in the sense that new batches of data keep coming over time. One fundamental research problem for analyzing such big data streams in a given application is to sequentially monitor the underlying process behind the observed data to see whether it is longitudinally stable, or how its distribution changes over time. To monitor a sequential process, one major statistical tool is the statistical process control (SPC), which has been used mainly for monitoring production lines in manufacturing industries during the past several decades. With many new and versatile methods developed in recent SPC research, SPC can provide a powerful tool for handling many other applications. In this talk, I will introduce some traditional and more recent SPC concepts and methods, and discuss some challenges in the interface of the existing SPC methods and some big data applications as well.

4 - Big Data Origins and New Frontiers

Lulu Kang, Illinois Institute of Technology, 10 West 32nd Street, Chicago, IL, 60616, United States, lkang2@iit.edu

Under the big data paradigm, the application and study of data science are crucial to many sciences, engineering, and business disciplines. We invite three prominent scholars to present their discoveries, knowledge, and experiences in the field of data science. Dr. Ron S. Kennett will present a framework for evaluating, analyzing, and improving the quality of information. Dr. Yu Ding will give a talk on data science's interaction and relevance to INFORMS communities. Dr. Peihua Qiu will introduce some traditional and more recent Statistical Process Control concepts and methods and discuss some challenges in the interface of the existing SPC methods and some big data applications as well.

Disaster and Emergency Management II

Contributed Session

Chair: Alireza Inanlouganji, Arizona State University, Tempe, AZ, 85282, United States

1 - Drone Aided Road Recovery and Relief Operation in Disasters

Mohammad Amin Farzaneh, Florida International University, Miami, FL, United States, mfarz004@fiu.edu, Shabnam Rezapour

Recovery of primary roads accelerates relief distribution in disasters. In this paper, three interconnected models are proposed for damage assessment and road recovery in a way that maximizes the speed of relief distribution to reach out the disaster affected areas as soon as possible and consequently save more people. The first model is about the drone aided damage assessment, the second one is about the road recovery process and the third one is for relief operations. models are tested for a road network on the southeast coast of the US and the results are compared with benchmarks.

2 - A Hierarchical Decision-making Framework for the Efficient Disaster Management Strategy

Seunghan Lee, University of Arizona, Tucson, AZ, United States, shlee17@email.arizona.edu, Saurabh Jain, Young-Jun Son

The importance of improvising effective disaster management policies has increased over the past decade. However, due to the increasing effects of social networks and the diversity of individual opinions, predicting people's behaviors during the disaster becomes challenging. Thus, we propose a generalized decision-making framework to represent realistic human behavior in a disaster situation. The framework assists us in examining the interaction effects within the social network, which will help to analyze innovation diffusion and opinion formation processes. We also demonstrate the necessary conditions for the best policy for maximizing the level of disaster preparedness and responses.

3 - Empirical Study: Noncompetitive Contracts and Public Assistance Alternative Programs in Post-disaster Recovery

Andriy Shapoval, Georgia Tech, Atlanta, GA, United States

This work considers use of Public Assistance from U.S. Federal Emergency Management Agency (FEMA). Alternative procedures are still called pilot programs and subject to updates and changes. Features of large-scaled recovery projects are analyzed together with situations of noncompetitive contracts.

4 - Simulation Based Rollout Algorithm for Disaster Response in Large Power Networks

Alireza Inanlouganji, Arizona State University, Tempe, AZ, United States, ainanlou@asu.edu, Giulia Pedrielli

This work investigates the problem of real-time recovery of power networks under iteratively updated natural disaster information, where the stochastic model of the effect of weather conditions over the state of the power network is known. We formulate the problem as a Stochastic Dynamic Program, and deal with the curse of dimensionality by developing a novel Rollout algorithm that uses a local optimization as base heuristic. The reward is estimated using a simulator for the network. We evaluate the performance of the algorithm in terms of both solution accuracy and computational time.

IISE Transactions Invited Session

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Judy Jin, University of Michigan, Ann Arbor, MI, 48109-2117, United States

1 - A Prediction and Compensation Scheme for In-plane Shape Deviation of Additive Manufacturing with Information on Process Parameters

Andi Wang, Georgia Institute of Technology, Atlanta, GA, United States, andi.wang@gatech.edu, Longwei Cheng, Fugee Tsung

Shape fidelity is a critical issue that hinders the wider application of Additive Manufacturing (AM) technologies. In this article, we aim to improve the shape fidelity of AM products through compensation, with the information on the process parameters. To achieve this, a two-step scheme is proposed to predict the in-plane deviation of the product shape, which relates to the process parameters and the two-dimensional input shape. Based on this prediction procedure, a shape compensation strategy is developed that greatly improves the dimensional accuracy of products. Experimental studies of fused deposition modeling processes validate the effectiveness of our proposed scheme.

2 - Monitoring Serially Dependent Categorical Processes with Ordinal Information

Jian Li, Xi'an Jiaotong University, Xi'an, China, jianli@xjtu.edu.cn, Jiakun Xu, Qiang Zhou

There is usually natural order among the attribute levels of categorical variables. We consider monitoring a serially dependent ordinal categorical process, which is driven by a latent autocorrelated continuous process. The unobservable values of the continuous variable determine the levels of the ordinal variable. We transform the data into a multi-way contingency table and describe them with our proposed novel ordinal log-linear model. This model can incorporate both the marginal distribution of attribute levels and the serial dependence. A chart is finally proposed to monitor if there is shift in the location parameter or in the autocorrelation coefficient of the latent continuous variable.

3 - Identifying Nonlinear Variation Patterns with Deep Autoencoders

Phillip Howard, Intel Corporation, Chandler, AZ, United States, Daniel Apley, George Runger

The discovery of nonlinear variation patterns in high-dimensional profile data is an important task in quality control and manufacturing. We present an automated method for discovering nonlinear variation patterns using deep autoencoders. The approach provides a functional mapping from a low-dimensional representation to the original spatially-dense feature space of the profile data that is interpretable and efficient. We compare our approach to other methods for discovering variation patterns in profile data. Our results indicate that deep autoencoders outperform alternative approaches in reproducing the original profiles from the learned variation sources.

4 - Layer-wise Spatial Modeling of Porosity in Additive Manufacturing

Jia (Peter) Liu, Virginia Tech, Blacksburg, VA, United States, Chenang Liu, Yun Bai, Prahalad Rao, Chris Williams, Zhenyu (James) Kong

In additive manufacturing (AM), porosity has a direct impact on the part functional integrity. To quantify the underlying mechanism of porosity formation and evolution in an AM part, an augmented layer-wise spatial log Gaussian Cox process (ALS-LGCP) model is developed by leveraging the spatiotemporal correlation among pores on the sequential X-Ray CT scans. ALS-LGCP unveils the structure of pore formation and predicts when and where the pores progress on future layers. This research marks a critical step towards a model-based understanding of defect formation in additive manufacturing and has promising potential to be applied in online, in-situ X-Ray-based monitoring of AM processes.

Online Monitoring and Anomaly Detection in Spatio-temporal Data

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Hao Yan, Tempe, AZ, 85281, United States

1 - Rapid Detection of Hot-spot by Tensor

Yujie Zhao, Georgia Institute of Technology, Atlanta, GA, United States, yzhao471@gatech.edu

In bio-surveillance and healthcare applications, it is possible that data has circular patterns. One monitors multiple data sources from spatial locations over time and is interested in detecting hot-spots from some data sources and some sparse spatial locations that are persistent outliers over time. We propose a tensor decomposition method to detect which, where, when the hot-spots occur. Our proposed methods represent the observed raw data as three-dimensional tensor and decompose it into three components: smooth global trend, local hot-spot, and residuals. A combination of lasso and fused lasso is used to estimate parameters with regularization term for continuity and circularity.

2 - Spike Slab Based Partial Observable Online Monitoring with Thompson Sampling

Chen Zhang, Tsinghua University, e1-07-26, 3 Engineering Drive, Singapore, 117576, Singapore, zhangchen01@tsinghua.edu.cn

We consider online multivariate process change detection when only partial observations can be achieved for each sampling point. In particular, we pre-define some interested anomaly patterns, and test whether the online data have significant projections on these patterns via spike slab variational inference in the Bayesian framework. We also design an adaptive sampling framework to decide which dimensions to observe for the next sampling point based on Thompson sampling algorithm.

3 - High-dimensional Anomaly Detection with Adversarial Autoencoders

Nurettin Dorukhan Sergin, Arizona State University, Tempe, AZ, United States, nsergin@asu.edu, Hao Yan, Huai-ming Yeh

Nonlinear profile and image-based process monitoring and diagnosis have recently attracted increasing attention among researchers as well as practitioners. Yet, existing profile monitoring techniques based on linear models such as PCA fail to represent the complex spatial in-control pattern. Inspired by the recent development and success of deep learning techniques, we propose to combine deep generative models with process monitoring techniques. Our findings suggest that a regularized deep generative model can work well with small amounts of in-control data. We demonstrate in-depth results both in simulated profile datasets and a real-life case of a steel manufacturing process imagery.

Lightning Round: HAS Doctoral Students and Post-docs on the Job Market

Sponsored: Health Applications

Sponsored Session

Chair: Anahita Khojandi, University of Tennessee, Knoxville, TN, 37996, United States

Co-Chair: Hadi El-Amine, George Mason University, Fairfax, VA, 22030, United States

1 - Moderator

Anahita Khojandi, University of Tennessee, 521 Tickle Building, Knoxville, TN, 37996, United States

The purpose of this session is to bring visibility to the students and postdocs looking for academic positions with a focus on health applications and/or theory, and facilitate recruitment for departments interested in growing their capabilities in healthcare-related research/teaching. The participants in the session each will have up to 4 minutes to present 1-2 slides about their research interests and past projects. After the presentations are over, the audience and participants will have time to mingle and have one-on-one interactions.

Panelists

- Ai Ren, University of Maryland-College Park, Robert H. Smith School of Business, College Park, MD, 20740, United States
- Carolina Vivas-Valencia, Purdue University, West Lafayette, IN, 47906, United States
- Esmaeil Keyvanshokooh, University of Michigan-Ann Arbor, Ann Arbor, MI, 48108-1020, United States
- Gian-Gabriel P. Garcia, University of Michigan, Ann Arbor, MI, 48105, United States
- Justin Kistler, University of South Carolina, Columbia, SC, 29212, United States
- Karen T. Hicklin, University of North Carolina at Chapel Hill, Chapel Hill, NC, 27599-7411, United States
- Lina Song, Harvard University, Cambridge, MA, 02138, United States
- Masoud Kamalahmadi, Indiana University, Bloomington, IN, 47405, United States, maskamal@iu.edu
- Sina Ansari, Tuck School of Business Dartmouth College, Hanover, NH, 03755, United States
- Temitayo Ajayi, Rice University, Houston, TX, 77004, United States

OR Applications in Cancer Care

Sponsored: Health Applications

Sponsored Session

Chair: Iakovos Toumazis, Stanford University, Stanford, CA, 94305-5446, United States

1 - Benefits and Harms of Mammography Screening for Women with Down Syndrome

Oguzhan Alagoz, University of Wisconsin-Madison, 3242 Mechanical Engineering Building, Madison, WI, 53706, United States, alagoz@engr.wisc.edu, Ali Hajjar, Sarocha Chootipongchaivat, Nicolien van Ravesteyn, Jennifer Yeh, Mehmet Ergun, Harry de Koning, Brian Chicoine, Barry Martin

Women with Down syndrome have lower life expectancies and risk of breast cancer compared to women without Down syndrome. We used two established Cancer Intervention and Surveillance Modeling Network (CISNET) simulation models that were used to inform national breast cancer screening guideline development to estimate the benefits, harms, and commonly used harm/benefit ratios of various mammography screening strategies for women with Down syndrome. The harm/benefit ratios for various mammography screening strategies in women with Down syndrome are not as favorable as those for average-risk women.

2 - Search and Sensitivity in the Creation of Natural History Models to Support Cancer Care

Michael J. Hintlian, University of Southern California, Los Angeles, CA, 90006, United States, Julia L. Higle

Model-based analysis that supports medical decision-making relies on disease models. Model parameter values are typically identified via a search process during calibration. Common search techniques include random sampling, Nelder-Mead, and simulated annealing. Search methods can have a significant impact on the parameters identified, as well as the results of subsequent analyses. We introduce search methods that expand on existing techniques and are designed to find models quickly while maintaining desirable properties. We demonstrate these methods on disease models at scale.

3 - Optimizing the Use of Supplemental Breast Screening Ultrasound and MRI

Burhaneddin Sandikci, University of Chicago, Booth School of Business, Chicago, IL, 60637, United States, burhan@chicagobooth.edu, Mucahit Cevik, David Schacht

Timely detection of breast cancer is hindered by the imperfect nature of the tests used. In the U.S. , the gold standard mammography screening is increasingly supplemented with ultrasound and MRI screening tests, particularly for high-risk women including those with dense breasts. Breast density not only impairs screening accuracy, but also significantly increases risk of developing breast cancer. We formulate a personalized dynamic optimization model tracking significant attributes of a women (e.g., her age and breast density) to optimize the use of supplemental tests and compare its results to mass screening guidelines to help quantify the value of supplemental screening.

4 - Improving the Efficiency of Patient-Centered Medical Decision Making for Preventive Screening

M. Gabriela Sava, Assistant Professor, Clemson University, College of Business, Clemson, SC, 29634, United States, msava@clemson.edu, Luis G. Vargas, Jerrold H. May, James G. Dolan

Sensitivity and stability analyses are important when employing a multi-criteria model for medical decision making. But the cost of gathering the data for those analyses may only be less than the benefit for atypical patients. For routine cases, it may be more efficient to maintain a library of archetypical analyses, and to select one based on easily obtained measures. We discuss that conjecture in the context of colorectal cancer screening, using data from a substantial set of real patients.

5 - Optimizing the Net-Benefit of Lung Cancer Screening Using a Partially Observable Markov Decision Process

Iakovos Toumazis, Stanford University, Department of Radiology, Stanford, CA, 94305-5446, United States, iakovost@stanford.edu, Oguzhan Alagoz, Ann Leung, Sylvia Plevritis

Current recommendations on lung cancer (LC) screening define eligibility based on age, smoking intensity and years since smoking cessation. Many other risk factors associated with LC incidence, along with the cost of screening are not taken into consideration leading to sub-optimal strategies from a cost-effectiveness point of view. We propose a partially observable Markov decision process (POMDP) that maximizes the net-benefit of a LC screening program. We develop a screening framework that offers individualized optimal cost-effective screening decisions based on the risk of ever-smoked individuals while accounting for past screening results and changes in individuals' smoking behavior.

Global Health Operations

Sponsored: Health Applications

Sponsored Session

Chair: Jonas Oddur Jonasson, MIT Sloan School of Management, Cambridge, MA, 02142, United States

1 - Machine Learning Based Risk Stratification for Early Detection of Diabetes and Hypertension in Resource-limited Settings

Justin J. Boutilier, University of Wisconsin-Madison, Madison, WI, United States, Timothy Chan, Manish Ranjan, Sarang Deo

The impending scale up of non-communicable disease screening programs coupled with limited health resources require that such programs are as efficient as possible. We demonstrate that machine learning risk stratification algorithms that are tailored for community-based screening programs in low-resource settings could save approximately $1.19 billion USD for diabetes and $960 million USD for hypertension by reducing missed diagnoses.

2 - Vaccine Distribution Chains in Low- and Middle-income Countries: The Case of Madagascar

Kim De Boeck, KU Leuven, Leuven, Belgium, kim.deboeck@kuleuven.be, Catherine Jenny Decouttere, Nico Vandaele

Access to immunization varies greatly across the world. In order to increase vaccine coverage, the required vaccines need to be able to reach the targeted population. However, in low- and middle-income countries, this often turns out to be a challenging task. We give an introduction to the case of Madagascar where the vaccine distribution chain is heavily impacted by the rainy season.

3 - Shared Medical Appointments – An Innovative Approach to Healthcare Delivery

Nazli Sonmez, London Business School, London, United Kingdom, nsonmez@london.edu, Kamalini Ramdas, Ryan Buell

We examine shared medical appointments (SMAs) as a substitute for regular one-on-one appointments. Under this innovative approach, a group of patients with similar chronic conditions meet with a doctor simultaneously and receive one-on-one care. We conduct a randomized controlled trial at the Aravind Eye Hospital, in Pondicherry, India to assess the effectiveness of shared medical appointments versus traditional one-on-one appointments for glaucoma. Preliminary results obtained with the data suggest that the knowledge and satisfaction level of patients who attend shared medical appointments is significantly higher than that of patients who attend one-on-one appointments.

4 - Operational Challenges in a Medical Transportation Platform in India

Gonzalo Romero, Rotman, University of Toronto, Toronto, ON, M4K 3H6, Canada, gonzalo.romero@rotman.utoronto.ca, Andre Du Pin Calmon, Luk N. Van Wassenhove

We model and analyze the operational challenges faced by a medical transportation platform in India. In many developing countries, there is no centralized ambulance dispatcher. Therefore, patients must call their local hospital or hire a private ambulance, resulting in long waiting times for patients and costly routes for ambulances.

5 - Perspective on (Research) Problems in Global Health Delivery

Ravi Anupindi, University of Michigan, Ann Arbor, MI, 48109, United States

In this talk I will share some my experiences / understanding of problems in global health delivery based on field projects / case studies in Africa and India. Through this lens I will try to reflect on the current state and future opportunities research in this space.

HAS Distinguished Speakers – I

Sponsored: Health Applications

Sponsored Session

Chair: Mark P. Van Oyen, University of Michigan, Ann Arbor, MI, 48109-2117, United States

Co-Chair: Hui Zhao, The Pennsylvania State University, Smeal College of Business, University Park, PA, 16802, United States

1 - Personalized Medicine: A Vision for Research and Education

Dimitris Bertsimas, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States

Medicine as taught in medical schools and as practiced today is not personalized. We present a research program to develop an algorithmic theory of personalized medicine applied to the major human diseases. Using electronic medical records, and genomic data and in collaboration with major medical centers and medical doctors, we present our ongoing efforts to develop algorithms that propose personalized treatments for individual patients that suffer from these diseases. The new personalized medicine algorithms are based on optimal classification, regression and prescription trees developed in Bertsimas and Dunn (2017,2019), machine learning methods that combine interpretability and state of the art performance We report on our work on cardiovascular disease, stroke, cancer, surgery, diabetes, blood pressure and liver transplantation and their impact in medical practice. We further discuss the implications of our work on the education of the next generation of doctors and analytics students.

2 - Health Care Collaboration: A Case Study

Martin L. Puterman, Professor Emeritus, University of British Columbia, Sauder School of Business, Vancouver, BC, V6T 1Z2, Canada, martin.puterman@sauder.ubc.ca

In this talk I will describe my lengthy collaboration with the British Columbia Cancer Agency. I will discuss how the collaboration came about, the research produced, the impact on practice and the training that has taken place. I will also explore (with the assistance of Leah Weber) the challenges of developing software in a health system environment. Throughout the talk, I will highlight both methodological and practical challenges and how they were overcome.

Disease Modeling to Inform Health Policy

Sponsored: Health Applications

Sponsored Session

Chair: Anneke Claypool, Stanford University, Stanford, CA, 94305, United States

1 - Quantifying Positive Health Externalities of Disease Control Interventions: Modeling Chikungunya and Dengue

Anneke Claypool, Stanford University, Stanford, CA, 94305, United States, Margaret L. Brandeau, Jeremy Goldhaber-Fiebert

Health interventions can generate positive externalities not captured in traditional, single-disease cost-effectiveness analyses (CEAs), potentially biasing results. For example, when a mosquito species can transmit multiple diseases, a single-disease CEA comparing disease-specific interventions (e.g., vaccination) with interventions targeting the mosquito population (e.g., insecticide) would underestimate insecticide's benefits. We develop three dynamic transmission models: chikungunya, dengue, and combined chikungunya and dengue. We compare the models' predictions of cost-effectiveness of an insecticide, a chikungunya vaccine, and an insecticide plus vaccine campaign.

2 - An Agent-based Algorithm for Studying the Dynamics of Transmission Clusters for HIV

Sonza Singh, University of Massachusetts-Amherst, Amherst, MA, 01003, United States, sonzasingh@umass.edu, Anne Marie France, Yao-Hsuan Chen, Zihao Li, Paul Farnham, Stephanie Sansom, Alexandra Oster, Chaitra Gopalappa

We test the capacity of an evolving contact network algorithm to generate HIV transmission clusters of different sizes in a hypothetical population, and we examine the sensitivity of behavioral and care parameters on the cluster properties. Identifying a methodology to generate the dynamics related to transmission clusters can help develop a simulation model for HIV transmissions in the US and inform intervention strategies.

3 - When and What to Test for: A Cost-effectiveness Analysis of Test-and-treat Strategies for Undifferentiated Febrile Illness in the Era of Responsible Antibiotic Use

Zhenhuan Zhang, PhD Candidate, University of Minnesota, Minneapolis, MN, 55414, United States, Diana Maria Negoescu, Claudia Munoz-Zanzi

Febrile illness caused by viral and bacterial infectious diseases often have similar symptoms and are difficult to differentiate without diagnostic tests. If not treated appropriately, patients may experience serious complications. The question of what diagnostic tests to use to inform the timing of antibiotic therapy remains an open problem for health services facing limited resources. We constructed Markov models to capture febrile illness progression and formulated the problem of minimizing the weighted average of antibiotic underuse and overuse to inform optimal test-and-treat strategies in two settings in Thailand with contrasting bacterial versus viral disease prevalence.

4 - Resource Allocation for Hepatitis C Elimination

Qiushi Chen, Assistant Professor, Pennsylvania State University, University Park, PA, 16802, United States, Turgay Ayer, Jagpreet Chhatwal

More than 70 million people are chronically infected with hepatitis C virus (HCV) globally. With the recent availability of new treatments, the World Health Organization (WHO) set an ambitious target to eliminate HCV by 2030. However, high treatment cost and unawareness of infection remain major barriers to elimination. In this study, we develop an HCV transmission model that aids in optimal allocation of resources to scale-up HCV screening and treatment that can lead to HCV elimination. We present optimal allocation policies in different health care settings and target population profiles.

5 - Performance Assessment Methods for U.S. Organ Donation Rates

Luke DeRoos, University of Michigan, Ann Arbor, MI, 48104, United States, lkbruski@umich.edu, Wesley Marrero, Mariel Sofia Lavieri, David W. Hutton, Neehar Parikh

Organ transplantation is a life-saving and cost-effective treatment for patients with end-organ failure. However, the current supply of donors is unable to match demand, resulting in increased mortality of waitlisted patients. To understand the performance of different organ procurement organizations (OPOs), we analyze temporal and spatial trends in U.S. organ donation for different demographics. We compare potential OPO grading systems using rank correlation techniques and discuss the impact of performance assessment on transplantation policy.

Location Models for Healthcare Access

Sponsored: Location Analysis

Sponsored Session

Chair: Kayse Lee Maass, Northeastern University, Boston, MA, 02115, United States

1 - Designing a Dynamic Network of Dialysis Facilities

Michael G. Klein, San Jose State University, San Jose, CA, 95192-0069, United States, michael.klein@sjsu.edu

Kidney failure is treated with dialysis until transplant or death. Regardless of the travel burden, many patients always opt to go to a facility, while some always opt for home dialysis. For others, the choice varies depending on the location of available facilities. Existing patients also switch dialysis modes (e.g. from facility-based dialysis to home dialysis) bringing different requirements for providers over time. I propose a new model to determine the best network of dialysis facilities from an access to care perspective. Through a California case study, I propose to illustrate the model and help identify areas for improvement.

2 - Optimizing Deployment of Mobile Screening Team to Eradicate HAT

Joris Van de Klundert, Professor, Vice Dean, Mohammad bin Salman College, Saudi Arabia, jklundert@mbsc.edu.sa, Harwin de Vries, Albert P. M. Wagelmans

Deceased donor kidney waiting time inequities among patients of various blood types and races are persistent despite reduction efforts. In the USA, the wait list continues to increase above 100.000 patients, with considerable variation in waiting time and survival rate. We consider queuing models with patient and deceased donor kidney arrivals and analyse system performance for blodd types and races. We present necessary and sufficient conditions for equitable waiting time (growth) across blood types and races for unstable and for stable systems, using a novel network flow formulation. It enables to maximize various forms of equity, for which we present results using UNOS data for the USA.

3 - Optimal Defibrillator Deployment Versus Actual Deployment

Timothy Chan, University of Toronto, Mechanical and Industrial Engineering, Toronto, ON, M5S 3G8, Canada, Christopher Sun

Public defibrillators, which are located throughout cities worldwide, can resuscitate cardiac arrest victims by bystanders with no training. However, location decisions to date are not data-driven. In this talk, we present a head-to-head comparison of optimal defibrillator locations against actual defibrillator locations using nine years of real data. At every decision epoch, the optimization model can only make decisions based on past data. On out-of-sample, future cardiac arrests, the optimization model improves spatiotemporal coverage by 50-100% compared to actual location decisions, translating to significant increases in estimated bystander resuscitation and survival.

4 - Using Simulation to Evaluate Scheduling Policies for Specialty Care to Consider Patient Preferences

Adam VanDeusen, Doctoral Candidate, University of Michigan, Ann Arbor, MI, 48109, United States, ajvandeu@umich.edu, Sameer Saini, Megan Adams, Jacob Kurlander, Amy Cohn

Healthcare appointments can now be conducted in many modalities, including face-to-face, phone, or video visits. Patients have preferences about how they receive healthcare; these preferences are often related to geographic distance to care. We present a case study for considering such preferences in patients with gastroesophageal reflux disease using simulation. In this study, we model different scheduling policies to evaluate how accommodating patient preferences impacts patient access. We hope such models can improve access to specialty care, especially for patients who would travel long distances to receive care.

1 - Prioritizing Hepatitis C Treatment in U.S. Prisons

Can Zhang, Duke University, Durham, NC, 27708, United States, Turgay Ayer, Anthony Bonifonte, Anne Spaulding, Jagpreet Chhatwal

HCV prevalence in prison systems is ten times higher than the general population, and hence prison systems offer a unique opportunity to control the HCV epidemic. New HCV treatment drugs are very effective, but providing treatment to all inmates is prohibitively expensive. As such, current practice recommends prioritizing treatment based on clinical and incarceration-related factors. However, there is controversy about how these factors should be incorporated because of the complicated tradeoffs. In this study, we propose a modeling framework to support hepatitis C treatment prioritization decisions in U.S. prisons.

2 - Can Yardstick Competition Reduce Waiting Times?

Ozlem Yildiz, University of Virginia, Darden School of Business, Darden School of Business, Charlottesville, VA, 22903, United States, yildizo@darden.virginia.edu, Nicos Savva, Tolga Tezcan

We study whether an alternate pay-for-performance method can alleviate Emergency Department (ED) overcrowding through incentivizing socially-desired ED capacity levels, although the healthcare regulator does not know the capacity cost structure. Using yardstick competition, we propose a regulatory scheme that achieves this using the waiting time and arrival rate information of each ED.

3 - The Impact of Reimbursement Policy on Social Welfare, Revisit Rate and Waiting Time in a Public Healthcare System: Fee-for-service vs. Bundled Payment

Yulan Wang, The Hong Kong Polytechnic University, Department of Logistics and Maritime Studies, Faculty of Business, Kowloon, Hong Kong, yulan.wang@polyu.edu.hk, Pengfei Guo, Christopher S. Tang, Ming Zhao

This paper examines the impact of two reimbursement schemes, Fee-for-Service and Bundled Payment, on the social welfare, the patient revisit rate, and the patient waiting time in a public healthcare system. We find that when the patient pool size is large, the bundled payment scheme dominates the fee-for-service scheme in terms of higher social welfare and a lower revisit rate, whereas the fee-for-service scheme prevails in terms of shorter waiting time. When the patient pool is small, the bundle payment scheme dominates the fee-for-service scheme in all three performance measures.

1 - Digital Verification and Inclusive Access to Credit: Evidence from Equifax

Xiang Hui, Washington University in St. Louis, St. Louis, MO, 63130-4899, United States, hui@wustl.edu, Tat Chan, Naser Hamdi, Zhenling Liang

We study how the digitization of employment and income verification impacts credit origination by further reducing asymmetric information over and beyond the use of credit scores. We find a disproportionate increase in loan origination and in lenders' profitability in the subprime segment, while interest rate and other loan characteristics stay similar. While the average delinquency rate increases, its impact on profitability is offset by the growth in loan origination volume. These findings are consistent with a model where instant access to verified data improves information in the market and allows for an expanded access to finance.

2 - Blockchain for Supply Chain Management: Challenges and Opportunities

Zhe Shan, Miami University, Oxford, OH, United States, Akhil Kumar, Rong Liu

In this work, we review some fundamental concepts of Hyperledger Fabric, one of the most mature permissioned Blockchain implementations. Then, we use the context of a food supply chain to highlight key design and implementation challenges for Blockchain, and provide a strategic assessment of its prospects. Our aim is to dispel misguided notions and myths about Blockchain as a silver bullet for all businesses. Our paper offers enterprises a systematic way to understand the real costs and risks of Blockchain adoption. The insights gained in the SCM context also apply to other areas such as financial services and healthcare that could leverage the full potential of Blockchain technology.

3 - Funding Open Source Software with Cryptocurrency Tokens

Wei Chen, University of Arizona, Tucson, AZ, United States, Karen Xie, Weifeng Li

Blockchain-based initial coin offerings (ICOs) allow start-ups to get funding for early-stage growth and attract open-source contribution for product development. We investigate the impact of ICOs' exchange listing on open-source contribution. The findings suggest an economically significant surge of open-source contribution following an ICO's exchange listing, which is primarily driven by external contributors rather than internal ones. Additionally, ICOs with a higher price tends to receive an influx of external contribution. These findings provide managerially relevant implications on open-source project management that is centric to blockchain-based entrepreneurship.

4 - The Effect of Secondary Market Liquidity on Primary Market Liquidity: a Natural Experiment in Peer-to-peer Lending

KAI LU, University of Science and Technology of China, Hefei, China, kailu666@ustc.edu.cn, Holden Craig, Mingfeng Lin, Zaiyan Wei, Jun Yang

We use the unexpected closure of Prosper.com's secondary market to study how secondary market liquidity affects primary market liquidity, as well as how the liquidity of one market affects that of a competing market. We show that primary market liquidity decreases for both institutional and individual loans across all levels of credit quality. Specifically, funding time increases, and funding quantity falls substantially. Moreover, credit spreads increase by approximately 90 to 130 bps for the loans most actively traded in the secondary market before its closure. We further document a spillover effect of the negative liquidity shock from Prosper to its close competitor Lending Club.

1 - On the Distributions of Infinite Server Queues with Batch Arrivals

Jamol Pender, Cornell University, Ithaca, NY, United States, Andrew Monroe Daw

Queues that feature multiple entities arriving simultaneously are among the oldest models in queueing theory, and are often referred to as "batch" (or, in some cases, "bulk") arrival queueing systems. In this work, we study the effect of batch arrivals on infinite server queues. We assume that the arrival epochs occur according to a Poisson process, with treatment of both stationary and non-stationary arrival rates. We consider both exponentially and generally distributed service durations, and we analyze both fixed and random arrival batch sizes. In addition to deriving the transient mean, variance, and moment-generating function for time-varying arrival rates, we also find that the steady-state distribution of the queue is equivalent to the sum of scaled Poisson random variables with rates proportional to the order statistics of its service distribution. We do so through viewing the batch arrival system as a collection of correlated sub-queues. Furthermore, we investigate the limiting behavior of the process through a batch scaling of the queue and through fluid and diffusion limits of the arrival rate. In the course of our analysis, we make important connections between our model and the harmonic numbers, generalized Hermite distributions, and truncated polylogarithms.

2 - A Vector-Borne Contamination Model to Assess Food-Borne Outbreak Intervention Strategies

Jessye Talley, Morgan State University, Washington, DC, 20020, United States, Lauren Davis

Food-borne illness occurs through the consumption of food that has been tainted at some point in the food supply chain. While most contamination is accidental, there is some evidence of intentional food adulteration. This study explores the relationship between food safety practices and consumer behavior in a two-stage food supply chain. We use a vector-borne model to represent the spread of contaminated food through the supply chain. Based on our computational study,we determine the number of consumers that become ill as a result of a contamination event, describe the effect of consumer consumption and purchase behavior on the spread of food-borne illness, and evaluate the effects of various intervention strategies on consumer illness.

3 - A Two-Stage Route Optimization Algorithm for Light Aircraft Transport Systems

Shadi Sharif Azadeh, Erasmus University-Rotterdam, Rotterdam, 3062 PA, Netherlands, Michel Bierlaire, Youseef Maknoon

This paper presents a route optimization algorithm for light aircraft operating under visual flight rules. The problem aims at finding a minimum-duration, collision-free route in three spatial dimensions with possible aircraft maneuvers. The optimal route takes into account the aircraft kinodynamic characteristics and its interaction with external wind. A data processing approach is presented to recast the flying environment as a series of polyhedrons based on which a mixed-integer linear model is formulated. A two-stage route optimization model is then introduced to solve real-life instances. Computational experiments depict the efficiency of this approach.

4 - A New Epidemics-Logistic Model: Insights into Controlling the Ebola Virus Disease in West Africa

Esra Buyuktahtakin Toy, New Jersey Institute of Technology, Mechanical and Industrial Engineering Dept, Mechanical Engineering Center, Newark, NJ, 07102, United States, Emmanuel Des-Bordes, Eyyub Kibis

Compartmental models have been a phenomenon of studying epidemics. However, existing compartmental models do not explicitly consider the spatial spread of an epidemic and logistics issues simultaneously. In this study, we address this limitation by introducing a new epidemics-logistics mixed-integer programming (MIP) model that determines the optimal amount, timing and location of resources that are allocated for controlling an infectious disease outbreak while accounting for its spatial spread dynamics. The objective of this proposed model is to minimize the total number of infections and fatalities under a limited budget over a multi-period planning horizon. The present study is the first spatially explicit optimization approach that considers geographically varying rates for disease transmission, migration of infected individuals over different regions, and varying treatment rates due to the limited capacity of treatment centers. We illustrate the performance of the MIP model using the case of the 2014-2015 Ebola outbreak in Guinea, Liberia, and Sierra Leone. Our results provide explicit information on intervention timing and intensity for each specific region of these most affected countries. Our model predictions closely fit the real outbreak data and suggest that large upfront investments in treatment and isolation result in the most efficient use of resources to minimize infections. The proposed modeling framework can be adopted to study other infectious diseases and provide tangible policy recommendations for controlling an infectious disease outbreak over large spatial and temporal scales.

1 - Pitfalls of Bitcoin's Proof-of-work: Research Arms Race and Mining Centralization

Humoud Alsabah, Columbia University, New York, NY, 10025, United States, hwa2106@columbia.edu

Does Bitcoin's proof-of-work (PoW) protocol serve its intended purpose of enabling and supporting a decentralized payment system? We propose a two-stage game to answer this question. Firms first invest in research and development (R&D) to subsequently compete in a mining game. We demonstrate that PoW drives the mining industry towards centralization, against the core principles of cryptocurrencies. Firms fail to capture the surplus created from their research because more research translates into a more aggressive mining game. Promoting R&D spillovers not only reduces wasteful R&D duplication and increases firms' profits, but may also improves the security of the Bitcoin system.

2 - Cross-sectional Learning of Extremal Dependence Among Financial Assets

Xing Yan, City University of Hong Kong, Kowloon, Hong Kong, yanxing128@gmail.com, Qi Wu, Wen Zhang

We separate the modeling of tail dependences of risk variables from their correlations by proposing a transformation of standard normal random vector. The resulting new random vector has distinct marginal tail heaviness. More importantly, the novelty lies in that pairwise tail dependence of any two dimensions can vary according to its own parameter rather than correlation parameter, which is an essential advantage over commonly used methods like multivariate t and elliptical distributions. It is also intuitive to interpret and easy to track comparing to the copula approach. We show its flexible tail dependence structure through simulation and verify its modeling ability in empirical studies.

3 - Crowdsourcing on the Blockchain

Gerry Tsoukalas, Wharton School of Business, Philadelphia, PA, 19104, United States, gtsouk@wharton.upenn.edu

Blockchain-based systems are increasingly using token weighted voting to crowdsource information from their users for a wide range of applications, including content curation, and on-chain governance. We examine the effectiveness of such decentralized systems at harnessing the ``wisdom" and ``effort" of the crowd.

4 - The Role of Blockchains for Modern Supply Chains

Chandra Narayanaswami, IBM Research, Yorktown Heights, NY, 10598, United States

In this talk we will cover the role of Blockchains in Supply Chain applications - including providing provenance of products using cryptoanchors for improving supply chain integrity, transparency and monitoring; improving efficiency of supply chain workflows by utilizing smart blockchain contracts for automation; protection of intellectual property such as product designs; and the role of incentives to encourage participation in Blockchain networks. The talk will also cover some lessons learned from deploying Blockchain infrastructure and networks.

1 - Design of Incentive Programs for Optimal Medication Adherence

Sze-chuan Suen, University of Southern California, Los Angeles, CA, 90089-0193, United States, Diana M. Negoescu, Joel Goh

We consider how to design a schedule of incentive payments to induce optimal treatment adherence levels with heterogeneous patient preferences for adherence. A unique challenge in this problem is that any prior commitment that a patient makes to a given level of treatment adherence cannot be contracted upon, rendering existing contract-theoretic approaches ineffective. We develop new models and analyses to capture this feature and conduct a numerical study using representative data in the context of the tuberculosis epidemic in India.

2 - Value of High-Quality Logistics: Evidence from a Clash Between SF Express and Alibaba

Ruomeng Cui, NA, Decatur, GA, United States, Meng Li, Qiang Li

We study the extent to which customers value a high-quality delivery experience in online e-commerce. We exploit a natural clash between SF Express and Alibaba which resulted in Alibaba unexpectedly removing SF Express as a shipping option from Alibaba's retail platform for 42 hours in June 2017. We find that the removal of the high-quality delivery option reduced sales by 14.56% during the clash but did not impact the variety and logistics rating of sold products. We also find that the clash is more obstructive for star, expensive and less-discounted products.

3 - Dynamic Assortment Planning with Changing Contextual Information

Xi Chen, New York University, New York, NY, 10012, United States, xchen3@stern.nyu.edu, Yining Wang, Yuan Zhou

In this talk, we consider an important problem in revenue management —- dynamic assortment planning with changing feature information. Customers' utility parameters are modeled by items' feature vectors together with an unknown linear model. We present a dynamic policy for simultaneous learning preference models and maximizing expected revenues. We further establish the near-optimal regret analysis.

Scheduling and Project Management Applications

Emerging Topic: Project Management & Scheduling

Emerging Topic Session

Chair: Rodrigo A. Carrasco, PhD, Universidad Adolfo Ibáñez, Santiago, 7941169, Chile

1 - Operating Room Scheduling under Waiting Time Constraints: The Chilean GES plan

Susana Mondschein, Universidad Adolfo Ibanez, Penalolen, Santiago, 7550000, Chile

In 2000, Chile introduced a profound health reform, establishing, among other things, a maximum waiting time between diagnosis and treatment for a set of diseases. If this is exceeded, the patient is referred to another facility and receives a voucher to cover the additional costs. With the collaboration of a Chilean hospital, we formulated a stochastic dynamic programming model to schedule surgeries in order to minimize the cost of referrals. Given the problem's size, we developed a heuristic to compute good solutions in reasonable time and analyzed its performance. Our experimental results, show that our algorithm performs close to optimum and improves upon the current practice.

2 - Optimal Decisions for Salvage Logging After Wildfires

Gianluca Baselli, Universidad Adolfo Ibáñez, Santiago, Chile, gbaselli@alumnos.uai.cl, Felipe Contreras, Matías Lillo, Magdalena Marín, Rodrigo A. Carrasco

During the summer of 2017, Chile suffered the most massive wildfires in its history, affecting many small forestry companies. In many cases, crown fires passed through forests quickly and only the tree's bark was burnt. Hence, the rest of the tree could still be harvested. The decision on how to proceed in this setting is known as the salvage logging problem: should the company make insurance claims or harvest what is left. We present a novel mixed-integer optimization-based approach to maximize the cash position of the company at the end of the harvest, considering the insurance claims, the harvesting income, and payments to workers, through an optimal workforce assignment.

3 - Setting Wait Time Targets in a Multi-Priority Patient Setting: An Inverse Optimization Approach

Vusal Babashov, PhD Candidate, University of Ottawa, Ottawa, ON, K2B 8K3, Canada, vusal.babashov@uottawa.ca, Antoine Sauré, Onur Ozturk, Jonathan Patrick

Advanced patient scheduling approaches in the Operations Research literature typically assume that wait time targets are given a priori and aim to reduce patient delays based on given priority-specific target parameters. We believe that often wait time targets are arbitrarily determined without any analytical reasoning. Consequently, patients wait longer than needed with no meaningful benefit to clinics in terms of resource management. Through this research, we have developed a rigorous analytical method to study the definition of wait time targets in a multi-priority patient setting.

4 - Application of a Resource Augmentation Algorithm for underground Mine Production Scheduling

Rodrigo A. Carrasco, Universidad Adolfo Ibáñez, Santiago, 7941169, Chile, rax@uai.cl

Mine production scheduling has been historically a very manual process, but one of great importance, since it relates extraction capacity, costs, and the economic benefits of the mining process. One of the main complexities of this schedule is the extensive collection of precedence constraints that need to be satisfied and respond to both physical limitations/requirements and capacity constraints. In this work, we present an approximation algorithm, which we apply to the mine production scheduling problem, and in particular to the underground setting. Our numerical results show that the practical performance is significantly superior to the theoretical bounds.

Crowds, Incentives and Management

Emerging Topic: New Product Development

Emerging Topic Session

Chair: Konstantinos Stouras, Blackrock, Ireland

1 - Risk-Return Implications of Offering Product-Service portfolio in the Software Industry

Sara Rezaee-Vessal, PhD, ESSEC, Paris, France, rezaee@essec.edu, Mehdi Nezami, Shantanu Dutta, Kapil Tuli

Drawing on a longitudinal data set of 377 publicly traded software firms, this study examines the performance effects of the service ratio, i.e., a firm's share of revenue generated from selling services, from both an accounting and a financial market perspective. Results show that the service ratio has U-shaped effects on accounting-based measures of firm risk and return, as respectively reflected in cash flow volatility and level. The service ratio also has U-shaped relationships with financial market-based measures of firm performance, as reflected in stock returns risk and firm value.

2 - Entrepreneurial Market Research: When Hypotheses Outnumber Samples

Evgeny Kagan, Johns Hopkins Carey Business School, 701 Tappan Ave, Ross School of Business, Office R5425, Baltimore, MD, 48103, United States, William S. Lovejoy, Stephen Leider

This paper investigates the search strategies for an entrepreneurial team commercializing a new technology.

3 - Designing Reward Structure for Crowdfunding Campaigns

Param Pal Singh Chhabra, Grad Student, Georgia Institute of Technology, Atlanta, GA, United States, param.chhabra@scheller.gatech.edu, Manpreet Singh Hora, Karthik Ramachandran

This study empirically investigates the association between reward structure design and performance of a crowdfunding campaign. Using data for campaigns on a crowdfunding platform, we assess parameters that are part of the reward structure design. We test the hypothesized associations and make recommendations for creators to improve campaign performance.

4 - Optimal Duration of Innovation Contests

C. Gizem Korpeoglu, Bilkent University, Ankara, Turkey, Ersin Korpeoglu, Sidika Tunc

We study optimal duration and award scheme of an innovation contest where an organizer elicits innovative solutions from agents. Each agent exerts costly effort to improve her solution and faces an output uncertainty. We find that optimal contest duration may increase with novelty and sophistication of solutions that organizer seeks. We show that an organizer with moderate or high urgency in obtaining solutions may adopt winner-take-all award scheme, while an organizer with low urgency may give multiple awards. This may explain many contests on platforms that give multiple awards. Consistent with empirical evidence, we show that optimal duration and optimal total award are positively correlated.

Sustainable Growth

Emerging Topic: Sustainable Growth

Emerging Topic Session

Chair: Hayri Onal, University of Illinois, Urbana, IL, 61801, United States

1 - Productivity and Challenges in Agriculture

Canberk Ucel, The Wharton School, Philadelphia, PA, United States, ucel@wharton.upenn.edu, Marshall L. Fisher, John Paul MacDuffie

Agriculture industry demonstrated outstanding productivity growth globally, in the past half-century. These productivity gains came with sweeping technological and organizational changes. There is emerging public concern about the environmental and health effects of this unfamiliar mode of agricultural production. Despite all of its successes and controversies, there has been relatively little business scholarship evaluating modern agricultural systems. I draw lessons from The Machine that Changed the World to explore various trends and challenges in farming and agricultural supply chains, and propose directions for operations management research on this interesting industry.

2 - Land Use Optimization for Nutrient Reduction under Stochastic Precipitation Rates

Gorkem Emirhuseyinoglu, Iowa State University, Ames, IA, United States, gorkem@iastate.edu, Sarah M. Ryan

Nitrogen and phosphorus are key nutrients needed in agricultural production, but farmland runoff causes nutrient loads in waterways and reduces the oxygen level downstream by contributing to eutrophication. From the viewpoint of a policy maker concerned with regional costs and benefits, we build a multi-stage stochastic mixed-integer program for land-use decisions to maximize the agricultural profits of a watershed while meeting target reductions in nitrate and phosphorus levels under uncertain precipitation rates. Numerical sensitivity analyses reveal interactions among the nutrient reduction and labor availability constraints as well as precipitation levels and crop prices.

3 - A Dynamic Optimization Model for Renewable Energy Supply Chain Design

Raza Ali Rafique, Assistant Professor, Lahore University of Management Sciences, Lahore, Pakistan, raza.ali@lums.edu.pk, Hakeem Ur Rehman, Mohsin Nasir Jat

Growing energy demand and environmental concerns of the conventional energy production has augmented the importance of renewable energy supply systems. Recently the modeling and optimization of renewable supply chains has received a significant attention of researchers. We present an optimization model to dynamically design a cost-effective and sustainable renewable energy supply chain with the objective to increase the renewable energy share in the national energy-mix over time. Unlike the existent research, the model takes a more holistic view by considering electricity generation and distribution by managing cost and time trade-offs.

4 - Developing Sustainable Technology for Capturing Phosphorous From Agricultural Wastewater

Amir Kordijazi, University of Wisconsin-Milwaukee, Milwaukee, WI, United States, kordija2@uwm.edu

Phosphorous pollution from agricultural runoff is of concern since it is one of the main controlling factors in eutrophication that is detrimental to aqueous organs and public health. The purpose of this study is investigating use of phosphate sorbing materials (PSMs) as a cost efficient method for removal and recovery of phosphorous from agricultural runoff. To do this, results of laboratory experiments of different sorbent materials were used to develop a mathematical model of the process. Then the model was used to predict performance of different materials in actual field condition. And finally cost of removal and recovery treatment was calculated for different categories of sorbent materials.

Emerging Topics in TIMES

Sponsored: Technology, Innovation Management & Entrepreneurship

Sponsored Session

Chair: Onesun Steve Yoo, University College London, London, E14 5AB, United Kingdom

1 - Smart Manufacturing via Crowd Sourcing

Onesun Steve Yoo, University College London, School of Management, United Kingdom, onesun.yoo@ucl.ac.uk, Christopher S. Tang, Kevin F. McCardle

We examine a smart crowd-sourcing model of manufacturing practiced widely by leading manufacturers in China. A key feature is the use of virtual images of their products to learn whether there is sufficient demand for them before engaging in costly physical production. Using virtual images are less attractive for consumers (uncertainty of getting the item, delays), so the firms must charge a lower price. We analyze the optimal hybrid approach that combines both use of virtual images (made-to-order) and more traditional production (made-to-stock). We compare it with the current practice of some of the leading Chinese manufacturing firms (e.g., Alibaba, Gaofan), and discuss its efficacy.

2 - The Impact of Product Diversification on Pharmaceutical Process Innovation

Ivan Lugovoi, HEC Paris, Paris, 75015, France, Dimitrios Andritsos, Claire Senot

We empirically explore the link between a pharmaceutical firm's product diversification and the qualitative characteristics of its portfolio of process innovations. We find that diversifying in related products negatively impacts both the novelty and scope of a firm's process innovation. However, diversifying in unrelated products negatively impacts the scope but positively impacts the novelty of a firm's process innovation.

3 - Luxury Brand Licensing: Free Money or Brand Dilution?

Kenan Arifoglu, University College London, Gower Street, Management Science and Innovation, London, WC1E 6BT, United Kingdom, k.arifoglu@ucl.ac.uk, Christopher S. Tang

Licensing enables luxury brands to reach out to their aspirational, low-end consumers ('followers') who value a brand more when more high-end consumers ('snobs') use it. However, over-licensing might dilute the brand for snobs who value brand exclusivity. We develop a game-theoretic model to study these two countervailing forces of licensing. Under fixed-fee licensing contract, we find that the monopolist brand should not license when snobs' desire for exclusivity is high. However, in a duopoly, fixed-fee contracts soften price competition so that licensing (even for free) is always profitable for both brands. We also study royalty contracts and compare them with the fixed-fee contracts.

4 - Workplace Environment Transparency, Employee Satisfaction, and Firm Innovation Performance

Hyunwoo Park, The Ohio State University, Columbus, OH, 43210, United States, park.2706@osu.edu, Morvarid Rahmani

We study the relationship between employee satisfaction measured in multiple dimensions and firm innovation performance measured by patenting activities. Our preliminary analysis indicates that transparency and multi-faceted employee satisfaction have mixed and nuanced relationships with innovation performance.

Forestry II: Forest Management and Conservation

Sponsored: Energy, Natural Res & the Environment/Forestry

Sponsored Session

Chair: Robert G Haight, US Forest Service, Saint Paul, MN, 55108, United States

1 - Crop Allocation Spatial Decision-making Using Stakeholder Engagement, Sustainability Indicators and Multi-attribute Optimization

Veronika Vazhnik, Idaho National Laboratory, Idaho Falls, ID, United States, Mohammad S. Roni, Saurabh Bansal, Jason Hansen, Tom L. Richard

Perennial crops can provide multiple benefits to agriculture including biomass feedstocks, improved water and soil quality, wildlife habitat and diversified farm income streams. Agricultural fields are spatially variable, so placing perennial grasses in environmentally and economically marginal plots within a field can improve the resilience of that landscape system. The exact placement and ratio between parts of the field with perennial and annual crops requires performing complex tradeoffs between farmers' multi-dimensional preferences. We discuss how to model these preferences using utility theory and optimize them using genetic algorithms.

2 - Optimal Planning of Multi-day Pest Surveillance Campaigns

Denys Yemshanov, Natural Resources Canada, Sault Ste. Marie, ON, Canada, denys.yemshanov@canada.ca, Robert G. Haight, Christian MacQuarrie, Frank H. Koch, Ning Liu, Robert Venette, Krista Ryall

Surveillance is critical for detecting biological invasions. We propose a model that allocates daily survey routes to detect the infestation. We adapt a team orienteering problem to plan daily inspections of biological invasions and use acceptance sampling to delimit the extent of an invasion. The inspector selects daily inspection routes, survey sites and the inspection intensities at each site. The objective minimizes the expected number of undetected infested trees subject to upper bounds on daily inspection time and the length of the survey campaign. We apply the model to surveillance of emerald ash borer in Winnipeg, Canada.

3 - Locating Watercraft Inspection Stations to Prevent Spread of Aquatic Invasive Species

Robert G. Haight, USDA Forest Service, Saint Paul, MN, 55108, United States, rhaight@fs.fed.us, Nicholas Phelps, Denys Yemshanov

Zebra mussel and starry stonewort are aquatic invasive species (AIS) that cause severe economic and ecological damage in lakes and streams in the eastern U.S. AIS spread when people move infested boats among lakes, and boat inspection at landings is the primary means of prevention. Using the location of infested and un-infested lakes, estimates of boat traffic between lakes, and likelihood of AIS establishment, we formulate an IP to locate inspection stations to minimize the likelihood of AIS establishing in un-infested lakes subject to a budget constraint. We present results that have been incorporated into AIS prevention plans for Minnesota counties.

Challenges in Charging Electrical Vehicles

Sponsored: Energy, Natural Res & the Environment/Electricity

Sponsored Session

Chair: Luce Brotcorne, INRIA, Villeneuve D'Ascq, 59650, France

1 - A Data-driven Forecasting Model for an Aggregator of Electric Vehicles via Inverse Optimization

Ricardo Fernández-Blanco, University of Malaga, Malaga, Spain, ricardo.fcarramolino@uma.es, Álvaro Porras, Salvador Pineda, Juan Miguel Morales

We develop a data-driven forecasting model for an aggregator of electric vehicles (EVs) aiming to forecast the charging power of its fleet of EVs in the short term. The forecasting model is derived by using a data-driven inverse optimization approach based on a novel two-step estimation procedure, which requires to sequentially solve two linear programs. The resulting linear programs depend on a penalty parameter which is adjusted by using cross-validation. Finally, the behavior of the aggregated EVs is explained by using the electricity prices and historical data of driving patterns.

2 - Evaluation of Coupled Driving and Charging Incentives for Electric Vehicles

Benoit Sohet, EDF Labs, Saclay, France, benoit.sohet@edf.fr, Yezekael Hayel, Olivier Beaude, Alban Jeandin

As Electric Vehicles penetration increases, more impacts on urban systems are observed and related to both driving (e.g., on traffic congestion and reduced pollution) and charging (e.g., on the electrical grid). Therefore, there is a need to design coupled incentive mechanisms. To propose and numerically to evaluate such incentives, a game theory model is adopted. Its originality comes from the coupling between the charging cost and the driving decisions: to drive downtown or to charge at an e-Park & Ride hub with solar panels and then take public transport, in order to reach destination. Optimal ticket fares and panel surfaces are computed using real photovoltaic production data.

3 - Electric Vehicle Battery Aggregator – Multiple Market Participation

Ivan Pavic, University of Zagreb, Zagreb, Croatia

The road transport system is on a verge of complete transformation where fossil-fueled vehicles are being replaced with fully automated electric vehicles. The effect of transformation prolongs to power system as well, as it must provide timely and sufficient energy to satisfy mobility requirements. The electric vehicle users desire the lowest possible charging cost and such could be achieved by aggregated participation of vehicles on multiple power markets. This research will provide a model and results where aggregator realizes the lowest cost for its users.

Sponsored Session

1 - Time-Adaptive Unit Commitment

Salvador Pineda, University of Malaga, Malaga, 29071, Spain, spinedamorente@gmail.com, Ricardo Fernandez-Blanco, Juan Miguel Morales Gonzalez

Due to historical reasons, the unit commitment problem is solved over a time horizon consisting of the 24 hourly periods of a day. We show that, as a result of the increasing penetration of renewable generation, this arbitrary division of time may prove to be significantly suboptimal and counterproductive. Instead, we propose a time-adaptive day-ahead unit commitment formulation that better captures the net-demand variability throughout the day. Numerical results show that, without increasing the computational burden, the proposed time-adaptive unit commitment allows for a more efficient use of the system flexibility, a lower operating cost and a higher penetration of renewable production.

2 - Upgrades and Refurbishment of Power Plants under Limited Long-term Information

Andreas Kleiven, Norwegian University of Science and Technology, Alfred Getz vei 3, Trondheim, 7491, Norway, andreas.kleiven@ntnu.no, Danial Mohseni-Taheri, Selvaprabu Nadarajah, Stein-Erik Fleten, Hans Ole Riddervold

Upgrades and refurbishment of power plants with storage is a long-term planning problem affected by operations and multiple uncertainties including prices, weather and plant condition. We formulate a Markov decision process (MDP) with operational decisions, meaning the decision to produce today or delay production, and investment decisions including refurbishment timing and capacity upgrade. We handle model misspecification on long-term investments using a robust terminal value in the MDP and assess the impact of misspecification by comparing against a pure model-based approach.

3 - Optimal Power System Black-Start Planning with Damaged Communications

Amelia Musselman, Lawrence Livermore National Laboratory, Livermore, CA, United States, Ignacio Aravena

The optimal power system black-start planning problem usually assumes that energization decisions can be reliably communicated across the grid. However, the functionality of the monitoring and control network may be affected in power outages, especially in the case of cyber-attacks. We overlay a communications network on top of the power grid in order to model the impact of compromised communications infrastructure on power system black-starts. We present a specialized branch-and-cut algorithm for solving the resulting mathematical program and numerical experiments on realistic-size instances.

Natural Gas Markets

Sponsored: Energy, Natural Res & the Environment/Energy Sponsored Session

Chair: Felipe A Feijoo, Chile

1 - Does the Portfolio Business Model Affect LNG Trade? A Model-based Approach

Olivier Massol, Associate Professor, IFP School, Rueil-Malmaison, 92852, France, olivier.massol@ifpen.fr

Historically the cornerstone of the LNG industry has been the long-term contract with restrictions on destination. However, market liberalization in North America and Europe and the temptation to make contracts more flexible have encouraged the rise of ‘portfolio players’ that apply trading optimization skills to derive additional value through supplying non-supply source specific LNG to buyers. We first discuss the economics of that business model to identify an adapted modeling approach. We then solve that model using standard techniques (i.e., linear programming and mixed complementarity problems). Lastly, we present the results and discuss the implications on LNG trade and LNG shipping.

2 - Co-optimized vs. Separately Optimized Natural Gas and Power Systems Considering Gas Priorities

Dan Hu, Iowa State University, Ames, IA, 50010, United States, danhu@iastate.edu, Sarah M. Ryan

The growing proportion of electric power generated from natural gas motivates greater coordination between the two energy markets. Many gas-fired generators rely on interruptible contracts with gas suppliers. The resulting uncertainty of contracted gas availability, combined with volatility in gas spot prices, can result in high wholesale electricity prices. We formulate optimization models for the day-ahead and real-time electricity markets having different types of interactions with gas market models. The role of the reliability unit commitment step in reducing overall cost is explored.

3 - GCAM-LAC: The Role of Natural Gas in South America under Climate Change Constraints

Felipe A. Feijoo, Assistant Professor, PUCV, Av. Valparaiso, Chile, felipe.feijoo@pucv.cl

We develop a detailed version of the Global Change Assessment Model (GCAM) for Latin America, called GCAM-LAC. We demonstrate the benefits of considering higher regional resolution when developing regional and country level energy and environmental policies and the role that natural gas plays in the region.

4 - A Two Stage Stochastic Programming for Natural Gas Production Planning under Chance and Conic-Flow Constraints

Andrea Arriet, Pontificia Universidad Catolica de Valparaiso, Valparaiso, Chile, andrea.arriet@pucv.cl, Felipe A. Feijoo

We developed a stochastic natural gas supply model that considers randomness in both, the sectoral demand and in the natural gas resources. Each uncertainty is handled and modeled differently. For the demand, a scenario-based approach, with associated probabilities, is taken. Uncertainty in the natural gas resources is modeled via chance-constraint optimization. Furthermore, we model the distribution network using a non-convex formulation, named Weymouth equations. Then, a relaxation technique is used to reformulate the model as a Second Order Cone Program (SOCP). The full model is solved using decomposition techniques. A case study of North America is proposed.

Chair: Felipe A Feijoo, Pontificia Universidad Católica de Valparaíso, Av. Brasil, Valparaíso, Chile

1 - Environment-friendly Practices and Firm Performance: The Role of Proactive Management

Anqi Wu, University of Illinois, Urbana, IL, United States, Ramanath Subramanyam

This study examines the performance of pro-environmental management initiatives in firms and the financial consequences of firm actions. We identify proactive environmental management as a strategic lever for environmentally sustainable firm behavior. Specifically, we focus on fine-grained components of proactive environmental management which help firms achieve their social responsibilities. Our results suggest that firms with a higher quality of proactive environmental management are more likely to achieve better financial performance. Further, we observe that such proactive management mitigates firms’ economic burden of reducing negative environmental impacts.

2 - Study on Environmental Performance Evaluation System for Enterprises in Regions Along the “Belt and Road”

Junrong Chen, Beijing Union University, Beijing, China, chenjunrong@buu.edu.cn

The implementation of the “Belt and Road Initiative” faces the contradiction between environmental protection and economic development. We need to build a mechanism for sharing environmental benefits and establish an environment coordination agency. In order to provide the theoretical basis for environmental institutional innovation, this paper proposes the concept of Environmental Performance Evaluation (EPE) for regional enterprises, puts forward the policy system of energy conservation and environmental protection(ECEP) that includes economic indicators

3 - Why Do Firms Adopt Costly Green Technologies

Wenqing Zhang, University of Minnesota Duluth, Labovitz School of Business and Economics, Duluth, MN, 55812, United States, Prasad Padmanabhan, Chia-Hsing Huang

There has been increased interest by a variety of stakeholders to motivate firms to invest in green technology. Given the high monetary cost of adoption of green technologies, what are the factors that can explain a firm’s decision to adopt green technologies, government subsidies notwithstanding? Using simulation models, we attempt to provide answers to the related questions. Our results show that the adoption of green technology is industry and firm specific, and may depend on the degree of competition and exposure of the firm (or industry) to the social limelight. Our results provide a partial explanation for industry and firm level differences in the degree of adoption of green technologies.

4 - Multi-modal Traffic Signal Timing Coordination

Aikaterini Deliali, PhD Candidate, UMass-Amherst, Amherst, MA, United States, adeliali@umass.edu

Previous work on the person-based optimization of signal timings for cars and buses is extended to include cyclists when bike signals are present at an intersection. The objective function of this mathematical program is the summation of delays of all users weighted by their passenger occupancy. Constraints include minimum and maximum phase duration and cycle length. The developed delay models are flexible to accommodate any number of signal phases, conflicting transit routes, and bike infrastructure treatments (e.g., bike lanes, cycle tracks, etc.).

Modeling for Electricity Access

Sponsored: Energy, Natural Res & the Environment/Energy
Sponsored Session

Chair: Juan Pablo Carvallo, Lawrence Berkeley National Laboratory, CA, United States

1 - A Guide to Scalable Electricity Planning

Ayse Selin Kocaman, Bilkent University, Endustri Muhendisligi, Ankara, 06800, Turkey, selin.kocaman@bilkent.edu.tr, Simone Fobi, Jay Taneja, Vijay Modi

The lack of access to electricity in developing regions necessitates rapid and yet prudent decision making on electrification options. In this paper, we propose a set of metrics that could be used to measure the value of networked options for a given area. We subsequently demonstrate the computation of such metrics for the entire country of Kenya.

2 - Changing the Policy Paradigm: A Benefit Maximization Approach to Electricity Planning in Developing Countries

Destenie S. Nock, Carnegie Mellon University, Pittsburgh, PA, 01035, United States, destenienock5@gmail.com

Governments in emerging economies are often faced with the challenge of increasing access to electricity within budgets set by foreign aid and resource allocations. This paper develops a methodology for finding the optimal expansion of a power system under the objective of maximizing social benefit. We formulate the problem as a utility-maximization mixed integer program and apply it to Liberia. We find that a high preference for equality between rural and urban areas often leads to lower overall electricity generation, greater investment in transmission infrastructure, and wider adoption of residential solar; indifference to equality leads to the development of urban areas first.

3 - Electricity Infrastructure Development: Application for Sub-Saharan Africa

Yuang Chen, Georgia Tech, Atlanta, GA, United States, yuang.chen@gatech.edu, Valerie Thomas

Many people across the world especially in sub-Saharan Africa are still without access to electricity. This talk presents both static and dynamic electrification planning optimization models in order to advise electricity infrastructure development decisions under many constraints. The electrification planning models help to understand the balance between centralized and decentralized power investment and generation.

4 - The Economic Value of Integrating Distributed Energy Resources into Electric Utility Resource Planning

Juan Pablo Carvallo, Lawrence Berkeley National Laboratory, Berkeley, CA, United States

Distribution-transmission-generation capacity expansion model shows 10%-20% cost savings using a centralized investment and dispatch coordination for distributed resources compared to the status quo.

5 - Geospatial Electrification Planning: The REM Model

Pablo Duenas, MIT, Cambridge, MA, United States, Reja Amatya, Andres Gonzalez, Pedro Cutillas, Fernando de Cuadra, Robert Stoner, Ignacio Perez-Arriaga

The Reference Electrification Model (REM) is a computer-based optimization tool that is able to identify lowest cost system designs to most effectively provide desired levels of electricity access to populations of any given size. In doing so, the model determines the most suitable modes of electrification for each individual consumer. This software tool has been used in real planning activities in sub-Saharan Africa and South Asia. REM stands apart from other planning tools because of its high granularity and its capability to provide concrete plans for a wide range of geographical scales.

Data Mining in Networks (Graph-based Data Mining)

Sponsored: Data Mining
Sponsored Session

Chair: Mehrnaz Amjadi

1 - Understanding Network Embedding Techniques

Yuxiao Dong, Microsoft Research, Redmond, WA, United States

Over the past few years, representation learning has been offering a revolutionary paradigm for mining and learning with network data. In this talk, I will give a systematic introduction for this ongoing paradigm shift. I will start the talk with industry examples to explain how graph mining is benefiting from representation learning. Then I will show how current developments on this problem can conceptually fall into three different categories. Importantly, I will demonstrate how these methods can be theoretically connected and unified with each other. Finally, I will show how we can leverage sparse matrix factorization for learning representations on large-scale networks.

2 - Compositional Fairness Constraints for Graph Embeddings

William Hamilton, McGill, Montreal, QC, Canada

Learning high-quality node embeddings is a key building block for machine learning models that operate on graph data, such as recommender systems. However, existing graph embedding techniques are unable to cope with fairness constraints, e.g., ensuring that recommendations do not correlate user attributes, such as age or gender. I will introduce an adversarial framework to enforce flexible fairness constraints on graph embeddings. For instance, in the context of social recommendations, our framework would allow a user to request that their recommendations are invariant to both their age and gender. Experiments on recommender system benchmarks highlight the utility of our proposed framework.

3 - Mining Graphs at Scale: Ego-networks, Clusters and Embeddings

Alessandro Epasto, Senior Research Scientist, Google, New York, NY, United States

We present recent advances in graph mining based on the analysis of local structures in graphs known as ego-nets (i.e., the subgraph induced by the neighborhood of each node). In particular, we present the Persona Graph method, a novel framework for graph analysis that allows to detect clusters in complex networks and to improve graph embedding methods. Our framework leverages ego-network analysis to disambiguate polysemous nodes in graphs and to facilitate graph embeddings. Our method is a highly scalable and flexible framework, has provable theoretical guarantees, and shows state-of-the-art results in a vast variety of ML tasks from clustering to link prediction.

4 - Spatial-Temporal Recommendation Systems

Mehrnaz Amjadi, UIC, UH2401, Chicago, IL, United States, Theja Tulabandhula

We study various approaches to exploit temporal, spatial, and hierarchical information while designing modern recommendation systems, and investigate their practical effectiveness using a hotel recommendation dataset.

5 - Bringing Knowledge Graph Semantics to Information Systems

Chenyan Xiong, Microsoft Research AI, Redmond, WA, United States

The recent development of knowledge graphs has provided semantic information with decent coverage and high quality to impact one of the most widely used AI systems—-search engine. In this talk, I will present the current state-of-the-art approaches in leveraging knowledge graphs to improve the capabilities of search engines. More specifically, I will start with a brief overview of recent developments, including the definition, construction, alignment, and utilization of knowledge graphs in real-world information systems. Then I will present a detailed example of how we leverage knowledge graph semantics to improve a deep learning system for a popular search engine task.

Chair: Akash Gupta

1 - An Initialization Procedure for the Hidden Markov Model Learning Algorithm that Supports Implementation of Multilevel Disease Progression Models

Akash Gupta, California State University-Northridge, Northridge, CA, 747075, United States, akashg@okstate.edu, Tieming Liu, Dursun Delen, Christopher Crick

Learning parameters of Hidden Markov Models (HMMs) is a computationally expensive task. In this work, we propose an initialization framework for HMM learning algorithm. The proposed procedure generates a pseudo sequence of hidden states from the observed data. Using pseudo hidden states, the initial values of the HMM parameters are derived. The results showed that the guided initialization improved the speed and time performance of the HMM learning algorithm. The proposed method facilitates the development of disease progression model with high granularity in disease states.

2 - Identify Essential Risk Factors for Diabetic Retinopathy

Ru Wang, Oklahoma State University, Stillwater, OK, United States, ru.wang@okstate.edu, Ye Liang, Tieming Liu, Zhuqi Miao

Diabetic retinopathy (DR) is a leading cause of blindness among working-aged adults globally and it's symptomless in early stages. The objective of our research is to identify essential predictors to build a cost-effective diagnosis model for early detection of DR. We performed a retrospective study based on data extracted from a large electronic health records (EHR) database. Stepwise variable selection with logistic regression and 10-fold cross validation AUC were utilized to build and evaluate the model. Ten variables were included in the diagnosis model and the AUC was 0.93.

3 - An Electronic Health Record-based Markov Decision Process Model for Sepsis Management

Sareh Meshkinfam, NC State University, Raleigh, NC, 27606, United States, Smeshki@ncsu.edu, Julie Ivy, Muge Capan, Santiago Romero-Brufau

Sepsis is the life-threatening organ dysfunction caused by a dysregulated host in response to infection. The diagnosis and treatment of sepsis is complex and uncertain as the patient's condition is dynamically changing during the diagnosis process. We develop a continuous time Markov decision process model where the state is characterized by a function of 40 EHR-based vitals and labs, and the age of the information, new or existing. We solve this model as an optimal stopping problem to determine first intervention, anti-infective or fluid, for sepsis management to reduce expected morbidity and mortality for hospitalized patients.

4 - Predicting Medical Incidents Based on EHR Data: A Knowledge-enhanced Deep Learning Approach

Qingpeng Zhang, City University of Hong Kong, Kowloon, 12180, Hong Kong, qingpeng.zhang@cityu.edu.hk, Zhongzhi Xu, Siu Fai Paul Yip

Predicting medical and clinical incidents are usually very difficult given the absence of comprehensive data about the patient's health status. In this research, we develop a novel knowledge-enhanced deep learning model that can predict self-harms (and a few other types of medical incidents) using the EHR data. We develop a comorbidity network based on historical data and then use the topological structure of the network to enhance the predicting performance. Experiments with EHR data in HK demonstrate the superior performance of the proposed method.

1 - Routing under Congestion-an Empirical Study of Triage Drift in Emergency Departments

Shuai Hao, University of Illinois at Urbana-Champaign, Champaign, IL, United States, Yuqian Xu, Zhankun Sun

Triage drift is a well-known controversy in the emergency medicine society. What is unclear is its impact on ED patient ow and other performance measures. Triage drift is observed during the process of triage score assignment as well as fast-track routing. In this work, we are particularly interested in the fast-track routing behavior under ED congestion. Our goal is three-fold. First, we want to examine the impact of ED congestion on fast-track routing decision. Second, we want to explore the outcomes of fast-track routing, and the mechanism behind those outcomes. Finally, we aim to derive potential policy implications to help improve the fast-track performance.

2 - Patient Prioritization in Cardiac Catheterization Labs

Lida Anna Apergi, University of Maryland, ISR, College Park, MD, 20742, United States, John Baras, Bruce L. Golden, Kenneth Wood

This research tackles the problem of prioritizing patients waiting to go through a cardiac catheterization lab. Considering cardiac catheterization labs in a hospital, where outpatients, inpatients, and emergency patients use the same resources, a model is designed and developed towards minimizing the patients' waiting costs. While outpatients are given a higher priority, this may change on the day of the procedure in order to improve efficiency. The model takes into account the uncertainty in the duration of each step that the patients go though as well as delays resulting from the unpreparedness of the outpatients. An Approximate Dynamic Programming approach is used to prioritize the patients.

3 - Identifying Unsuitable Doctors using Online Reviews

David Anderson, Villanova School of Business, Villanova, PA, 07030, United States, davidrybergandersong@gmail.com, Shannon Lantzy

We use data from RateMDs.com to show that online reviews can be used to predict which doctors will receive sanctions from their state medical boards in the future. We show that most of the predictive information comes from the "punctuality" rating, which can be directly observed and evaluated by patients, rather than from the "knowledge" rating, which is more of a credence attribute.

Chair: Salar Fattahi, University of California, Berkeley, CA, United States

Co-Chair: Somayeh Sojoudi, University of California-Berkeley, Berkeley, CA, 94703, United States

1 - On Local Optimality in Cubic Optimization

Jeffrey Zhang, Princeton University, Princeton, NJ, United States, Amir Ali Ahmadi

In this paper we examine local optimality in unconstrained cubic optimization. We give a characterization of when a point is a strict or nonstrict local minimum of a cubic polynomial, and show that these characterizations are checkable in polynomial time. We then address the problem of finding local minima of cubic polynomials.

2 - Low-complexity and Massively Parallelizable Convex Relaxations

Ramtin Madani, Assistant Professor, The University of Texas at Arlington, Arlington, TX, 76015, United States, ramtin.madani@uta.edu, Muhammad Adil

In this talk, we introduce convex relaxations and numerical algorithms with an unprecedented level of scalability to accommodate nonlinear functions and integer variables. In lieu of local search algorithms, computationally demanding relaxations, and linearization techniques, we pursue novel low-complexity relaxations that are fundamentally more efficient compared to the state-of-the-art methods for nonlinear optimization. Lastly, a highly parallelizable numerical method is introduced that can leverage GPUs and distributed computation platforms with orders-of-magnitude time improvements.

3 - Learning Large-scale Sparse Graphical Models: Theory and Algorithm

Salar Fattahi, University of California, Berkeley, Berkeley, CA, 94702, United States, fattahi@berkeley.edu, Somayeh Sojoudi

Graphical Lasso (GL) is a popular method for learning the structure of graphical model, which is based on an l-1 regularization technique. The existing algorithms are incapable of solving high-dimensional instances of the problem. The major impediment to the scalability of the current solvers is their expensive runtime; the fastest known algorithm for the GL has complexity O(n^4). We ask the following somewhat ambitious question: can we reduce the complexity of solving the GL from O(n^4) to O(n^2)? In this work, we provide an affirmative answer to this question. In particular, we provide a class of algorithms with near-quadratic time complexity that can obtain a near-optimal solution to the GL.

4 - Implicit Deep Learning

Laurent El Ghaoui, Professor, UC Berkeley, Berkeley, CA, 94703, United States, Fangda Du, Armin Askari, Bertrand Travacca

We define a new class of “implicit” deep learning prediction rules that generalize the recursive rules of feedforward neural networks. These models are based on the solution of a fixed-point equation involving a single a vector of hidden features, which is thus only implicitly defined. The new framework greatly simplifies the notation of deep learning, and opens up new possibilities, in terms of novel architectures and algorithms, robustness analysis and design, interpretability, sparsity, and network architecture optimization.

5 - Some Advances in Distributed and Multistage Optimization

Andy Sun, Georgia Institute of Technology, Atlanta, GA, 30332-0205, United States

Multistage dynamics, nonconvex, and distributed computation jointly pose some very challenging computational problems for optimization. In this talk, we overview some recent advances in efficient computational methods for solving a broad class of challenging distributed nonconvex optimization problems.

1 - Time-critical Deficits in Cross-border Information Exchange: An Agent-based Study of Cross-national Crisis Cooperation

Miriam Klein, Karlsruhe Institute of Technology, Karlsruhe, Germany, miriam.klein@kit.edu, Marcus Wiens, Frank Schultmann

Historical natural disasters that occurred across national borders highlighted the yet untapped potential of cross-border collaboration. In particular, the timely exchange of information proofed to be crucial. In this contribution, we develop an agent-based model to analyze information flows between citizens and crisis response actors organizing the distribution of essential goods. By quantifying the information delays due to misunderstandings and mistrust among the actors from both sides of the border, our model provides critical insights into the strategic planning phase in crisis response.

2 - Optimization Model for Allocating Emergency Vehicles with Integration Dispatch

You Zhao, Kansai University, Osaka, Japan, k819381@kansai-u.ac.jp, Hiroshige Dan

In this research, we consider an optimization problem for allocating and dispatching emergency vehicles (EVs). First, we developed an optimization model which considers the integration dispatch of EVs in a large area. We generated some random scenarios to deal with uncertainty in the real world and conducted numerical experiments. However, we found that our model may fail to find the optimal solution by using optimization solvers. Therefore, we modified the model to fix the allocation of EVs and the modified model can find the optimal or nearly optimal dispatch under the fixed allocation.

3 - Analyzing Effectiveness of Prescribed Fires in the United States

Laura Devine, University at Buffalo, Buffalo, NY, United States, Esther Jose, Jun Zhuang

Prescribed fires are increasingly being used as a countermeasure to the rising intensity of prescribed fires in the United States of America: Prescribed fires have been carried out by more than 48 states in the USA- more than 100,000,000 acres in prescribed fires have been burned from 2003-2017. To the best of our knowledge, there has been no study on the effectiveness of these prescribed fires in decreasing intensity of wildfires. In this paper, we study the effectiveness of prescribed fires based on data from 2003-2017 and construct a linear optimization model to minimize the costs associated with prescribed fires while also decreasing the intensity of wildfires.

4 - New Information Infrastructure for Handling the Opioid Epidemic - A Blockchain Perspective

Wei Chen, Assistant Professor, York College of Pennsylvania, York, PA, United States, wchen@ycp.edu, Benjamin V. Neve

The U.S. is in the midst of an unprecedented opioid crisis, where the number of deaths due to opioid overdoses continue rising. U.S. Counties, tasked with front-line response to the epidemic, create their own information systems to monitor opioid overdose patients. Most systems are fragmented among the several providers and government agencies, and they lack effective communication mechanisms. We propose a new information infrastructure system that integrates all current systems under a blockchain framework. The proposed system provides interoperability and transparency for patients, providers and government agencies, as well as maintains compliance with federal privacy laws.

5 - Dynamic Fortification Decisions of Hierarchical Healthcare Facilities Against Intentional Disruptions

Girish Chandra Dey, IIT Kharagpur, Kharagpur, India, deygirish@gmail.com, Mamata Jenamani

This paper dynamically allocates the fortification resources among the critical hierarchical healthcare facilities to minimize the impact of worst-case disruptions. The problem is formulated as a bi-level mixed-integer program and solved by super valid inequalities based decomposition algorithm. Computational results of a case study on the healthcare system in Malkangiri district of Odisha, India are analyzed for efficient fortification decisions.

1 - Improving Interpretability in Deep Learning Models for Semiconductor Manufacturing

Sangyong Lee, Myongji University, Korea, Republic of, sangyonglee@mju.ac.kr, Eunji Jo, Dohyun (Norman) Kim

Many studies using deep neural networks (DNNs) have been performed in semiconductor manufacturing processes. However, one of the major drawbacks of the DNN model is that it is not easy to explain which variables are more important. The purpose of this study is to explain the importance of variables in a DNN model and to improve the model’s ability to interpret.

2 - Virtual Metrology on Thin Film Deposition Process for Semiconductor Fabrication

Jeongeun Choi, Myongji University, Yongin, Korea, Republic of, wjddms1353@naver.com, Sangjeen Hong

Stringent process control with precise metrology is a key to success in current nano-scale semiconductor manufacturing. To ensure the quality of the fabricated devices, a large number of metrology steps are required; however, it increases the cost and throughput. In this research, simple neural networks are employed to enhance the understanding of the thin film deposition process and its physical and chemical mechanism in plasma as a mean of virtual metrology. Established neural network model is capable of the prediction of the deposited film thickness of amorphous carbon layer in plasma enhanced chemical vapor deposition process.

3 - Decomposition of Variance Based on Transmissions in Multi-stage Process: A Study on the Semiconductor Industry

Bokyoung Kang, Samsung, Hwasung, Korea, Republic of, by.kang@samsung.com

Conventional applications of data mining algorithms have been suggested to identify critical metrology variables in semiconductor manufacturing process, but they commonly have assumed an one-stage model irrelevant to orders, which can cause impractical interpretations. To improve such limitations, this paper proposes a variance propagation through multi-stages manufacturing process by series metrology based variance transmission modeling. The proposed approach models linear relationships between metrology variables corresponding to physical orders upon the multi-stage process flows, and then independently decomposes the influence of each variable to the total variance of output.

4 - Deep Learning-based Clustering for Identifying Defective Wafer Maps

Dohyun (Norman) Kim, Myongji University, Yongin si, Korea, Republic of, ChulHee Lee

Wafer maps are used to visualize defect patterns and identify potential process issues in semiconductor manufacturing. Wafer map defective pattern clustering can assign defects to similar types, allowing engineers to focus on the cause of each type of defect. This study proposes a deep learning-based clustering algorithm for mapping defective wafer patterns to low dimensions and clustering them simultaneously.

Chair: Zhen Xu

1 - Adaptive Influencer Marketing with Intermediary Constraints

Shatian Wang, Columbia University, New York, NY, 10027, United States, sw3219@columbia.edu, Zhen Xu, Van-Anh Truong

We consider the scenario in which a brand promotes a product over multiple rounds of influencer marketing on a social network, with the goal of reaching the maximum number of users in the network. Our problem is closely related to the adaptive influence maximization problem. However, we introduce a novel constraint that limits the number of times an uncompensated user will help spread the product information. This constraint, while more realistically captures user behaviors, adds challenges to the analysis. We also assume that the brand needs to learn the parameters of the underlying influence diffusion model over time. We propose an online learning algorithm and give regret guarantees.

2 - A Scalable Sparse Completely Positive Relaxation of the Modularity Maximization for Community Detection

Junyu Zhang, University of Minnesota Twin Cities, Minneapolis, MN, United States, zhan4393@umn.edu

We consider a community detection problem for social networks which is often solved by an NP-hard modularity maximization formulation. We propose a sparse and low-rank completely positive relaxation for modularity maximization problem and then develop an efficient block coordinate descent algorithm to solve the relaxation. A fast rounding scheme is constructed to retrieve the community structure from the solution. Non-asymptotic high probability bounds on misclassification rate are established under proper assumptions. Extensive experiments on both synthetic and real-world networks show that the proposed approach enjoys advantages in both clustering accuracy and numerical efficiency.

3 - Online Learning and Recommendation with Linear Threshold Model

Shuoguang Yang, Columbia University, New York, NY, 10027, United States

We consider a variation of influence maximization problem on the social network. We first propose a linear threshold model-based diffusion processes that obtains monotonicity and submodularity. We then develop an online learning algorithm which learns the diffusion parameter by past observations, and give suboptimal recommendations based on the current information learnt. We conduct regret analysis and give a theoretical guarantee on the average regret of the algorithm. We conduct numerical experiments to support our theoretical results.

4 - Prediction and Risk Stratification of Surgical Site Infection

Zhenhuan Zhang, PhD Candidate, University of Minnesota, Minneapolis, MN, 55414, United States, Mustafa Y. Sir, Kalyan Pasupathy, Diana Maria Negoescu, Priya Sampathkumar, John O'Horo

Surgical Site Infections are one of the most common healthcare-associated infections, accounting for $3.2 billion attributable healthcare cost per year in the United States. It is also the most frequent cause of unplanned readmissions after surgery. With Mayo Clinic five-year inpatient surgery data, we first performed univariate descriptive analysis, and then applied various machine learning techniques (logistic regression, random forest, boosting and SVM), and casual-inference modeling techniques (covariate matching, casual tree, two-stage OLS) to predict, and stratify SSI risk.

1 - Can Deep Reinforcement Learning Improve Inventory Management? Performance and Implementation of Dual Sourcing-mode Problems

Joren Gijsbrechts, KU Leuven, Leuven, Belgium, joren.gijsbrechts@kuleuven.be, Robert Boute, Jan A. Van Mieghem, Dennis Zhang

The popularity of reinforcement learning is growing but is it effective in operations? We provide proof of concept that deep reinforcement learning (DRL) can be applied to classic, yet intractable dual-sourcing or dual-mode inventory replenishment problems. Step-by-step guidance on how to apply DRL to a real data set is proffered together with the code and a careful discussion of its performance, strengths and weaknesses.

2 - Blockchain Based Visibility and Supply Chain Gains

Pavithra Harsha, IBM Research, Yorktown Heights, NY, United States, Ajay Deshpande, Ali Koc, Ashish Jagmohan, Brian Quanz

Blockchain enables ability to share network state information by various actors in a supply chain. We simulate various inventory policies based on information shared by different actors and demonstrate gains in supply chain in terms of demand loss, inventory waste and inventory freshness.

3 - A Practical End-to-end Inventory Management Model with Deep Learning

Meng Qi, University of California, Berkeley, Berkeley, CA, 94704, United States, Yuanyuan Shi, Chenxin Ma, Rong Yuan, Di Wu, Max Shen

We investigate the data-driven multi-period inventory replenishment problem with uncertain demand and vendor lead time. Different from the traditional two-step predict-then-optimize (PTO) solution framework, we propose an end-to-end (E2E) framework that uses deep-learning models to output the suggested replenishment amount directly from input features without any intermediate steps. By conducting a series of numerical experiments using real data from JD.com (one of the leading e-commerce companies), we demonstrate the advantages of the proposed E2E model. For industry, our E2E model provides an automatic inventory management solution with the possibility to generalize and scale.

4 - Shaping Inventory Control via Reinforcement Learning

Reza Nazari, Lehigh University, Murray H. Goodman Campus, Bethlehem, PA, 18015, United States, mon314@lehigh.edu, Lawrence V. Snyder, Martin Takac

Student-teacher reinforcement learning (RL) is a new framework in which an RL agent learns to maximize its reward while also not deviating too much from a "teacher" policy. We apply student-teacher RL to a variety of single-stage inventory optimization problems. We show that RL can handle various types of uncertainties and cost structures that are difficult to address using classical inventory optimization methods. We use continuous-action policy gradient methods as our main training algorithms. We show that student-teacher RL can shape the inventory policy to be similar to base-stock or other policies that managers find intuitive or otherwise desirable.

1 - One Side Does Not Fit All: Personal Match and Marketing Message Effectiveness on Social Networks

Yuan Qu, Rutgers University, Newark, NJ, 07102, United States, yuan.qu@rutgers.edu, Jingyuan Yang

The goal is to improve participation and eventually marketing effectiveness of this kind of marketing (group marketing) according to user-article match. Technique-wise, this is a new problem compared to existing work. A traditional problem setting usually looks for a good match between users and product, and the goal is to maximize user interest in the product. Here our problem is the user and product match which leads to marketing effectiveness.

2 - More is More? understanding the Effect of Consumer Complaint Properties

Ramah Al Balawi, University of Illinois at Chicago, Chicago, IL, United States, Yuheng Hu

In this working project, we aim to understand how firms' complaint practices are affected by changes in customers' complaint properties on social media. We make use of a design change implemented by Twitter in which a message (tweet) character limit was increased from 140 to 280 characters to understand how complaint properties influence firm responses.

3 - To Be or Not To Be Friends: Exploiting Social Ties for Venture Investments

Hao Zhong, Rutgers University, Newark, NJ, United States, zhhao31@gmail.com

From both financial and managerial perspectives, decision-making process and successful rates of venture capital (VC) investments can be greatly improved if the investors well know team members of target startups. However, not much efforts have been made on understanding the impact of prominent social ties between members of VC firms and start-up companies on investment decisions. To this end, we propose to study social relationships and see how it can contribute to foreseeing potential investment deals. We aim at providing analytical guidance for the venture capitalists in choosing right investment targets, by developing a Social-Adjusted Probabilistic Matrix Factorization (PMF) model.

4 - Smart Driving for Smart City: The Theory and Solutions of Multi-user Mobile Sequential Recommendation

Zeyang Ye, Stony Brook University, College of Business, Stony Brook, NY, 11794, United States, Keli Xiao, Yong Ge

Smart cruising strategies for taxi drivers significantly reduce the traffic pressure for the cities. They are studied by the mobile sequential recommendation (MSR) problem. For a single user, we develop new methods to provide a real-time search for the optimal route, which reduces the computational time from days to seconds. For multi-user, the direct accumulations of the single-user solutions lead to a significant increase in the computation time and overlapped recommendations. We develop new parallel methods, which again reduces the time from hours to seconds. We also develop a theory for MSR to unify the original form and its variations and make the hyperparameters auto-adjusted.

5 - A Hierarchical Career-Path-Aware Neural Network for Job Mobility Prediction

Qingxin Meng, Rutgers University, Piscataway, NJ, United States

The understanding of job mobility can benefit talent management operations in a number of ways, such as talent recruitment, talent development, and talent retention. While there is extensive literature showing the predictability of the organization-level job mobility patterns (e.g., in terms of the employee turnover rate), there are no effective solutions for supporting the understanding of job mobility at an individual level. To this end, in this paper, we propose a hierarchical career-path-aware neural network for learning individual-level job mobility. Specifically, we aim at answering two questions related to individuals in their career paths: 1) who will be the next employer? 2) how long will the individual work in the new position? Specifically, our model exploits a hierarchical neural network structure with embedded attention mechanism for characterizing the internal and external job mobility. Also, it takes personal profile information into consideration in the learning process. Finally, the extensive results on real-world data show that the proposed model can lead to significant improvements in prediction accuracy for the two aforementioned prediction problems. Moreover, we show that the above two questions are well addressed by our model with a certain level of interpretability. For the case studies, we provide data-driven evidence showing interesting patterns associated with various factors (e.g., job duration, firm type, etc.) in the job mobility prediction process.

Sponsored Session

Chair: Carri Chan, Columbia Business School, New York, NY, 10027, United States

Co-Chair: Noa Zychlinski, Technion - Israel Institution of TechnologyHaifa, 34354, Israel

1 - Process Flexibility for Multi-period Production Systems

Yuan Zhong, University of Chicago / Booth School of Business, 5807 S. Woodlawn Avenue, Chicago, IL, 60637, United States, yuan.zhong@chicagobooth.edu, Cong Shi, Yehua Wei

We consider process flexibility in a multi-period make-to-order production (MTO) system. First, using a new chaining notion, termed the Generalized Chaining Gap (GCG), we prove that in a general system with high utilization, a sparse flexibility structure with m+n arcs is needed to achieve similar performance as full flexibility, where m and n are the number of plants and of products, respectively. We also provide a simple and efficient algorithm for finding such sparse structures. Moreover, we show that the requirement of m+n arcs is necessary, as for some systems, even the best flexibility structure with m+n-1 arcs cannot achieve the same asymptotic performance as full flexibility.

2 - Shift Effect in Emergency Departments

Tianshu Lu, University of Toronto, 105 St. George Street, Toronto, ON, M5S 3E6, Canada, Tianshu.Lu15@Rotman.Utoronto.Ca, Dmitry Krass, Opher Baron

We study how a self-interested physician in an emergency department (ED) allocates her capacity between new patients and re-entrant patients, focusing on the time-dependent behavior pattern. For the physician, we characterize her optimal strategy; for the ED manager, we show the undesirable effect of physician’s strategy on time to physician initial assessment (TPIA). We analyze physician’s strategy by using MDP, and analyze its impact with a fluid queueing model. In MDP, we show that physician’s strategy is of two phases: in the first, the physician is more willing to serve new patients, while re-entrant in the second. In the fluid model, we show that the p-th (p>50) percentile of TPIA becomes longer.

3 - Adaptive Task Replication in Data Centers: A Robust Queueing Approach

Chaithanya Bandi, 1987, Evanston, IL, 60208, United States, c-bandi@kellogg.northwestern.edu

Replication is a widey used approach for reducing delays in multi-server distributed queueing systems. The idea behind replication is that customers can greatly reduce response time by waiting in multiple queues at the same time, thereby experiencing the minimum time across queues. In this talk, we leverage on Robust Queueing and Multi-stage robust optimization to design optimal adaptive routing policies. In particular, we model the adaptive replication problem as a finitely adaptive two stage robust optimization and present the structure of the optimal solution.

4 - Managing Queues with Different Resource Requirements

Noa Zychlinski, Columbia Business School, Israel, NYC, NY, 34354, United States, nz2307@columbia.edu, Carri Chan, Jing Dong

We propose a multi-server queueing model with multiple customer classes, where customers may require different amount of resources to be served. This model is motivated by healthcare settings in which clinical guidelines suggest classifying the patients based on the level of medical attention/supervision they require. We show that and index-based policy, which accounts for customer’s dis-utility of waiting, expected service time, and resource requirements, is optimal in several settings. Additionally, we show that an idle-aware variant of our proposed policy exhibits several properties that make it desirable for use in practice.

Bandits and Reinforcement Learning

Sponsored: Applied Probability

Sponsored Session

Chair: Christina Lee Yu, Cornell University, Ithaca, NY, 14853, United States

1 - Correlated Multi-armed Bandits with a Latent Random Source

Gauri Joshi, Carnegie Mellon University, Pittsburgh, PA, United States

We consider a novel multi-armed bandit framework where the rewards obtained by pulling the arms are functions of a common latent random variable. The correlation between arms due to the common random source can be used to design a generalized upper-confidence-bound (UCB) algorithm that identifies certain arms as non-competitive and avoids exploring them. As a result, we reduce a K-armed bandit problem to a C+1-armed problem, where C+1 includes the best arm and C competitive arms. As a result, there are regimes where our algorithm achieves an O(1) regret as opposed to the typical logarithmic regret scaling of multi-armed bandit algorithms.

2 - On Reinforcement Learning Using Monte Carlo Tree Search with Supervised Learning: Non-asymptotic Analysis

Qiaomin Xie, Cornell University, Ithaca, NY, United States, Devavrat Shah, Zhi Xu

AlphaGo Zero (AGZ) introduced a new reinforcement learning algorithm that has achieved superhuman performance in the game of Go. A key innovation is use of Monte-Carlo Tree Search (MCTS) with Supervised Learning (SL) for learning the policy. We shall argue that MCTS with expressive enough SL learns the optimal solution at nearly minimax optimal rate. This is the first complete and rigorous non-asymptotic analysis of MCTS. We correct a fundamental error in the well cited MCTS algorithm and its proof. Interestingly, the AGZ had already utilized this correction in its implementation. Our results hold for both infinite horizon MDPs as well as two-player Markov games.

3 - Mostly Exploration-free Algorithms for Contextual Bandits

Khashayar Khosravi, Stanford University, Stanford, CA, United States, khosravi@stanford.edu, Hamsa Sridhar Bastani, Mohsen Bayati

The contextual bandit literature has focused on algorithms that address the exploration-exploitation tradeoff. Exploration-free greedy algorithms are desirable in settings where exploration may be costly or unethical. We prove that, under some assumptions on the distribution of the contexts, the greedy algorithm is rate-optimal for the two-armed bandit. Also, even absent these assumptions, we show that a greedy algorithm is optimal with nonzero probability. Thus, we introduce Greedy-First, an algorithm that uses only observed contexts and rewards to decide whether to follow a greedy algorithm or to explore. Greedy-First is rate-optimal without any additional assumption.

4 - Coordinated Exploration in Concurrent Reinforcement Learning

Maria Dimakopoulou, Netflix, Los Gatos, CA, United States

We consider a team of reinforcement learning agents that concurrently learn to operate in a common environment. We identify three properties - adaptivity, commitment, diversity - which are necessary for efficient coordinated exploration and we propose seed sampling, a posterior sampling algorithm that satisfies them. We proceed to design concurrent reinforcement learning algorithms that achieve these three properties in real systems with potentially enormous state spaces, where tabular methods do not scale. There is a multitude of commercial applications that can benefit from this algorithmic framework, ranging from recommendation systems, to robot automation, to self-driving cars.

Chair: Daniel Lacker, Columbia University, New York, NY, 10027, United States

1 - The Social Planner Problem with Finite State Space

Asaf Cohen, University of Michigan, Ann Arbor, MI, 48103, United States, shloshim@gmail.com, Erhan Bayraktar

We consider a finite state continuous-time social planner problem with weakly interacting symmetric N agents. The social planner controls the rate of transition of the agents, aiming to minimize a cost. In addition to the control, agents move from one state to another according to an external force; both the transition rates and the cost depend on the empirical distribution of the agents over the states. We set up a (limiting) diffusion control problem whose set of optimal controls is exactly the set of all the limit points of all the asymptotic optimal control sequences in the N-agent problem. Moreover, we show a possible connection between the limiting problem and a nonlinear Kimura PDE.

2 - Pareto Optimality Versus Nash Equilibrium, Price of Anarchy Versus Price of Stability

Xin Guo, University of California-Berkeley, Piedmont, CA, 94611, United States, xinguo@berkeley.edu, Renyuan Xu

Pareto optimality (PO) is an important concept in game theory to measure the global efficiency when players collaborate. In this talk, we start with the PO for a class of continuous-time stochastic games with finite number of players. To explicitly solve for a PO, we consider a central controller who coordinates the system and transform the problem into a sequence of Skorokhod problems. We then discuss the PO with infinity number of players, which leads the McKean-Vlasov dynamics. Another common criterion in game theory is the Nash equilibrium (NE) which captures the stability under competition. In the end, we compare the PO solution with the NE via price of stability and price of anarchy.

3 - Many-player Games of Optimal Consumption and Investment under Relative Performance Criteria

Agathe Soret, Columbia University, New York, NY, 10027, United States, acs2298@columbia.edu, Daniel Lacker

We study a portfolio optimization problem for competitive agents with CRRA utilities and a common finite time horizon. The utility of an agent depends not only on her absolute wealth and consumption but also on her relative wealth and consumption when compared to the averages among the other agents. We derive a closed form solution for the n-player game and the corresponding MFG, which is unique in the class of equilibria with constant investment and continuous time-dependent consumption. Compared to the classical Merton problem with one agent, the competitive model exhibits a wide range of highly nonlinear and non-monotone dependence on the agents' risk tolerance and competitiveness parameters.

4 - Stochastic Graphon Games: The Static Case

Mathieu Lauriere, Princeton University, Princeton, NJ, 08540, United States, Rene Carmona, Daniel Cooney, Christy Graves

We introduce a class of static games with a continuum of players as limits of finite player static games for which players get idiosyncratic random signals. We analyze the limits as graphon games and we emphasize the differences with static mean field games.

Sponsored Session

Chair: Gabriel Weintraub, Stanford Graduate School of Business, Stanford, CA, 94304, United States

1 - Supplier Competition and Investment: An Experimental Investigation

Cuihong Li, University of Connecticut, School of Business, Storrs, CT, 06269, United States, cuihong.li@uconn.edu, Elena Katok, Zhixi Wan

We consider a buyer facing two suppliers who invest in cost reduction before bidding for contracts. Using laboratory experiments, we investigate how supplier competition and investment observability affect suppliers' cost-reduction effort and buyer's reserve price decisions.

2 - Pay-as-Bid Procurement Mechanisms for Differentiated Products

Je-ok Choi, Stanford University, Stanford, CA, 94305, United States, jchoi89@stanford.edu, Daniela Saban, Gabriel Weintraub

The rules of public procurement mechanism must be simple and transparent. In practice, this typically results in such mechanisms being implemented as pay-as-bid (or first price) auctions. In this work, we consider the mechanism design problem of finding an optimal pay-as-bid mechanism that balances two objectives of the procurement agency: purchasing at low prices and providing enough variety in an assortment to accommodate heterogeneous buyers. On a stylized Hotelling model, we show the optimality of a simple class of assortment mechanisms called soft reserve rules. We also provide evidence of the robustness of soft reserves and of their performance under more general demand models.

3 - Position Ranking and Auctions for Online Marketplaces

Leon Chu, USC Marshall School of Business, University Park Campus, Los Angeles, CA, 90089, United States, leonyzhu@usc.edu, Hamid Nazerzadeh, Heng Zhang

Online e-commerce platforms such as Amazon and Taobao connect thousands of sellers and consumers every day. In this work, we study how such platforms should rank products displayed to consumers and utilize the top and most salient slots. We present a model that considers consumers' search costs and the externalities sellers impose on each other. This model allows us to study a multi-objective optimization, whose objective includes consumer and seller surplus, as well as the sales revenue, and derive the optimal ranking decision. In addition, we propose a surplus-ordered ranking (SOR) mechanism for selling some of the top slots. This mechanism is motivated in part by Amazon's sponsored search program.

4 - Information Design in Dynamic Contests

Mohamed Mostagir, University of Michigan, Ann Arbor, MI, 48109, United States, Yan Chen

Contests are usually modeled as all-pay auctions, with the majority of existing results corresponding to static one-shot auctions where participants make a single decision about their effort levels ("payments"). This paper considers these contests in a dynamic setting, where the question of how to provide information over time becomes important for extracting the maximum effort from participants. We design a novel experiment that examines how subjects behave in the lab under different information mechanisms, and detail the advantages and disadvantages of these mechanisms for both the designer's objective as well as the welfare of participants.

Customer Behavior and Information in Service Systems

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Tamer Boyaci

Co-Chair: Caner Canyakmaz, ESMT Berlin (European School of Management and Technology), Berlin, 10178, Germany

1 - Service Systems with Rationally Inattentive Customers

Caner Canyakmaz, ESMT European School of Management and Technology, Berlin, 10178, Germany, caner.canyakmaz@esmt.org, Tamer Boyaci

Many service systems are “opaque” in that customers cannot discern precise queue lengths upon arrival due to information frictions and/or cognitive restrictions. We model this using rational inattention theory and develop a strategic queuing framework that naturally bridges observable and unobservable queues. Customers optimally select the type and quantity of information they need and ignore information that is not worth obtaining in an endogenized information acquisition process, trading-off the benefits of better information against its cost (measured as the reduction in Shannon entropy). We characterize equilibrium behavior and demonstrate throughput/welfare implications.

2 - Efficient Inaccuracy: User-generated Information Sharing in a Queue

Jianfu Wang, Nanyang Business School, Nanyang Technological University, Block S3-B2C-85, 50 Nanyang Avenue, Singapore, 639798, Singapore, Ming Hu

We study a service system which does not have the capability of monitoring and disclosing its real-time congestion. However, customers can observe and post their observations online. Future arrivals can take into account such user-generated information when deciding whether to go to the service facility. We perform pairwise comparisons of the shared, full, and no queue length information structures in terms of social welfare. We show that a little, inaccurate and lagged, shared queue length information can go a long way and that it may be more socially beneficial to encourage the sharing of user-generated information among customers than to provide them with full real-time queue length information.

3 - Pay What You Want Pricing under Demand Learning

Haoyu Liu, HKUST, Clear Water Bay, Kowloon, 999077, Hong Kong, haoyu.liu@connect.ust.hk, Ying-Ju Chen

We explore the possibility of adopting Pay What You Want (PWYW) pricing as a selling strategy when the consumers’ valuation is unknown. We compare PWYW with two benchmarks where the firm uses either a fixed price or dynamic pricing and identify the conditions under which PWYW achieves superior performance to other selling strategies. We show that when the consumers are myopic, PWYW always dominates the fixed price (FP) policy. More interestingly, when the consumers are strategic, PWYW dominates Pay As Asked (PAA) when the generosity level is above a threshold, and the threshold is decreasing in cost. We also discuss several potential directions for the firm to improve its profitability.

4 - Designing Digital Rollovers: Managing Obsolescence through Release Times

Esma Koca, Imperial College London, PhD Student, Postbox, Tanaka Building, London, SW2 7AZ, United Kingdom

When releasing a new product, a firm tries to attract new customers and persuade existing customers to upgrade. This is achieved through a rollover, which compromises the price of the new product and the decision to cease the sale of the old product (solo) or to sell the old product at a discount (dual). The release timing of the new product is a commonly overlooked third lever. It influences the consumers’ perception of obsolescence, by which an old product is considered obsolete merely by reference to a new product. We show that the release time enables the firm to induce its customers, strategic or not, to upgrade so that a solo rollover is optimal.

5 - Omnichannel Queue with Partial Information

Yuting Yuan, Simon Business School, University of Rochester, University of Rochester, Rochester, NY, United States, yuting.yuan@simon.rochester.edu, Ricky Roet-Green

Numerous retailers have adopted online order technology as a complement to their existing offline physical stores. In this paper, we study the impact of such omnichannel service system on consumers’ queueing strategies, operator’s revenue, and social welfare. In our model, a firm serves two streams of arriving consumers (online and offline). The queues are partially observable as only the number of offline customers is known. Assuming no transitions between two channels, we investigate the individual consumer’s decision whether to queue or not, under FCFS priority policy. We find neither fully observable system nor partially observable system dominates in revenue or social welfare.

Chair: Ruomeng Cui, Emory University, Decatur, GA, 30033, United States

1 - Evolution of Ride Services

Daehoon Noh, University of Maryland, College Park, MD, 20740, United States, nobe301@rhsmith.umd.edu, Tunay Tunca, Yi Xu

Ride services bring together drivers and customers in two-sided matching markets. As these services mature multiple competing operational models emerge. In this paper, we utilize a multi-stage multi-firm model to analyze the competition between different ride service models. We identify the factors that determine pricing and shaping of market segmentation.

2 - Moderation in Pursuit of Truth: Prescriptions for News Publishers and Social Media Platforms

Senthil Veeraraghavan, University of Pennsylvania, Wharton School OPIM Department, 545 3730 Walnut Street, Philadelphia, PA, 19104, United States, senthilv@wharton.upenn.edu, Jiding Zhang, Ken Moon

In this paper, using social media data, we design prescriptions for both news publishers and social media platforms, aiming at controlling the fake news from spreading. We compare multiple potential policies: limiting supply for each source, and encouraging readers to flag fake news. Our paper sheds lights on the effective operational process and steps in managing dynamics of online content.

3 - Estimating and Optimizing the Impact of Photo Assortment in Sharing Economy

Hanwei Li, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, hanweili@mit.edu, David Simchi-Levi, Michelle Wu, Weiming Zhu

Using data from a leading home-rental platform, we investigate the impact of photo quality and photo assortment on apartment and platform revenue. In particular, we employ Convolutional Neural Network to obtain the quality and the context of each photo posted by apartment owners. Exploiting the unique data structure, we develop a pairwise rank-based choice model to consistently estimate customer preferences over listing characteristics such as price, photo quality and photo assortment. We further conduct counterfactual analysis to study the implication of the optimal assortment strategy on apartment and platform revenue.

4 - Wholesale Price Discrimination in Global Sourcing

Jingyun Li, California State University Stanislaus, Stanislaus, CA, United States, jli9@csustan.edu, Ruomeng Cui, Meng Li, Lili Yu

There is limited study on suppliers’ pricing behaviors in B2B markets. In this research, we study wholesale price discrimination by collaborating with a global trading company which runs a field experiment on a global sourcing marketplace. We find no difference in the wholesale prices quoted to buyers selling in US and South African markets. We also find that suppliers quote higher wholesale prices to White buyers than to Asian and Black buyers regardless of country. Price discrimination disappears when buyers present market information to suppliers, whereas social information can reduce price quotes for only Black and White buyers, but not for Asian (particularly Chinese) buyers.

Sponsored Session

Chair: Arash Asadpour, New York University, New York, NY, 10012, United States

1 - Maximum Weight Online Matching with Deadlines

Amin Saberi, Stanford University, San Francisco, CA, 94105, United States, saberi@stanford.edu

We study the problem of matching agents who arrive at a marketplace over time and leave after d time periods. Agents can only be matched while they are present in the marketplace. Each pair of agents can yield a different match value, and the planner’s goal is to maximize the total value over a finite time horizon. First we study the case in which vertices arrive in an adversarial order. We provide a randomized 0.25-competitive algorithm building on a result by Feldman et al.

(2009) and Lehman et al. (2006). When the arrival order is chosen uniformly at random, we show that a batching algorithm, which computes a maximum-weighted matching every (d+1) periods, is 0.279-competitive.

2 - Overcoming Inefficiencies of Dynamic Pricing in Spatial Settings

Daniel Freund, Lyft/MIT, Cambridge, MA, 14850, United States, df365@cornell.edu, Garrett J. van Ryzin

Dynamic (surge) pricing is a frequently used tool to match supply and demand in the gig economy. The comparatively fast-paced dynamics of supply and demand have also led to dynamic pricing featuring prominently in the recent operations research literature.

3 - Designing an Autonomous Rideshare Network

Chinmoy Dutta, Research Scientist, Lyft, San Francisco, CA, 94040, United States, cdutta@lyft.com

We consider the network design problem for an autonomous rideshare service. The objective is to maximize the utilization of the autonomous fleet, given the ride demand flow. We provide a mathematical modeling for the problem and evaluate the effectiveness of the proposed approach.

4 - Batching Policies in Ridesharing Matching

Arash Asadpour, Lyft Inc., Stern School of Business, Kaufman Management Center, New York, NY, 10012, United States, aasadpour@lyft.com

Matching passengers with drivers is an essential part of ridesharing platforms. We study the effect of spatial patterns of demand on the efficiency of various matching policies. In particular, we investigate how the performance of batching policies are affected by such patterns. We will use optimal offline and online policies as the benchmark.

1 - Predicting Human Discretion to Adjust Algorithmic Prescription: A Large-scale Field Experiment in Warehouse Operations

Jiankun Sun, Imperial College London, London, 60201, United Kingdom, Dennis Zhang, Haoyuan Hu, Jan A. Van Mieghem

Conventional optimization algorithms focus on efficiency yet tend to overlook human behavioral deviations. We identify such behavioral deviations in the packing process, and propose a new algorithm that predicts discretionary behavior using machine learning to pro-actively adjust the algorithmic prescription. In our randomized field experiment at Alibaba Group, we find that our new algorithm reduces the deviation probability of workers and their average packing time of targeted packages (i.e. packages for which workers are more likely to deviate). This idea of incorporating human deviation to improve optimization algorithms could also be generalized to other processes in logistics.

2 - Blockchain Adoption for Traceability in Food Supply Chain Networks

Puping Jiang, Washington University in St. Louis, Washington University Olin Business School, St. Louis, MO, 63130-4899, United States, jiang.p@wustl.edu, Lingxiu Dong, Fasheng Xu

Innovative retailers in food supply chains have been exploring the use of blockchain as a part of ongoing effort of reducing continuing contamination risks and food waste. We investigate how the adoption of blockchain technology can affect incentives of supply chain members and whether and how its anticipated benefits may be realized. We study a three-tier supply chain with multiple top tier (tier-2) suppliers and characterize the equilibrium contractual arrangement and corresponding tier-2's risk-mitigation effort for both the cases with and without blockchain.

3 - Personal Fabrication as an Operational Strategy: Value of Delegating Production to Customer

Nagarajan Sethuraman, UNC Chapel Hill, Chapel Hill, NC, 27514, United States, Ali Kemal Parlakturk, Jayashankar M. Swaminathan

In this paper, we study an operational strategy enabled by 3D printing – Personal Fabrication (PF) – in which a firm focuses on product's design and delegates its production to customers. Using a 2-dimensional personalization model, we characterize the conditions under which, such a strategy benefits the firm. We study the implications of various roadblocks for such a strategy: high production costs of 3D printing, intellectual property concerns, and product liability issues.

4 - IoT Data Ownership and After-sales Service Supply Chain Management

Cuihong Li, University of Connecticut, School of Business, 2100 Hillside Road, Storrs, CT, 06269, United States, cuihong.li@uconn.edu, Brian Tomlin

For uptime-critical assets, the Internet of Things (IoT) enables condition-based maintenance (CBM) through sensor-generated data combined with advanced analytics. Oftentimes, the asset is designed, built, and maintained by one firm (the OEM) but operated by another firm (the user). In this research, we examine the implications of data ownership (i.e., whether data owned by OEM or user) on the provision and adoption of CBM.

1 - Global Supply Chain Management: The Effect of Outsourcing Decisions on Auditor Performance

Ashley Palmarozzo, PhD Candidate, Harvard Business School, Boston, MA, United States, apalmarozzo@hbs.edu, Michael Toffel, Jodi Short

To assess the extent to which working conditions at supplier factories meet a brand's standards, many brands require that social audits be conducted of these factories. In doing so, they face a make-buy decision of whether to use in-house auditors, third party auditors, or both. To shed insight on this decision, we use proprietary data from an apparel brand to identify several circumstances under which in-house versus third party auditors (a) conduct more rigorous audits, and (b) better stimulate improvements in working conditions.

2 - Managerial Insight and "Optimal" Algorithms in Supply Chains

Blair Flicker, University of South Carolina, Columbia, SC, 75208, United States, blair.flicker@moore.sc.edu

Stylized models omit many real-world phenomena. By accounting for unmodeled dynamics, human managers can improve decision making. Human newsvendors endowed with superior demand information should improve profits, but experiments reveal costly suboptimal ordering. I propose a human-machine hybrid ordering approach that consistently outperforms either humans or machines operating alone.

3 - Relative Performance Transparency: Effects on Sustainable Choices

Yanchong Zheng, Massachusetts Institute of Technology, Sloan School of Management, Cambridge, MA, 02139, United States, Ryan W. Buell, Shwetha Mariadassou

We study how transparency into the levels and changes of relative sustainability performance affects consumer choices. Our work considers two forms of transparency: process transparency, in which customers receive information about the company's sustainability performance relative to other companies, and customer transparency, in which customers receive information about their own sustainability performance relative to other customers. Through three studies with 7,308 participants, we observe that revealing the levels of relative performance is more motivating for customers in the process transparency domain, whereas revealing relative changes in performance is more motivating for customers in the customer transpa

rency domain. We employ structural equation modeling to identify the underlying mechanisms for these results. We show that levels information is more reflective of objective performance comparison, thus strengthening motivation in the domain of process transparency. In contrast, changes information helps to mitigate self-serving attribution biases in the customer transparency domain, thus playing a more significant role in affecting motivation.

4 - Focusing Provider Attention: an Empirical Examination of Incentives and Feedback in Influenza Vaccinations

Robert Niewoehner, Kenan-Flagler Business School, Chapel Hill, NC, 27516, United States, Bradley R. Staats

The US Center for Disease Control has been trying to improve flu vaccination uptake for years without much effect. Academic efforts trying to drive the demand side (patients seeking vaccines) have shown limited results. There is a lack of research looking into improving the supply side (providers recommending vaccines), despite the knowledge that providers have a strong influence over their patients' decisions. Working with a vaccine management company focused on driving improvement, we explored whether multiple interventions can lead to an increase in flu shots given, in addition to testing for the presence First-Place Loving behavior, Last-Place Aversion, and Goal Gradient behavior.

1 - Show or Tell: What Improves Agent Decision Making in The Mobile Money Industry? – Evidence from a Field Experiment In Tanzania

Jason Acimovic, Penn State University, University Park, PA, 16802, United States, Christopher Dalton Parker, David F. Drake, Karthik Balasubramanian

Two key decisions operations managers must make when designing systems to support their employees are: 1) what guidance to deliver, and 2) what kind of training (if any) to provide. We examine these choices in the context of mobile money platforms. In partnership with a Tanzanian mobile money operator, we perform a randomized controlled trial to examine how differing types of guidance and training impact the agents' inventory management. Agents who are trained in person and receive an explicit recommendation are less likely to stockout of electronic currency during the day.

2 - An Efficient Frontier Approach to Scoring and Ranking Hospital Performance

Daniel Adelman, University of Chicago, Booth School of Business, 5807 South Woodlawn Avenue, Chicago, IL, 60637, United States

The Centers for Medicare and Medicaid Services (CMS) Star Ratings methodology for publicly evaluating hospitals uses a latent variable model that is based on the presumption of a single, but unobservable, hospital-specific quality factor. We show how under this approach, even if hospitals improve along every dimension, they may nonetheless score lower. We develop a new approach that does not exhibit this behavior, yet also has the capability to autonomously adjust weights as measures are added or subtracted over time. Using data we score and rank nearly every hospital in the United States, and demonstrate the extent to which it agrees or disagrees with the existing approach to the CMS Star Ratings.

3 - Tax-induced Inequalities in the Sharing Economy

Yao Cui, Cornell University, Ithaca, NY, 14853, United States, Andrew M. Davis

We use a machine learning method (generalized causal forest) to study the heterogeneous treatment effects of the tax policy on Airbnb. While the tax regulation is intended to alleviate the pressure that Airbnb creates to hotels, we find that it has led to unintended consequences for Airbnb participants. In particular, the tax policy adversely affects residential listings more than commercial listings, and adversely affects those listings whose service offerings are more differentiated from hotels. These distributional impacts indicate that the goal of the tax policy is not effectively achieved. We further provide insights to policy makers and sharing economy platforms regarding tax regulation.

4 - How Many Undocumented Immigrants Are There in the US?

Edward H. Kaplan, Yale University, Yale School of Management, Box 208200, New Haven, CT, 06520-8200, United States, Scott Rodilitz

The number of undocumented immigrants in the US is one of the most controversial quantities at the heart of the US immigration debate. The Mexican Migration Project reports departure dates to and return dates from the United States for undocumented Mexican immigrants sampled in Mexico after their return from the US along with the total number of trips for each household sampled. Such samples can be analyzed using newly developed probability models to obtain new estimates of the number of undocumented immigrants in the US over time. The resulting estimates are much larger than those commonly reported in the media, and are broadly consistent with the findings of Fazel-Zarandi, Feinstein and Kaplan (2018).

Sponsored Session

Chair: Michael R Wagner, University of Washington, Seattle, WA, 98195, United States

Co-Chair: Soraya Fatehi

1 - Reward-based Crowdfunding Campaigns: Informational Value and Access to Venture Capital

Rachel Rong Chen, University of California-Davis, One Shields Avenue, Davis, CA, 95616, United States, rachen@ucdavis.edu, Paolo Roma, Esther Gal-Or

We consider an entrepreneur who designs a reward-based crowdfunding campaign when the campaign provides a signal about the future demand for the product and subsequent Venture Capital (VC) is needed. We find that both the informativeness of the campaign and considerations related to gaining access to VC funding affect the entrepreneur's choice of campaign instruments, as well as her decision of whether to run a campaign. As the use of crowdfunding platforms becomes more prevalent for entrepreneurial projects, our study offers a deeper understanding on the dual role of reward-based crowdfunding in terms of acquiring demand information and raising capital for early-stage startups.

2 - Choosing the Right Campaign Mode in Reward-based Crowdfunding

Simone Marinesi, The Wharton School, University of Pennsylvania, Philadelphia, PA, 19103, United States, marinesi@wharton.upenn.edu, Ekaterina Astashkina, Karan Girotra

We compare the two most popular forms of crowdfunding campaign, All-or-Nothing (AoN) and Flexible Funding (FF). The existing literature considers FF Pareto dominated by AoN, but FF is widely used in practice. Our model attempts to reconcile this discrepancy by showing that FF campaigns can outperform AoN camapaigns for certain type of crowdfunding projects.

3 - Crowdfunding via Revenue-sharing Contracts

Soraya Fatehi, University of Washington, Michael G. Foster School of Business, Seattle, WA, 98195-3200, United States, sfatehi@uw.edu, Michael R. Wagner

One of the newest versions of crowdfunding allows a firm to raise capital from a crowd of investors and repay them a multiple of their investment by sharing a percentage of its future revenue, under a revenue-sharing contract. This means that investors will receive M>1 dollars for every dollar that they have invested over an investment horizon of uncertain duration. This contract, as a flexible repayment agreement, is linked with the financial performance of the firm, allowing variable payments and investment horizons. We show that revenue-sharing contracts align firms' and investors' incentives in a way that was not possible with traditional contracts.

1 - Optimal Investment of Farming Mechanization in Rainfed Agriculture

Ying (Maggie) Zhang, Clemson University, Clemson, SC, United States, ying6@clemson.edu, Jayashankar M. Swaminathan

We study the procurement of seeds and farm equipment for a single crop in a multi-period planting horizon under budget constraint. The optimal procurement decision is made before the start of the horizon to maximize the final yield and the subsequent planting decisions are optimized. We show that under fixed budget, the optimal planting capacity is generally increasing under favorable planting conditions such as higher soil moisture level, higher seed quality and favorable climate conditions. In the computational study, we utilized field weather data in Southern Africa to explore the impact of machine cost and farm size on the optimal machine capacity.

2 - Assessing Post-harvest Losses under Vertical Coordination - Evidence from an Emerging Economy

Alwin Dsouza, PhD Candidate, Arizona State University, Mesa, AZ, United States, adsouza3@asu.edu, Ashok Mishra, Scott Webster

Post-harvest losses (PHL) in developing countries amount to 30-40 percent. Lack of proper transportation and marketing facilities along with failures to comply with minimum standards are the main reasons for high PHL. This study analyzes the links between contract farming (CF) (production (PC) and marketing contracts (MC)) and PHL. Using survey data from India on okra farming (highly perishable produce), we conclude that PC and MC growers have higher profits along with higher PHL compared to IF growers. Furthermore, we find that if the quantity rejected due to non-compliance to minimum standards is lowered, PC and MC growers make higher profits with lower PHL.

3 - Irrigation Management under Temporal and Spatial Variability

Erkut Sonmez, University of Nebraska-Lincoln, Lincoln, NE, United States, drerkutsonmez@gmail.com, Baris Ata, Derek Heeren

Several studies reported that agricultural production must at least double in the near future to supply rapidly growing world population and food demand. Irrigation is one of the main methods to improve agricultural productivity. Fresh water scarcity, increasing costs, and climate changes urge for sustainable and efficient methods for irrigation which accounts for 70 percent of global fresh water usage. In this paper, we study dynamic irrigation management considering temporal and spatial variability in relevant environmental and field properties.

4 - Too Good to Eat? Cosmetic Standards and Waste in Agricultural Supply Chains

Pascale Crama, Singapore Management University, 50 Stamford Road, Singapore, 178899, Singapore, pcrama@smu.edu.sg, Yangfang Zhou, Jiahui Xu

Agricultural waste starts at the farm, with a portion of the harvest discarded due to cosmetic standards set by the downstream retailers. We examine the supply chain interactions that cause downstream retailers to set high cosmetic standards in the face of customers who have prefer 'beautiful' food.

1 - Operations Research Improves Biomanufacturing Efficiency at Merck Sharp & Dohme

Yesim Koca, Eindhoven University of Technology, Eindhoven, Netherlands, y.koca@tue.nl, Tugce Martagan, Ivo Adan, Bram van Ravenstein, Marc Baaijens, Oscar Repping

Production and planning decisions in biomanufacturing are often challenging owing to batch to batch variability and uncertainty in the production yield and quality. To improve biomanufacturing efficiency, a multidisciplinary team of researchers collaborated over three years to develop a portfolio of decision support tools. These tools comprise optimization models, and provide a data-driven, operations research based approach to reduce biomanufacturing costs and lead times.

2 - Decision Tools for Biodiversity: A Breakthrough for Ecological Outcomes in Fire Management

Josephine MacHunter, Arthur Rylah Institute for Environmental Research, Heidelberg, Australia, Josephine.MacHunter@delwp.vic.gov.au, Libby Rumpff, Tracey Regan, Nevil Amos

Making decisions about fire management in Victoria, Australia requires difficult trade-offs to protect human life, property and biodiversity. However, evaluating and integrating the complex suite of risks to ecological values has been challenging. Working with government across multiple fire management regions, we applied multi-criteria decision making using a participatory process to develop a decision framework. The framework includes a user-friendly analysis module to enable faithful, transparent and rapid values-focused consideration of ecological values in fire management.

3 - Decision Analysis Meets Sustainable Planning in Québec City: The Case of Multicriteria Decision Aiding and Complete Streets

Francis Marleau Donais, Université Laval, Québec City, QC, Canada, francis.marleau-donais.1@ulaval.ca, Irene Abi-Zeid, E. Owen Waygood, Roxane Lavoie

Decision-making processes in transportation projects do not always explicitly take into account sustainability dimensions and often neglect aspects from fields other than engineering, such as environment and public health. Using multicriteria decision analysis, we structured and developed a new decision-making process for street redesign in Québec City. The objective was to identify the higher priority streets that should be redesigned as Complete Streets. The results were integrated in a spatial decision support system that has become an essential operational tool in use since 2017.

Preference-driven Decision Aiding

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Roman Slowinski, Poznan University of Technology, Poland

Co-Chair: Adiel de Almeida Filho, Brazil

1 - Post Consensus Analysis of Group Decision Making Processes by Means of a Graph Theoretic and Association Rules Approach

Evangelos Triantaphyllou, Louisiana State University, Division of Computer Science & Engineering, Baton Rouge, LA, 70803, United States, etriantaphyllou@yahoo.com, Juri Yanase

It is assumed that a group of experts evaluates a finite set of alternatives as part of a group decision making (GDM) process. The GDM process may go through a number of iterations. The experts use their personal preferences to make decisions. The process ends when a consensus has been reached or no expert is willing to alter his/her ranking. The GDM process may function for some time under the same or slightly changing group of experts. It is assumed that logs are kept of the sessions. An approach based on graph theory and the mining of association rules is proposed to analyze the data generated from such logs. Such analysis may reveal some potentially very useful information on the way the experts make decisions.

2 - Dominance-based Rough Set Approach to Revealing Patterns of Auto Loan Frauds

Adiel de Almeida Filho, Universidade Federal de Pernambuco, Recife, Brazil, adielfilho@cin.ufpe.br, Jerzy Błaszczy ski, Anna Matuszyk, Anna Matuszyk, Marcin Szel g, Roman Slowinski

Auto loan is a significant financial product not yet explored in the literature, unlike the misuse of credit cards, for instance. Given the recent increase in fraudulent transactions concerning auto loan applications, this work tests a new data set for auto loan applications using a technique not yet explored for financial fraud prediction, namely the Dominance-based Rough Set Balanced Rule Ensemble (DRSA-BRE).

3 - Preference-driven Cone Contraction Algorithms for Evolutionary Multiple-objective Optimization

Roman Slowinski, PhD, Professor, Poznan University of Technology, Poznan, 60-965, Poland, roman.slowinski@cs.put.poznan.pl, Milosz Kadzinski, Michal Tomczyk

We present a family of interactive evolutionary algorithms for multiple-objective optimization. In the phase of preference elicitation, a Decision Maker (DM) is asked to compare some pairs of solutions from the current population. Such holistic information is represented by a set of compatible instances of achievement scalarizing functions which contribute to the construction of preference cones in the objective space. These cones are systematically contracted during the evolutionary search, because an incremental specification of the DM's pairwise comparisons is progressively reducing the DM's most preferred region in the objective space.

4 - A Preference-driven Clustering Model for Multiple Criteria Decision Aiding with Mixed Evaluations

Sarah Ben Amor, University of Ottawa, 55 Laurier East (7123), Ottawa, ON, K1N 6N5, Canada, benamor@telfer.uottawa.ca, Ahmet Kandakoglu

In the context of preference driven decision-aiding, we address the problem of ordered clustering based on the multiple criteria aggregation procedure, MCAP-mix designed for mixed evaluations to deal with different types of information imperfections. The distances between preference relations generated for each pair of alternatives by MCAP-mix are used as a measure of closeness of the alternatives. Based on these distances, an extension of the K-medoids clustering algorithm is developed through an Integer Programming (IP) formulation to partition the set of alternatives into ordered clusters. A case study is provided to illustrate the proposed model.

Emerging Topic Session

Chair: Baojun Jiang, Washington University in St. Louis, St. Louis, MO, 63130, United States

Co-Chair: Wen Diao, Fudan University, Shanghai, China

1 - Consumer Fairness Concerns and Dynamic Pricing in a Channel

Wen Diao, Fudan University, Fudan University, Shanghai, China, Mushegh Harutyunyan, Baojun Jiang

This paper studies the dynamic pricing decisions in a channel where there is a segment of consumers who have fairness concerns about retail price increases. We show that, in a market with growing demand, the presence of consumers with fairness concerns can in equilibrium reduce both the first-period and second-period retail prices, resulting in an all-win situation for the manufacturer, the retailer, and the consumers.

2 - Implications of Product Substitutability in a Common Retailer Channel

Honggang Hu, University of Florida, Gainesville, FL, United States, Quan Zheng, Xiajun Amy Pan

We study the effect of product substitutability on firms' profits in a common retailer channel. Specifically, we analyze whether the retailer and manufacturers prefer more or less substitutability for settings with different demand functions, number of manufacturers, and bargaining powers between manufacturers and the retailer.

3 - Strategic Effects of Equity Ownership in Decentralized Channels

Baojun Jiang, Washington University in St. Louis, Olin Business School, St. Louis, MO, 63130, United States, baojunjiang@wustl.edu, Wen Diao, Yifan Xu

This paper develops an analytical framework to examine the strategic and economic impact of equity ownership in vertical relationships. We show that partial ownership can be an all-win situation for the manufacturer, the retailers and the consumers.

4 - Referral and Learning on Social Networks: Implications for Newsvendor

Guangwen Kong, University of Minnesota, Minneapolis, MN, 55414, United States, gkong@umn.edu, Ankur Mani, Yuanchen Su

We examine the impact of social learning in a referral program when customers' preferences are correlated. We characterize customers purchasing strategies based on their information and their types, and derive the demand distributions when customers are involved in social learning in a referral program. We identify the bias and variance trade-offs in the demand distribution and investigate the firm's inventory decision in a referral program. We find that the stock-out of one product influences the demand of the other product when customers are involved in social learning. The optimal design of a referral program generates market exposure with a moderate increase in inventory cost.

Best Service Science Paper II

Sponsored: Service Science

Sponsored Session

Chair: Ming-Hui Huang, National Taiwan University, Taipei, 10617, Taiwan

1 - How Price Dispersion Changes When Upgrades are Introduced: Theory and Empirical Evidence from the Airline Industry

Yao Cui, Cornell University, Ithaca, NY, United States, yao.cui@cornell.edu, A. Yesim Orhun, Izak Duenyas

We study the effect of introducing a new vertical differentiation strategy, paying for an upgrade to a premium product, on the price dispersion of the base product arising from existing price discrimination strategies. We first provide a theoretical analysis that highlights two competing pressures that the new upgrades will create on the price discrimination of the base product. We then conduct an empirical analysis based on a proprietary transaction-level data set from a major U.S. airline company who introduced the option to upgrade to a new type of premium economy seating within the coach cabin. Finally, we discuss implications of our results for firm revenues and consumer welfare.

2 - Dynamic Pricing for Heterogeneous Time-Sensitive Customers

Ramandeep Randhawa, University of Southern California, Los Angeles, CA, 90089, United States, ramandeep.randhawa@marshall.usc.edu, Negin Golrezaei, Hamid Nazerzadeh

A core problem in the area of revenue management is pricing goods in the presence of strategic customers. We study this problem when customers are heterogeneous with respect to their initial valuations for the item and their time sensitivities, i.e., the customers differ in both their initial valuations and the rates at which their initial valuation decreases with delay in purchase. We characterize the optimal mechanism for selling durable goods in such environments and show that delayed allocation and dynamic pricing can be effective screening tools for maximizing firm profit. We also investigate the impact of production and holding costs on the optimal mechanism.

3 - Intertemporal Price Discrimination via Randomized Pricing

Jiahua Wu, Imperial College Business School, Imperial College London, London, SW7 2AZ, United Kingdom, Hongqiao Chen, Ming Hu

Firms adopt dynamic pricing in a wide range of industries. The undesirable, but inevitable, consequence is that consumers are trained to time their purchases strategically. In this paper, we study randomized pricing, where the firm randomly varies prices over time, to counteract consumers' strategic behavior. The firm pre-commits to a price distribution ex ante, and in each period, a price is randomly drawn from the chosen distribution. We characterize the optimal price distribution and compare its performance against deterministic pricing policies, including static pricing and cyclic deterministic pricing policies.

4 - To Brush or Not to Brush: Product Rankings, Customer Search, and Fake Orders

Chen Jin, Assistant Professor, National University of Singapore, Singapore, Luyi Yang, Kartik Hosanagar

"Brushing"-the practice of online merchants placing fake orders of their own products to artificially inflate sales on e-commerce platform-has recently received widespread public attention. On one hand, brushing enables merchants to boost their rankings in search results, because products with higher sales volume are often ranked higher. On the other hand, rankings matter because search frictions faced by customers narrow their attention to only the few products that show up at the top. Thus, fake orders from brushing may affect customer choice. We build a stylized model to understand merchants' strategic brushing behavior and its welfare implications.

5 - Scan-based Trading and Bargaining Power: A Structural Model of Vertical Retail Supply Relationships

Stanley Lim, University of San Diego, San Diego, CA, United States, stanleylim@sandiego.edu, Timothy Richards, Elliot Rabinovich, Min Choi

Using a Nash-in-Nash bargaining model, panel data, and structural econometrics, we examine how the adoption of scan-based trading (SBT) contract relative to vendor managed inventory (VMI) contract influence retailer-supplier bargaining power in a vertical relationship. We find that both retailer bargaining power and inventory shrink are higher under SBT than VMI contracts. Through a series of counterfactual simulations, our results show that a switch from a VMI to an SBT contract arrangement generates an increase of about 46% in bargaining power for retailers, allowing these firms to extract a higher share of the total margin in their vertical relationships with the supplier.

Service Operation

Contributed Session

Chair: Jie Yang, Texas A&M University

1 - Bottleneck Analysis in Multistage Service Systems

Xiaofeng Zhao, University of Mary Washington, Fredericksburg, VA, United States, xzhao@umw.edu

The bottleneck is the key ingredient for improving the performance of the service systems. This research combines results on multiclass queuing networks and proposes approximations for the bottleneck analysis in service operations. The inter-arrival times of the arrival processes and the service times are generally distributed. The analysis is based on the method of decomposition where the entire network is broken up into subsystems which can be analyzed individually by assuming renewal arrival and departure processes.

2 - Analyzing Internal Barriers and Their Causal Relationship of Servitization of Automobile Industry Using Grey-DEMATEL Approach

Bibekananda Mishra, Research Scholar, Indian Institute of Technology-Kharagpur, Kharagpur, India, Biswajit Mahanty, Jitesh J. Thakkar

Adoption of servitization in manufacturing sector has attracted attention from the international researchers and practitioners recently. Though some manufacturing firms increased their revenue generation through servitization, still the topic is at its nascent stage striving hard for implementation. In this research we analyse the internal barriers and drivers of servitization strategies by employing Grey Decision Making Trial and Evaluation Laboratory (DEMATEL) approach for automobile industry. This research uncovers the Critical Success Factors and their causal relationships for effective adoption of servitization initiatives in the automobile service sectors.

3 - Digital Transformation in Retail Banking and the Role of Digital Service Development

Ting Cao, York University, Toronto, ON, Canada, tingc0109@gmail.com, Murat Kristal, Larry Menor

We empirically examine the impact of digital transformation on digital service performance in retail banking. A multi-dimensional construct, digital service development, is developed to capture banks' efforts in generating digital service options through the integration of digital technologies into the operational system. A two-stage approach is used for new multi-item scale development. A global based survey "Innovation in Digital Services" is conducted to collect data. The results offer not only "know-what" of digitalization but also the "know-how" of developing digital services by appropriately managing relevant perspectives to achieve higher digital service performance.

4 - Auctions in Staffing for Self-scheduling Service

Jie Yang, Texas A&M University, College Station, TX, United States, nemoyj1989@tamu.edu

This research examines an auction mechanism in managing staff capacity for sharing economy such as ride-sharing services and work-from-home call centers. The firm has two types of potential employees: type 1 staff is hired long before the work shift begins and type 2 is hired just before the start of the shift. We analyze the short-term scheduling and long-term planning of managing staff capacity jointly. The objective of this research is to provide insights to staff managers on whether and under which conditions auction can outperform the common fixed wage model.

5 - Optimizing Resource Allocation in Service Industries under the Effect of Learning and Forgetting

Hamid Afshari, University of British Columbia, Kelowna, BC, Canada, afsharih@myumanitoba.ca

Learning by repeating reduces the task completion time in production, while interruptions such as long work breaks could result in forgetting and longer completion time. There is a lack of research on the effects of learning and forgetting on service industries. This paper contributes to the literature by introducing a novel mathematical model to evaluate such effects and optimize resource allocation. Valuable results are expected when the model is implemented in safety and cost-sensitive services such as health care and maintenance projects as validated un a safety watch service industry.

6- Auctions in Staffing for Self-scheduling Service

Matthew F. Keblis, Yanling Chang

This research examines an auction mechanism in managing staff capacity for sharing economy such as ride-sharing services and work-from-home call centers. The firm has two types of potential employees: type 1 staff is hired long before the work shift begins and type 2 is hired just before the start of the shift. We analyze the short-term scheduling and long-term planning of managing staff capacity jointly. The objective of this research is to provide insights to staff managers on whether and under which conditions auction can outperform the common fixed wage model.

1 - The Interplay Between Perceived Quality and Resource Utilization: Does Product Size Matter?

Muge Yayla Kullu, University of Central Florida, Orlando, FL, 32816, United States, muge@ucf.edu, Dongling Huang, Praowpan Tansitpong

We empirically investigate how customer perceived quality and resource consumption differences of products may impact a firm's product line decisions, and how they relate to its success in the marketplace. Using an international airline data set, we find that an indirect effect of quality differentiation exists through resource allocation decisions of the firm. We confirm a positive relationship between the premium product focus and the market share. We also show that an increase in resource consumption levels has a negative impact on the allocation towards the premium segment and the overall performance therein.

2 - Effective Algorithms for Lead Time Quotation with Contingent Orders

Ana Muriel, University of Massachusetts, Dept of Mechanical & Industrial Engineering, Amherst, MA, 01003, United States, muriel@ecs.umass.edu, Ron Mallach

Make-to-Order (MTO) firms experience sparse and difficult-to-predict demand generated through the completion of successful project bids with potential customers. Demand is considered contingent until the bid is either accepted or declined by the customer and is reliant on competitive pricing and lead times. Due to uncertainty in the outcome of these customer decisions, firms may hedge against the possibility of losing project bids by bidding multiple projects requiring competing capacities. In this paper, we present simulation-based algorithms to accurately estimate lead time quotations for project bids, considering capacity-competing, contingent backlogs.

3 - Which Stage of the Industry Lifecycle Do Clinical Research Organizations Currently Reside in? An Exploratory Analysis Using Clinical Trials Data

Lidia Betcheva, University of Cambridge, Trumpington Street, Cambridge, CB2 1AG, United Kingdom, lb702@jbs.cam.ac.uk, Feryal Erhun

Analysts have offered various outlooks regarding the future of the clinical research organization (CRO) industry. Applying Bass diffusion methodology on an extensive dataset assembled from the AACT (Aggregate Analysis of ClinicalTrials.gov) database and other publicly available data, we aim to answer the following: Which stage of the industry lifecycle do CROs currently reside in? We further study the dynamics of CRO adoption. Our results carry important capacity and capability planning implications for CRO managers.

4 - Optimal Product Design Strategies with Critical Components and Brand Value Consideration

Kunpeng Li, California State University,Northridge, CA, 84332, United States, Dilip Chhajed, Suman Mallik

Critical components in a product determine the product performance and user experience. Critical components also have brand value, which directly affects consumer demand and the manufacturer's profit. Companies vary considerably in terms of how they implement critical components into their products. This paper aims to investigate how a manufacturer chooses its optimal product design strategy regarding critical component integration and how consumer brand preference affects this optimal strategy.

5 - On Rational Inattention and Product Variety

Tugce Vural, Smeal College of Business, State College, PA, United States, Aydin Alptekinoglu

We develop a choice model based on the theory of rational inattention and apply it to a retail format. By analyzing this model, we study the economics of the retailer's assortment decision when customers are assumed to be rationally inattentive.

Mechanism Design for Social Good

Sponsored: Auction and Market Design

Sponsored Session

Chair: Irene Yuan Lo, Palo Alto, CA, 94306, United States

1 - Group-fairness in Influence Maximization

Bryan Wilder, University of Southern California, Los Angeles, CA, 90016, United States, bryan.wilder0@gmail.com, Alan Tsang, Eric Rice, Milind Tambe, Yair Zick

Influence maximization is a widely used model for information dissemination in social networks in many socially important domains. A critical question is whether the benefits of such interventions are fairly distributed across different groups in the population; e.g., avoiding discrimination with respect to sensitive attributes such as race or gender. We introduce formal definitions of fairness in influence maximization, provide an algorithmic framework to find solutions which satisfy fairness constraints, and conduct experiments on real data from an HIV prevention intervention. In the process, we improve the state of the art for general multi-objective submodular maximization problems.

2 - Fair Division Without Disparate Impact

Christian Kroer, Columbia University, Computer Science Department, 5000 Forbes Avenue, New York, NY, 15213, United States, christian.kroer@columbia.edu, Alex Peysakhovich

We consider the problem of dividing items between individuals in a way that is fair, both in the sense of distributional fairness and in the sense of not having disparate impact across protected classes. We study the setting where allocations must be similar across protected classes, as measured by some objective. We introduce two variants of the standard CEEI mechanism: equitable equilibrium from equal incomes, which removes disparate impact in allocations, and competitive equilibrium from equitable incomes, which removes disparate impact in attained utility levels. We experimentally evaluate the tradeoffs between efficiency, equity, and disparate impact in a recommender-system market.

3 - Pay-for-quality or Pay-for-selection? Evidence of Reverse Cross Subsidization in Healthcare

Zhaowei She, Georgia Institute of Technology, Atlanta, GA, 30067, United States, zhaowei@gatech.edu, Turgay Ayer, Bilal Gokpinar

Risk-adjusted capitation payment models have been increasingly adopted by payers in the U.S. healthcare market during the past decade. However, early study shows that Medicare Advantage (MA), the largest capitation program in the U.S., has been suffering from the risk selection problem, where the payer (CMS) systematically over and under reimburses certain patient subgroups. This paper provides patient-level evidence on how risk selection is conducted in MA, and empirically shows that risk selection problem cannot be eliminated by pure statistical risk adjustment designs.

4 - Simple and Optimal Contract Design for Environmental Conservation

Wanyi Li, Stanford University, Stanford, CA, United States, wanyili@stanford.edu, Itai Ashlagi, Irene Yuan Lo

We consider the problem faced by a budget-constrained principal whose goal is to maximize conservation of environmental resources that are owned by agents, given that consumption is irreversible. We show that the optimal contract in this setting has a simple structure in terms of budget allocation and menu selection over time. The findings have implications for "Payment for Ecosystem Services" where governments and NGOs pay private-land-owners to not deforest or to reduce pollution.

Supply Chain Management IV

Contributed Session

Chair: Bosung Kim, Sauder School of Business, Vancouver, BC, Canada

1 - Direct Selling by Supplier Improves System-wide Information Flow

Zhongyuan Hao, Dongbei University of Finance and Economics, Dalian, China, lingyuran881201@163.com, Li Jiang

Consider a bilateral monopoly selling to a market with uncertain demand. The retailer has access to a demand signal. The supplier can add a direct channel, which grants it market access as well. The supplier and the retailer can acquire signals from each other with payments. We study the effects of direct selling by the supplier on the information flow in the system. We find that direct selling by the supplier has a fundamental impact on information flow. While no information flow is sustainable when the supplier stays with retailing, add-on direct selling incentivizes it to share the signal from market access with the retailer for free and acquire the retailer's signal as well.

2 - Online vs. Offline: How Should a Supplier Encroach on its Retailer with Traffic Consideration?

Jie Zhang, Guangdong University of Finance and Economics, Guangzhou, China, jiezh@gdufe.edu.cn

It is increasingly common for suppliers to encroach on its retailer with an online/offline direct channel. While direct channel management has been studied thoroughly in the literature, the effect of traffic congestion is often ignored. In this paper, we investigate a supplier's decision on whether and how to encroach by considering the traffic congestion cost. We analyze the equilibrium strategies and identify the supplier's channel preference under various conditions, and show that traffic congestion indeed reduces the supplier's incentive of encroachment.

3 - Long-term Collaboration in High-tech Manufacturing

Mirjam S. Meijer, Eindhoven University of Technology, Eindhoven, Netherlands, m.s.meijer@tue.nl, Ton de Kok, Willem van Jaarsveld

In high-tech manufacturing, shortage of a single component can lead to extremely costly delivery delays. To avoid such shortages a manufacturer tries to incentivize his suppliers to create sufficient capacity, which is not easy because overcapacity is costly. Therefore, we observe long-term relationships between a manufacturer and his suppliers. We model this relation as a repeated Stackelberg game in which the manufacturer is the natural leader. After each period, the manufacturer decides on her supplier for the next product generation. We compare the case in which supplier-performance is taken into account to the case where it is not and evaluate the effect on individual and supply chain profits.

4 - Collaborative Supply Chain Network Design with Overlapping Coalitions

Reza Alikhani, Postdoctoral Researcher, EM Normandie Business School, Le Havre, France, Alikhani64@gmail.com, Yann Bouchery, Benjamin Legros

In this study, we consider a collaborative network design with coalition formation. The model determines the optimal number of coalitions for a carrier as well as the number of players for each coalition. In addition, we consider the possibility of joining overlapping coalitions in which a carrier can join more than one coalition. We examine numerous instances to show the applicability of the model.

5 - Research on Supplier Relationship Management of Large Complex Equipment Enterprises

Xinyu Ma, Nanjing University of Aeronautics and Astronautics, Nanjing, China, mxywhispers@nuaa.edu.cn, Qing Zhang, Wei Zhang

Selecting suitable model of SRM is vital to improve enterprises' production efficiency and decrease costs. The article firstly classifies enterprise's suppliers using ABC classification and establishes evaluation model for suppliers marked as A and B by applying BSC and KPI to indicators construction. After determining index weight using AHP, grey clustering coefficients to judge suppliers can be calculated. Afterwards the supplier-manufacturer relationship can be divided into separate partnership through Maslow theory and existing results. The actual and should-be stage of cooperation are estimated by the output result, we can then conclude specific actions to strengthen cooperation.

6 - Sourcing Decision in the Presence of a Complementary Component

Bosung Kim, Pusan National University, Busan, Korea, Republic of, Jeongeun Sim

This paper examines the manufacturer's component sourcing decision in the presence of a complementary component. While there have been extensive studies on manufacturer's make-or-buy decisions, the impact of a complementary component on the decision has been largely ignored in the literature despite the fact that most products have multiple key components provided by different suppliers. We construct a game theoretical model between a manufacturer and a supplier (or suppliers), and compare the manufacturer's profit under the three sourcing regimes.

Tutorial: Field Experiments in Operations Management

Emerging Topic: Tutorials

Emerging Topic Session

1 - Tutorial - Field Experiments in Operations Management

Bradley R. Staats, University of North Carolina at Chapel Hill, Chapel Hill, NC, 27599-3490, United States, Maria R. Ibanez

Field experiments are controlled interventions in the real world that enable researchers to measure the effects of a treatment on a randomly assigned subset of subjects. In this paper, we review the advantages and disadvantages of field experiments and provide some practical prescriptions to attain and evaluate a field experiment's relevance—in other words, the theoretical implications of understanding the effects of the treatment— and rigor, based on many methodological considerations.

Chair: Lee Evans, PhD, United States Military Academy

1 - Economic Growth and U.S. Troop Deployments in Kuwait

Robert Lasater, US Army, West Point, NY, United States

Disentangling the direct effects of US troops on economic growth from indirect effects of conflict resolution and stability on growth is an empirical challenge. This paper provides new evidence on the economic impact of troop deployments by studying Kuwait in early period of the Iraq War. Utilizing synthetic control matching, this paper estimates the effects of an exogenous increase of security from a large deployment of US troops without the destruction of conflict and finds an increase in economic growth. I explore mechanisms for growth, finding evidence for the growth caused by the security umbrella, lesser by expenditures, and limited evidence for effects of diffusion.

2 - Time-staged Network Flow Modeling and Transportation Planning for U.S. Noncombatant Evacuation Operations in South Korea

John Kearby, US Army, West Point, NY, United States, john.a.kearby.mil@mail.mil

We formulate a network model of the South Korean noncombatant evacuation system as a mixed integer linear program to determine an optimal flow configuration that minimizes total evacuation time. The solution considers the capacity and resource constraints of each transportation mode and vehicle routing completes the plan by producing an exact schedule for each individual asset throughout the operation. A case study introduces additional restrictions during mission planning and disrupts the network and fleet during the actual evacuation to demonstrate the usefulness of the complete procedure.

3 - Utilizing Industrial and Systems Engineering Tools to Reduce Healthcare Associated Infections

Jose Jimenez, Assistant Professor, United States Military Academy, West Point, NY, United States, jose.jimenez@westpoint.edu

Healthcare acquired infections (HAIs) have decreased over the last decade. Nevertheless, HAIs are still a burden for healthcare systems. In addition to the increase in morbidity and mortality of patients that are already at risk, HAIs create resource constraints in healthcare facilities. Different solution approaches involve early detection of HAIs using statistical tools, incorporation of special sociotechnical interventions, high performance computer simulation, human factors design, and application of public health practices. Many of the current tools utilized by healthcare facilities were developed through a systems-based, multidisciplinary approach.

4 - Network Flows Applied Modular Classes Within Academic Terms

Daniel Meadows, United States Military Academy, West Point, NY, 10996, United States

A directed network can be created from course concept maps of multiple courses. Academic departments can choose concepts required for specific majors and apply a shortest path algorithm to find the minimum blocks of instruction necessary to cover desired topics. A network flow model can then be used to schedule blocks of instruction and constraints can be written for resource limitations such as number of instructors, hours and classrooms available.

5 - Combining Regression and Mixed-Integer Programming to Model Counterinsurgency

David Galbreath, United States Military Academy, Marvin Lee King, Alexandra M. Newman, Amanda Hering

We develop a mixed-integer program to provide an estimate of the number of forces required to maximize the probability of a favorable resolution to counterinsurgent and host-nation countries engaged in a counterinsurgency, while minimizing unfavorable resolutions and the number of counterinsurgent deaths. This program integrates a multivariate piecewise-linear regression model to estimate the number of counterinsurgent deaths each year and a logistic regression model to estimate the probability of four types of conflict resolution over a fifteen-year time horizon. We use Somalia as a case study to estimate how counterinsurgent strategies affect the probability of the conflict resolution.

6 - Forecasting for the Afghan National Army

Christopher Collins, United States Military Academy, West Point, NY, United States

Given a fiscally austere and tumultuous future strategic environment, the Government of the Islamic Republic of Afghanistan (GIRoA) must maintain an All-Volunteer Army force with sufficient capacity and capability to respond to domestic security threats. The Afghan All-Volunteer Army Model (AAVAM) answers the Commanding General, Combined Security Transition Command-Afghanistan question of what size force the Afghan National Army (ANA) could field in 2021 given the current recruiting and attrition environment. The analytical approach utilizes a heuristic, providing sufficient deterministic modeling where an optimal solution is not guaranteed. Time-series forecasting and regression each provide a data-driven basis for approximating the force size the ANA could field in 2021 under the current operational environment and disparate accession enterprise

1 - A Branch-and-Bound Framework for Infinite-horizon Multi-model Markov Decision Processes

Vinayak Ahluwalia, University of Michigan, Glenview, IL, 60026, United States

Markov decision processes (MDPs) are models for sequential decision-making that inform decision making in many fields, including healthcare. However, MDPs are subject to parameter ambiguity because parameters estimated from different data sources may lead to different recommendations. A study of this problem for finite-horizon MDPs succeeded with a branch-and-bound approach, so we extend the study to infinite-horizon MDPs and recommend algorithmic designs that reduce computation time. We use previously-published computational studies to demonstrate our algorithm's effectiveness.

2 - Incorporating Equity into the School Bus Scheduling Problem

Dipayan Banerjee, Northwestern University, Evanston, IL, United States

We consider the school bus scheduling problem (SBSP) which simultaneously determines school bell times and route schedules. Often, the goal of the SBSP is to minimize the number of buses required by a school district. We extend a time-indexed integer programming model to incorporate additional considerations related to equity and efficiency. We seek to equitably reduce the disutilities associated with changing school start times via a minimax model, then propose a lexicographic minimax approach to improve minimax solutions. We apply our models to randomized instances based on a moderately-sized public school district to show the impact of incorporating equity.

3 - Energy Aware Scheduling of a Material Handling Robot in an m-Machine Robotic Cell

Rabia Taspinar, TOBB University of Economics and Technology, Ankara, Turkey, Hakan Gultekin, Sinan Gurel

In this study, we consider a bi-criteria robotic cell scheduling problem for determining the trade-off between the cycle time and robot's energy consumption in an m-machine cell by the efficient planning of robot movements' sequence and corresponding robot speeds. We proposed two mathematical models and a heuristic algorithm to solve this problem. Their performances are tested by a computational study. Our results indicate that robot speed control can reduce the energy consumption significantly for the same cycle time while providing a set of pareto-efficient solutions for the decision maker.

1 - Multistage Adaptive Mixed Integer Optimization Using Improved Piecewise Decision Rule

Zukui Li, University of Alberta, Edmonton, AB, T6G1H9, Canada, zukui@ualberta.ca, Farough Motamed

The decision rule method is popular for multistage adaptive mixed integer optimization under uncertainty. Compared to linear decision rule, piecewise linear decision rule elevates the approximation quality by having multiple slopes (i.e. decision rule coefficients) while inheriting the tractability feature. However, the method relies on the pre-selected breakpoints for each uncertain parameter. This selection may significantly affect the quality of the piecewise decision rule solution. We propose a method to optimize the breakpoint locations with a given number of breakpoints and achieve improved piecewise decision rule for multistage adaptive mixed integer optimization.

2 - A Data-driven Branching on Decomposition of Stochastic Mixed-integer Programs

Kibaek Kim, Argonne National Laboratory, 9700 South Cass Avenue, Building 240, Lemont, IL, 60439, United States, kimk@anl.gov

We consider the dual decomposition of stochastic mixed-integer programs, which is based on the Lagrangian relaxation of the problem with respect to nonanticipativity constraints and known to provide a tight dual bound of the optimal objective value. Due to duality gap, branch-and-bound method may be required for finding a global optimum. We present branching methods in the dual decomposition and the numerical results for comparing different branching methods.

3 - Applications in Optimizing Dynamic Systems under Uncertainty

Bethany Nicholson, Sandia National Laboratories, 5516 Sabrosa Dr NE, Albuquerque, NM, 87111, United States

In this talk we will highlight several applications of combining the PySP, a software framework for stochastic programming, and Pyomo.DAE, a tool for formulating and solving dynamic optimization problems. By combining these frameworks for stochastic programming with dynamic optimization we are able to quickly formulate complex models that directly incorporate uncertainty and system dynamics. Our applications will span a variety of engineering disciplines and demonstrate the value of simultaneously considering dynamics and uncertainty.

4 - A Global Optimization Algorithm for Stochastic Nonlinear Programs

Yankai Cao, University of British Columbia, Vanvouver, BC, Canada, yankai.cao@ubc.ca

We present a reduced-space spatial branch and bound (BB) strategy for two-stage stochastic nonlinear programs. At each node, a lower bound is constructed by relaxing the non-anticipativity constraints and an upper bound is constructed by fixing the first-stage variables. Both lower and upper bounds can be computed by solving individual scenario subproblems. Another key property is that we only need to perform branching on the first-stage variables to guarantee convergence. We present an implementation of the algorithm called SNGO. We also present different heuristics to significantly accelerate the solution process.

1 - A Data-driven Approach for the Price-setting Newsvendor Problem

Mahsa Mardikoraem, University of Wisconsin-Milwaukee, Milwaukee, WI, United States, mardiko2@uwm.edu, Ehsan S. Soofi

Quantile regression has been considered for estimating demand in the price-setting newsvendor problem. In order to incorporate uncertainty about the model, we use Bayesian quantile regression. We apply Stochastic Frontier Models for unobservable censored demands. Our model provides predictive distributions for the optimal quantile of the demand and the expected profit given price.

2 - Competitive Price-matching Policy in a Two-stage Supply Chain

Jinpeng Xu, Xidian University, Xi'an, China, Xiaolan You, Gengzhong Feng

This paper considers a supply chain consisting of a Stackelberg supplier and a retailer selling a product with linear demand function. The retailer decides on whether adopting the competitive price-matching policy under which the consumers can apply to match the lowest price they observe in the market after purchase. We use a Stackelberg game model to derive the optimal wholesale price for the supplier and the optimal retailing price for the retailer when the policy is adopted. We compare the prices and resulting profits with the case without adopting the policy to show when the policy can benefit the retailer and the supplier.

3 - Supply Chain Coordination Mechanisms for Price Dependent Stochastic Demand

Bhavin J. Shah, Associate Professor, Indian Institute of Management-Indore, Indore, Madhya Pradesh, India, bhavinj@iimidr.ac.in, Hasmukh Gajjar

In this paper, we study channel coordination issues with price dependent stochastic demand. We discuss various contracts and conditions to achieve coordination in centralized and decentralized setting. Numerical examples are presented to highlight the theoretical results.

4 - The Price of Myopia and the Price of Anarchy in Supply Chain Analysis

Fouad El Ouardighi, ESSEC Business School, Cergy Pontoise, France, elouardighi@essec.edu, Konstantin Kogan

This paper compares static and dynamic equilibria in a supply chain composed of one manufacturer and one retailer solutions to determine the price of myopia and the price of anarchy.

Discrete Optimization and Duality

Sponsored: Optimization/Integer and Discrete Optimization

Sponsored Session

Chair: Temitayo Ajayi, Rice University, Houston, TX, 77004, United States

1 - Projection and Duality

Christopher Ryan, University of Chicago, Chicago, IL, 60637, United States, Lisa Hillis, Guanyi Wang

We expand on a framework proposed by Ryan and Trotter to generalize conic and monoid dualities. We extend to ``affine" settings and explore the relationship between properties of affine dualities with ``projection" properties that generalize the classical notion that polyhedra project to polyhedra. For example, a key property of a duality is the Weyl property, where a set described by ``combinations" of finitely many elements is the intersection of finitely many ``constraints". We show that a duality with a projection property satisfies the Weyl property. Several related conditions are explored with examples and counterexamples that illustrate their significance.

2 - The Gap Function: Evaluating Integer Programming Models Over Multiple Right-hand Sides

Temitayo Ajayi, Rice University, Houston, TX, 77004, United States, ta21@rice.edu

The linear programming relaxation gaps are important to assessing a model's quality for a given set of data. There is no consensus, however, on appropriate measures of model quality when the evaluation considers multiple instances parametrized by right-hand sides of constraints. We propose evaluating models over many right-hand sides by using metrics based on gap functions. In particular, we formulate optimization problems to compute the expectation and extrema of gap functions over bounded hyper-rectangles. These optimization problems are linear programs (albeit of an exponentially large size) that contain at most one special ordered set constraint.

3 - Iterative Combinatorial Auctions for Managing Product Transitions in Semiconductor Manufacturing Using Subadditive Duals of MILP

Ankit Bansal, North Carolina State University, Raleigh, NC, 27606, United States, Osman Ozaltin, Reha Uzsoy

We model the negotiations between multiple product development groups (PDGs) and a manufacturing group (MFG) for access to manufacturing capacity to support product development activities in the semiconductor industry. We develop an Iterative Combinatorial Auction (ICA) framework based on the subadditive duals of MILP that maximizes the number of agents for which a bid is selected in the final solution. We conduct a single shot auction between the auctioneer and MFG at the end where MFG gives the auctioneer a production schedule that improves corporate revenue. The approach aims to achieve coordinated decisions between the two groups with better duality gaps compared to a LP duality based ICA.

4 - Intersection Cuts or Sets with a Distance Oracle

Chen Chen, Ohio State University, Columbus, OH, United States, chenicus@gmail.com

We explore the use of S-free sets, or convex forbidden zones, in order to generate cutting planes for tighter convex relaxations. If S is equipped with a Euclidean distance oracle, then an intersection cut can be generated in polynomial-time. With the appropriate representation, such an oracle is available for mixed-integer linear programming, (nonconvex) polynomial optimization. as well as special sets involving cardinality, or permutations. We also consider implementation issues, including cut strengthening, and exploiting problem sparsity.

5 - Complexity Results for Split Cuts and Disjunctions.

Hongyi Jiang, Johns Hopkins University, Baltimore, MD, United States, hjiang32@jhu.edu, Amitabh Basu

We firstly show that the split closure in two dimensional space has polynomial complexity, which settles an open (to the best of our knowledge) conjecture in integer programming theory. Next, we present a polynomial-time cutting plane algorithm based on split cuts for pure integer programming in two-dimensional space. Finally, we compare the complexity of branch-and-bound and cutting plane algorithms, both based on variable disjunctions, on 0-1 polytopes in general dimensions.

6 - Intersection Cuts for Sets with a Distance Oracle

Daniel Bienstock, Gonzalo Munoz

We explore the use of S-free sets, or convex forbidden zones, in order to generate cutting planes for tighter convex relaxations. If S is equipped with a Euclidean distance oracle, then an intersection cut can be generated in polynomial-time. With the appropriate representation, such an oracle is available for mixed-integer linear programming, (nonconvex) polynomial optimization. as well as special sets involving cardinality, or permutations. We also consider implementation issues, including cut strengthening, and exploiting problem sparsity.

7 - Complexity Results for Split Cuts and Disjunctions.

Michele Conforti, Marco Di Summa

We firstly show that the split closure in two dimensional space has polynomial complexity, which settles an open (to the best of our knowledge) conjecture in integer programming theory. Next, we present a polynomial-time cutting plane algorithm based on split cuts for pure integer programming in two-dimensional space. Finally, we compare the complexity of branch-and-bound and cutting plane algorithms, both based on variable disjunctions, on 0-1 polytopes in general dimensions.

Robust Optimization and Mechanism Design

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Dan Andrei Iancu, Stanford University, Stanford, CA, 94107, United States

Co-Chair: Daniel Kuhn, Ecole Polytechnique Federale de Lausanne (EPFL), Lausanne, Switzerland, 1015, Switzerland

1 - A Two-layer Multi-armed Bandit Approach for Online Multi-item Pricing

Cagil Kocyigit, Ecole Polytechnique Federale de Lausanne (EPFL), Avenue de Chailly 44, Lausanne, Switzerland, 1012, Switzerland, cagil.kocyigit@epfl.ch, Napat Rujeerapaiboon, Daniel Kuhn

The revenue-maximizing mechanism for selling I items to a buyer with additive and independent values is unknown, but the better of separate item pricing and grand-bundle pricing extracts a constant fraction of the optimal revenue. We study an online version of this pricing problem, where the items are sold to (each of) T identical and independent buyers arriving sequentially. We address this problem with a two-layer multi-armed bandit algorithm (reminiscent of the UCB algorithm) and prove that the proposed online algorithm offers an asymptotic constant-factor approximation guarantee relative to the (unknown) best offline mechanism that benefits from full distributional information.

2 - Prior-Independent Optimal Auctions

Omar Besbes, Columbia University, Graduate School of Business, New York, NY, 10027, United States, ob2105@gsb.columbia.edu, Amine Allouah

Auctions are widely used in practice. While also extensively studied in the literature, most of the developments rely on the significant common prior assumption. We study the design of optimal prior-independent selling mechanisms: buyers do not have any information about their competitors and the seller does not know the distribution of values, but only a general class it belongs to. We characterize properties of optimal mechanisms, and in turn establish fundamental impossibility results through upper bounds on the maximin ratio. By also deriving lower bounds on the maximin ratio, we are able to crisply characterize the optimal performance for a spectrum of families of distributions.

3 - Salesforce Contracting under Uncertain Demand and Supply: Double Moral Hazard and Optimality of Smooth Contracts

Tinglong Dai, Johns Hopkins University, Baltimore, MD, 21202, United States, dai@jhu.edu, Kinshuk Jerath

We consider the compensation design problem of a firm that hires a salesperson to exert effort to increase demand. We assume both demand and supply to be uncertain. Under single moral hazard (i.e., when the salesperson's effort is unobservable to the firm), we show that the optimal contract has an extreme convex form. Under double moral hazard, we show that the optimal contract is smoother to assure the salesperson that the firm does not have an incentive to deviate to an action that will hurt the agent; in fact, under certain conditions, the contract is concave in sales. We also determine conditions under which the firm should postpone contracting until after supply is realized.

Robust Sequential Decision Making: Theory and Applications

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Hideaki Nakao, University of Michigan, Ann Arbor, MI, 48105, United States

1 - Sensitivity of Preventive Decisions for Deteriorating Markovian Systems

Lauren N. Steimle, University of Michigan, Ann Arbor, MI, 48105, United States, Brian T. Denton

Determining an optimal preventative maintenance strategy for a deteriorating system is common in many application areas including medical decision making, machine maintenance, and forestry management. Markov decision processes (MDPs) have found success in informing preventative maintenance of stochastically deteriorating systems, but there is a concern that the optimal decisions resulting from MDPs are sensitive to model parameters which must be estimated in practice. In this work, we discuss the sensitivity of common MDP formulations for optimal preventive maintenance and illustrate our findings using case studies related to preventive treatment decisions for chronic disease.

2 - Multistage Stochastic and Distributionally Robust Optimization with Prioritization

Xian Yu, University of Michigan, Ann Arbor, MI, 48105, United States, yuxian@umich.edu, Siqian Shen

We consider multistage activity-selection problems with uncertain demand and budget at each stage. We place activities into a priority list before the uncertainty is revealed, and enforce the activity selections to obey the priority list after realizing the uncertainty. The priority list can be either fixed or changing adaptively through stages. In the latter case, we only form the priority list for activities that have not been selected at each stage. We formulate a stochastic integer program and a distributionally robust model. We develop Stochastic Dual Dynamic integer Programming (SDDiP) approach for both two models and test the results using randomly generated instances.

3 - Robust Dynamic Media Selection with Yield Uncertainty: Max-Min Policies and Dual Bounds

Justin Goodson, Saint Louis University, Saint Louis, MO, United States, goodson@slu.edu, Luca Bertazzi, Reuven R. Levary

Uncertainty in exposure yield can degrade advertising effectiveness. Resources available to smaller firms are often inadequate to recapture exposure lost due to bumps before the end of a media campaign. Recognizing the need to buffer against yield uncertainty, we consider strategies to make media buys across time. Our study of static policies motivates the need for dynamic policies, which we show can offer significant advantages. We construct dynamic policies from static policies, and in so doing extend rollout theory to max-min dynamic programs. Because our information-based dual bound is also generally applicable, our work provides tools to both identify policies and to benchmark performance.

4 - Distributionally Robust Partially Observable Markov Decision Process

Hideaki Nakao, University of Michigan, Ann Arbor, MI, 48105, United States, nakaoh@umich.edu, Ruiwei Jiang, Siqian Shen

We consider a distributionally robust formulation of partially observable Markov decision process (POMDP), where the transition probabilities and observation probabilities are assumed to be unknown, and vary over time. We use conic constraints to characterize the moment information for the ambiguity set of the joint distribution of the two types of probabilities. We propose a distributionally robust heuristic search value iteration (DRHSVI) algorithm under a setting where the decision maker obtains the value of the transition and observation probability at the end of every time step.

5 - Sensitivity Analysis of the Inventory Model Governed by Autoregressive Demand Process

Yi Cheng, ISyE Georgia Tech, Atlanta, GA, United States, Guanghui Lan, Alexander Shapiro

Classical analysis of the multistage inventory (newsvendor) model assumes that the involved demand process is stage-wisely independent. In that case the basestock policy is optimal. We consider the setting where the demand is modeled as an autoregressive process and study sensitivity of the corresponding optimal value with respect to the autoregressive parameters. The analysis is based on construction of dual optimization problem and application of the SDDP algorithm.

1 - Distributionally Robust Chance Constrained Assignment Problem with an Application to Operating Rooms

Sanjay Mehrotra, Northwestern University, Dept of I. E. / M. S. C246 Tech Inst, 2145 Sheridan Road, Evanston, IL, 60208-3119, United States, mehrotra@iems.northwestern.edu, Shanshan Wang, Jinlin Li

We study a class of assignment problems with distributionally robust chance constraints. We show how to use the robust framework towards strengthening the big-M coefficients. We also use a bi-linear formulation of the problem and provide ways to identify strengthen cover inequalities. We present computational results for a branch-and-cut implementation of our problem. We also show the value of including distributional robustness using l1 Wasserstein metric.

2 - Distributionally Robust Nonlinear Optimization

Jianzhe Zhen, École Polytechnique Fédérale de Lausanne (EPFL), Rijtse Akkers 174, Lausanne, 5037JW, Switzerland, jianzhe.zhen@epfl.ch, Daniel Kuhn, Wolfram Wiesemann

Leveraging a generalized `primal-worst equals dual-best' duality scheme for robust optimization, we derive from first principles a strong duality result that relates distributionally robust to classical robust optimization problems and that obviates the need to mobilize the machinery of abstract semi-infinite duality theory. In order to illustrate the modeling power of the proposed approach, we present convex reformulations for data-driven distributionally robust optimization problems whose ambiguity sets constitute type-p Wasserstein balls for any p in [1,\infty].

3 - Distributionally Robust Expectation Using Shape Information

Ruiwei Jiang, University of Michigan, Ann Arbor, MI, 48109, United States, ruiwei@umich.edu, Yuanyuan Guo

This talk discusses the expectation of a random function when the distributional information of the uncertain parameters consists of moment (e.g., mean, covariance, support) and probabilistic dominance information. We find that the expectation in this setting can be bounded using conic programming. Finally, we demonstrate the theoretical results via case studies on appointment scheduling.

4 - Two-stage Wasserstein Distributionally Robust Convex Programs with Zero-one Uncertainties

Anirudh Subramanyam, Argonne National Laboratory, Lemont, IL, 60302, United States, Mohamed El Tonbari, Kibaek Kim

We address discrete-valued zero-one random parameters in two-stage convex conic optimization problems in which the goal is to minimize the worst-case expectation of the random cost, over all distributions in a Wasserstein ball centered at the empirical distribution. We provide a simple, tractable and scalable technique that provides a conservative approximation. Our method relies on a reformulation that constrains some variables to lie in the convex hull of feasible points of a mixed-integer conic set, followed by an approximation of this convex hull using lift-and-project techniques. Numerical experiments illustrate the practical viability and benefits of our method over existing schemes.

Sponsored Session

Chair: Sam Davanloo Tajbakhsh, Ohio State University, Columbus, OH, 43210, United States

1 - High Dimensional Stochastic Optimization under Low Rankness

Hongcheng Liu, University of Florida, Gainesville, FL, 32606, United States, Charles Hernandez, Hung Yi Lee

The talk concerns high-dimensional a stochastic programming problem of minimizing the expected function of a matrix argument. To this problem, the traditional sample complexity theories of the sample average approximation require the sample size to be polynomial in the problem dimensionality. Such a sample requirement becomes easily prohibitive when optimizing functions of matrix arguments. Indeed, for a problem optimizing over a p-by-p matrix, the sample complexity grows rapidly at a quadratic rate in p. To reduce the sample complexity this paper considers a low-rankness-inducing regularization scheme and shows that the sample complexity can be substantially reduced to almost linear in p.

2 - On Push Pull Gradient Methods for Distributed Optimization Over Directed Graphs in Absence of Strong Convexity

Mostafa Amini, Oklahoma State University, Stillwater, OK, 74075, United States, moamini@ostatemail.okstate.edu, Farzad Yousefian

We consider distributed optimization in multi-agent systems where each agent is associated with a merely convex function and agents communicate over a directed graph. The goal is to collaboratively minimize the sum of the cost functions. We develop an iteratively regularized distributed push-pull gradient method where the decision variable information is pushed to the neighbors and the gradient information is pulled from the neighbors. We establish the convergence of the method and derive a rate statement. Preliminary numerical results for a big data application will be discussed.

3 - Fair Rényi Inference

Sina Baharlouei, University of Southern California, OHE 340, Los Angeles, CA, 90089, United States, baharlou@usc.edu

Machine learning algorithms have been increasingly deployed in critical automated decisions that directly affect human lives. Several reported instances have demonstrated that these algorithms may suffer from systematic discrimination against individuals based on their sensitive attributes (gender, race,). In this talk, we introduce Hirschfeld-Gebelein-Rényi (HGR) correlation principle as a tool to impose several known group fairness measures. Using HGR coefficient, we propose a min-max game formulation for fair statistical inference. Our framework leads to natural fair supervised and unsupervised learning methods which enjoy theoretical performance guarantees.

4 - An Alternating Direction Method of Multipliers with the Sharing Scheme for Statistical Learning under Structured Sparsity

Dewei Zhang, The Ohio State University, Columbus, OH, United States, zhang.8705@osu.edu, Yin Liu, Sam Davanloo Tajbakhsh

To achieve more interpretable statistical models, sometimes it is preferred that the learning solution obeys an a priori known hierarchical structure represented as a directed acyclic graph. Inducing such structures requires nonsmooth penalty functions that exploit group overlapping of the decision variables. Our study focuses on the optimization problems with such penalties. We develop an ADMM algorithm with the sharing scheme to solve high-dimensional instances of these problems. In the absence of strong convexity, linear convergence of the algorithm has been established provided a primal and dual error bound. Some numerical results supporting the proposed algorithms will be provided.

CC- Room 610

Conic Mixed Integer Programming

Sponsored: Optimization/Linear and Conic Optimization

Sponsored Session

Chair: Sven Wiese, Mosek ApS, Copenhagen, 2100, Denmark

1 - Conic Optimization in Mosek 9: New Cones and Algorithms

Sven Wiese, Mosek ApS, Copenhagen, Denmark, sven.wiese@mosek.com

Conic optimization is a popular paradigm because it preserves many desirable properties of Linear Programming, but is also quite versatile when it comes to modeling. In fact, the by now accepted folklore is that the linear, quadratic, semidefinite, exponential and power cones are enough to express almost all practical convex optimization problems. The software package MOSEK has for a long time been able to optimize over the former three, the symmetrical cones. The new version 9 also handles the latter two, the non-symmetric ones. This talk gives an overview on applications of this breakthrough, and on the employed algorithms, both in the continuous and mixed-integer case.

2 - A Branch-and-cut Algorithm for Solving Mixed-integer Semi-definite Optimization Problems

Ken Kobayashi, Fujitsu Laboratories LTD., Kawasaki, Japan, ken-kobayashi@fujitsu.com, Yuichi Takano

We consider a cutting-plane algorithm for solving mixed-integer semidefinite optimization (MISDO) problems. In this algorithm, we relax the positive semidefinite (psd) constraint, and solve the resultant mixed-integer linear optimization problem repeatedly, imposing at each iteration a valid inequality for the psd constraint. Moreover, to speed up the computation, we devise a branch-and-cut algorithm, in which we add valid inequalities dynamically during a branch-and-bound procedure. Our numerical experiments showed that, for many problem instances, our branch-and-cut algorithm outperformed other general-purpose MISDO solvers in terms of computational efficiency and stability.

3 - On the Circuit Diameter Conjecture

Tamon Stephen, Simon Fraser University, Surrey, BC, Canada

A key concept in optimization is the diameter of a polyhedron. From the point of view of optimization, we would like to relate it to the number of facets f and dimension d of the polyhedron. Following Klee and Walkup (1967), we consider analogous questions for a variant of the combinatorial diameter called the circuit diameter. Here paths are built from the circuit directions of the polyhedron, and can travel through the interior. We show that many of the Klee-Walkup results and techniques translate to the circuit setting. Joint work with Steffen Borgwardt and Timothy Yusun.

4 - Convex Hull Representations for Bounded Products of Variables

Kyungchan Park, University of Iowa, Iowa City, IA, United States, kyungchan-park@uiowa.edu, Kurt M. Anstreicher, Samuel Burer

Convex hull for {(x,y,z) z=xy, 0≤x,y≤1} is given by Reformulation-Linearization Technique (RLT) constraints. Belotti et al. (2010) and Miller et al. (2011) derived convex hull with additional upper/lower bounds on z as an infinite family of inequalities, requiring a separation algorithm to implement. We show the convex hull for upper or lower bounded product is given by original RLT constraints, the bound on z, and a single SOC constraint. For upper/lower both bounded product, we show convex hull remains SOC-representable on a dissection of the domain of (x,y). Also, volumes of the feasible space with bounds on z are calculated and compared to the relaxation that imposes only the RLT constraints.

Analysis and Optimization of Critical Infrastructure Systems

Sponsored: Optimization/Network Optimization

Sponsored Session

Chair: N. Orkun Baycik, Shenandoah University, Winchester, VA

1 - Enhancing Resilience of Complex Infrastructure Components

Cameron MacKenzie, Iowa State University, Industrial and Manufacturing Systems Engr, Ames, IA, 50011, United States, camacken@iastate.edu, Ramin Giahi

Critical infrastructure components should be designed to be resilient to sudden and adverse events. The design should also incorporate future maintenance decisions about whether to repair or replace worn-out components. Many designs of critical infrastructure require complex simulations, which can be difficult to optimize. We apply Bayesian optimization techniques to optimize the design and maintenance of resilient critical infrastructure.

2 - A Hybrid Data-driven Game-theoretic Optimization Framework for Resilient Interdependent Infrastructure Networks

Alireza Rangrazjeddi, University of Oklahoma, Norman, OK, 73019, United States, ajeddi@ou.edu, Andres David Gonzalez, Kash Barker

Infrastructure networks are constantly under natural and anthropogenic hazards that may affect their performance and the communities they serve. Thus, it is imperative to propose efficient modeling techniques that support adequate decision-making before and after disruptive events. However, infrastructure networks are complex systems that involve multiple interdependencies and stakeholders with goals that are not always aligned. To address these issues, we propose a hybrid data-driven game-theoretic optimization framework to develop efficient mitigation and recovery plans for systems of interdependent infrastructure networks with multiple decision makers involved.

3 - Modeling the Interdependency of Emergency Services and Power Outages During Critical Events

Ann Suhaimi, Northeastern University, Boston, MA, 02115, United States, nmsuhaimi@gmail.com, Jacqueline Griffin

Effective emergency medical services (EMS) are crucial in promoting safety and health of populations especially during critical events. While a lot of studies on network optimization have considered the role of transportation networks, the reality of most emergency response lies indirectly on power networks as demand for EMS are dependent on power availability. We model our EMS network based on an existing power network in Greater Boston Area and integrate the probability of demand for emergency services during critical events coupled with power outages based on historical data. MIP model is developed to minimize both the response time of emergency services and the cost of virtual power generation.

4 - An Interdiction-based Approach to Identify Damage in Interdependent Critical Infrastructures

N. Orkun Baycik, Shenandoah University, School of Business, Winchester, VA, 22601, United States, Thomas Sharkey

We study the problem of determining the damage in multiple interdependent infrastructures given outage reports from the customers (or service receivers). Demand nodes within these infrastructure networks may have an outage either from damage that occurred within its infrastructure or due to cascading failures across infrastructures. We present a network interdiction based approach to identify the order in which components should be inspected in order to determine the damage within these networks based on the outages reported by customers.

Joint Session ICS/Practice Curated: Binary Decision Diagrams Applications

Sponsored: Computing

Sponsored Session

Chair: Leonardo Lozano, University of Cincinnati, Cincinnati, OH, 45219, United States

1 - A Decision Diagram Based Integer Programming Formulation for the Paired Job Scheduling Problem

Leonardo Lozano, University of Cincinnati, Cincinnati, OH, 45219, United States, leolozano@uc.edu, Michael Magazine, George G. Polak

The paired job scheduling problem seeks to schedule n jobs in a single machine, each one consisting of two tasks for which there is a mandatory minimum waiting time between the completion of the first task and the start of the second task. We provide complexity results for problems defined by three commonly used objective functions. We propose an integer programming formulation based on a decision diagram decomposition that models the objective function and some of the challenging constraints in the space of the diagrams flow variables. Computational results show a that our proposed model performs considerably better than a standard time-indexed formulation over a set of randomly generated instances.

2 - A Network-based Formulation for Scheduling Clinical Rotations

Andre Augusto Cire, University of Toronto Scarborough, Department of Management, UTSC, 1265 Military Trail, Toronto, ON, M1C-1A4, Canada, acire@utsc.utoronto.ca, Adam Diamant, Tallys Yunes, Alejandro Carrasco

We investigate the practices of a medical school that must assign a cohort of students to a series of clinical rotations. We propose a network-flow model that leverages the structure of the data to compactly represent feasible schedules. Such a model can be used either to find optimal assignments when incorporated into a mathematical programming formulation, or to provide insights as to the cost sensitivity of the various problem parameters. Our analysis also indicates significant cost reductions in comparison to current scheduling policies.

3 - Embedding Perfect Structures in Process Systems

Arvind Raghunathan, Mitsubishi Electric Research Laboratories, Cambridge, MA, 02139, United States, raghunathan@merl.com

Combinatorial Optimization (CO) problems are significantly challenging to solve, in spite of impressive progress in the development of robust, commercial mixed integer programming solvers. In this talk, we propose the idea of embedding perfect structures (convex hulls) in the formulations using Decision Diagrams. We explain our formulation methodology through two applications in Electricity Generation (Unit commitment) and Heat Exchanger Design (Heating, Ventilation and Air Conditioning). In each of these cases we show that our approach provides significant improvement over state-of the-art algorithms in the respective problem domains.

4 - Optimization Algorithms for the Bin Packing Problem with Minimum Color Fragmentation

Saharnaz Mehrani, University of Connecticut, Storrs, CT, United States, David Bergman, Carlos Henrique Cardonha

In the bin packing problem with minimum color fragmentation (BPPMCF), we are given a bounded number of bins, a collection of items each with a size and a color, and the goal is to use as few bins as possible to pack items of the same color. This problem has several real-world applications in areas as diverse as accommodation assignment in sport events, production planning, logistics, and health care. In this work, we present several exact optimization algorithms to solve BPPMCF, including mixed-integer programming formulations, a branch-and-price algorithm, and two decision diagram-based algorithms. Our computational experiments show the efficiency of our proposed algorithms.

5 - End to End Learning and Optimization on Graphs

Bryan Wilder, University of Southern California, Los Angeles, CA, 90016, United States, bryan.wilder0@gmail.com, Eric Ewing, Bistra Dilkina, Milind Tambe

Real-world applications often combine learning and optimization problems on graphs. E.g., edges are often only partially observed, introducing a link prediction problem which must be solved prior to a decision problem (such as locating facilities, partitioning the graph, etc). We propose an approach to integrate a differentiable proxy for common graph optimization problems into machine learning training. This focuses training specifically on the downstream task that the predictions will be used for. Our end-to-end system performs better on example optimization tasks than can be obtained by combining state of the art link prediction with expert-designed graph optimization algorithms.

Machine Learning for Discrete Optimization

Sponsored: Computing

Sponsored Session

Chair: Bistra Dilkina, University of Southern California, Los Angeles, CA, 90089, United States

1 - Learning to Solve the Unit Commitment Problem

Alinson Santos Xavier, Argonne National Laboratory, Lemont, IL, United States, axavier@anl.gov, Feng Qiu, Shabbir Ahmed

Unit Commitment (UC) is a fundamental problem in power systems, being solved daily to clear the energy markets. In practice, UC is repeatedly solved via Mixed-Integer Linear Programming (MILP) with only minor changes in input data. In this work, we propose a number of machine learning (ML) techniques to extract information from previously solved instances in order to improve the computational performance of MILP solvers when solving similar instances in the future. Computational results on a diverse set of realistic and large-scale instances show that UC can be solved on average 12 times faster, with no negative impact on solution quality.

2 - Neural Integer Optimization: Learning to Satisfy Generic Constraints

Elias B. Khalil, Polytechnique Montréal, Montréal, QC, 30309, Canada, lyes@gatech.edu, Rakshit Trivedi, Bistra Dilkina

There has been a recent surge in research on learning heuristics for combinatorial optimization problems over a distribution of instances. Despite promising results on problems such as the TSP, existing learning methods are only capable of handling simple constraints. Our work is an attempt at learning heuristics for discrete optimization problems subject to general linear inequalities. The key contribution lies in incorporating projection into a recurrent neural network model that generates soluti

ons to a discrete optimization problem with intricate constraints. We show promising results on instances from various classes of discrete optimization problems.

3 - A Language Processing Algorithm for Predicting Tactical Solutions to Operational Planning Problems under Uncertainty

Emma Frejinger, Universite de Montreal, FAS, Pavillon Andre-Aisenstadt, Montreal, QC, H3C 3J7, Canada, Eric Larsen, Andrea Lodi

We focus on predicting tactical (high-level) solutions to operational planning problems in short computing time under uncertainty. This work extends Larsen et al. 2018 (arXiv:1807.11876) by predicting more detailed, variable-length solutions. The machine learning model originates from language processing and we construct vocabularies and syntax describing the problem instances and solutions. Extensive numerical results for an application on train loading demonstrate excellent predictive accuracy and very short computing times.

4 - Robust Optimization under a Machine Learning Lens

Liangyuan Na, Massachusetts Institute of Technology, MIT, Cambridge, MA, United States, lyna@mit.edu, Dimitris Bertsimas, Bartolomeo Stellato

We propose an interpretable machine learning framework for robust optimization. For different classes of continuous and discrete robust optimization problems we obtain insights on the logic behind the optimal solutions. Our approach allows us to understand robust solutions by learning the relationship between the problem parameters and the worst case uncertainties in the problem data. With several examples we show that our method not only achieves high accuracy and interpretability, but is also able to compute the optimal solutions at higher speed than state-of-the-art algorithms.

Continuous-time Perspective in Optimization

Sponsored: Optimization/Nonlinear Programming

Sponsored Session

Chair: Jelena Diakonikolas

1 - Worst-case Algorithm Analysis: Bridging Discrete and Continuous Time

Laurent Lessard, University of Wisconsin-Madison, Madison, WI, United States, laurent.lessard@wisc.edu

Iterative optimization algorithms are often analyzed in terms of their worst-case performance. Such analyses can be directly carried out on the iterative algorithm (discrete time analysis), or one can study the continuous-time limit, or gradient flow, which is an ordinary differential equation (ODE). While these two approaches often agree, there are important cases where they do not. This talk will explore some fundamental differences between discrete- and continuous-time analyses by relating them to established concepts from robust control theory, such as the Lur'e problem and the Aizerman and Kalman conjectures.

2 - Achieving Acceleration via Direct Discretization of Heavy-ball ODE

Jingzhao Zhang, Massachusetts Institute of Technology, Cambridge, MA, United States, Aryan Mokhtari

We study gradient-based methods obtained by directly discretizing a second-order ODE related to the continuous limit of Nesterov's accelerated gradient method. When the function is smooth enough, we show that acceleration can be achieved by a stable discretization of this ODE using standard Runge-Kutta integrators. We prove that under smoothness, convexity, and order-(s+2) differentiability assumptions, we obtain at a rate of $O(N^{-2s/(s+1)})$, where s is the order of the Runge-Kutta numerical integrator. We also introduce a new local flatness condition on the objective, under which rates even faster than $O(N^{-2})$ can be achieved with low-order integrators and only gradient information.

3 - A Variational Approach to the Design of First-order Methods via Self-dual Convex Functionals Over Path Space

Lorenzo Orecchia, Boston University, Boston, MA, 02215, United States

We present a novel approach to analyze and design first-order methods for convex optimization via the calculus of variation. Specifically, we show that the continuous-time dynamics underlying these methods arise as the unique solutions of the minimization of natural convex functionals over the space of absolutely continuous paths from a given starting point. While previous work has characterized these continuous-time dynamics as critical points of certain functionals, i.e., solutions to Euler-Lagrange equations, our work is the first to give a convex formulation of these functionals.

4 - A Hamiltonian Perspective on Momentum-based Methods

Jelena Diakonikolas, UC Berkeley, 475 Evans Hall, Berkeley, CA, 94720, United States, Michael I. Jordan

We shed new light on momentum-based methods by showing that a broad class of methods that contains Nesterov's accelerated method and Polyak's heavy ball method can be generated as equations of motion of a certain class of time-varying Hamiltonians. We further show that the Hamiltonians generating the equations of motion lead to invariants that can be used to analyze the convergence of these methods in the settings of both convex and non-convex optimization.

Co-Chair: Changhyun Kwon, University of South Florida, Tampa, FL, 33620, United States

1 - Pessimistic Bilevel Toll Pricing Problem for Mitigating Hazardous Materials Transport Risk

Mahdi Takalloo, University of South Florida, Tampa, FL, 33613, United States, mtakalloo@mail.usf.edu, Joey Huchette, Changhyun Kwon

We study the pessimistic bilevel toll pricing problem for mitigating the risk of transporting hazardous materials. We compare the pessimistic and the optimistic hazmat toll pricing problems and study the existence of a solution to those problems. We use disjunctive programming to formulate an approximation to the pessimistic problem and develop solution approaches.

2 - Enhancing Roadway Network Resilience to Disruptions from Maintenance and Restoration Activities

Sohrab Mamdoohi, George Mason University, 9916 Fairfax Square, # 54, Fairfax, VA, 22031, United States, Elise Miller-Hooks

Roadway maintenance & restoration activities impact traffic, interrupting network equilibria conditions. An analytical model is presented that jointly optimizes maintenance/restoration downtime scheduling & traffic diversion strategies with the aim of mitigating the impact of roadway downtime, & enhancing system resilience. The system is resilient if an equilibrium is quickly re-established.

3 - Road Network Pricing and Design for Ordinary and Hazmat Vehicles. Integrated Model and Specialized Local-search

Armando Gabriel Guarnaschelli, Pontificia Universidad Católica de Valparaíso, Brasil 2147, Valparaíso, Chile, armando.guarnaschelli@pucv.cl, López-Ramos Francisco, Stefano Nasini

We propose an optimization framework to integrate a road operator s decisions on network tolling, regulation, and expansion, accounting for vehicle flow carrying hazardous materials. A mixed-integer nonlinear bi-level problem represents the operator (acting as a leader), and a set of vehicles (acting as a follower) that flow through the network. The leader maximizes its profit, composed of toll incomes minus construction costs and risk costs induced by hazmat vehicle circulation. The follower minimizes toll charges and the cost of travel time increased by congestion. A reformulation approach reduces the problem's complexity. Moreover, we provide an efficient mechanism to solve it.

4 - Stochastic Multi-player Investment Optimization for Maritime Port Network Resiliency and Reliability

Ali Asadabadi, FedEx, Germantown, TN, 38138, United States, Elise Miller-Hooks

This work develops stochastic, bi-level, game theoretic optimization models for assessing and improving the resiliency and reliability of a maritime shipping network, specifically the port network, connected through liner shipping service routes. The proposed models account for port-related disruptions and their rippling consequences that cascade across the maritime system. The models seek optimal protective investments accounting for a competitive, but potentially cooperative (co-opetitive) environment.

Health Care, Modeling and Optimization I

Contributed Session

Chair: Ping Zhang, Hong Kong Polytechnic University, Hung Hom, Kowloon, Hong Kong, China

1 - Predicting Hospital Choice Decision Based on EHR Information

Bowen Pang, Tsinghua University, Beijing, China, Xiaolei Xie, Haibo Wang

Residents with critical diseases in China often prefer to visit larger hospitals in another province, which results in tremendous service burden to well-known hospitals in major cities. This phenomenon increases the waiting time of patients and reduces the quality of care services. In this work, we analyze the factors influencing the hospital choice of inpatients and formulate a predictive model on the decision of patients including whether to see care services in non-local provinces as well as the selection of provinces and hospitals based on demographic and disease-related information.

2 - The Operational Performance of Hospital: The Effect of Telemedicine on Chronic Care

Ji Fang, Southeast University, Nanjing, China, itfangji@163.com, Haiyan Wang

A large number of patients with chronic diseases do not seek treatment because of the traveling costs and waiting costs. Telemedicine is an effective way to short the traveling distance and improve the medical resources utilization. We study a non-profit hospital whether should offer telemedicine and how to allocate the service level to face-to-face service and telemedicine service. The results show that the ratio of patients who receive treatment will increase when the hospital offering telemedicine in the limited service capacity. We also provide the optimal distribution of service level on dual-channel.

3 - Hospital Emergency Overflow Utilization Planning and Analysis using Simulation

Abelardo Mayoral Fierros, Fraser Health Authority, Surrey, BC, Canada, Nazanin Shabani

Population growth and aging in BC communities have resulted in congestion in some of the hospitals in past several years. Emergency departments have been experiencing a high number of inpatient admissions waiting for placement in an inpatient bed. Overflow beds can be a temporary solution to balance the load between the ER and other inpatient units during peak hours. A discrete event simulation model was developed to help a hospital leadership team to study different configurations of overflow capacity location for medicine inpatients waiting for placement in an acute care bed. The model results identified the optimum number of flow beds while quantifying the impact in ER occupancy and patient flow.

4 - Modelling the Large-scale Hospital by Discrete-event Simulation

Chengye ZOU, The University of Hong Kong, Hong Kong, Hong Kong, zcypaul@hku.hk

The large-scale hospital makes the medical resources connected, where the poor system management can lead to low efficiency, long waiting time and extra healthcare expenditure. In this research, a large-scale hospital is modeled by discrete-event simulation, including several outpatient clinics and examinations, with changeable doctors' schedules and patients' arrival distributions. The measurement and evaluation of the efficiency of the system are discussed by experiments.

5 - The Impacts of Medical Inventory Sharing on Hospital Returns in Consignment Contracts

Ping Zhang, The Hong Kong Polytechnic University, Hong Kong, China, ping.zp.zhang@connect.polyu.hk, King Wah Pang, Hong Yan

Hospitals adopt consignment contract to purchase disposable medical items. When a hospital anticipates stockout, another hospital may have excess inventory and need to return to dealer. We propose a dealer-dominated inventory sharing policy between two independent hospitals which have a common dealer. We aim at exploring whether the sharing policy can benefit dealer and hospitals by reshaping the return policy.

1 - Modeling Shifts in World-wide Maritime Flows in a Changing Global Landscape

Wenjie Li, George Mason University, Fairfax, VA, United States, Elise Miller-Hooks

This presentation presents modeling techniques for analyzing shifts in world-wide maritime flows associated with international trade of bulk and container cargo. A changing global landscape, including: changes in maritime shipping route and interior railway corridor characteristics; port capabilities, capacities and operations; ocean carrier alliances; and vessel dimensions, are considered in assessing changing trends in optimal global flows.

2 - Designing a Centralized Marketplace for Transportation Services - A Framework to Ensure Equitable Distribution

Arim Park, North Carolina A&T State University, Greensboro, NC, 07102, United States, Mark Rodgers, Soohyun Cho, Yao Zhao

We would like to design an efficient mechanism for an electronic market of transportation services (trucking) in Korea. Under such a market mechanism, shippers get what they pay for (best services at the lowest price) and all service providers (truckers), large or small, have an equal chance to compete.

3 - Logistics Network Design for Fresh Flowers

Alan Erera, Georgia Institute of Technology, School of Industrial & Systems Eng, Atlanta, GA, 30332-0205, United States, alan.erera@isye.gatech.edu, Yaarit Cohen, Jonathan Zribi, Benoit Montreuil

The floral industry is a global, dynamic, rapidly growing industry. In China, 70% of domestic flower transportation is currently conducted using air transport. Although air transport is faster, it is more costly than ground transportation and does not provide the temperature control required to maximize flower freshness. We consider the design of a ground transportation network for fresh flowers in China. We build a path-based time-expanded network design model to minimize logistics costs. The model attempts to fulfill as much demand as possible by ground transport, and incorporates a model of flower freshness decay and perishability that limits which demand can be feasibly served by trucking.

Joint Session TSL/Urb/Practice Curated: Data-Driven Optimization for Urban Transit

Sponsored: Transportation Science & Logistics/Urban Transportation

Sponsored Session

Chair: Julia Y Yan, Massachusetts Institute of Technology, Cambridge, MA, 02143, United States

Co-Chair: Dimitris Bertsimas, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States

1 - The Edge of Optimization in Large-scale Vehicle Routing for Paratransit

Julia Y. Yan, Massachusetts Institute of Technology, 10 Stanford Terrace, Cambridge, MA, 02143, United States, jyyan@mit.edu, Dimitris Bertsimas

The Americans with Disabilities Act (1990) mandates that door-to-door transit be made available to people who cannot use fixed routes due to disability. While “paratransit” is a critical safety net, it is also very costly. Our goal is to reduce costs by developing quality routing algorithms that find efficient routes and account for service quality, labor regulations, and vehicle availability. We take a hierarchical approach that can run in an hour, and test our algorithm on real data from Boston with over 7,000 requests. Our algorithm improves upon Boston’s current productivity by 10%.

2 - From Transportation to Policy: Optimizing School Start Times and Bus Routes

Arthur J. Delarue, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, Dimitris Bertsimas, Sebastien Martin

Spreading start times allows school districts to reduce transportation costs by reusing buses between schools. However, assigning each school a time involves both estimating the impact on transportation costs and reconciling additional competing objectives. These challenges force many school districts to make myopic decisions, leading to an expensive and inequitable status quo. We propose an algorithm to jointly solve the school bus routing and bell time selection problems. Our application in Boston led to $5 million in yearly savings (maintaining service quality despite a 50-bus fleet reduction) and to the unanimous approval of the first school start time reform in 30 years.

3 - Transit Integration with Multiple Providers

Yeesian Ng, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, Dimitris Bertsimas, Julia Y. Yan

In many regions, individual travel needs often extend beyond the service area of a single agency. As a result, many commuters need to make transfers between different transit services. However, when multiple transit services are taken into account for integration, the scale of the networks makes it difficult to manually synchronize the schedules of the various services. We develop data-driven formulations for coordinating between multiple transit operators in multi-modal networks while synchronizing transfers across connecting services and accounting for operator budget concerns.

4 - Reliable Frequency Regulation Through Vehicle-to-grid

Dirk Lauinger, PhD Student, Ecole Polytechnique Fédérale de Lausanne (EPFL), Lausanne, Switzerland, dirk.lauinger@epfl.ch, Francois Vuille, Daniel Kuhn

Vehicle-to-grid aims to increase the low utilization of electric vehicles by making their batteries available to the power grid. We formulate an optimization problem that maximizes the expected profit from selling primary frequency regulation to the power grid, while guaranteeing that all market commitments can be met for all frequency deviations in an uncertainty set informed by new EU legislation. Depending on the charger and battery size annual profits range from 83 Euro to 165 Euro per vehicle in 2018. We show that profits increase with charger size only up to a certain threshold, above which they saturate, contradicting the predictions of existing deterministic models.

Sponsored Session

Chair: Debjit Roy, Indian Institute of Management, Ahmedabad, 560078, India

1 - A Grid-based Goods-to-Person Order Picking System

Mina Shekari, University of Louisville, Louisville, KY, United States, Kevin Gue

As robotic arms replace humans for e-commerce order picking, there will be a need to feed these robots at ever higher rates of product totes per minute. We describe a grid-based goods-to-person order fulfillment system that uses decentralized control to move items quickly to and from picking stations on any side of the grid. We prove some throughput bounds and show how the grid-based system compares.

2 - Collaborative Order Picking with Pick-support AGVs

Alexandros Pasparakis, Rotterdam School of Management, Rotterdam, Netherlands, pasparakis@rsm.nl, Jelle De Vries, René De Koster

Automated guided vehicle (AGV) systems may be used to support the manual order picking process in warehouses. We conducted an experiment to compare multiple scenarios and see what collaboration system (human leading vs robot leading) leads to the best picker performance, satisfaction, and self-evaluation, based on individual picker personality attributes. Results indicate that promotion focused individuals and individuals with external work locus of control tend to underperform while being led by robots (compared to when they lead the robots). Evidence that the collaboration with AGVs may negatively affect the picker self-evaluation (self-efficacy & self-esteem) was also established.

3 - Stochastic Model for Integrated Storage-Order Picking System with Multi-Line Orders

Vishal Bansal, Indian Institute of Management Ahmedabad, Ahmedabad, 380015, India, fpm16vishalb@iima.ac.in, Debjit Roy

Due to demanding service levels in e-commerce order fulfillment, modeling and analysis of integrated storage and order picking processes in warehouses deserve special attention. With a particular focus on multi-line e-commerce orders, we develop a queuing network modeling framework for integrated analysis of upstream (SBS/R system) and downstream (pick system) networks. We also propose a novel hybrid simulation/analytic model to evaluate performance measures. We analyze the effect of the storage system configuration on the order throughput time at pick station. The results indicate that the hybrid simulation/analytic approach works best in the estimation of the performance measures.

4 - A Hybrid Genetic Algorithm for Online Batching in High Throughput Poultry Processing Lines

Bert Hundscheid, Eindhoven University of Technology, Eindhoven, Netherlands, Kay Peeters, Jelle Adan, Tugce Martagan, Ivo Adan,

We consider batching processes in high throughput poultry processing lines. The key objective is to form batches of arrivingitems that minimize the difference between the actual and targetbatch weight. Items are allocated first-come-first-serveddiscipline to available bins in the batching machine and the exactweight of items is known over a given horizon of arriving items. Wedevelop a hybrid algorithm combining a genetic algorithm and localsearch methods to assignt items to the available bins. Simulationsbased on real-world data suggest that the proposed algorithmproduces high quality solutions within a feasible time limit.

5 - Being Responsive or Efficient in Order Picking

Jelmer Pier van der Gaast, Fudan University, Shanghai, China

In many order picking systems during the day there are several moments of time criticality, e.g., delivery trucks are scheduled to depart from the warehouse. Warehouse companies normally want to be efficient in their resources as this reduces the operating costs, but need to be responsive when deadlines are coming up. However, being responsive is only required at time criticality moments as it would otherwise increase the operating costs of the warehouse significantly. We develop a mathematical model that determines when and for how long the order picking process should be efficient or responsive by either changing the way of order picking or by changing the number of resources in the system.

1 - Deliver or Not? Optimal Revenue, Capacity, and Delivery Fee Policies for Future Drone-based Delivery Systems

Zhangchen Hu, UMASS Amherst, Amherst, MA, United States

Drones are expected to become a key component of commercial delivery services for retailers and courier companies. Using currently available retail data, we formulate a stochastic dynamic programming model to determine some optimal revenue, capacity, and delivery fee policies under uncertain demand for future drone-based delivery systems. Both analytical and numerical analyses are presented.

2 - On-demand Urban Aerial Mobility: Strategic Vertiport Network Design

Kai Wang, The Hong Kong Polytechnic University, Homantin, Kowloon, Hong Kong

Urban Aerial Mobility (UAM) will rely on a vertiport network—where eVTOL aircraft are operated. This paper optimizes the number, location, and capacity of vertiports while capturing the interdependencies between strategic vertiport deployment, tactical eVTOL operations, and customer adoption. This is cast as a nonlinear mixed integer model, including a queuing network of UAM operations and a robust optimization of customer adoption. We propose an iterative discretization algorithm to reformulate it as a second-order conic program. Results provide insights on future UAM systems in urban areas.

3 - Designing Mission Abort Strategies Based on Early-Warning Information: Application to UAV

Qiuzhuang Sun, National University of Singapore, Singapore, Singapore

An effective action to reduce the risk of casualties of unmanned aerial vehicles (UAVs) is the mission abort. This study designs the optimal mission abort policies based on information of early-warning signals that indicates possible forthcoming malfunction. Depending on the acquisition time of such information, operators may immediately abort the mission or ignore the information and continue the task. The optimal abort policy is obtained by carrying out an economic analysis. A case study on a UAV executing power-grid inspection missions is used to illustrate the applicability of the model.

Joint Session RMP/Practice Curated: Analytics in Online Platforms

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Daniela Saban, Stanford University, Palo Alto, CA, 94305, United States

Co-Chair: Kostas Bimpikis, Stanford University, Stanford, CA, 94305, United States

1 - First Delivery Gaps: a Supply Chain Lever to Reduce Product Returns in Online Retail

Divya Singhvi, MIT, 5010 A, 235 Albany Street, Cambridge, MA, 02139, United States, dsinghv@mit.edu, Georgia Perakis

We consider the problem of reducing product returns in online retail. Working with one of the largest fashion retailers of India, we perform an extensive observational data study, and an RCT to investigate the causal relationship of delivery gap and delivery promise on product returns. We estimate cost savings of as much as $1.5 million per year on account of reduced returns, due to faster deliveries. We then propose a data-driven delivery expediting framework that optimally balances delivery expediting costs with reverse logistics costs to minimize retailer's overall costs.

2 - Two-Sided Assortment Optimization

Ignacio Rios, Stanford University, Stanford, CA, 94305, United States, iriosu@stanford.edu, Daniela Saban, Fanyin Zheng

We study how assortments and history change users' behavior in a dating platform. We provide evidence that the assortment composition and the number of recent matches affect the probability that a given user is liked. Based on these results, we formulate the dynamic two-sided assortment optimization problem faced by the platform to decide the optimal assortment to offer to each user in each period, so as to maximize the number of matches. We show that the problem is NP-complete, and derive properties of the optimal solution in some special cases. We use these insights to propose simple heuristics and show that these can significantly improve the number of matches generated by the platform.

3 - Restaurant Delivery Platforms

Xuanming Su, University of Pennsylvania, The Wharton School, Philadelphia, PA, 19104, United States, xuanming@wharton.upenn.edu, Jaelynn Oh, Chloe Kim Glaeser

Restaurant delivery platforms have the potential to create value for customers, restaurants, and couriers. We analyze game-theoretic models to highlight best practices for all parties involved.

4 - understanding Customer Preferences: Labor Markets, Public Transport and Bike-share

Karan Girotra, Cornell Tech/Johnson Cornell University, New York, NY, 10044, United States, girotra@cornell.edu

I will present my experiences from estimating customer preferences in online labor marketplaces, ride-hailing services and bike-share systems. We will discuss the methodological developments and ways in which we have used these estimates to improve system performance.

Innovations in Pricing and Assortment Optimization

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Venus Lo, Cornell University, Ithaca, NY, 14853, United States

1 - The Exponomial Choice Model: Assortment Optimization and Data-driven Estimation Case Studies

Jacob Feldman, Olin Business School, Saint Louis, MO, 63108-1291, United States, jbfeldman@wustl.edu, Ali Aouad, Danny Segev

In this paper, we consider the yet-uncharted assortment optimization problem under the Exponomial choice model, where the objective is to determine the revenue maximizing set of products that should be offered to customers. Our main algorithmic contribution comes in the form of a fully polynomial-time approximation scheme (FPTAS), showing that the optimal expected revenue can be efficiently approached within any degree of accuracy. Furthermore, we conduct empirical evaluations of the Exponomial choice model. We present a number of estimation case studies using real-world data sets, spanning retail, online platforms, and transportation.

2 - Multi-stage and Multi-customer Assortment Optimization with Inventory Constraints

Elaheh Fata, Massachusetts Institute of Technology, Aeronautics and Astronautics, Cambridge, MA, 02139, United States, efata@mit.edu, Will Ma, David Simchi-Levi

We consider an assortment optimization problem where a customer chooses an item from a sequence of non-overlapping sets shown to her, while limited inventories constrain the items offered to a sequence of customers over time.In the special case where all of the assortments have size one, our problem captures the online stochastic matching with timeouts problem. For this problem, we derive a polynomial-time approximation algorithm which earns at least 1-ln(2-1/e), or 0.51, of the optimum. This improves upon the previous-best approximation ratio of 0.46, furthermore, we show that it is tight. For the general assortment problem, we establish the first constant-factor approximation ratio of 0.09.

3 - A Choice Modeling Framework for Service Time Windows

Xiao Lei, Columbia University, New York, NY, 10027, United States, xl2625@columbia.edu, Adam Elmachtoub

On-demand services have become increasingly common, and typically allow customers to choose a time window to receive the service. As a result, there is a natural trade-off between on-time customer service and operational cost. To address this issue, some service providers offer large time windows with rewards, together with the normal small ones. In this paper, we provide a choice modeling framework to address how customers choose among time windows, and apply this framework to evaluate various strategies for time window design.

4 - Omnichannel Assortment Optimization under the Multinomial Logit Model with a Features Tree

Venus Lo, Cornell University, Cornell University, Ithaca, NY, 14853, United States, vhl8@cornell.edu, Huseyin Topaloglu

We consider a retailer who sells online and in a physical store. Products are described by their features. A customer who purchases online can visit the physical store to try out products. Her preferences depend on the features of the products that she sees in the physical store's assortment. The retailer chooses an assortment to offer in-store to maximize total expected revenue from both stores. We organize products on a tree so that a leaf is a product. A non-leaf vertex is a feature common to leaves in its subtree. Assortment optimization is NP-hard and we present a FPTAS. Numerically, we show how we can approximate products with arbitrary combinations of features, and that our FPTAS performs well.

Mechanisms for Online Marketplaces

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Nikhil Garg, Menlo Park, CA, 94025, United States

1 - Driver Surge Pricing

Nikhil Garg, Stanford University, Stanford, CA, 94025, United States, nkgarg@stanford.edu, Hamid Nazerzadeh, Hamid Nazerzadeh

Ride-hailing marketplaces use dynamic pricing — surge — to balance the supply of available drivers with the demand for rides. We study pricing mechanisms for such marketplaces, from the perspective of drivers, and present the theoretical foundation that has informed the design of Uber's new additive driver-surge mechanism. We present a non-stationary stochastic model to capture the impact of surge pricing on driver earnings and their strategies to maximize earnings. We propose an incentive-compatible pricing mechanism for this environment. Even-though this mechanism can take a complicated form, we show that it is well-approximated by a additive-surge mechanism.

2 - A Pricing Framework for the Mobility Marketplace

Chamsi Hssaine, Cornell University, Ithaca, NY, 90025, United States, Siddhartha Banerjee, Ragavendran Gopalakrishnan, Samitha Samaranayake

The exploding popularity of ride-hailing services has led to a number of questions regarding the way they interact with other transportation modes. We study the design of an efficient mobility marketplace: a centralized platform where private firms and public transit can jointly offer hybrid multimodal trips to riders. We develop a framework for pricing such trips, with the objective of maximizing social welfare conditioned on every agent enjoying a weakly Pareto improving outcome compared to their status quo. We use our framework to propose two natural policies and show that these policies are Pareto improving, under a condition that captures a notion of the efficiency gains of multimodal transit.

3 - Consumer Reviews and Regulation: Evidence From NYC Restaurants

Chiara Farronato, Harvard Business School, Cambridge, MA, 02163, United States, Georgios Zervas

We study how hygiene cards and online reviews affect restaurant demand and hygiene. To extract signals of hygiene from reviews, we exploit the fact that health inspectors look for different types of violations to predict the occurrence of each violation from reviews. We find that reviews are more informative about food handling and pest violations than facilities and maintenance. We then estimate the effect of hygiene information from reviews on demand and restaurant hygiene. We find that demand is sensitive to signals of hygiene in reviews, and restaurants reviewed online are more likely to comply with hygiene standards for which reviews provide informative signals.

4 - Managing Market Mechanism Transitions: Evidence From a Field Experiment

Apostolos Filippas, Assistant Professor, Fordham University, New York, NY, 10012, United States, apostolosfilippas@gmail.com, Srikanth Jagabathula, Arun Sundararajan

We report on a field experiment conducted during a pricing mechanism change on a sharing economy platform. Providers who formerly set prices for their assets were assigned to groups with varying levels of pricing control. Even when faced with significantly higher revenues, providers retaliate against the mechanism change by exiting the platform, reducing asset availability, and cancelling transactions. Allowing providers to retain partial control lowered retaliation across all channels. We discuss "bring-to-market" costs and information asymmetry as explanations for our results.

Pricing under Quality Differentiation and Bundling

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Alexandre Jacquillat, Carnegie Mellon University, Pittsburgh, PA, 15213, United States

Co-Chair: Maxime Cohen, NYU Stern, New York, NY, 10012, United States

1 - Revisiting Bertrand Competition in the Face of Firm Asymmetry and Customer Heterogeneity

Haotian Song, NYU, New York, NY, United States, Maxime Cohen, Alexandre Jacquillat

Bertrand competition has been studied for over a century. It is a simple yet powerful game-theoretic model for price competition. In its basic form, customers are homogenous and are offered the same price. In many practical settings, however, firms cater to a heterogeneous mix of customers and can offer a different price to each customer segment. This paper extends our understanding of Bertrand competition by incorporating these two features. We convey that customer heterogeneity allows the firms to escape the Bertrand paradox, and that price discrimination is not necessarily beneficial.

2 - On-demand Service Sharing with Collective Dynamic Pricing

Mustafa Dogan, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, mdogan@andrew.cmu.edu, Alexandre Jacquillat

We design a dynamic allocation and pricing mechanism for an on-demand platform that can serve customers individually, or together via sharing. We consider a setting with time-sensitive and heterogenous agents who arrive stochastically. The optimal policy features interdependencies across agents and over time. Nonetheless, it is governed by a simple index rule, based on the collective virtual value (CVV): as soon as the CVV exceeds a threshold, the platform serves all agents with a positive virtual value. Our findings highlight that, in the presence of sharing, time can be used as a discriminatory lever — in contrast with the classical results on dynamic pricing with commitment.

3 - Bundling under Price and Quantity Competition

Uday S. Karmarkar, LA Times Professor of Technology and Strategy, UCLA Anderson School of Management, Los Angeles, CA, United States, ukarmark@anderson.ucla.edu, Araz Khodabakhshian, Guillaume Roels

Bundling is the offering of a combination of products and services, usually in fixed proportions, for a single price. We address bundling strategy under competition, which has received limited attention in the past. We consider price competition in a Bertrand duopoly with both independent and bundled components, and quantity competition in a Cournot oligopoly with entry costs. In general, bundling is a successful strategy, though independent component suppliers can survive.

4 - Revenue Management with Bundles

Tarek Abdallah, Northwestern University, Evanston, IL, United States, tarek.abdallah@kellogg.northwestern.edu, Arash Asadpour, Joshua Reed

We study the optimal dynamic bundling and pricing problem when a multi-item firm has limited inventory and a finite selling horizon. We model the problem as a classical network revenue management problem where the resources are the items and the products are the different possible bundles. The standard fluid regime for this problem is intractable due to the exponential number of bundles. We analyze the problem by scaling different model parameters to capture different market dynamics. More interestingly, for some of these regimes we show that the limiting problem is tractable and we can provide closed form asymptotically optimal solutions.

5 - Pricing with Fairness

Xiao Lei, Columbia University, New York, NY, 10025, United States, Maxime Cohen, Adam Elmachtoub

While discriminative pricing has become common, regulators often aim to impose fairness. We consider the problem of pricing with fairness constraints. We first propose four definitions: fairness in (1) price, (2) demand, (3) surplus, and (4) no-purchase valuation. We then analyze the pricing strategy of the seller, and the impact of fairness. Under a linear demand, we show that imposing some fairness in price or no-purchase valuation increases social welfare, whereas fairness in surplus or demand are always detrimental. A similar pattern is also observed for other common demand models.

Revenue Management with Online Learning

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Yiwei Chen

1 - Dynamic Learning and Market Making in Spread Betting Markets with Informed Bettors

Yifan Feng, University of Chicago, Chicago, IL, United States, yfeng4@chicagobooth.edu, John R. Birge, N. Bora Keskin, Adam Schultz

The spread betting market is a prevalent form of prediction market, where participants bet on whether the outcome of a future event exceeds a certain spread line. We study how the market maker should move the spread line dynamically to maximize profit. Anonymous bettors with heterogeneous strategic behavior and information levels participate in the market. The non-omnipotent market maker strives to extract information from the market while guarding against the strategic manipulation of an informed bettor.

2 - A Dimension-free Algorithm for the Contextual Continuum-armed Bandit Problem

Ningyuan Chen, University of Toronto, Clear Water Bay, Toronto, ON, Canada, Jeff Hong, Wenhao Li

In multi-armed bandit problems, when the contextual information and the decision variable are both continuous and high-dimensional, it is known that the optimal rate of regret scales exponentially with both dimensions. In this project, we show that when the objective function is globally concave in the decision variable, we can alleviate the curse of dimensionality.

3 - Learning Non-parametric Contextual Demand Curves in Repeated Auctions

Jason Cheuk Nam Liang, Massachusetts Institute of Technology, Cambridge,, MA, United States, Negin Golrezaei, Patrick Jaillet

We study dynamic pricing for repeated contextual second-price auctions facing strategic buyers who aim to maximize their long-term discounted utility. The seller has limited information about buyer demand, which depends on context vectors for auctioned items and a non-parametric noise distribution that captures buyers' idiosyncratic taste. We propose a policy robust to buyers' strategic (corrupted) bids, which sets contextual reserve prices to maximize seller's revenue. Our policy controls the number of periods during which buyers significantly corrupt bids, and achieves a T-period regret of $O(\sqrt{dT})$ against a clairvoyant policy that has full information of the buyers demand.

4 - Network Revenue Management with Online Inverse Batch Gradient Descent Method

Yiwei Chen, University of Cincinnati, Cincinnati, OH, 45206, United States, Cong Shi

We study a family of price-based network revenue management problems in which the revenue rate is concave in market shares. The firm does not know the demand function in advance and must learn it over time. We propose an online inverse batch gradient descent algorithm. It proceeds in batches. In each batch, the firm posts a series of prices perturbed around a reference price. The firm uses the sales data under these prices to estimate market shares. The firm then carries out a stochastic gradient descent step in the market share space to get a new reference price for the next batch. We establish an upper bound on the regret of this algorithm that is independent of the number of products or resources.

Joint Session PSOR/Practice Curated: Decision Analytic Models for Public Health

Sponsored: Public Sector OR

Sponsored Session

Chair: Nidhi Khurana, CDC, Atlanta, GA, 30333, United States

1 - Impact of Targeting Pre-exposure Prophylaxis to Individual Transmission Groups in the United States

Nidhi Khurana, CDC, Atlanta, GA, 30333, United States, kqt3@cdc.gov, Paul G. Farnham, Katherine A. Hicks, Justin Carrico, Stephanie Sansom

We used a dynamic, compartmental model of the sexually active U.S population to estimate the impact of delivering pre-exposure prophylaxis (PrEP) to persons at high risk of acquiring HIV in individual transmission groups (men who have sex with men, persons who inject drugs, heterosexual males, and heterosexual females). In alternative scenarios, we modeled the application of PrEP to high-risk persons in each transmission group, and we assessed the number of infections averted across all transmission groups, the number of people on PrEP per infection averted, and the total cost incurred from 2020 through 2024.

2 - Modeling the Future of HIV in Turkey: Disease and Cost Implications of Improving Diagnosis and Treatment

Emine Yaylali, Assistant Professor, Istanbul Technical University, 2995 Rosebrook Drive, Istanbul, 30033-3822, Turkey, emineyaylali@itu.edu.tr, Melisa Erdogan

There were 17,884 cases of HIV infection reported until the end of 2017 in Turkey. Although the prevalence rate of Turkey could be considered as low (0.1 - 0.3%), the number of diagnosed HIV cases in the last five years has been tripled with a particularly high rate of infection for men who have sex with men (MSM). We developed a dynamic compartmental model of HIV transmission and progression in Turkey to determine HIV incidence and prevalence, to assess current continuum of care and to analyze the disease burden of cost of two scenarios: (i) keep status quo and (ii) improve diagnosis and treatment of HIV.

3 - Cost-effectiveness of Pre-exposure Prophylaxis and HIV Testing Strategies in India

Pooyan Kazemian, Harvard Medical School, Boston, MA, 02114, United States, pooyan.kazemian@mgh.harvard.edu, Sydney Costantini, Rochelle P. Walensky, Kenneth A. Freedberg

Using a detailed microsimulation model of HIV disease, we developed a novel method to incorporate the indirect community benefit of pre-exposure prophylaxis (PrEP) into incremental cost-effectiveness ratios for cost-effectiveness analysis. We assessed clinical and economic outcomes as well as the budget impact of various PrEP and HIV testing strategies for men who have sex with men in India.

4 - A Reinforcement Learning Algorithm to Inform Optimal Policy for Eliminating HIV in the U.S.

Seyedeh Nazanin Khatami, University of Massachusetts-Amherst, Amherst, MA, 01002, United States, skhatami@umass.edu, Chaitra Gopalappa

We address the question of how to reduce new HIV incidences close to zero in the US by formulating the problem as a Markov decision process with decision-making steps at 5-year intervals over a finite time period, and solved using a reinforcement learning algorithm. The objective of the model is to identify an intervention strategy that maximizes the expected total reward, the difference in the total quality-adjusted life-years saved multiplied with the gross domestic product per capita in the US and the associated costs of the strategy for heterosexuals, men who have sex with men, and persons who inject drugs.

5 - Assessing the Benefits of Reducing HIV Diagnosis Delay and Increasing Adherence to HIV Treatment

Nidhi Khurana, CDC, Atlanta, GA, United States, Evin Jacobson, Zihao Li, Paul Farnham, Stephanie Sansom

We used an agent-based simulation model to follow for 20 years a representative cohort of persons infected with HIV in the year 2015. We assessed the benefits of diagnosing HIV early and taking HIV antiretroviral therapy (ART) as prescribed on the percentage of persons surviving 20 years after infection and their average annual HIV transmission rate. Persons living with HIV or at risk of acquiring it can enhance their survival and greatly reduce their risk of sexual transmission to partners by frequent testing for HIV and, among those diagnosed with HIV, adhering to ART.

Immigration Policy

Emerging Topic: Policy & Government

Emerging Topic Session

Chair: Nick Arnosti

1 - Snapshot Models of Undocumented Immigration

Edward H. Kaplan, Beach Professor of Operations Research, Yale University, Yale School of Management, Box 208200, New Haven, CT, 06520-8200, United States, Scott Rodilitz

The Mexican Migration Project samples undocumented Mexican immigrants to the United States after their return to Mexico. We focus on sampled migrants' most recent trip to the United States. Such data are subject to an extreme physical bias: to be included in the sample, migrants must have returned to Mexico by the time of the survey. Our analysis distinguishes between solitary and repeat (circular) migrants, and allows "retirement" from circular migration. We show that migrants remain in the US much longer than previously estimated, and produce lower bounds on the total number of undocumented immigrants that exceed conventional estimates based on US-based census-linked surveys.

2 - Is Ice Enforcing the Law? A Machine Learning Approach

Mohammad Fazel-Zarandi, Massachusetts Institute of Technology, Cambridge, MA, 06510, United States, fazel@mit.edu, Dimitris Bertsimas

In this work, we use individual-level administrative data from the immigration and customs enforcement (ICE) and the state of the art interpretable machine learning tools to answer the following questions: Does the data support ICE's claim of prioritizing deportations based on severity of crimes? Given a significant change in policy in 2014, is the new policy more effective in aligning ICE's prioritization objective to how the policy is actually enforced by ICE offices across the US? This work is a first step in our overall aspiration to use interpretable machine learning tools and large data to analyze and improve public policy for significant societal challenges.

3 - Dynamic Management of Local Community Capacity for Refugee Resettlement

Narges Ahani, Worcester Polytechnic Institute, Worcester, MA, United States, nahani@wpi.edu, Andrew C. Trapp, Alexander Teytelboym, Alessandro Martinello, Tommy Andersson

Local communities in the US voluntarily resettle refugees, and government-approved capacities are set every September. However, refugees arrive stochastically over the year. Resettlement agencies must ensure that they neither overshoot nor undershoot approved capacities by the close of the fiscal year. As local communities provide heterogeneous integration services to refugees, the greedy placement decisions they currently make could result in inefficient use of resettlement capacity, and lower refugee welfare. We model the stochastic nature of US refugee arrivals using historical data to dynamically inform capacity estimates, thereby improving the performance of placement decisions.

4 - Visa Lottery Design

Nick Arnosti, Columbia Business School, New York, NY, 10027, United States

Lotteries play an important role in determining which visa applicants are accepted. Many existing lotteries include multiple categories of visas, targeted to distinct but overlapping populations. We study several ways to accommodate these targeting criteria, and analyze the ways in which they differ. We use our results to discuss recent changes in the H1B lottery procedure.

1:30-2:15 Optimization Direct / 2:15-3:00 MyEducator

Vendor Tutorials

1 - A DOCplex and ODH|CPLEX Python primer

Alkis Vazacopoulos, Optimization Direct, Inc., Harrington Park, NJ, 07640, United States

This short tutorial shows participants how to build a basic model using the DOCplex API in Python. This session includes setting the Python environment, reading data from a csv or spreadsheet, creating variables, objective functions, constraints, solving the model, and returning the results. Additionally this session points the participants to further reading so that they may expand their capabilities. Furthermore we will present the brand new ODH|CPLEX API for Python, which improves solution times for large models.

2 - This is the Future of Education!

Scotty Pectol, MyEducator, Orem, UT, United States, Jaret Wilson

This is the future of education! An affordable alternative to OER with up-to-date content from world-class author teams. Created by professors for professors, MyEducator smart interactive textbooks and learning resources are ideal for any classroom setting. Our approach enhances student engagement, improves learning outcomes, instructors receive better teaching evaluations, and students have more fun in the classroom. Each smart learning resources is hosted on our intuitive platform with auto-graded assessments, ample instructor material, robust analytics, all with seamless single sign-on LMS integration, low student cost, lifetime access, and best-in-class service. Full access will be given to any book on our platform to attendees.

1 - Analysis-of-marginal-tail-means (ATM): A Robust Method for Discrete Black-box Optimization

Simon Mak, Duke University, Durham, NC, 30308, United States, C.F. Jeff Wu

We present a new method, called Analysis-of-marginal-Tail-Means (ATM), for effective robust optimization of discrete black-box problems. One weakness of existing methods is that they are not robust: these methods perform well under certain assumptions, but yield poor results when such assumptions (which are difficult to verify in black-box problems) are violated. ATM addresses this by combining both rank- and model-based optimization, via the use of marginal tail means. We demonstrate the effectiveness of ATM in two real-world problems: the first on robust parameter design of a circular piston, and the second on product family design of a thermistor network.

2 - A Decomposition of Total Variation Depth for Understanding Functional Outliers

Huang Huang, National Center for Atmospheric Research, Boulder, CO, United States, huang.huang@kaust.edu.sa, Ying Sun

There has been extensive work on data depth-based methods for robust multivariate data analysis. Recent developments have moved to functional data. We propose a notion of depth, the total variation depth, for functional data, which has desirable features and is suited for outlier detection. We show that the novel formation of the total variation depth leads to useful decomposition associated with shape and magnitude outlyingness of functional data. Compared to magnitude outliers, shape outliers are often masked among the rest of samples and more difficult to identify. We then further develop an effective procedure and visualization tools for detecting both types of outliers.

3 - Controlling Sources of Inaccuracy in Stochastic Kriging

Wenjia Wang, SAMSI, Durham, NC, United States, wenjia.wang234@duke.edu, Benjamin Haaland

Scientists and engineers commonly use simulation models to study real systems. For expensive simulations, stochastic kriging is commonly used to generate predictions for simulation model outputs subject to uncertainty due to function approximation and stochastic variation. We develop and justify a few guidelines for experimental design, which ensure accuracy of stochastic kriging emulators. We decompose error in stochastic kriging predictions into four components and provide means to control each in terms of properties of the experimental design. The design properties implied for each source of error are weakly conflicting and broad principles are proposed. A few examples are presented.

1 - A Spatial-adaptive Sampling Procedure for Online Monitoring of Big Data Streams

Andi Wang, Georgia Tech, Atlanta, GA, United States, andi.wang@gatech.edu, Xiaochen Xian, Kaibo Liu, Fugee Tsung

This presentation proposes a Spatial Adaptive Sampling and Monitoring (SASAM) procedure to detect shifts occurred in big data streams when (1) only partial information can be observed at each time, and (2) out-of-control (OC) variables are clustered in a small and unknown region. This procedure integrates two ideas to leverage the spatial information of data streams: (1) random sampling that searches for possible OC variables; and (2) directional sampling that focuses on OC variables clustered in a suspicious region. Simulation and real example show that the proposed method significantly outperforms the existing method without taking the spatial information into consideration.

2 - Change Detection in a Dynamic Stream of Attributed Networks

Mostafa Reisi Gahrooei, University of Florida, Gainesville, FL, United States

We propose a methodology for monitoring a stream of attributed networks. In order to model both structural and temporal behavior of a sequence of networks, we integrate generalized linear model with state space modeling. This model is used along with an Exponentially Weighted Moving Average (EWMA) control chart for quick detection of abrupt changes. We tested our proposed approach in two real-world data sets.

3 - Pareto Optimization of an Injection Molding Process using a Sequential Design for a Combined Simulator and Physical Experiment

Thomas Santner, Professor, Ohio State University, Columbus, OH, 43210, United States, santner.1@osu.edu, Angela Dean, Allen Po-Hsu Chen, Maria Villarreal-Marroquın, Rachma Mulyana, Jose M. Castro

This talk will describe a sequential method for identifying the settings of control variables to Pareto optimize multiple characteristics of a manufactured product. The methodology is based on experiments that combine the output from physical and simulator platforms. The method is described in an application that selects the settings of an injection molding machine to minimize component shrinkages when both a deterministic computer simulator of the injection molding machine is available as well as runs on the molding machine itself. The method is based on a Bayesian calibrated predictor of the mean of the physical system and an expected improvement criterion.

4 - JQT Highlights – The New Sections on Data and Software

Bianca Maria Colosimo, Professor, Politecnico di Milano, Via La Masa, 1, Milan, I-20156, Italy, biancamaria.colosimo@polimi.it

JQT has recently revised the Case Study Section and introduced a new JQT Software Section. In this presentation, we will introduce these revised/new Departments of the Journal, in order to encourage new submissions in these areas.

Advances in Healthcare Analytics

Sponsored: Health Applications

Sponsored Session

Chair: Van-Ahn Truong

1 - Simultaneous Offering under Rational Inattention

Ronghuo Zheng, University of Texas at Austin, Austin, TX, United States, Tinglong Dai

In the US, when an organ from a deceased donor becomes available, an organ procurement organizations (OPO) will offer the organ to multiple transplant centers using an online, automated offering system called DonorNet. Surgeons conduct research into the details of the offer and decide whether to accept or reject it. Ultimately, the organ is offered to the patient with the highest priority first, then second highest priority, and so on. In this study, motivated by an OPO's problem of determining the optimal number of simultaneous offers, we model the strategic interaction among transplant centers both within and across batches, leading to structural properties and computational insights.

2 - Should Returning Customers Be Prioritized in Booking an Appointment?

Yichuan Ding, University of British Columbia, Vancouver, BC, Canada, daniel.ding@sauder.ubc.ca, Diwakar Gupta, Xiaoxu Tang

We study how to manage returning customers in an appointment-based slotted-service queue with the goal of maximizing service volume. Returning customers prefer to be served by the same server that they visited in their previous visit. We consider a simple strategy that a service provider may use to reduce balking among returning customers designate some returning customers as high-priority customers. We show that with limited waiting-room, a service system should not prioritize some returning customers in order to maximize the throughput rate. However, it is always optimal to prioritize some customers in the system when there is no limit on the waiting room.

3 - Data-driven Stochastic Optimization Approaches to Determine Decision Thresholds for Risk Estimation Models

Gian-Gabriel P. Garcia, University of Michigan, Ann Arbor, MI, United States, garciagg@umich.edu, Mariel Sofia Lavieri, Ruiwei Jiang, Thomas McAllister, Michael McCrea, Steven Broglio

The growing availability of data has popularized risk estimation models in healthcare. Yet, utilizing these models for accurate diagnosis decisions is challenging. We formulate the two-threshold problem (TTP) as a stochastic program to determine when a risk estimation model can accurately make a positive or negative diagnosis, or if the model is inconclusive. We characterize the optimal solution to TTP using a related linear program (TTP*) and derive additional frameworks for which our analytical results hold. We solve TTP* using quantile estimation and distributionally robust optimization, then apply TTP* to concussion assessment data where we find that it outperforms traditional methods.

4 - Learning to Rank under Evolving Customer Reviews

Jingtong Zhao, Columbia University, New York, NY, United States, jz2477@columbia.edu, Van-Anh Truong, Zhen Xu, Jie Song, Xin Pan

In many electronic healthcare platforms, patients are encouraged to leave reviews. Subsequent patients and the platforms make use of the information to infer the quality of the physicians. An important service provided by a platform is the recommendation of physicians that best meet patients' care criteria. We study how a platform can learn from patient reviews, as well as the way that they make subjective choices when presented with such recommendations. We provide an algorithm to learn from data and to make personalized recommendations to patients. The objective is to maximize patients' long-term satisfaction. We use the notion of regret to evaluate the algorithm's performance.

Pierskalla Award Finalists

Sponsored: Health Applications

Sponsored Session

Chair: Jonathan Helm, Indiana University, Bloomington, IN, 47401, United States

Co-Chair: Pengyi Shi, Purdue University, West Lafayette, IN, 47907, United States

1 - Adaptive Clinical Trial Designs with Surrogates: When Should We Bother?

Arielle Elissa Anderer, The Wharton School, Wynnewood, PA, 19096, United States, Hamsa Bastani, John Silberholz

Surrogate outcomes have long been used in clinical trials when the true outcome of interest is expensive, time consuming, or otherwise difficult to measure. In this work we propose optimal adaptive clinical trial designs that integrate surrogate and true outcomes, and we analytically and empirically characterize regimes where our designs are especially beneficial.

2 - How Do Tumor Cytogenetics Inform Cancer Treatments? Dynamic Risk Stratification and Precision Medicine Using Multi-armed Bandits

Zhijin Zhou, University of Washington, University of Washington, Foster School of Business, Seattle, WA, 98195, United States, Yingfei Wang, Hamed Mamani, David G. Coffey

This work presents a data-driven approach to develop personalized treatment strategies for multiple myeloma patients. Using fine-grained clinical dataset, we first develop a Hidden Markov model to understand patients' treatment responses, we then formulate the treatment recommendation problem as a Bayesian contextual bandit by considering patient disease dynamics and cytogenetic variants. Compared with other benchmark strategies, our method results in the best overall survival outcomes, with higher improvement for aging or high-risk patients with more complications.

3 - An Achievable-Region-Based Approach for Kidney Allocation Policy Design with Endogenous Patient Choice

Yichuan Ding, McGill University, University of British Columbia, 6333 Larkin Drive, Montreal, QC, V6T 1C3, Canada, Baris Ata, Stefanos Zenios

We seek kidney allocation policies considering patients' strategic choices. We analytically prove that it suffices to use priority scores affine in the patient's waiting time, and numerically show that life years can be increased by allowing patient rankings to depend on kidney quality. Consequently, the policy change in 2014, that implemented prioritizing the healthiest patients when allocating the highest 20% quality organs, is a step towards the right direction. Nevertheless, further improvements can be achieved by also prioritizing the least healthy patients for the lowest-quality organs.

4 - Design of Incentive Programs for Optimal Medication Adherence

Joel Goh, NUS Business School, Mochtar Riady Building, 15 Kent Ridge Drive, 08-04, Singapore, 119245, Singapore, Sze-chuan Suen, Diana Maria Negoescu

We consider how to design a schedule of incentive payments to induce optimal treatment adherence levels with heterogeneous patient preferences for adherence. A unique challenge in this problem is that any prior commitment that a patient makes to a given level of treatment adherence cannot be contracted upon, rendering existing contract-theoretic approaches ineffective. We develop new models and analyses to capture this feature and conduct a numerical study using representative data in the context of the tuberculosis epidemic in India.

Drug Shortages

Sponsored: Health Applications

Sponsored Session

Chair: Emily L. Tucker, University of Michigan, Ann Arbor, MI, 48109, United States

1 - Analysis of Supply Volatility in U.S. Antibiotics Drug Shortages (2010-2016)

Rozhin Doroudi, Northeastern University, Boston, MA, United States, doroudi.r@husky.neu.edu, Ozlem Ergun

A more comprehensive view of the entire supply chain, employing a data-driven approach has the potential to strengthen the ability of the FDA, or other supply chain stakeholders, to proactively anticipate and respond to drug shortages.Using IQVIA's comprehensive data on US drug supply chain, we aim to study network structure of the supply chain and analyze supply volatility of products.

2 - Analyzing Disruption Patterns in Pharmaceutical Supply Chains

Jackie Griffin, Northeastern University, Boston, MA, United States, ja.griffin@northeastern.edu, Rana Azghandi

Pharmaceutical supply chains are vulnerable to various disruptions. Closer investigation of this type of supply chain reveals that the risk of disruptions is usually inevitable. Meanwhile, traditional supply chain models fail to recover from these disruptions in a reasonable time objective. In this research, we aim to predict recall disruptions as a mitigation effort. By using pattern recognition methods based on recall data we develop a sophisticated disruption model to help decision-makers to anticipate the risk in the supply chain in the future.

3 - Mitigating Drug Shortages: Should Hospitals Use Their Own Drug Manufacturer?

Hongmei Sun, Ivey Business School, Western University, London, ON, Canada, hsun.phd@ivey.ca, Gregory S. Zaric, Hubert Pun

Drug shortages are a problem in many countries. Some US hospitals established a drug company to manufacture certain medicines in order to mitigate shortage. Our goal is to investigate under what circumstances a hospital will benefit from owning an inhouse manufacturer. We construct a game theoretic model to study the interaction between a hospital and an outside manufacturer. The hospital could procure a drug either from an inhouse producer or from the outside manufacturer whose production has a random yield which can cause a drug shortage. The hospital also has a chance to make emergency production. Our study reveals the hospital's optimal production plan under different combination of parameters.

4 - Modelling & Analysis of Drug Shortages in Europe

Vincent Hargaden, University College Dublin, School of Mechanical & Materials Engineering, Engineering & Materials Science Centre, Belfield, D04 V1W8, Ireland, vincent.hargaden@ucd.ie

Based on the research carried out in a European wide project (COST Action 15105 - European Medicines Shortages Research Network), we develop system modelling approach in five European countries with the goal of reducing the impact of hospital based drug shortages.

5 - Pharmaceutical Supply Chain Resiliency and Drug Shortages

Emily L. Tucker, University of Michigan, Ann Arbor, MI, United States, eltuck@umich.edu, Mark S. Daskin, Burgunda V. Sweet, Wallace J. Hopp

Shortages of medically-necessary drugs continue to occur in the United States. Each shortage lasts for over a year on average and can have substantial effects on health system costs and patient care. The highly-regulated industry has limited ability to adapt once a shortage occurs, and strategic resiliency decisions are highly influential on a company's ability to meet demand after supply shocks. We present a model of resiliency decisions for a pharmaceutical supply chain and analyze market conditions that may contribute to shortages. We discuss the effects of competition.

HAS Distinguished Speakers – II

Sponsored: Health Applications

Sponsored Session

Chair: Mark P. Van Oyen, University of Michigan, Ann Arbor, MI, United States

Chair: Hui Zhao, The Pennsylvania State University, Smeal College of Business, University Park, PA, United States

1 - Machine Learning and Personalized Healthcare

Mohsen Bayati, Associate Professor, Stanford University, 655 Knight Way, E363, Stanford, CA, 94305, United States

Over the last decade, there has been a surge in application of machine learning methods in healthcare. In this talk, we will discuss a few examples of these applications as well as some of the methodological challenges going forward.

2 - Public Health Screening: Models, Algorithms, and Policies

Ebru Korular Bish, Associate Professor, Virginia Tech, Dept Ind/Sys Eng, Blacksburg, VA, 24061-0118, United States, ebru@vt.edu

Screening for diseases is an important, and extensively used, public health tool; early detection can improve clinical outcomes and reduce the spread of the disease, especially for diseases that have slow to develop and/or initially non-specific symptoms (e.g., Babesiosis, Zika, hepatitis, cystic fibrosis). A major challenge is to design public health screening policies that can accurately classify a large number of subjects, having different risk factors, with limited resources and imperfect tests. I will present an overview of this research area, discuss several key models to optimize resource allocation in public health screening, and highlight the challenges and opportunities.

CC- Tahoma 5

Patient Scheduling: New Models and Innovative Applications

Sponsored: Health Applications

Sponsored Session

Chair: Nan Liu, Boston College, Chestnut Hill, MA, 02467, United States

1 - Breaking the Post-anesthesia Bottleneck in Perioperative Care

John Lyons, Western University-Ivey Business School, 23 Pine Ridge Drive, London, ON, N5 X. 3G7, Canada, jlyons@ivey.ca, Mehmet A. Begen, Peter Bell

We schedule surgeries in multiple operating rooms (ORs) feeding a single post anesthesia care unit (PACU) with limited bed capacity where most (90%+) patients need to recover. If the PACU is full, a patient cannot leave the OR, and subsequent surgery in that OR may be delayed/cancelled. We develop a scheduling framework that allows a central planner to sequence surgeries to avoid PACU patient load surges, and to highlight direct and cascading impacts of ward unit bed unavailability and PACU holds on OR delays. We are working with a large regional tertiary care hospital to test and further refine our model as an aid to improve throughput and reduce elective surgery backlog.

2 - How to Manage Doctor Appointments with a Shared Medical Appointment Option

Nazli Sonmez, London Business School, Regent's Park, London, NW1SN, United Kingdom, nsonmez@london.edu, Kamalini Ramdas, Sarang Deo

Shared medical appointments are an alternative to traditional one-on-one appointments for routine care of chronic diseases that offer an innovative, interactive approach to healthcare delivery. They are not widely used even though there is a high potential. To adopt this new healthcare delivery method, the service providers must make an upfront decision on how to allocate service capacity. We develop a model that will incorporate what we learn about how patients make trade-offs while choosing an appointment, when offered two different appointment types using the data from a healthcare provider. This model will provide insight into how many appointments from each type need to be scheduled.

3 - Multi-priority Multi-class Advance Patients Scheduling

Yan Liang, University of Toronto, Toronto, ON, Canada, yan.liang@rotman.utoronto.ca, Hossein Abouee Mehrizi, Opher Baron, Oded Berman

In this paper, we study an advanced scheduling problem. Patients are from multiple service types with multiple priority classes. The service time is deterministic for each service type. Different priority classes have different wait time targets to patients. Each patient can be scheduled to any day within the booking horizon or be diverted to other providers at a higher cost.

4 - Dynamic Inter-day and Intra-day Appointment Scheduling

Christos Zacharias, University of Miami, Coral Gables, FL, 33146, United States, czacharias@bus.miami.edu

The simultaneous consideration of appointment day (inter-day) and time of day (intra-day) in dynamic scheduling decisions has not been addressed adequately in the Operations Research literature due to its large dimensionality and computational complexity. The scope of this research is to provide an optimization platform that solves this problem effectively and efficiently. We leverage the multimodularity property of the static intra-day problem and its propagation through dynamic programming recursion.

5 - On Scheduling Appointments in Tandem Service Systems

Nan Liu, Boston College, Chestnut Hill, MA, 02467, United States, nan.liu@bc.edu, Guohua Wan, Shan Wang

In many healthcare settings, patients come for a series of services instead of a single one. Each of these service stages may require a substantial amount of time with significant variability. For instance, in an infusion center, patients usually go through three main stages of services—blood draw, physician exam (to finalize/verify the treatment plan), and finally, infusion; in an orthopedic clinic, a common care path involves an X-ray exam, followed by a physician consultation, and finally, the service by orthopedic technicians. We study how to manage appointment scheduling in such tandem service systems.

Hub Location

Sponsored: Location Analysis

Sponsored Session

Chair: Sibel Alumur Alev, University of Waterloo, Waterloo, ON, N2L 3G1, Canada

1 - Hub Location and Route Dimensioning: Strategic and Tactical Intermodal Transportation Hub Network Design

Baris Yildiz, Asst. Prof., Koc University, Koc University IE Department, Rumelifeneri Yolu, Istanbul, Turkey, Hande Yaman, Oya Ekin Karasan

We propose a novel hub location model which does not make any assumptions on the structure of the network and on the discount due to economies of scale. Our model extends the literature in three dimensions: (1) instead of connecting non hub nodes directly to hub nodes, we consider routes that visit several non-hub nodes and carry their traffic to the their associated hub and back, (2) instead of connecting pairs of hubs directly, we design routes that can visit several hub nodes, (3) vehicle types and quantities are optimized concurrently with the network design. An efficient branch and cut algorithm is developed to solve realistic size problem instances.

2 - Hub Location under Congestion and Capacity Considerations

Vedat Bayram, TED University, No: 48, Ankara, 06420, Turkey, vedat.bayram@tedu.edu.tr, Baris Yildiz, Mohammad Saleh Farham

In this study, the effect of congestion on the number, location and the capacity of hubs is analyzed and policies that simultaneously minimize the cost of installing hubs, building capacities and transportation, and the effect of congestion is developed. We model the congestion effect by presenting a novel path based formulation of the hub location problem, which enables us to determine the optimal number, locations and capacities of hubs considering the tradeoff between the cost and the congestion effect. We use large scale optimization methodologies such as Benders decomposition, column generation and second order cone programming to solve the problem efficiently.

3 - Two Formulations for a Profit Maximizing Hub Location Problem with Hub Congestion, Time-sensitive Demands and 1-stop Paths

Armin Lüer-Villagra, Universidad Andres Bello, Santiago, Chile, armin.luer@unab.cl, Elena Fernández

Hub-and-spoke network topology is commonly used if it is reasonable to consolidate flows at intermediate facilities. Hub location models have been used to design such networks, and have been extended to consider hub congestion, time-sensitive demands, competitive settings, etc. We study a problem where a profit-maximizing company wants to design a hub-and-spoke network with p hubs. The demand is sensitive to total travel time, and hubs processing times depends on inbound flow. We consider that every path includes at most one hub. We propose two formulations and different procedures to solve instances up to 50 nodes.

4 - Robust-stochastic Models for Profit Maximizing Hub Location Problems

Sibel A. Alumur, University of Waterloo, Waterloo, ON, N2L 3G1, Canada, sibel.alumur@uwaterloo.ca, Gita Taherkhani, Seyed Mojtaba Hosseini

We introduce robust-stochastic models for profit maximizing hub location problems simultaneously incorporating two different types of uncertainty. Initially, a two-stage stochastic program is presented for the stochastic demand. Robust optimization techniques, including both interval uncertainty and discrete scenarios, are used to incorporate uncertain revenues into the stochastic problem. Robust-stochastic models with a max-min criterion and a min-max regret objective are then formulated. Exact algorithms based on Benders decomposition coupled with sample average approximation scheme are developed and enhanced by novel acceleration techniques.

Joint Session MSOM/HC/Practice Curated: Empirical Health Care Operations

Sponsored: Manufacturing & Service Oper. Mgmt/Healthcare Operations

Sponsored Session

Chair: Hummy Song, Philadelphia, PA, 19104, United States

1 - Recovering from Critical Incidents: Evidence from Paramedic Performance

Jonas Oddur Jonasson, MIT Sloan School of Management, Cambridge, MA, 02142, United States, joj@mit.edu, Hessam Bavafa

We examine operational performance in settings where workers can encounter critical incidents (CIs)—jobs which are sufficiently disturbing to challenge workers' coping mechanisms. Using data on 902,002 ambulance activations we find that Crews who have encountered one prior CI (two prior CIs) spend on average 2.6% (7.5%) more time completing each remaining ambulance activation in the shift. The largest effects come from the sub-processes which are least standardized and where paramedics cannot rely on standard operating procedures.

2 - Improving MRI Hospital Waiting Times Using Geographical Partial Pooling: An Empirical Analysis of 72 Hospitals in Ontario, Canada

Yangzi Jiang, Northwestern University, Evanston, IL, United States, yangzi.jiang@kellogg.northwestern.edu, Jan A. Van Mieghem

There are 72 MRI hospitals from Ontario Canada connected under the Local Health Integration Networks that aim to serve 90% of their patients within their target wait time. Our dataset covering the last 5 years, however, shows that the actual number is only 40% meaning that over 60% of the patients experience waits in excess of their target. We show that smart routing of patients to farther, yet nearby lower utilized hospitals can increase the service level to 75% without adding capacity. Our analysis uses a geographical resource sharing queuing model that trades off increased driving distance with waiting time reduction to determine the effect of resource sharing under high server utilization.

3 - The Impact of Waiting Location on Customer Satisfaction: An Empirical Analysis of Preoperative Patient Flow

Dawson Kaaua, University of Pennsylvania, Philadelphia, PA, 19104, United States, kaaua@wharton.upenn.edu, Christian Terwiesch, Santiago Gallino

We study patients in an ambulatory endoscopy center who wait in reception then pre-op before receiving a procedure. We find evidence that (i) patients experience steeper declines in satisfaction in response to wait times in pre-op versus reception, (ii) patients may track first-in-first-out queue discipline in transparent areas of the queue despite the fact that patients do not observe the physician assignment of others waiting, and (iii) patients may be aware of the degree to which their wait concludes before or after a scheduled appointment time. We support and inform our observational findings with three experiments.

4 - Speed-quality Tradeoffs in Home Health: The Effects of Visit Length on Hospital Readmission

Hummy Song, The Wharton School, Philadelphia, PA, 19104, United States, hummy@wharton.upenn.edu, Elena Andreyeva, Guy David

This study uses a novel dataset from a home health agency to examine the presence of a speed-quality tradeoff in the context of home health care delivery. Specifically, we use an instrumental variable approach to quantify the effects of the length of a post-acute home health visit on the likelihood of readmission to the hospital. We find that longer than average home health visits are associated with a significant reduction in the likelihood of hospital readmission.

IT-enabled Business Innovation

Sponsored: EBusiness

Sponsored Session

Chair: Yi-Jen (Ian) Ho, Pennsylvania State University, University Park, PA, 16802, United States

1 - Can Own-account Software Bring Performance to a Firm?

Jin Sik Kim, University of California, Irvine, Irvine, CA, 92602, United States, j.s.kim@uci.edu, Vijay C. Gurbaxani, Hwan Heo

As the data usage and software to process the data have become new resources to compete in daily transactions for all business, we hypothesize that it is own-account software creating unique value for a firm. As more software is acquired via the cloud as a service, software can be considered as a commodity rather than resources that underlie competitive advantage because of the RBV 4 conditions. However, we conclude that own-account software may bring the performance a firm by answering these questions: does the own-account software (AI) outperform in demand estimation than (1) human and (2) Cloud-based AI S/W? And, (3) does the own account AI give economic benefits for a firm by estimating demand better?

2 - Mobile App Adoption and Portfolio Diversification Evidence from a Quasi-natural Experiment in China

Che-Wei Liu, Indiana University, Bloomington, IN, 47405, United States, cwliu@iu.edu, Sunil Mithas, Po-An Hsieh, Yang Pan

Despite the economic importance and significance, few studies have examined the effects of mobile app use on individual investors' financial decisions. We leverage a quasi-natural field experiment with a difference-in-difference specification, and our results suggest that mobile app use by individual investors leads to an increase of 4.7% in portfolio diversification and an increase in the number of stocks. We also show that mobile app adoption leads to a decrease of portfolio volatility because of the increase of portfolio diversification. We conduct a variety of robustness tests to assess the stability of our findings and discuss implications for research, and practice.

3 - Estimating the Economic Impact of `humanizing' Customer Service Chatbots

Scott Schanke, University of Minnesota, Minneapolis, MN, 55401, United States, schan067@umn.edu, Gordon Burtch, Gautam Ray

We consider the economic impacts of `humanizing' autonomous customer service agents (chatbots) and do so via a field experiment. We automate a clothing buy-back process, where individuals engage with a chatbot to sell their used clothing. We estimate the impact on transaction conversion and price sensitivity by exposing consumers to exogenous variation of (1) price offers, (2) levels of chatbot anthropomorphism. We show that while introducing either a small or large degree of anthropomorphism increases conversion rates, introducing only moderate anthropomorphism is counterproductive. We also show that a large degree of anthropomorphism causally increases consumers' price sensitivity.

4 - The Impact of Emotion on Social Media Content Consumption: Evidence from Video Analysis on Live Streaming Platforms

Keran Zhao, University of Illinois at Chicago, Chicago, IL, United States, kzhao23@uic.edu, Yuheng Hu, Yingda Lu

As an emerging social media service, live streaming has been widely adopted by advertisers and companies as a powerful market tool. In this study, we examine how streamers' emotional expression influence the audience's engagement. To answer this question, we utilize the deep-learning methods to acquire both the emotional expression and audience attention from streaming video and chatting script. Our analysis yields that there is a positive relationship between emotion fluctuation and audience engagement. Our results provide actionable suggestions and shed light on understanding the live interaction on the live streaming platforms.

5 - The Price of Price on Online Advertising: Evidence From Randomized Field Experiments

Yi-Jen (Ian) Ho, The Pennsylvania State University, Smeal College of Business, University Park, PA, 16802, United States, ian.ho@psu.edu, Nitish Jain, Suresh Muthulingam

Consumers access the incomplete information of products while shopping online. The asymmetric product information results in uncertainty. We consider uncertainty driven by price and product valuation. Specifically, we examine the effect of price revelation on consumer choice and how the effect is moderated by search cost and product popularity. We conduct randomized field experiments on Facebook to qualify the causalities. The results show that the impacts of price revelation vary. While showing price deters the click-through rate, the consumers who click on the are more engaged. Mobile users prefer having price information, and popular products suffer from price revelation.

Software for Network Analytics

Sponsored: Telecommunications and Network Analytics

Sponsored Session

Chair: Matthew Galati, SAS Institute, Inc., Glen Mills, PA, 19342, United States

1 - Pattern Matching for Graph Queries in Sas® Viya® 3.4

Matthew Galati, SAS Institute, Inc., 1164 Avonlea Circle, Glen Mills, PA, 19342, United States, matthew.galati@sas.com

SAS® Visual Data Mining and Machine Learning 8.4 in SAS® Viya® 3.4 includes the new patternMatch action, which you can use to execute graph queries that search for copies of a query graph within a larger graph, with the option of respecting node or link attributes (or both). This presentation also provides computational comparisons to both iGraph and Neo4j. Example applications include social network search and value-added tax fraud.

2 - Detecting Aberrant Linking Behavior in Directed Networks

Mark Velednitsky, University of California-Berkeley, Berkeley, CA, United States, marvel@berkeley.edu, Dorit Simona Hochbaum, Quico Spaen

Agents with aberrant behavior are common in today's networks: fake profiles, websites, news spread misinformation. The distinguishing behavior of networks with aberrant agents is that normal agents rarely link to aberrant ones. Based on this, we propose a directed Markov Random Field formulation for detecting aberrant agents. The formulation is solved optimally and efficiently. To assess our method, we develop a new variant of "modularity." In an empirical experiment, we compare to PageRank, TrustRank, and AntiTrustRank. We demonstrate that our method outperforms other detection algorithms.

3 - A Nonnegative Matrix Factorization Approach to Track Communities in Temporal Networks Using Node Features

Renny J. Márquez, PhD student, Universidad de Chile, Santiago, Chile, marquezrennyj@ug.uchile.cl, Richard Weber, André C.L.F. de Carvalho

Community detection is primarily based on the adjacency matrix of a network. Adding node attributes to the identification of groups can improve the detection of communities. This improvement can further increase when working with temporal networks. Besides, soft overlapping assignment of nodes to communities can be a good alternative to deal with uncertainty in data. In this context, we propose a community detection algorithm for finding soft overlapping groups in temporal networks with node attributes. Our approach is based on a non-negative matrix factorization generative model. Preliminary results on toy and artificial networks have been very promising

Diversity/PSOR/MIF: Diversity, Equity and Inclusion in OR/MS/Analytics: Innovations in Research and Practice

Sponsored: Diversity, Equity, and Inclusion

Sponsored Session

Chair: Michael P Johnson, University of Massachusetts-Boston, Boston, MA, 02125-3393, United States

1 - A Research Agenda for Diversity, Equity and Inclusion in the Decision Sciences

Michael P. Johnson, PhD, University of Massachusetts-Boston, Department of Public Policy & Public Affairs, Boston, MA, 02125-3393, United States, michael.johnson@umb.edu

Scholarly research on diversity, equity and inclusion (DEI) in the decision sciences is largely concentrated in areas of management and organization design. However, DEI is relevant to other domains of inquiry, and can be understood in terms other than economic efficiency and organization effectiveness. I discuss what a research agenda in decision sciences would look like if DEI, and a focus on social costs and benefits and social justice were central to this work. Examples to be discussed include: the new economy, climate resilience and disaster response, and human services.

2 - Locating Cannabis Establishments in Areas of Disparate Impact

Jeffrey Moyer, MS, University of Massachusetts-Boston, Boston, MA, 02125-3393, United States, Jeffrey.Moyer001@umb.edu

How can a public agency aiming to correct previous criminal justice disparities and drive social equity pick the most eligible geographic areas for consideration? This paper will use cannabis establishment siting as an example of how to develop and conceptualize a diversity, equity, and inclusion agenda within the field of operations research by formulating measures of equity and fairness that reflect experiences of underserved, underrepresented or marginalized population and embrace multi- and trans-disciplinary alternative approaches.

3 - Migrant Inclusion in Development Management: A Social Network Analysis

Christopher C. Graham, MS, University of Massachusetts-Boston, Boston, MA, 02124, United States, chriscordellgraham@gmail.com

This study uses social network analysis (SNA) to conduct a meso-level investigation of migrant-driven development social systems. The SNA applies degree and eigenvector centrality measures to assess the inclusiveness of migrant organizations in collaborative networks within those social systems. Findings indicate that while migrant organizations are involved in development management, they are underrepresented or absent in highly-collaborative resource exchange networks. These findings offer new perspectives on how development policy-makers evaluate and understand migrant inclusion.

Risk Management for Performance-driven Energy Systems

Sponsored: Finance

Sponsored Session

Chair: Kory W. Hedman, PhD, Advanced Research Projects Agency-Energy US Department of Energy, Washington, DC, United States

1 - Performance of Energy Systems

Agostino Capponi, Columbia University, New York, NY, United States, ac3827@columbia.edu

We discuss robustness and resiliency of network architectures in a systemic context, with an emphasis on energy risk. We consider a network model, consisting of (1) a network interaction matrix capturing the pattern and extent of interaction between the generators of the energy network, (2) a demand and supply function, and (3) a network interaction function used by each generator in the network to compute its state based on the states of the others.

We introduce the metric of matrix majorization to quantify concentration of the network interaction matrix. We study how the interplay of demand-supply imbalance, and concentration of the network interaction matrix affect failures of generators.

2 - Renewable Energy Sources and the Risks they Pose: A Financial Industry Perspective

Ronnie Sircar, Princeton University, Princeton, NJ, United States, Rene Carmona

We present a parallel between the modeling challenges faced by the financial industry when attempting to estimate and predict the costs associated with defaults on debts, and the risks and costs faced by grid operators dealing with uncertain sources of energy. Next, we review some of the risk measures and credit products used by the financial industry to mitigate these risks, and we speculate on how these concepts could be leveraged in the context of the search for safe and reliable energy delivery.

3 - Enabling On-site Solar Transactions Through Novel Insurance Products

Jeffrey McAulay, Energetic Insurance, Boston, MA, United States

Solar Photovoltaics are one of the fastest growing sources of new electricity generation in the US. However, several risks still limit faster growth and adoption. While utility-scale and residential markets show strong growth, the commercial sector in particular has been largely flat. Here we review several known risks and highlight how insurance approaches can enable scale. Examples risks include electricity generation, off-taker credit, utility tariff rates and tax equity recapture. When paired with storage, high density solar deployment can be deployed in targeted areas to enable electric grid resiliency and defer infrastructure investment.

4 - Using Stochastic Models for Day-ahead Electricity Markets

John Birge, University of Chicago, Chicago, IL, United States, john.birge@chicagobooth.edu

Models for forward electricity markets that match deterministic bids and offers have an inherent inability to match both prices and quantities. This results in inefficiencies due to the lack of credible commitment. This talk will discuss this phenomenon in general and potential market remedies to improve efficiency.

Joint Session PMS/ED: Transforming a Project Management Course

Emerging Topic: Project Management & Scheduling

Emerging Topic Session

Chair: Theodore D. Klastorin, University of Washington, ISOM Department, Seattle, WA, 98195-3226, United States

1 - Teaching Agile versus Waterfall in Project Management Courses

Theodore D. Klastorin, University of Washington, ISOM Department, Seattle, WA, 98195-3226, United States

Agile Project Management is widely discussed and implemented but poorly understood. In this talk, we compare Agile to Waterfall and discuss how these two methodologies relate to various classes of risk (e.g., requirements risk versus schedule risk). In addition, we will define important open questions that must be considered by Agile users.

2 - A Case Based Project Planning/Risk Lesson

Gary Mitchell, University of Portland, Portland, OR, 97203-5798, United States

Most complex projects are characterized by a great deal of uncertainty and risk. Project managers must identify tasks, develop estimates, and determine schedules and costs under these conditions of uncertainty. Effectively teaching students about identifying and planning projects under risk requires establishing a theoretical foundation, providing practical tools they can understand and apply, and a practical application with which they can gain experience. In this talk, we present a case-based term project that has proven to be an effective method for teaching project managers planning under risk.

3 - Teaching Critical Chain Project Management: A Review of the Decade's Developments

William P. Millhiser, Baruch College City University of NY, New York, NY, 10010, United States

Critical Chain Project Management (CCPM) has been popular among practitioners and business schools but a subject of disagreement among scholars. We will review subsequent developments in CCPM practice and pedagogy, new teaching games, and share evidence of CCPM's transformation in teaching important PM thinking skills despite industry's wholesale movement toward agile methods in the modern digital economy.

4 - Teaching Forward-Looking Earned Value Analysis (EVA)

Jim Salmon, Boeing Company, Seattle, WA, United States

Traditional Earned Value Analysis (EVA) reporting methods emphasize the sanctity of the initial plan and comparisons of recent progress to it. Given EVA's prevalence in many types of projects, especially among those beholden to government contracting rules or oversight from external project customers, it behooves project managers to both understand and incorporate simple visualization tools and cues that compel re-articulation of plans based on possible future outcomes on an ongoing basis.

S- Greenwood

Network Research in Innovation and Knowledge Management

Sponsored: New Product Development

Sponsored Session

Chair: Hyunwoo Park, Ohio State University, Columbus, OH, 43210, United States

1 - An Economic Model of Knowledge Outsourcing

Jaeseok Lee, The University of Auckland Business School, Auckland, 0620, New Zealand, Cheryl Gaimon, Karthik Ramachandran

We introduce a game-theoretic model of knowledge outsourcing. We study how the interaction between a knowledge buyer and supplier is affected by two distinctive aspects of knowledge outsourcing: absorptive capacity and the ability to leverage prior knowledge. We also investigate how uncertainty and information asymmetry influence the equilibrium outcomes.

2 - The Impact of Service Failure of Competitors on Innovation

Seongkyoon Jeong, PhD Student, Arizona State University, 451B, Department of Supply Chain Management, Business Administration, Tempe, AZ, 85281, United States, sjeong19@asu.edu, Adegoke Oke

Firms can not only learn from service failure of rivals but also capture new customer base resulting from the service failure. Using the data of online game services, we investigate how firms gain value from service failure of competitors through innovation and the role that supply chain plays in this process. Using 65 major service failure and update data of 435 online game services hosted between 2014 and 2017, this study finds that competitor's service failure shortens the duration of major service updates and that the publisher-developer tie strength has an inverted U-shape relationship with the responsiveness of major service updates to the competitor's service failure.

3 - Technological Innovation Spillover in Supply Networks

Hyunwoo Park, Ohio State University, Columbus, OH, 43210, United States, park.2706@osu.edu, Waleed A. Muhanna

In this work, we study how innovation outcomes propagate in supply networks. We examine whether suppliers' innovation is substitute or complement to the innovation portfolio of the buyer. Thus, our empirical analysis include the effect of supplier innovation on buyer's supplier portfolio and own innovation activities. We also consider spillover through indirect relationships in supply networks.

4 - Incentive Metrics in the Presence of Project Performance and Task Interdependence Uncertainties

Antoine Feylessoufi, University of Cambridge, Cambridge, United Kingdom, af545@jbs.cam.ac.uk

We analyse how team and individual incentives affect an organization's propensity to adopt a risky strategic project. We recognize that these projects are mostly carried out by a cross-functional team of specialists whose tasks are interdependent and uncertain, and the degree to which their tasks interact is also uncertain. In particular, we show that the project performance uncertainty and the uncertainty around the interdependence of the tasks can impact the incentive metrics in opposite ways.

■ SC79

S- Issaquah A

Market Design for a Low-Carbon Electricity Grid

Emerging Topic: Sustainable Growth

Emerging Topic Session

Chair: Jacob Mays, Northwestern University, Evanston, IL, 60208, United States

Co-Chair: Brent Eldridge, Johns Hopkins University, Baltimore, MD, 21201, United States

1 - Long-term Equilibrium in Low-carbon Electricity Markets

Audun Botterud, Massachusetts Institute of Technology, Cambridge, MA, 02140, United States, audunb@mit.edu, Magnus Korpås

We formulate generation capacity portfolio planning in the power grid as a least-cost optimization problem and derive analytic expressions for the cost recovery conditions for dispatchable generation, variable renewable energy (VRE), and energy storage. Using a simple load duration representation of electricity demand, we illustrate how the long-term market equilibrium changes for different VRE penetration levels. We also illustrate how long-term contracts for VRE typically do not account for the resulting balancing needs in the system. We propose alternative mechanisms that align better with short-term system needs and long-term equilibrium conditions.

2 - Do Electricity Market Price Formation Efforts Still Matter in a High Renewable World?

Robin Broder Hytowitz, Electric Power Research Institute, Palo Alto, CA, 94062, United States, Erik Ela

With more zero marginal cost resources coming online, there are questions as to the value of alternative pricing mechanisms in electricity markets. This presentation will discuss market designs behind US ISO and RTO efforts dealing with price formation. We will explore the relevance of these efforts in light of higher penetration renewable energy and ongoing market changes.

3 - Implications of Indivisibilities on Pricing with Constrained Delivery

Alberto J. Lamadrid, Lehigh University, Bethlehem, PA, United States, ajl259@cornell.edu

We study a market with non-convexities for goods delivered over a network subject to congestion. Our model is inspired on an electricity market with non-convexities associated with commitment costs and convex quadratic generation costs, from the viewpoint of a market-maker that determines market clearing prices for participants.

4 - A Learning Algorithm to Estimate Inefficiencies in Electricity Markets

Brent Eldridge, Johns Hopkins University, Baltimore, MD, United States, breldridge@gmail.com, Richard O'Neill

Independent System Operators (ISOs) are largely effective at coordinating wholesale electricity markets. In such markets, the ISO determines prices and quantities based on the solution of a Unit Commitment (UC) problem. However, the UC problem is non-convex, e.g., due to lumpy start-up costs or on/off commitment decisions, so prices cannot generally support the optimal schedule. Various pricing methodologies have been proposed, but there is no accepted consensus of what constitutes an optimal pricing policy. This presentation applies agent-based modeling (ABM) to model how various pricing methodologies may affect generator offer curves and consequently the affect on market efficiency.

Driving Innovation in Different Industries

Sponsored: Technology, Innovation Management & Entrepreneurship

Sponsored Session

Chair: Jochen Schlapp, Frankfurt School of Finance & Management gGmbH, Frankfurt am Main, 60322, Germany

1 - Operations in Space: Exploring a New Industry

Joel Wooten, University of South Carolina, Columbia, SC, United States, Christopher S. Tang

Private, commercial spaceflight is changing the course of space exploration. This new space market presents different challenges, and as a result, our paper analyzes the opportunities for novel contributions from the operations management community.

2 - Sourcing Innovation: The Role of Internal Suppliers in Procurement Contests

Zhi Chen, INSEAD, 1 Ayer Rajah Ave, Singapore, 138676, Singapore, zhi.chen@insead.edu, Jurgen Mihm, Jochen Schlapp

One of the central questions in the strategic procurement of innovative goods is whether a buyer should own a stake in a critical supplier or not. In this study, we analyze when a buyer should source from external suppliers exclusively and when it should (partially) own one of the suppliers.

3 - Sparking Manufacturing Innovation: How Temporary Interplant Assignments Affect Employee Idea Values

Fabian J. Sting, University of Cologne, Albertus-Magnus-Platz, c/o WiSo-Sekretariat Universitaetsstrasse 91, Cologne, 50923, Germany, sting@wiso.uni-koeln.de, Philipp Benjamin Cornelius, Bilal Gokpinar

We study how interplant assignments - short-term, temporary employee moves between factories - influence employee-driven manufacturing innovation. Using unique idea-level data from a large European car parts manufacturer, we show that interplant assignments are a significant driver of employee idea values by fostering the short-term transfer of production knowledge as well as long-term employee learning. We also find that both knowledge transfer and employee learning are facilitated by assignments to plants that are functionally similar (i.e., plants that have similar products and processes).

4 - A Simple Economic Analysis of Contest Platforms

Sanjiv Erat, University of California-San Diego, Rady School of Management, Otterson Hall, La Jolla, CA, United States

Firms, such as Innocentive and Topcoder, offer platforms that enable crowdsourcing of innovations and of technical solutions from large communities of potential solvers. The current talk shall develop a simple economic model of contest platforms that clarifies how the challenges of conducting a contest on a platform is distinct from the case of "monopolist" contests (analyzed in all of past literature). Insights and contingent recommendations are derived that explain when and which type of platforms offer firms a better value and why.

5 - Product Selling Versus Pay-per-use Service: A Strategic Analysis of Competing Business Models

Stylianos Kavadias, Margaret Thatcher Professor of Innovation & Growth, University of Cambridge, Judge Business School, Trumpington Street, Cambrige, CB2 1AG, United Kingdom, s.kavadias@jbs.cam.ac.uk, Konstantinos Ladas, Christoph H. Loch

We present a model that explains why "pay-per-use" (PPU) business models may have become profitable alternatives to traditional selling business models across a wide range of goods in a competitive setting. Our model features goods of any production cost, used by consumers who vary in their usage. We find that PPU models are more profitable than selling models, as long as their logistics costs are not too high, a requirement more easily fulfilled as new technologies reduce logistics costs. These results hold across a wide variety of settings. If the service providers vary their service level they further increase their advantage because they lure away even the high usage consumers.

■ SC81

Forestry III: Wildfire Management

Sponsored: Energy, Natural Res & the Environment/Forestry

Sponsored Session

Chair: David L Martell, University of Toronto, Toronto, ON, M5S 3B3, Canada

1 - Data Driven Metrics for Resource Scarcity Within the Wildland Fire Response System

Erin Belval, Research Scientist, Colorado State University, Fort Collins, CO, United States, Dave Calkin, Crystal Stonesifer

Quantitative measures of resource scarcity are crucial for making decisions across a range of spatial and temporal scales within the wildfire response system in the United States. From national preseason decisions to real-time incident level decisions, accurate measures of resource scarcity may affect a variety of resource allocation decisions. Despite the potential utility of resource scarcity metrics, the question of how to define resource scarcity can be difficult to answer. Using a variety of available resource use data we define scarcity measures for national resources at multiple spatial and temporal levels and discuss their relevance to ongoing management challenges.

2 - Contingency Fireline Selection in Large Fire Suppression

Yu Wei, Colorado State University, Department of FRWS, Forestry 102, Fort Collins, CO, 80523, United States, yu.wei@colostate.edu, Matthew Thompson, Erin Belval, Benjamin Gannon, Dave Calkin

Large fire management decisions often need to be made with uncertainties. One of the major uncertainties is due to potential fireline breaching. Key primary firelines may need to be backed up by contingency lines to lower the risk of line breaching. Building contingency lines is costly, but may create necessary redundancies in the large fire suppression system. A MILP model is used to explore where contingent firelines should be built to improve the expected system performance during large fire suppression.

3 - Predictive Analytics and Machine Learning in Wildfire Management

Matthew Thompson, U.S. Forest Service, Fort Collins, CO, United States, Christopher O'Connor, Dennis Hallema, Yu Wei

Inspired by Dave Martell, this presentation will outline an integrated analytics management framework in the context of fire suppression operations. We will introduce a descriptive fire line effectiveness framework, and describe its role in serving as a connective thread for predictive and prescriptive analytics. Emphasis will be placed on predictive models built with machine learning algorithms, and we will share real-world examples of their use for planning and decision support. Lastly we will outline research directions for machine learning, including aiming to build predictive models of suppression operations like fire line construction, aerial drops, and resource use dynamics.

4 - A Daily Airtanker Deployment Decision Support System

David L. Martell, University of Toronto, Faculty of Forestry, 33 Willcocks Street, Toronto, ON, M5S 3B3, Canada, david.martell@utoronto.ca

Each day forest fire managers must decide where to deploy their airtankers and their alert status throughout the day to minimize their response time to new initial attack fires. The airtanker system can be viewed as a complex spatial queueing system with fires as customers, airtankers as servers, fire arrival rates that vary over time, uncertainty concerning the number of airtankers required to serve each customer and service times that depend on waiting time. We describe a hybrid decision support system comprised of a simple deterministic location model that is coupled with a simulation model that can be used to help evaluate daily airtanker deployment strategies.

Capacity Expansion of Energy Systems under Uncertainty

Sponsored: Energy, Natural Res & the Environment/Electricity

Sponsored Session

Chair: Liang Xu, University of Pittsburgh, Pittsburgh, PA, 15261, United States

1 - A Nonconvex Regularization Scheme for the Stochastic Dual Dynamic Programming Algorithm

Arnab Bhattacharya, Staff Research Scientist, Pacific Northwest National Laboratory, Richland, WA, 99354, United States

A novel nonconvex regularization scheme is proposed to improve the performance of the stochastic dual dynamic programming (SDDP) algorithm for solving multistage stochastic linear programs. Specifically, a class of nonconvex functions, called folded-concave penalty, is used to improve both solution quality and convergence rate of SDDP. Equivalent mixed-integer programming formulations are derived, and global optimality and convergence guarantees of the procedure are established. The potential benefits of the regularization scheme are demonstrated for two large-scale multistage problems in energy and finance.

2 - Multiple N-1-1 Contingency-Constrained Two-Stage Stochastic Expansion Planning with Corrective Actions

Daniel A. Zuniga Vazquez, University of Arizona, Tucson, AZ, United States, danielzunigav@email.arizona.edu, Neng Fan

Shortages of critical loads may be generated due to unexpected outages caused by extreme weather conditions, among other factors. Therefore, to achieve a reliable transmission and generation expansion planning security criterions must be ensured. A two-stage stochastic optimization model is presented for minimizing the expansion planning cost considering DC optimal power flow, and contingency-constrained DC optimal power flow, such that it satisfies multiple N-1-1 survivability criteria with corrective actions. For an efficient solution, a decomposition algorithm is adapted, and the model is assessed using modified versions of IEEE test cases.

3 - Capacity Expansion of Wind Farm in a Market Environment under Uncertainty

Liang Xu, University of Pittsburgh, Pittsburgh, PA, 15261, United States, lix21@pitt.edu, Bo Zeng

Uncertainty and instability are widely existing in wind power generation. To have reliable investment decisions, we introduce a bilevel model considering uncertainty. The upper level aims to maximize wind power profit subject to investment budget constraints while the lower level is to minimize the overall cost through a market clearing problem. By computing instances from typical test beds, we note that our proposed model and solution methods demonstrate significant advantages in practice.

4 - Enabling Smart Ports Through the Integration of Microgrids

Anahita Molavi, University of Houston, Houston, TX, United States, amolavi@uh.edu, Jian Shi, Gino J. Lim

This paper presents a systematic framework for port microgrid planning as well as evaluating the influence of microgrids adoption on an industrial port's performance. A set of modified Smart Port Index (SPI) metrics are incorporated in the proposed framework to demonstrate how the microgrid integration can holistically improve the smartness of the port. A two-stage stochastic mixed-integer model was developed to evaluate the effectiveness of the proposed approach under uncertainties. Numerical results indicate that compared with the minimum cost planning approach, the proposed framework is capable of improving the productivity, sustainability, and reliability of the port operations.

Energy pricing for Demand Response

Sponsored: Energy, Natural Res & the Environment/Electricity

Sponsored Session

Chair: Juan Gomez Herrera

1 - Optimal Time-and-level-of-use Price Setting for an Energy Retailer

Juan Alejandro Gomez-Herrera, Polytechnique Montreal, 1350 Palerme 111, Montreal, QC, J4W 0A1, Canada, Miguel F. Anjos, Luce Brotcorne

We present a novel pricing optimization problem for an energy retailer in a smart grid. In this framework the retailer buys energy from multiple generators via bilateral contracts and sells it to a population of smart homes using Time-and-Level-of-Use tariffs (TLOU). TLOU is an energy price structure recently introduced in the literature, where the prices vary depending on the time and the level of consumption. This problem is formulated as a bilevel optimization problem, in which the energy retailer wants to set the prices that maximize the profit, anticipating the reaction of a population that wants to minimize the cost by shifting load.

2 - Sustainable Management of Data Centers with Onsite Renewables Considering Reduction of Greenhouse Gases Emissions

Jose Luis Ruiz Duarte, University of Arizona, Tucson, AZ, 85721, United States, jlruizduarte@email.arizona.edu, Neng Fan

The processing of large amounts of data is an essential task addressed by data centers, which account for an important portion of the power consumed by information technologies. There is a necessity to improve the data centers' energy efficiency. In this presentation, the development of a two-stage robust optimization model for job migration and assignment of a network of interconnected data centers, each of them equipped with energy storage systems and renewable energy sources with uncertain power output and operating under demand-side management policies, is shown. A sensitivity analysis is performed under scenarios of connectivity and availability of technologies used on each center.

3 - Time of Use Pricing for Demand Response

Luce Brotcorne, INRIA, 40 Avenue Halley - Bat A, Parc Scientifique de la Haute Borne, Lille, 59650, France, luce.brotcorne@inria.fr

We present an optimal pricing approach for an energy retailer in a context of smart grid and demand response. The retailer buys energy on the energy market and sells it to a smart grid aggregator whose goal is to schedule consumers' household appliances at the lowest cost with regard to electricity prices and delays. The smart grid operator has a renewable energy source and a battery. A multi-period stochastic bilevel model is defined. Numerical results are commented on.

4 - A Hybrid Genetic Algorithm - MILP Solver Bilevel Approach to Optimize Electricity Dynamic Time-of-use Pricing

Carlos Henggeler Antunes, University of Coimbra, INESCC, Dept Electrical and Computer Engineer, University of Coimbra, Polo 2, Coimbra, 3030-290, Portugal, ch@deec.uc.pt

In smart grids, dynamic tariffs are expected to become commercial offers by retailers to encourage the adoption of different consumption patterns using the flexibility in the operation of end-use loads. Bilevel optimization is adequate to model the interaction between the retailer and consumers. The retailer aims to set prices to maximize profits and the consumer responds by selecting, under that price setting, a load scheduling decision to trade-off cost vs. comfort. A hybrid genetic algorithm - MILP solver approach is proposed to deal with this problem.

Performance Based Energy Resource Feedback, Optimization, and Risk Management (PERFORM)

Sponsored: Energy, Natural Res & the Environment/Energy

Sponsored Session

Chair: Kory Hedman, ARPA-E, US DOE, DC, United States

1 - Demand Side Risk Management for Electricity Supply

Shmuel S. Oren, University of California-Berkeley, Berkeley, CA, United States, shmuel@berkeley.edu

The emerging penetration of distributed resources and renewable resources into the electricity supply mix and increased demand side participation in the management of the electric power system requires new business models for electric utilities and innovative approaches for risk management along the electricity supply chain. The economic gains from a transactive energy paradigm that envisions the proliferation of energy balancing through increased self supply and peer to peer transactions at the distribution level can only be realized by mitigating part of the supply risk through demand side mechanisms and edge technologies. This talk will discuss such mechanisms and service contracts.

2 - The Four Classes of Policies for Stochastic Optimization in Energy Systems

Warren Powell, Professor, Princeton University, Princeton, NJ, United States, wbpowell328@gmail.com

Energy systems, especially with the growth of renewables, represents a rich class of sequential decision problems under uncertainty. I will review the four classes of policies that are the foundation for any sequential decision problem, and illustrate this using a simple energy storage system. I will highlight a powerful strategy, the parametric cost function approximation, that formalizes a practice widely used in industry for problems such as unit commitment, and I will demonstrate that this approach will outperform the scenario-tree approach to stochastic unit commitment.

3 - Dealing with Risk and Uncertainty in the Electric Sector: Lessons from the Financial Sector

Richard D. Tabors, Tabors Caramanis Rudkevich, Boston, MA, United States, rtabors@tcr-us.com, Michael Caramanis, Panagiotis Andrianesis, Alexandr Rudkevich, Pablo Ruiz

The objective of this paper is to work from the realities of the electric power system of today and look to alternate paradigms that can provide both insights and mathematical approaches to address the increases in risk and uncertainty brought about by renewable technologies and distributed energy resources. The development of the Black-Scholes and binomial models in option theory are but two examples of ways in which uncertain futures have been quantified in the financial sector. How can these be used to address the critical operational and planning variables of space and time in the electric sector.

4 - Fuel Neutrality in Capacity Markets

David Morton, Northwestern University, Evanston, IL, United States, david.morton@northwestern.edu

We investigate the fuel neutrality of capacity mechanisms implemented in liberalized electricity markets. We consider a stochastic equilibrium model for a competitive, but incomplete, market with risk trading. Our results suggest that introduction of a capacity mechanism can have asymmetric effect on the risk profile of different generation technologies. This is joint work with Jacob Mays and Richard O'Neill.

Natural Gas Markets II

Contributed Session

Chair: Felipe A. Feijoo, Pontificia Universidad Católica de Valparaíso, Av. Brasil 2241, Office 6-8, Valparaíso, Chile

1 - Are We Facing a Globally Integrated Natural Gas Market? – A Spatial Equilibrium Approach

Ekaterina Dukhanina, MINES ParisTech, Paris, France

We applied a spatial equilibrium model, allowing estimation of unobservable part of transaction costs and arbitrage rent, to examine the degree of integration between natural gas markets in different regions (i.e., Europe, North America, and Asia). Based on the optimality conditions of a swing LNG producer's profit-maximization problem, the model estimates probabilities of observing spatial equilibrium between the markets using maximum likelihood method. The results show that it is too early to speak about a perfectly integrated global gas market, because the estimated probability of the markets to be in spatial equilibrium remains low and a spatially inefficient trade is detected by the model.

2 - A Multistage Stochastic Programming Approach for Preventive Maintenance Scheduling of Gencos with Natural Gas Contract

Zhouchun Huang, Nanjing University of Aeronautics and Astronautics, Nanjing, China, zhouchun.huang@knights.ucf.edu, Qipeng Phil Zheng

A preventive maintenance scheduling problem is presented for generation companies (GENCOs) with natural gas power plants, taking into account signed natural gas contracts and the opportunity of purchasing and selling natural gas in the spot market. This paper considers the uncertain prices of both natural gas and electricity in the spot market, and develop a multistage stochastic mixed integer programming model seeking the optimal operations regarding generation dispatch, maintenance outage plan and natural gas trading. A progressive hedging algorithm based on the scenario-based decomposition is developed and implemented with parallel computing for solving large-scale problems.

Open-source Tools for Energy-Water-Land-Climate Assessment

Sponsored: Energy, Natural Res & the Environment/Energy

Sponsored Session

Chair: Daniel Huppmann, International Institute for Applied Systems Analysis (IIASA), Vienna, 1100, Australia

1 - Wind Power Versus PV: The Cost of Undisturbed Landscapes

Sebastian Wehrle, University of Natural Resources and Life Sciences, Vienna, Austria, Johannes Schmidt

In Austria, the system cost minimizing mix of renewable electricity generation technologies is dominated by wind power. However, land-use constraints may limit the deployment of additional wind turbines. Using the power system model MEDEA, we investigate the effects of substituting wind power with PV. Preliminary results suggest that a) a small deviation from the power system-wide least cost technology mix might be beneficial for Austria (but not for its neighbors) and b) strong substitution of wind power with PV increases system cost, emissions from power generation and producer surplus.

2 - An Open Platform or Optimizing Energy-water-land System Transformations Towards Sustainable Development

Adriano Vinca, International Institute for Applied Systems Analysis, Laxenburg, Austria, vinca@iiasa.ac.at
Adriano Vinca, University of Victoria, Victoria, BC, Canada, vinca@iiasa.ac.at, Simon Parkinson

The NExus Solutions Tool (NEST) is a new open modeling platform that integrates multi-scale water-energy-land (WEL) resource optimization with distributed hydrological modeling designed to aid decision-makers with complex planning regarding the integrated development of WEL resources in a river basin. NEST provides insights into the vulnerability of resources to future socioeconomic and climatic change and solutions to improve the resilience and sustainability of transformation pathways while avoiding counterproductive interactions among sectors. We apply NEST to the Indus River Basin, a region where long-term management of WEL systems is fundamental for the sustainable development.

3 - Reinforcement Learning Methods for Energy Market Auctions

Claude Kloeckl, University of Natural Resources and Life Sciences, Vienna, Austria, Johannes Schmidt, Christoph Graf

Auctions are essential in economics & the energy sector. Traditionally, auctions are treated by game theory, but analytical treatment is hard. Real-world game theoretic models (e.g.: the Italian energy market) introduce numerous binary constraints. This impairs their numeric solvability. An alternative may be reinforcement learning, that adapts an initially naive strategy towards an efficient strategy. It divides into q-learning & policy gradient methods. Both suffer from complementary drawbacks that hinder the analysis of auctions. Recently, deep q-learning gained attention by learning to play video games. It reconciles the disadvantages of prior methods and may help explain auctions.

4 - Hector - A Computationally-efficient, Open-source, Community-based Global and Regional Climate Emulator

Corinne Hartin, Joint Global Change Research Institute, Riverdale, MD, United States, Ben Bond-Lamberty, Pralit Patel, Robert Link, Abigail Snyder, Kalyn Dorheim

Recent developments to Hector, a reduced-form climate model and a series of open-source, computationally efficient, well documented tools allow a user to emulate global means from the CMIP5 archive (or any other climate model), sample parametric uncertainty space, and run large ensembles of regionally resolved temperature and precipitation based off on an arbitrary emission pathway. These capabilities open the door for significant research on human-earth system impacts within a fully coupled framework.

5 - The Potential for Re-powering Wind Turbines: Reducing Turbines, Increasing Output

Peter Regner, University of Natural Resources and Life Sciences, Vienna, Austria, Katharina Gruber, Johannes Schmidt, Claude Klöckl

Re-powering old wind turbines, i.e. replacing old ones by newer models, is a way of increasing energy output at productive locations, re-using existing infrastructure and reducing conflicts over land. We study the potential for re-powering wind turbines on the basis of a case study in the US. The increase of power output is estimated by simulating the output of an optimal deployment of new turbines using wind speed data. In addition, also other effects of re-powering, such as variability of output, size and distances between turbines, are assessed.

6 - Pyam: An Open-source Python Package for Integrated-assessment Analysis & Visualisation

Daniel Huppmann, International Institute for Applied Systems Analysis (IIASA), Vienna, 1100, Austria, huppmann@iiasa.ac.at, Matthew Gidden

We present the open-source `pyam` Python package for analysis, validation and visualisation of IAMC-style timeseries, including results from integrated assessment models of the energy system, sustainable development, and climate change mitigation. The talk showcases how `pyam` supported the assessment in the IPCC Special Report on Global Warming of 1.5°C, and steps to increase transparency and reproducibility of the IPCC analysis.

CC- Room 6A

Keynote: Structured Optimization for Dexterous Robots

Emerging Topic: Keynote

Emerging Topic Session

1 - Structured Optimization for Dexterous Robots

Russ Tedrake, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States

Despite the incredible apparent success of robotics on youtube, robots are still surprisingly bad at some tasks that we expect them to do well — for example, robots are still relatively inept when it comes to manipulating objects with their hands. A major challenge in robotic manipulation is the diversity of the desired tasks: how do we rigorously formulate the problem of chopping vegetables, or putting away the dishes? Taking an optimization-based approach, then what is the cost function and what are the constraints? Can we even evaluate the performance of the system before we have developed a perception system that is capable of interpreting raw camera images to understand the number and location of various vegetables and/or plates in the scene?

In this talk, I'll describe our attempts to bring rigorous tools from optimization to bear on the problem of "open-world" robot manipulation. I will describe the non-smooth mechanics of making and breaking contact between the robot and the world, and how planning and control for non-smooth mechanics can be formulated using combinatorial+convex optimization like mixed-integer programming and/or semidefinite relaxations. I'll describe the deep learning approaches that we are using for perception and learning "intuitive physics". And I'll describe some of the challenges of verifying learning autonomous systems of this complexity, including calibrating the complex distributions (with categorical and continuous random variables) that we use to describe the distribution over environments.

1 - Operations Research Methods for Enhancing Efficiency in Plant Breeding

Saba Moeinizade, Iowa State University, Ames, IA, 50014, United States, sabamz@iastate.edu, Guiping Hu, Lizhi Wang

Genomic selection (GS) is a technique that plant breeders use to select individuals to mate and produce new generations of species. To enhance the efficiency of breeding projects, we design an operations research framework to develop new GS algorithms. This framework has two main components: 1) Optimization and 2) Simulation. The first component is optimizing the selection, mating and allocation decisions that are critical in a breeding project and the second component is simulating the reproduction step to generate the next generation of individuals. We demonstrate the effectiveness of our algorithms using case studies with realistic datasets.

2 - A New Method for Plant Diseases Recognition with Small Dataset Based on Generative Adversarial Network

Guiping Hu, Iowa State University, 3014 Black Engineering, Ames, IA, 50011, United States, gphu@iastate.edu, Luning Bi

Convolutional neural network (CNN) is among the widely used methods for plant diseases classification with image data. However, training the model requires significant amount of labeled data. In most cases, the dataset used for training is often small due to significant data collection and annotation work. In this case, the CNN will have the overfitting problem. In this study, a Generative Adversarial Network (GAN) based method has been proposed to enlarge the dataset. Different from the ordinary GAN, our GAN is combined with a regularization kernel. Experiments show that adding the GAN-generated data effectively improves the recognition accuracy of plant diseases by 3%-5%.

3 - Designing Optimized Weighted Ensembles to Predict Corn Yield

Mohsen Shahhosseini, Iowa State University, Ames, IA, 50010, United States, mohsen@iastate.edu

Predicting corn yields for Iowa counties with the use of machine learning algorithms is the objective of this study. An optimization framework is designed that finds the optimal weights in creating ensembles from multiple individual learners with respect to tuned hyperparameters. The yields are derived from USDA-NASS. Besides, SSURGO database was used to obtain soil parameters, and weather information was retrieved from Daymet. The performance of designed framework is evaluated and compared with individual learners and unweighted average ensembles. Furthermore, data requirements for achieving acceptable prediction accuracy and ranking the importance of different inputs is discussed.

4 - Prediction of the Performance of Maize Hybrids via Machine Learning Methods Using Dna Markers and Seedling Transcriptome Profiles of Parents and Offspring

Fatemeh Amini, Iowa State University, Ames, IA, United States, famini@iastate.edu

Agronomic traits of maize hybrids with complex genetic architecture can be predicted by combining genomic data of both parents and offspring. As the dimension of variable (predictor) space increases, the model complexity increases with the reduction of information lost. To handle this challenge, a linear model is designed to predict the hybrids phenotypes using DNA and RNA sequence data from parents and offspring as its variable sets. Partial Least Squares (PLS) is used to predict gene expression patterns (RNA accumulation) of parents and offspring based on their DNA markers prior to predicting final traits. The proposed model was tested on 27 inbred parents and their offspring with ~6,600 genes.

5 - Deep Learning Based Models for Crop Yield Prediction

Saeed Khaki, Iowa State University, Ames, IA, 50010, United States, skhaki@iastate.edu

Crop yield is a highly complex trait determined by multiple factors such as genotype, environment, management practices, and their interactions. Deep learning models are powerful tools which can reveal the functional relationship between yield and these interactive factors. In this talk, we present how these models can be used to accurately predict crop yield across different environments.

1 - Human Learning-guided Design of a Transfer-learning Framework for Text Analytics

Long Xia, Virginia Tech, Blacksburg, VA, 24061, United States, longxia1@vt.edu, Alan Gang Wang, Weiguo Fan

Transfer learning has been widely utilized in many real-world applications, including text analytics. However, there is limited research on how to project this human learning ability and use cognitive theory to guide machine learning design. In this study,we follow the design science paradigms to propose a research framework to integrate different transfer learning approaches. We evaluate our design artifact on a wide spectrum of text analytics tasks, and consistent improvements could be obtained by our proposed transfer learning framework. The detailed implementations and results, as well as theoretical and practical implications will be presented.

2 - A Simulation Based Framework to Study Opinion Dynamics in Social Networks

Derya Ipek Eroglu, Virginia Tech, Blacksburg, VA, 24061, United States, deryaipek@vt.edu, Onur Seref

Learning opinion shifts over a social network using agents has been a trending topic of interest. In this study, we introduce a framework that combines text analytics, simulation, and machine learning to analyze underlying patterns in opinion dynamics in social media. We study the effect of information generated by users or news websites and shared by the agents on a social network to develop an opinion model. Based on this opinion model, we build a network-based simulation model, whose input comes from textual Twitter data. The output of the simulation model is then fed to a machine learning model to study the underlying opinion dynamics.

3 - Context Maps: An Efficient, Flexible and Interpretable Framework for Visualizing Text

Onur Seref, Associate Professor, Virginia Tech, Pamplin Hall, Blacksburg, VA, 24061, United States, seref@vt.edu, Sukhwa Hong, Michelle M.H. Seref

We present a novel text analytics framework that combines conventional text mining methods, graph theory, distributed representations, and information theory to create efficient, flexible, and interpretable visualizations for textual data that we call context maps. We apply context maps to consumer reviews to identify regions of interest with respect to contrasts in review features. We use information-theoretic measures to compare different context maps, and track changes over time for a longitudinal analysis of time-stamped corpora.

4 - Exploring the Landscape of Consumer Review Helpfulness via Context Maps

Sukhwa Hong, Virginia Institue of Technology, Pamplin College of Business, 880 West Campus Drive, Blacksburg, VA, 24061, United States, sukhwa@vt.edu, Onur Seref, Michelle M.H. Seref

Understanding qualitative factors of online reviews that determine the consumer's perceived helpfulness is important for understanding the purchase process and consumers' decision making. We study the qualitative factors that determine the helpfulness of online product reviews using context maps. We provide a comparative study of other text visualization methods in the literature as a benchmark and highlight the capabilities of context maps against these methods.

Optimization Methods for Data Assimilation

Sponsored: Data Mining

Sponsored Session

Chair: Dimitri Papadimitriou

1 - Data-driven MIP-based Optimisation for Efficient Failure Detection in Large-Scale Systems

Tiejun Ma, University of Southampton, Southampton, United Kingdom, Btissam Er Rahmadi

We propose a new Mixed-Integer Programming (MIP)-based Failure Detector (FD), which consists on estimating optimal FD parameters that explore the optimal trade-off between FD's performance metrics, such as accuracy and speed. We model the system as a MIP optimization problem that aims at maximizing performance metrics while considering network conditions and resource constraints. Basically, this FD analyses then fits the behavior of messages delays and losses to include them in the FD decisions. We also propose a heuristic algorithm to address scalability challenge. Collected test results (Amazon EC2) show consistent improvement of overall failure detection quality and scalability.

2 - Second-Order Optimization Methods for Data Assimilation

Dimitri Papadimitriou, University of Antwerp, 24 rue du Charme, Brussels, 1190, Belgium, dimitri.papadimitriou@uantwerpen.be

The interplay between optimization and data science has mainly focused since so far on either algorithmic or statistical data modeling methods. However, optimization methods underlying data assimilation, the process of combining time ordered data with computational model (based on dynamical systems) to learn hidden states and unknown parameters, also deserves attracting similar level of interest. Data assimilation finds a large spectrum of applications ranging from geophysics/climatology to biophysics and beyond. This paper analyzes second-order optimization methods underlying data assimilation. For this purpose, results obtained with representative datasets are being considered.

3 - Forecasting with Periodic Autoregressive Model and Support Vector Regression

Ku Ishida, Osaka University, Suita, Osaka, Japan, Hiroshi Morita

This study aims to predict seasonal data by using a periodic autoregressive model. We consider to perform feature selection and parameter estimation simultaneously by second-order cone optimization. Then we combine support vector regression to adjust residuals of a periodic autoregressive model by cross-validation criterion.

4 - A Revisit to Bayesian Model Averagingin Forecasting Influenza with Google Search Queries

Hao Pan, City University of Hong Kong, Hong Kong, Hong Kong, haopan2-c@my.cityu.edu.hk, Yang Zhao, Kwok Leung Tsui

Forecasting problem is one of the crucial considerations in the subject of epidemiology, especially in dealing with the influenza data with internet search queries. It's known that there is no single method perform best on all types of data, bearing their unique advantages and limitations. Under this circumstance, there has been an increasing interest in ensemble learning approaches to model assimilation for achieving better forecasting performance, typically by the Bayesian model averaging. In this work, we focus on the statistical properties of Bayesian model averaging in the forecasting problem. Additionally, we conduct a comparative study using the ILI-GOPC data in the U.S. and Hong Kong.

1 - Weighted Bayesian Support Vector Data Description

Mehmet Turkoz, Assistant Professor NTT, Rutgers University, Piscataway, NJ, 08854, United States, Romulo Ely

Support Vector Data Description (SVDD) is an important anomaly detection procedure which describes the target data with a spherically shaped boundary without needing any distribution assumption. However, the parameters of SVDD are obtained in a deterministic way for the target data and this may not be realistic in most of the real-life applications. Moreover, SVDD is sensitive to the selection of trade off parameter. To overcome these problems, we introduce a weighted Bayesian SVDD procedure by utilizing k-nearest neighbors based novel procedure to obtain the weight of each datum. We demonstrate the superiority of the proposed method by using various simulated and real-life data sets.

2 - An Inner Approximation-based Optimal Design Algorithm to Generate Experimental Points for Nonconvex Design Space

Mehmet Turkoz, Rutgers University, 16 Rachel Terrace, Piscataway, NJ, 08854, United States, turkoz@scarletmail.rutgers.edu, Akin Ozdemir

Traditional experimental designs are effective to generate experimental points under standard design spaces, such as cube or sphere. However, for a nonconvex design space, traditional experimental designs are not appropriate due to nonstandard design conditions. The aim of this paper is to develop a new algorithm based on an inner approximation approach for nonconvex design space. In addition, the proposed algorithm efficiently produces experimental points for nonstandard experimental situations. It is also provided a fair comparison of the performance of the proposed algorithm. In addition, numerical examples are presented to illustrate the proposed method.

3 - "Zooming Out the Map": Quality Manufacturing Applied to Input-output Analysis

Romulo Ely, MSIS - Rutgers Business School, Piscataway, NJ, 08854, United States, romulo.ely@rutgers.edu, Mehmet Turkoz

Although input-output (IO) databases (DB) are periodically produced by governamental institutions around the globe, non-governmental research groups are constantly building new databases. They adapt the DBs to their particular cases including estimating multi-regional IO DBs. Our work is applied to both cases. However, we understand that benefits are easily observed in particular cases such as the estimation of waste sectors and energy efficiency scenarios. We assess the replication of methods such as support vector data description into the field of IO analysis. Sectors where the aggregation is high are naturally more challenging to be treated. We suggest an approach to deal with such cases.

4 - How to Increase Out-of-home Advertising Ratings and Efficiency with Computer Vision and Deep Learning Methods

Marcus Studart, CR, San Marino, CA, United States, Romulo Ely

Quality improvement problems are usually applied to manufacturing processes. We squeezed and stretched the traditional approach, re-shaping and driving it to a unique type of industry: advertising. We enhance the capability to deliver the message to potential consumers by reducing the number of unsuitable receivers and raising the number of suitable receivers. Advertisings delivered to unsuitable receivers are like defective products, translated into a waste of resources. By using computer vision and deep learning methods in this work, we improve the efficiency of the message delivered by raising the rate of reaching the target audience

5 - Shape Theory and Topological Statistics

Kemal Gursoy, Assistant Professor, Rutgers University, 111 North 9th Avenue, Piscataway, NJ, 08904, United States, kgursoy@business.rutgers.edu

Normal 0 false false false EN-US X-NONE X-NONE The known methods of geometry and topology are now investigated to supplement and provide new tools to use for large scale of data. In this work shape manifold and manifold estimation would be investigated for possible applications.

1 - Statistical Methods for Quantifying Phenotypic Heterogeneity

Kevin Leder, University of Minnesota, Minneapolis, MN, 55455, United States, lede0024@umn.edu

An important problem when designing cancer treatment is understanding the heterogeneity of the cancer cellular population. While genomic methods can identify subpopulations, there are several shortcomings to such approaches. In particular, one is often more interested in phenotypic heterogeneity as opposed to genotypic heterogeneity. In this work, we develop a statistical method that uses easily obtained experimental data to quantify phenotypic heterogeneity in the cellular population. This method is demonstrated on experimental and simulated data. Based on joint work with J. Foo, A. Frigessi, A. Kohn-Luque and E. Ødegaard.

2 - Network-based Multimodal Physiological Data Fusion for Characterizing Dynamic Interactive Patterns

Miaolin Fan, Northeastern University, 360 Huntington Avenue, Boston, MA, 02115, United States, fan.mi@husky.neu.edu, Chun-An Chou

In this study, we aim to characterize the dynamic interaction of human body as a complex system present a new multimodal data fusion method. Representing the multimodal interactive patterns using network models, the underlying dynamics of interactions among the brain and peripheral physiological responses to different emotional states are modeled by joint recurrence plots and temporal network metrics. Our method was applied to a bench mark dataset (DEAP) for a three-level emotion classification task of valence and arousal using temporal network-based features. The results demonstrate the capability of our multimodal information fusion model at the signal level.

3 - Applications of Finite- and Infinite-horizon Markov Decision Processes for Robust Medical Decision-making

Vinayak Ahluwalia, University of Michigan, Ann Arbor, MI, 60026, United States, vahluw@umich.edu, Lauren N. Steimle, Brian T. Denton

Markov decision processes (MDPs) are models for sequential decision-making that inform decision making in many fields, including the treatment of chronic diseases. However, MDPs are subject to parameter ambiguity because parameters estimated from different data sources may lead to different recommendations. A study of this problem for solving finite-horizon MDPs to optimality succeeded with a branch-and-bound approach, so we extend the study to infinite-horizon MDPs and recommend algorithmic designs that minimize computation time. We use a computational study that demonstrates our algorithm's effectiveness on random test instances and a previously published model for HIV treatment.

4 - Feature and Instance Selection in Semi-supervised Learning for Smartphone-based Telemonitoring of Parkinsons Disease

Nathan B. Gaw, Arizona State University, Tempe, AZ, 85258, United States, ngaw1@asu.edu, Jing Li

Monitoring Parkinson's Disease (PD) with mobile devices can greatly affect treatment outcomes. Activity collected from smartphones can be transformed to useful features that can help better understand characteristics of the disease and monitor disease progression. We introduce a first-of-its-kind semi-supervised feature selection algorithm for prediction of PD severity using data collected from smartphones. This approach uses particle swarm optimization (PSO) for selection of smartphone-based telemonitoring features, and a graph-based sampling method that reduces the computational time by selecting a smaller-representative subset of the larger training data population.

5 - Developing Personalized Forecasts of High- and Normal-tension Glaucoma Progression using Kalman Filtering

Luke DeRoos, University of Michigan, Ann Arbor, MI, 48104, United States, lkbruski@umich.edu, Koji Nitta, Mariel Sofia Lavieri, Mark P. Van Oyen, Pooyan Kazemian, Chris Andrews, Kazuhisa Sugiyama, Joshua Stein

Machine learning techniques like Kalman filtering can provide personalized and dynamically-updated forecasts of glaucoma progression trajectories. We trained, tested, and validated a Kalman filter that can predict changes in mean deviation over a 5-year time horizon at different target intraocular pressures (IOP) for patients with high- and normal tension glaucoma. Clinicians and patients can use these personalized menus of target IOP to help guide management decisions.

1 - Under the Same Roof: Value of Shared Living in Airbnb

Yao Cui, Cornell University, Ithaca, NY, 14853, United States, yao.cui@cornell.edu, A. Yesim Orhun, Ming Hu

An important difference between lodging sharing economy marketplaces and traditional hotels is that the guest may be sharing the property with the host, which blurs the line between economic and social exchanges. In this paper, using Airbnb as a relevant application, we study how the social exchanges affect transaction prices in a sharing economy. We first offer empirical evidence that the guest's desire to stay with the host impacts transaction prices. The empirical evidence thus suggests that the guest may obtain a utility from staying with the host, which we term the social utility. We then theoretically investigate the implications of social utility for the sharing economy stakeholders.

2 - The Effect of Congestion and Queueing on Primary and Ancillary Product Sales

Ozge Sahin, Johns Hopkins University, Baltimore, MD, 11222, United States, ozge.sahin@jhu.edu, Ricard Gil

Businesses rely on their ancillary product sales in addition to primary goods to remain viable and profitable, in a congestion prone environment, understanding the effect of congestion on primary and secondary good sales is crucial. Using transaction-level data from a UNESCO World Heritage Site in Southern Europe, we investigate the impact of queuing and congestion on primary good sales and ancillary product sales.

3 - Sourcing Strategy under Financial Distress: Evidence From a Natural Experiment

Karca Aral, Syracuse University, Syracuse, NY, 13244, United States, Erasmo Giambona

We study financially distressed firms' sourcing strategy, both analytically and empirically. Using a difference-in-difference setting we find that firms near financial distress shifted to multi-sourcing following an increase in the protection of suppliers in case of buyer's bankruptcy. In line with our theory predictions, we also find that increasing supplier protection leads to an increase in buyer firms' performance (as measured by number of customers, sales, operating margin, and firm value).

4 - Sharing Demand Forecast with Retailer under Upstream Competition

Aditya Jain, Baruch College, Zicklin School of Business, New York, NY, 10010, United States, aditya.jain@baruch.cuny.edu

We analyze demand information sharing behavior of two competing manufacturer with a retailer. We show that by not sharing information a manufacturer ends up inflating its wholesale price as well as that of the competing manufacturer who may be sharing information. When product substitutability is low, this inflation increases the double marginalization and hurts all parties. However, when product substitutability is high, this inflation benefits manufacturers by allowing then to offset downward pressure on wholesale prices. Thus, in equilibrium the manufacturers share information in the former case, but do not share information in the latter.

1 - Predicting and Preventing Patient No-show Through Bayesian Decision Support Tool.

Serhat Simsek, Montclair State University, Montclair, NJ, 36830, United States

Patients who miss their appointments (no-shows) create difficulties for medical providers. No-shows reduce revenues and impair the delivery of quality healthcare. We employed Random Forest, Logistic Regression, Artificial Neural Network and their combinations (ensemble learning) to predict whether a patient will be a no-show. With public data, our results can be compared to other approaches easily. We also developed a web application that allows efficient appointment scheduling and thus can be used by clinics to reduce no-show rates while increasing the clinic's productivity.

2 - Stochastic Optimization Model with Bayesian Network Update: The Case of Breast Cancer Chemotherapy Treatment

Kazim Topuz, Assistant Professor of Business Analytics, University of Tulsa, Tulsa, OK, 74104, United States, kazim-topuz@utulsa.edu, Eyyub Yunus Kibis, Ozlem Cosgun

Machine learning algorithms and optimization models have been utilized to complement clinical treatment for breast cancer for the last decades. However, the heterogeneous nature of cancer along with patient-related factors increases the level of stochasticity in cancer treatment models. This study determines the optimal chemotherapy dosage and frequency for stage-II breast cancer patients by integrating Bayesian belief networks into a mixed integer-programming model. Results suggest that there is no rule-of-thumb treatment method; however, dosage and frequency should be adjusted based on prognostic factors.

3 - Aggregating Machine Learning Techniques for Predicting Diabetes in Imbalance Data

Tahir Bachar Issa, Aubun University, Auburn, AL, United States

In this talk, I will present a method based on aggregating independent machine learning techniques to combat class imbalance in binary classification. I first compare ensemble learning techniques using area under PR curves and show that Stochastic Gradient Boosting and Random Forest are the bests in this order. Next I will show that aggregating independent machine learning techniques such as Logistic Regression, Random Forest and Stochastic Gradient Boosting is superior to Random Forest and Stochastic Gradient Boosting in term of specificity and sensitivity. Finally I will show aggregating dependent techniques such as Trees and Random Forest does not improve the classification.

4 - Prediction of Patient Heterogeneous Drug Dispensing Behavior Using Finite Mixture Approach

Zhouyang Lou, Purdue University, West Lafayette, IN, 47904, United States, zlou@purdue.edu, Nan Kong

Some anticholinergic drugs are harmful, causing cognitive impairment, particularly to the elderly with multiple chronic conditions, and mental disorders. Anticholinergic burden (ACB) score is used to measure the harmfulness. To help pharmacists prevent patients' problematic drug use and alert physicians, we use pharmacy claims data to develop a prognostic model for predicting the heterogeneous patient ACB score trajectory. We use a finite mixture approach with incorporation of random effects to account for the unobserved heterogeneity.

5 - Do Analysts Mislead Medical Practitioners? A Comprehensive Analytics Technique to Better Detect Non-surviving Cancer Patients

Eyyub Yunus Kibis, The College of Saint Rose, Albany, NY, 12203, United States, Serhat Simsek, Ali Dag

Analysis of survival times of cancer patients is crucial for medical practitioners to determine possible outcomes and make better future-plans for the patients. In the literature, it is common to see employment of machine learning algorithms to predict survivability of cancer patients. We detected the common misleading methodology that has been used in the literature in predicting the surviving and non-surviving cancer patients and propose a comprehensive modeling technique that overcomes the issue of misprediction of survival. In order to illustrate the issue and its solutions, the comprehensive model is applied on rectum cancer data and results are validated with SEER breast cancer dataset.

Interpretable Machine Learning

Emerging Topic: Artificial Intelligence & Machine Learning

Emerging Topic Session

Chair: Tong Wang, University of Iowa, Iowa City, IA, 52245, United States

1 - Faithful and Customizable Explanations of Black Box Models

Himabindu Lakkaraju, Postdoctoral Fellow/Assistant Professor, Harvard University, Cambridge, MA, United States, hlakkaraju@hbs.edu

As predictive models increasingly assist human experts (e.g., doctors) in day-to-day decision making, it is crucial for experts to be able to explore and understand how such models behave in different feature subspaces in order to know if and when to trust them. To this end, we propose Model Understanding through Subspace Explanations (MUSE), a model agnostic framework which provides customizable and faithful explanations of any given black box. Experimental evaluation and user studies demonstrate that our approach can generate highly compact, easy-to-understand, yet accurate explanations.

2 - Focused Concept Miner (FCM): An Interpretable Deep Learning for Text Exploration

Dokyun Lee, Carnegie Mellon University, Tepper School of Business, Pittsburgh, PA, 15213, United States, Dokyun@cmu.edu, Emaad Manzoor, Zhaoqi Cheng

We introduce the Focused Concept Miner (FCM), an interpretable deep learning text mining algorithm to (1) automatically extract interpretable “concepts” from text data, (2) “focus” the mined concepts to explain any existing user-specified business outcomes, such as purchase conversion (linked to reviews read) or crowdfunding success (linked to project descriptions), and (3) quantify the correlational relative importance of each mined concept for business outcomes, along with their relative importance to other user-specified explanatory variables. Compared to existing methods that partially achieve FCM’s goals, FCM achieves higher interpretability and predictive performance.

3 - Hybrid Machine Learning: When an Interpretable Model Collaborates with a Black-box Model

Tong Wang, University of Iowa, Pappajohn Business Build, Iowa City, IA, 52245, United States, tong-wang@uiowa.edu

We find an interpretable substitute for a given black-box model on a subset of data where a black box is (nearly) overkill. This way, on this subset of data, the model gains complete interpretability and transparency, which is obtained at minimal cost or no cost of the predictive performance. Under this framework, we develop Hybrid Rule Sets (HyRS) model that uses decision rules to capture the subspace of data where the rules are as accurate or almost as accurate as the black-box provided. HyRS is agnostic to the black-box model. To train a HyRS, we devise an efficient search algorithm that iteratively finds the optimal model and exploits theoretically grounded strategies to reduce computation.

4 - Optimal Classification and Regression Trees

Jack Dunn, Interpretable AI, Cambridge, MA, 02141, United States, Dimitris Bertsimas

Decision trees have been one of the most widely used approaches in machine learning across industry and academia, due in large part to their interpretability. However, this interpretability comes at a price—the performance of classical decision tree methods is typically not competitive with state of-the-art methods. We present Optimal Classification and Regression Trees, a novel and tractable method that produces decision trees that deliver interpretability and state-of-the-art performance simultaneously. We show how the interpretability of these trees has led to transformational impact with a variety of cases in healthcare, insurance, financial services, cybersecurity, and more.

5 - Interpretable AutoML for Mission Critical Supply Chain Planning

Chantal Bisson-Krol, Kinaxis, Ottawa, ON, Canada

We introduce how we are using AutoML in our software at Kinaxis, a software company in the supply chain space based in Ottawa. Machine Learning of course is all the rage in industry, so we have had considerable demand from our customers for Machine Learning powered solutions. Our users are supply chain experts, we empower them to seamlessly benefit from Machine Learning by applying AutoML principles while at the same time ensuring interpretability of models and providing explainability of predictions which helps in establishing trust in users with limited or no Machine Learning experience.

1 - Chasing Total Solar Eclipses on Twitter

Yunhe Feng, University of Tennessee, Knoxville, TN, United States, yfeng14@vols.utk.edu, Wenjun Zhou, Qing Cao

With the popularity of social networks, big social data analytics are creating value in various applications, such as discovering trends, monitoring public emotions, and identifying human mobilities. In this paper, we take the opportunity of The 2017 Great American Eclipse, a once-in-a-lifetime event, to look into the potential social, emotional, and human movement impacts of a single event at a national level. We collected over five million English eclipse-mentioned tweets in a real-time manner using Twitter Streaming APIs. Then we profiled spatiotemporal distributions, extracted both hashtagged and latent topics, analyzed emotions, and revealed eclipse-chasing travel patterns.

2 - Context-aware Energy Disaggregation

Yuyue Chen, Drexel University, Philadelphia, PA, United States, Chuanren Liu

When data is collected at aggregated levels, one big challenge is to disaggregate the data into significant constituents to support fine-grained analysis. We develop a general framework to address this challenge and apply it for energy disaggregation. Specifically, with a single measure of household utility consumption, we aim to separate the aggregated energy consumption into measurements for specific appliances or activities. While most existing approaches are supervised with training data for good generalization performances, our framework discovers various types of inter-correlations in complex energy consumption systems to improve accuracy, robustness, and interpretability.

3 - A Machine Learning Approach to Identity the Model-based Behavior of the Mutual Fund Advisors

Wenqiang Feng, Sr. Data Scientist, HR & Block, Kansas City, MO, United States, von198@gmail.com

Mutual fund advisors in financial companies are following the models, e.g., platform codes, to trade mutual fund products. Hence, the compliance to the models is important for the financial companies. In this work, we propose a machine learning approach which is the first study to investigate the degree of model-based behavior of the mutual fund advisors. In particular, the proposed method implements a multinomial logistic regression model using PySpark, whereas the features include the information from the sale and redeem peak days of the transaction data. The evaluation results, together with positive client feedback, demonstrate the effectiveness and efficiency of our approach.

4 - Financial Performances Prediction Using Asynchronous Time Series

Zheng Zhang, University of Tennessee-Knoxville, Knoxville, TN, United States, zzhan100@vols.utk.edu, Wenjun Zhou

Many econometric and machine learning methods have been applied to financial performances predictions. However, asynchronous time series make analysis from classical theories cannot be applied directly. In this paper, we apply the traditional vector auto-regressive (VAR) model and weighted generalized elastic-net Granger (WEGEG) to forecast the financial indices based on predictors from social media and third-party platforms. We offer the financial institutions managerial suggestions when facing negative evaluations from the Internet. Moreover, we find that WEGEG performs better the state-of-art method especially when the distribution of the data is hard to be identified.

5 - Confounder Balancing for Treatment Effect Estimation

Wangcheng Yan, The University of Tennessee-Knoxville, Management Science, Knoxville, TN, 37996, United States, wyan3@vols.utk.edu, Wenjun Zhou

Causal inference, identifying the causal effect of a given treatment, is a fundamental problem in many disciplines. Randomized trials are needed to guarantee balanced confounders in two groups; However, this is often impossible, especially in high-dimensional data. In this work, we adopt and extend a new confounder balancing technique to obtain an unbiased estimation of the average treatment effect. When matching subjects by similarity in individuals’ confounders, this technique also differentiates the weights of these covariates, which is novel to existing literature. The experimental results on both synthetic and real-world data show the effectiveness and efficiency of this approach.

1 - Learning Manipulation Through Information Dissemination

Xinyuan Zhang, Sauder School of Business, University of British Columbia, Mochtar Riady Building, BI Z. 1 8-69, 15 Kent Ridge Drive, Vancouver, BC, 119245, Canada, xinyuan.zhang@sauder.ubc.ca, Jussi Keppo, Michael Jong Kim

We consider the problem of optimally manipulating a Bayesian learner through adaptive provisioning of information. The problem is motivated by settings in which a firm can disseminate possibly biased information at a cost, to influence the public's belief about a hidden parameter related to the firm's payoffs. For example, firms advertise to sell products. We study a sequential optimization model in which the firm dynamically decides on the quantity and content of information sent to the public. We solve the associated Bayesian dynamic programming equation and characterize the optimal manipulation policy in closed-form. We also encode the evolution of the public's belief under such manipulation.

2 - Thompson Sampling with Information Relaxation Penalties

Seungki Min, Columbia Business School, New York, NY, 10463, United States, SMin20@gsb.columbia.edu, Costis Maglaras, Ciamac Cyrus Moallemi

We consider a finite time multi-armed bandit problem, for which we develop a Bayesian framework that naturally generalizes Thompson sampling (TS). Analogous to TS that at each decision epoch pulls an arm that is best with respect to the randomly sampled parameters, our algorithms simulate the entire future reward realizations and take a corresponding best action, but in the presence of 'penalties' that prevent them from choosing an action overly optimized for a particular scenario. In construction of suitable penalty functions, we leverage ideas from the information relaxation framework that has been used to obtain performance bounds for the stochastic Markov decision processes via simulations.

3 - Misconducts in Organizations

Minglong Zhou, NUS, 1 Business Link, Singapore, Singapore, Jussi Keppo, Esa Jokivuolle

Insider misconducts has caught public attention recently. These misconducts arise partly from high-powered financial incentives that are influenced by laws, regulations, and firms own policies. In this paper, we model the interaction among lawmakers, firms, and their employees under the risk of insider misconducts. Employees, with private information, are potential cheaters. Firms interact with employees and enforce a certain level of costly monitoring. Lawmakers affect other parties' incentives by imposing legal penalties. Our model supports that middle management typically causes large-scale misconducts. We also study how the our model helps in designing effective regulations.

4 - Competition Between Two-sided Platforms under Demand and Supply Congestion Effects

N. Bora Keskin, Duke University, Fuqua School of Business, Durham, NC, 27708-0120, United States, bora.keskin@duke.edu, Fernando Bernstein, Gregory A. DeCroix

This paper explores the impact of competition between two ride-sharing platforms. Customers' and drivers' utilities are sensitive to the prices set by the platforms and to congestion in the system. We analyze and compare the equilibrium outcomes in two scenarios, one in which each driver works exclusively for a single platform ("single-homing") and another scenario in which drivers may work for both platforms ("multi-homing" or "multi-apping").

Joint Session APS/MSOM: Advances in Modeling Strategy and Behavior in Queueing Systems

Sponsored: Applied Probability

Sponsored Session

Chair: Ragavendran Gopalakrishnan, Cornell University, Ithaca, NY, 14853, United States

1 - Social and Monopoly Optimization in Observable Queues

Ran I. Snitkovsky, Tel Aviv University, George Weiss 20, Tel Aviv, 6997712, Israel, ransnit@gmail.com, Hassin Refael

Naor's celebrated paper studies customer decisions in an observable M/M/1 queue where joining-customers utility is linearly decreasing with the joining position. Naor derives the optimal threshold strategies for the individuals, social planner and monopolist, and proves the monopoly optimal threshold is smaller than the socially optimal threshold, which is smaller than the individually optimal one. Studies show, based on numerical observations and/or ad-hoc proof techniques, that this triangular relation holds within various specific setups. We point out properties that imply the aforementioned result, and suggest model applications for our findings.

2 - Strategic Servers in Queuing Systems and Dynamic Games

Hung Do, University of Vermont, Burlington, VT, United States, hdo@uvm.edu

We study the dynamic games of n-server queuing systems with strategic servers under different queue designs (e.g. single queue and queue design). We then extend our analysis to the case of asymmetric servers.

3 - Pooling Queues with Strategic Servers: The Effects of Customer Ownership

Hummy Song, The Wharton School, University of Pennsylvania, Philadelphia, PA, 19104, United States, hummy@wharton.upenn.edu, Mor Armony, Guillaume Roels

We examine how the performance of pooled versus dedicated queues compares when servers are strategic and exhibit varying degrees of customer ownership. We show that the benefits of pooling are in general completely annihilated in this setting. Keeping the scope of customer ownership unchanged, the choice of queue configuration is almost irrelevant unless (i) the customer unit holding cost is so low that the system operates at high utilization and (ii) servers care more about the processing time of the customers they are currently serving than about the waiting time of their customers in queue. Under these two conditions, adopting a dedicated queue configuration yields lower throughput times.

4 - To Pool or Not to Pool: Queueing Design for Large-Scale Service Systems

Yunan Liu, North Carolina State University, Raleigh, NC, United States, yliu48@ncsu.edu, Ping Cao, Shuangchi He, Junfei Huang

There are two queue structures in service systems: pooled structure where waiting customers are organized into a single queue served by a group of servers, and dedicated structure where each server has her own queue. Although the pooled structure, known to minimize the servers' idle times, is widely used in large-scale service systems, this study reveals that the dedicated structure, along with the join-the-shortest-queue routing policy, could be more advantageous for improving certain service levels. Using a fluid model substantiated by asymptotic analysis, we provide a performance comparison between the two structures for a moderately overloaded queueing system with customer abandonment.

Joint Session MSOM/Practice Curated: Assortment Planning in Retail Operations

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Stanley Lim, University of San Diego

1 - Improved Approximation Schemes for Sequential Assortment Optimization

Jacob Feldman, Olin Business School, Saint Louis, MO, 63108-1291, United States, jbfeldman@wustl.edu, Danny Segev

In this paper, we consider assortment optimization under the sequential MNL choice model. In this problem, the purchasing process of customers unfolds sequentially over T stages. Within each stage, the retailer selects an assortment of products to make available for purchase, with the intent of maximizing expected revenue. The caveat is that each product can be offered in at most one stage. Moving from one stage to the next, the customer either purchases one of the currently offered products according to MNL preferences and leaves the system, or decides not to make any purchase at that time. Our main contribution comes in the form of a strongly polynomial-time approximation scheme (PTAS).

2 - Scalability in Local Grocery Food Platforms: An Examination of Indirect Network Economies

Lina Wang, Arizona State University, Scottsdale, AZ, United States, lina.wang@asu.edu, Elliot Rabinovich, Timothy J. Richards

Key to the success of two-sided online platforms is their ability to increase their economic surplus by scaling simultaneously participation on both of their sides. We study this phenomenon through a structural model of indirect network economies in an online grocery platform. We estimate the number of vendors that maximizes consumers' demand and the economic surplus in equilibrium.

3 - A Generalized Markov Chain Model to Capture Dynamic Preferences and Choice Overload

Agathe Soret, Columbia University, New York, NY, 10027, United States, acs2298@columbia.edu, Vineet Goyal, Kumar Goutam

Many parametric random utility-based choice models have been considered in the literature to capture substitution. However, in these models, the probability of purchase increases as we add more options to the assortment, which is not true in many settings, because of choice overload. In this paper we address these serious limitations using a Markovian comparison model, which allows us to implicitly model the search cost in the choice process and thus model dynamic preferences and choice overload. We consider the assortment optimization problem where the underlying Markov chain is either of rank-1 (it generalizes the MNL model) or of low rank, and show it is NP-hard. We present a FPTAS in both cases.

4 - Sample Boxes for Retail Products: Bundling Experience Goods to Leverage Consumer Uncertainty

Alireza Yazdani, University of Oregon, Eugene, OR, United States, syazdani@uoregon.edu, Eren Basar Cil, Michael Pangburn

Consumers often try a few varieties of an experience product before establishing a shopping routine. Sample boxes potentially create value by helping consumers resolve their uncertainties regarding these varieties earlier and at a lower cost. In this paper, we study how firms and consumers share this added value under different market scenarios. We show that when a firm offers a sample box, consumers obtain equal or higher net expected surplus while the firm's expected profit may decrease. We also show that a firm can reverse the potential adverse profit impact of selling sample boxes by introducing an optimally specified future credit.

5 - Finding a Market for Ugly Produce: A Multiple Discrete-continuous Choice Analysis

Stanley Lim, University of San Diego, San Diego, CA, 85287, United States, stanleylim@sandiego.edu, Sanghak Lee, Sungho Park, Elliot Rabinovich

We examine demand for imperfect produce sourced from growers and sold directly to consumers via the Internet. We model consumers' multiple discrete choice and continuous consumption decisions to uncover relationships among choice, satiation effects, and utility maximization for wide assortments. We then estimate the value of assortment to improve revenues and provide guidance on inventory planning decisions.

New Technologies for Supply Chain Transparency

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Andre Du Pin Calmon, INSEAD, Fontainebleau, 77300, France

Co-Chair: Philippe Blaettchen, INSEAD, Fontainebleau, 77305, France

1 - The Value of Operational Transparency for Supply Chain Finance and Implications for Blockchain Adoption

Nikolaos Trichakis, MIT, Cambridge, MA, 02143, United States, ntrichakis@mit.edu, Jiri Chod, Gerry Tsoukalas

We examine how blockchains, which were originally designed to provide verifiability of digital goods transactions, can provide verifiability of physical goods transactions. We identify some of the unique implementation challenges and propose ways to mitigate them. To exemplify, we describe an open-source blockchain platform we developed and one of its use cases in agricultural supply chains. We then develop a theory showing how the proposed blockchain-enabled verifiability of physical goods transactions can be leveraged by high-quality firms to signal their operational capabilities through their upstream inventory orders, and thereby finance their operations more efficiently.

2 - A Blockchain Business Model for Green Sourcing

Xi Chen, University of Michigan-Dearborn, NUS Business School, Dearborn, MI, 119245, United States, xichenxi@umich.edu, Niyazi Taneri, Guangyu Wan, Saif Benjaafar

End-consumers pay substantial price premia for green certified sustainably sourced products. We investigate whether and how the pairing of a new technology like blockchain with an access-based business model can help better address information problems in the agro-supply-chain.

3 - Searching the Road From Farm to Fork: Adoption of Information Systems for Food Traceability

Philippe Blaettchen, INSEAD, Boulevard de Constance, Fontainebleau, 77305, France, philippe.blaettchen@insead.edu, Andre Du Pin Calmon, Sameer Hasija

Food supply chains are fraught with difficulties in certifying origins and managing contaminations. Modern technologies like blockchain promise to solve this problem with unprecedented levels of visibility into complex supply networks. They are prone to large network externalities, however, and so the path toward adoption is unclear. We analyze the optimal deployment strategy of a traceability system provider and ask whether the level of traceability attained is socially optimal. Specifically, we study how the nature of the product, the structure of the supply network, and the nature of the traceability system interact in the process of adoption.

4 - Traceability in Smallholder Supply Chains

Joann de Zegher, MIT Sloan, Cambridge, MA, 02142, United States, jfz@mit.edu

Smallholder farmers in developing and emerging economies supply over 50% of global food calories. These smallholder supply chains typically operate inefficiently, are non-traceable, and are difficult to study due to their informal nature. We will discuss how we are addressing these challenges holistically through the integration of large-scale field work and optimization.

Joint Session MSOM/SERV OP/Practice Curated: Platform Design in Nonprofit Sector

Sponsored: Manufacturing & Service Oper. Mgmt/Service Operations

Sponsored Session

Chair: Vahideh Manshadi, Yale University, New Haven, CT, 06511, United States

Co-Chair: Irene Yuan Lo, Stanford University, Stanford, CA, 94306, United States

1 - A Mechanism Design Approach for Medical Surplus Product Allocation

Can Zhang, Duke University, Durham, NC, 27708, United States, c.zhang@duke.edu, Atalay Atasu, Turgay Ayer, Beril L. Toktay

We analyze resource allocation problems faced by medical surplus recovery organizations (MSROs) that recovers medical products to fulfill the needs of under-served regions. We propose a mechanism design approach to elicit recipients' private needs information, and show that our proposed mechanism significantly improves MSRO's value provision compared with current practice.

2 - Operational Issues in Large Jail and Judiciary Systems

Charlie Hannigan, University of Chicago Booth School of Business, Chicago, IL, United States

We perform an analysis of a large jail and judiciary system with the goal of simultaneously reducing Length of Stay (LOS) and improving outcomes for detainees. Two primary issues contribute to high LOS: a large number of outstanding warrants and detainees' trials often lasting longer than their eventual sentences require. We model the jail as a queueing network and consider the benefits of letting low-level warrants expire. We also consider a continuous time choice model of detainees' behavior to estimate detainees sentence location sensitivity and resulting optimal trial termination time.

3 - Crowdsourcing Food Recovery: A Platform Design Study

Scott Rodilitz, Yale, New Haven, CT, 06511, United States

In collaboration with a nonprofit platform that relies on volunteers to transport weekly food donations, we leverage the heterogeneity in volunteer engagement levels by allowing "one-at-a-time" volunteers to sign up for last-minute individual recoveries while letting "adopters" sign up for weekly-recurring recoveries. We show that even though adopters provide certainty, prioritizing adoption may hurt the platform in the long run. This insight stems from our empirical analysis of volunteer behavior which reveals that having more recovery options positively impacts the engagement and retention of "one-at-a-time" volunteers.

4 - Optimal Facility Selection for Epa Compliance Assurance Program

Yasaman Mohammadshahi, PhD Student, Georgia Institute of Technology, Atlanta, GA, United States, yasaman@gatech.edu, Pinar Keskinocak, Beril L. Toktay, He Wang

EPA spends tremendous budget every year to inspect the facilities for compliance with the environmental laws. In this work, we utilize a multiarmed bandit frame work to help EPA with finding the optimal selection policy.

Managing Service Platforms

Sponsored: Manufacturing & Service Oper. Mgmt/Service Operations

Sponsored Session

Chair: Ozan Candogan, University of Chicago, Chicago, IL, 27708, United States

1 - The Unreasonable Effectiveness of Artificial Currencies

Artur Gorokh, Cornell University, Ithaca, NY, 14850, United States, ag2282@cornell.edu, Sid Banerjee, Krishnamurthy Iyer

The use of artificial currency markets to allocate resources over time is gaining in popularity - in cloud-computing platforms, food banks, etc. Despite this, little is known about the incentives and efficiency of such mechanisms. We will describe how simple repeated single-price auctions with artificial currencies enjoy surprisingly strong performance guarantees, for a wide class of combinatorial assignment problems, and under minimal rationality assumptions. Our results provide insights into how to set endowments, tradeoffs between notions of utility and fairness; they also uncover interesting connections between artificial currencies, fair allocation, and online decision-making.

2 - Multi-objective Online Ride-matching

Hai Wang, Singapore Management University, Singapore, 178902, Singapore, haiwang@smu.edu.sg, Guodong Lyu, Wang Chi Cheung, Chung-Piaw Teo

We study the multi-period multi-objective online ride-matching problem, in which the dynamic ride-sharing platform needs to match passengers and available drivers in real time considering multiple objectives without observing future information. We develop an efficient online matching policy that balances the trade-offs between objectives in a dynamic setting and provide a theoretical performance guarantee. We prove the proposed matching policy can achieve the "target-based optimal solution" that minimizes the distance to any pre-determined multi-objective target. Through numerical experiments using real data, we demonstrate that our approach brings value to all the stakeholders.

3 - Information Inundation on Platforms and Implication

Gad Allon, University of Pennsylvania, Philadelphia, PA, 19104, United States, gadallon@wharton.upenn.edu, Kimon Drakopoulos, Vahideh Manshadi

In this paper, we study a model of information consumption where consumers sequentially interact with a platform that offers a menu of signals (posts) about an underlying state of the world (fact). We show that in the presence of uncertainty about the accuracy of these posts, and as the number of posts increases, adverse effects such as slow learning and polarization arise. Specifically, we establish that, in this setting, bias emerges as a consequence of the consumer's screening process.

4 - Optimal Commissions and Subscriptions in Networked Markets

Hongfan Chen, University of Chicago, Chicago, IL, 60615, United States, hongfan.chen@chicagobooth.edu, John R. Birge, Ozan Candogan, Daniela Saban

We consider a platform that charges commission rates and subscription fees to sellers and buyers for facilitating transactions but does not directly control the transaction prices. We shed light on how the commissions/subscriptions should be set in networked markets. We provide a tractable convex optimization formulation to calculate the revenue-maximizing commissions/subscriptions. Our results highlight the suboptimality of commonly used payment schemes, and showcase the importance of accounting for the compatibility between different user types. Under mild assumptions, we establish that a revenue-maximizing platform achieves at least 2/3 of the maximum achievable social welfare.

1 - Sustainability in the Fast Fashion Industry

Xiaoyang Long, University of Wisconsin-Madison, Wisconsin School of Business, Madison, WI, 53706, United States, xiaoyang.long@wisc.edu, Javad Nasiry

A fast fashion system allows firms to react quickly to changing consumer demand by replenishing inventory (via quick response) and introducing more fashion styles. In this paper, we study the environmental implications of the fast fashion business model by analyzing its implications for product quality, variety, and inventory decisions.

2 - Enhancing Prepositioning Policies for Food Aid Supply Chains: An Economic Optimization Model for Usaid Food for Peace Program's Operations

Weijia Jing, Northeastern University, Boston, MA, United States, jing.we@husky.neu.edu, Ozlem Ergun, Keziban Rukiye Tasci, Stephen Vosti

United States Agency for International Development (USAID) office of Food For Peace (FFP) runs a global humanitarian supply chain. To help the organization achieving more effective decision making for procurement and food aid distribution, we built data driven models and a supply chain tool to apply optimization methods, ensuring cost effective procurement and distribution of food aid. Through scenario analysis, we developed insights on optimal prepositioning and warehouse location selection for a merged supply chain serving both long-tern operations and emergency response.

3 - Cost Analysis in Global Supply Chains with Tariff Increases Due to Trade Wars

Yuhong He, Assistant Professor, California State University-Fullerton, Fullerton, CA, 92831, United States, yuhe@fullerton.edu, Shuya Yin

This study demonstrates how tariff increases due to trade wars affect the members in supply chain network. More specifically, we focus on the effect of cost on global supply chain and how these effects are sensitive to the nature of products, the network structure, and the approach we incorporate the cost fluctuation.

4 - Dual Sourcing Models with Stock-out Dependent Substitution

Mustafa Hekimoglu, Assistant Professor, Kadir Has University, Istanbul, Turkey, mustafa.hekimoglu@khas.edu.tr, Alan Scheller-Wolf

Motivated by an example in the aviation industry, we introduce a finite horizon dual sourcing problem with stock-out dependent substitution (DSWS) which incorporates quality difference between two suppliers. Due to nonconvexity of the multi-period model, the optimal policy appears intractable. Using a proved relation between the optimal cost of DSWS and costs of other problem types - dual sourcing without substitution and single sourcing problems, we suggest two heuristics called dual index and inverse-dual index. Extensive numerical experiments show that the dual index policy outperforms other candidate solutions by at least 7% and its optimality gap is only 4% for short planning horizons.

Chair: Sebastian Souyris, The University of Texas at Austin, Austin, TX,United States

1 - On Last Mile Delivery in the Lake Tanganyika Region of the Democratic Republic of the Congo

Robert Montgomery, University of Chicago, Chicago, IL, United States, rmontgo0@chicagobooth.edu, Baris Ata

We study the effectiveness of strategic inventory placement in the last mile delivery context. We focus on systems with multiple modes of delivery transportation, where a high cost is associated with disruptions leading to delivery failures. The problem is motivated by work with an NGO providing preventative healthcare products to the Lake Tanganyika Region of the Democratic Republic of the Congo.

2 - Rent-to-Own Business Models in Developing Economies: An Empirical Analysis

Jose A. Guajardo, University of California-Berkeley, Haas School of Business, Berkeley, CA, 94720-1900, United States

The diffusion of technological innovations in developing economies has been facilitated by the use of rent-to-own business models, which give flexibility to customers by allowing them to make incremental payments over time. I empirically analyze an application of rent-to-own to the distribution of solar lamps in developing countries, characterizing different factors that influence operational performance.

3 - Peer Effects in the Diffusion of Solar Panels: A Dynamic Discrete Choice Approach

Sebastian Souyris, The University of Texas at Austin, Austin, TX, 10028, United States, sebastian.souyris@utexas.com, Jun Duan, Anantaram Balakrishnan, Varun Rai

We study the magnitude of economic factors and peer effects in the adoption of residential solar panels. We use a dynamic discrete choice model and perform counterfactual analysis to guide policy to incentivize adoption.

4 - Sourcing from a Self-Reporting Supplier? Strategic Communication of Social Responsibility in a Supply Chain

Tao Lu, Rotterdam School of Management, Erasmus University, Mandeville Building T09-03, Rotterdam, 3062 PA, Netherlands, Brian Tomlin

We examine whether supplier's social responsibility (SR) risk can be truthfully communicated through self-reported assessments. Adopting a cheap talk framework, we establish that truthful communication can occur if the buyer can audit (perhaps imperfectly) the supplier and the buyer's end market is sensitive to SR violations. Further, we show that the buyer may not benefit from a cheaper or more accurate audit capability.

Chair: Onur Boyabatli, Singapore Management University, Singapore, 178899, Singapore

1 - Supplier Diversification under Buyer Risk

Gerry Tsoukalas, Wharton School of Business, Philadelphia, PA, 19104, United States, Jiri Chod, Nikolaos Trichakis

When should a firm diversify its supply base? Most extant theories attribute supplier diversification to supplier risk. Herein, we develop a new theory that attributes supplier diversification to buyer risk. When suppliers are subject to the risk of buyer default, buyers may take costly action to signal creditworthiness so as to obtain more favorable terms. But once signaling costs are sunk, buyers sourcing from a single supplier become vulnerable to future holdup. Our theory can help explain sourcing strategies when risk in a trade relationship originates from the sourcing firm, for example, a small-to-medium enterprise or a start-up; a setting that has eluded existing theories so far.

2 - Platform Financing

Heikki Peura, Imperial College Business School, South Kensington Campus, London, SW7 2AZ, United Kingdom, h.peura@imperial.ac.uk, S. Alex Yang, S. Alex Yang

We consider how a two-sided platform manages its supplier through financing.

3 - The Impact of Production-budget Uncertainty on Stochastic Capacity Investment

Boya Yang, Singapore Management University, Singapore, Singapore, boyayang.2015@pbs.smu.edu.sg, Onur Boyabatli, Guiyun Feng

We consider a single-product firm that invests in capacity in the presence of demand and production-budget uncertainties. We examine how the budget variability and the correlation between budget and demand uncertainties shape the optimal capacity investment decision and firm's profitability. For example, we show that higher correlation increases the optimal capacity investment and profitability. We also investigate the significance of profitability loss incurred when the budget uncertainty is ignored, as commonly observed in the literature.

4 - The Endemic Population-trust and Supply Chain Networks

Volodymyr O. Babich, Georgetown University, McDonough School of Business, Washington, DC, 20057, United States, vob2@georgetown.edu, Gilles Hilary, Ziang Wang, Jing Wu

We apply the assortive matching theory of Becker (1973) to analyse the supply chain partnerships based on the endemic population trust attribute (trust of the communities in geographies where firms operate). Using a unique dataset, we find that the durability of supply chain links decreases in the trust distance in the steady state equilibrium, but increases in the average trust outside of steady state, after shocks to supply chains (hurricanes and class action lawsuits). This evidence is consistent with the strategic complementarity of the endemic population trust in supply chains partnerships and trust's role as capital affecting supply chain resilience.

1 - Expanding Access to Rooftop Solar through Community Solar Programs

Siddharth Prakash Singh, Carnegie Mellon University, Pittsburgh, PA, United States, siddharth.p.singh@gmail.com, Owen Wu

Several states in the U.S. have instituted enabling policies to encourage the development of community solar programs, with a view to expand solar access to customers who, for instance, are renters or do not have roofs suitable for rooftop solar. Community solar arrays are much larger than rooftop arrays and, therefore, enjoy economies-of-scale. The arrays are jointly owned by a community of subscribers in the locality; these subscribers typically pay a fixed fee and reap the benefits of the portion of the array owned by them. We study the interaction between the policy environment and commercial participation in community solar.

2 - Design of Electricity Demand-response Programs

Vishal Agrawal, Georgetown University, Washington, DC, 20057, United States, vishal.agrawal@georgetown.edu, Safak Yucel

Under demand-response programs, utility firms compensate electricity customers to reduce their consumption when the aggregate demand is expected to be high. Given that customers' demand is random and unobservable to a utility firm, the firm estimates the reduction in a customer's consumption by comparing observed consumption to an administratively set baseline. We study how the existence of a baseline affects the success of a demand response program by accounting for customers' participation and demand-shifting decisions.

3 - Estimating Supply Side Parameters with Local Entrants in Renewable Energy Market

Herbie Huang, University of North Carolina, Chapel Hill, Chapel Hill, NC, United States, Herbie_Huang@kenan-flagler.unc.edu, Nur Sunar, Jayashankar M. Swaminathan

Global warming has been rising as a pressing issue. One effective way to combat the global warming is to make the renewable energy technologies more accessible. Motivated by this, we study a renewable energy market to estimate local participation behavior of providers in the market.

1 - Risk Analysis and Structured Decision Making in U.S. Forest Service Research and Management

Bruce Marcot, USFS Pacific Northwest Research Station, Portland, OR, 97208, United States

USFS has been applying risk analysis and decision science to a wide variety of research and management issues, including: monitoring and threats assessments of federally-listed and at-risk species, impacts of engineering projects on research priorities, and analysis of potential injuriousness of introduced and invasive species. I review the SDM framework, tools for each stage, topics of study to aid applying SDM to natural resource risk management.

2 - A Structured Decision Making Approach to Addressing Wild Turkey Population Declines

Kelly Robinson, Assistant Professor, Michigan State University, East Lansing, MI, United States, kfrobins@msu.edu, Angela Fuller, Michael Schiavone, Duane Diefenbach, William Siemer

Turkey (Meleagris gallapavo) populations in New York have been declining in recent years. Reducing harvest of females during fall hunting season could potentially reduce the population decline but requires consideration of biological and social concerns. We used structured decision making to incorporate the multiple objectives associated with turkey hunting, stakeholder desires, and region-specific ecological and environmental factors that could influence fall harvest. The optimal fall harvest regulation was the most conservative of those evaluated, reflecting the concerns about recent declines in turkey abundance among agency wildlife biologists and the hunting public.

3 - Habitat Conservation Decisions for an Endangered Endemic Salamander in Alabama

Conor P. McGowan, USGS Alabama Cooperative Fish and Wildlife Research Unit, Auburn, AL, 36849, United States, cmcgowan@usgs.gov, Orin Robinson, J.J. Apodaca

We applied a decision dnalysis approach to habitat conservation decisions for the Red Hills Salamander (Phaeognathus hubrichti,), a severely range limited, endangered species in Alabama. Working with stakeholders, we developed an objectives hierarchy linking land protection actions to objectives and built a model to assess habitat quality for 5814 pixels of 1 square kilometer in the salamander's range and applied acquisition costs to each pixel. We devised a value function and calculated the value of each square kilometer under alternative objective weights. The results are being used by the State to identify land owners in the most valued pixels who are willing to sell their property.

4 - Spatial-temporal Variation Impacts Optimal Decision for Management of Feral Pigs (Sus Scrofa)

Melissa Price, University of Hawai'i at Manoa, Honolulu, HI, 96822, United States

Species distribution models are commonly used in spatial conservation planning to prioritize management decisions but seasonality is often excluded from the modelling process. In this study we aimed to address how temporal changes in species distribution might affect management decisions. We found significant variation in feral pig distribution between the two seasons of data collection. Incorporating the best-fitted model for each season into a prioritization framework aimed at addressing conservation and game management objectives led to different decision recommendations by season. This study highlights the importance of incorporating temporal variation into decision analyses.

5 - Multiple Objective Spatial Optimization for Managing 254 Invasive Species Across New York State

Jennifer L. Price Tack, Postdoctoral Researcher, Cornell University, Ithaca, NY, 14853, United States, jpricetack@cornell.edu, Qinru Shi, Carrie Brown-Lima, Jennifer Dean, Carla P. Gomes, Angela K. Fuller

Invasive species management decisions are inherently spatio-temporal, highly uncertain, and require consideration of species-specific biological attributes and treatment feasibility. We used structured decision making as a framework to develop a model for the spatial allocation of management actions considering multiple species that minimizes social, economic, and environmental impacts at the lowest cost. We apply our model to the management of 254 invasive species in New York and compute the Pareto frontier using a multi-objective optimization framework. Our approach provides managers with a robust decision and highly informative output for exploring tradeoffs among the objectives.

Chair: Murat Mustafa Koksalan, Middle East Technical University, Ankara, 06531, Turkey

1 - Interactive Two Response Design Parameter Optimization Considering Prediction Errors and the Specification Region

Melis Ozates, Middle East Technical University, Industrial Engineering Dept, Ankara, 06800, Turkey, mozates@metu.edu.tr, Gulser Koksal, Murat Mustafa Koksalan

We present an interactive approach to search for the desired parameter settings of a decision maker (DM) for the two-response product and process design problem. Our approach utilizes response surface models having prediction errors in the performance measures. The DM considers the magnitudes of prediction errors and nonconformance to specifications in searching for the solution. To aid the DM, we provide visual aids for joint prediction regions of selected solutions plotted over lower and upper specification limits and target values of the responses.

2 - UAV Routing to Maximize Information Gain in a Monitored Environment with Time and Radar Restrictions

Erdi Dasdemir, Research Assistant / PhD Student, Hacettepe University, Hacettepe University, Industrial Eng. Depart., Beytepe Campus, Cankaya, Ankara, Ankara, Turkey, edasdemir@hacettepe.edu.tr, Rajan Batta, Murat Mustafa Koksalan, Diclehan Tezcaner Ozturk

We address UAV routing to collect information from targets in a monitored environment. The information at each target varies by time. There are multiple trajectory options between target pairs with different travel time and threat attributes. A subset of targets may be visited in a mission due to time and detection threat considerations. The problem is a combination of target selection, determination of the sequence of visited targets and trajectories to follow between target pairs. We develop heuristics as well as a mixed integer program and implement a hybrid solution approach.

3 - Representing the Nondominated Set with a Small Subset in Multi-objective Mixed-integer Programs

Ilgin Dogan, University of California Berkeley, Berkeley, CA, 94708, United States, ilgindogan@berkeley.edu, Banu Lokman, Murat Mustafa Koksalan

In multi-objective mixed-integer programs (MOMIPs), generating a set of representative points to the decision maker often rises as an important practical issue since finding all nondominated points is typically hard. We observe that the shape and density distribution of nondominated frontier may be critical in defining the desired properties of the representative subset to be generated. We develop an exact algorithm to generate a small number of nondominated points that represent the frontier with a prespecified quality level. We perform extensive computational experiments yielding the outstanding performance of our approach in terms of solution quality and efficiency.

Mobility and Accessibility

Emerging Topic: Humanitarian and NotforProfit Operations

Emerging Topic Session

Chair: Pascal Van Hentenryck, Georgia Institute of Technology, Atlanta, GA, 30332, United States

1 - Mobility-on-demand Versus Fixed-route Transit Systems: An Evaluation of Traveler Preferences in Low-income Communities

Xilei Zhao, University of Florida, Gainesville, FL, United States, xilei.zhao@essie.ufl.edu, Xiang Yan, Yuan Han, Pascal Van Hentenryck, Tawanna Dillahunt

Transit observers envision future public transit to be integrated transit systems with fixed-route services running along corridors and on-demand ridesharing services covering lower-density areas. A switch from a fixed-route service to an integrated mobility-on-demand transit system, however, may elicit varied responses from local residents. This paper applies the ordered logit model to evaluate traveler preferences for a proposed integrated mobility-on-demand transit system versus the existing fixed-route system, with a particular focus on disadvantaged travelers in Detroit and Ypsilanti, MI. Most respondents preferred a mobility-on-demand transit system over a fixed-route one.

2 - Last-Mile Scheduling under Uncertainty

Thiago Serra, Bucknell University, Lewisburg, PA, 02139, United States, Arvind Raghunathan, David Bergman, John Hooker, Shingo Kobori

Shared mobility is revolutionizing urban transportation and has sparked interest in optimizing the joint schedule of passengers using public transit and last-mile services. Scheduling systems must anticipate future requests and provision flexibility to be adopted in practice. In this work, we consider a two-stage stochastic programming formulation for scheduling a set of known passengers and uncertain passengers that are realized from a finite set of scenarios. We present an optimization approach based on decision diagrams. We obtain, in minutes, schedules for 1,000 known passengers that are robust and optimized with respect to scenarios involving up to 100 additional uncertain passengers.

3 - An Integrated Car-and-ride Sharing System for Mobilizing Heterogeneous Travelers with Application in underserved Communities

Miao Yu, University of Michigan, Ann Arbor, MI, 48109, United States, miaoyu@umich.edu, Siqian Shen

We consider integrated car-and-ride sharing (CRS) for Type 1 drivers who rent shared cars and Type 2 passengers who need shared rides. We propose a two-phase approach where in Phase I we determine car allocation and Type 1 drivers to accept; in Phase II we solve a stochastic mixed-integer program to match the accepted Type 1 drivers with Type 2 users, and optimize their pick-up routes under random travel time. We demonstrate the performance of a CRS system using instances based on census data. We also demonstrate the computational efficacy of our decomposition algorithm benchmarked with the traditional Benders decomposition for solving Phase II.

4 - Design of Multimodal Transit Systems

Pascal Van Hentenryck, Georgia Institute of Technology, 755 Ferst Drive NW, Atlanta, GA, 30332, United States

This presentation reviews the design of on-demand multimodal transit systems that combine fleet of small vehicles with rail and buses. The presentation reviews the challenges and potential solutions to the design of such large-scale systems.

Best Service Science Paper III

Sponsored: Service Science

Sponsored Session

Chair: Ming-Hui Huang, National Taiwan University, Taipei, 10617, Taiwan

1 - The Effect of User-generated Content on Hotel Demand under a Competitive Framework

Sanghoon Cho, University of South Carolina, Columbia, SC, United States, Pelin Pekgun, Ram Janakiraman, Jian Wang

We investigate the impact of user generated content on hotel performance as captured by actual hotel bookings. We propose and estimate a consumer learning model that focuses on the effect of review sentiment on hotel demand taking into account the effect of competition and hotel prices. Drawing on prospect theory, we cast the competitive perception spillover effects in the form of gains and losses in review sentiment, and find that the relative negative sentiment has more influence on bookings than the relative positive sentiment.

2 - Call to Duty: Just-in-time Scheduling in a Restaurant Chain

Masoud Kamalahmadi, Indiana University, Bloomington, IN, 47405, United States, Qiuping Yu, Yong-Pin Zhou

Using a dataset of 1.4 million transactions from 25 stores of a full-service casual dining restaurant chain in the US, we study how just-in-time (JIT) scheduling (i.e., short-notice and real-time schedules) impacts worker productivity. We show that short-notice schedules do not harm server productivity but real-time schedules do, by 4.4%. We then propose an analytical scheduling model that accounts for both the value of staffing flexibility created through JIT scheduling and its impact on server productivity to inform the firm whether and how to use JIT scheduling to improve profitability. We show that restaurants can increase their profit by about 4.5% by incorporating our behavioral insights.

3 - Value of High-quality Logistics: Evidence from a Clash Between SF Express and Alibaba

Ruomeng Cui, Emory University, Decatur, GA, 30033, United States, ruomeng.cui@emory.edu, Meng Li, Qiang Li

In this research, we explore the extent to which customers value a high-quality delivery experience when shopping online. We exploit a natural clash between SF Express and Alibaba which resulted in Alibaba unexpectedly removing SF Express as a shipping option from Alibaba's retail platform for 42 hours in June 2017. We find that the removal of the high-quality delivery option from Alibaba's retail platform reduced sales by 14.56% during the clash, increased the contribution of long-tail to total sales by 3%, but did not impact the variety and logistics rating of sold products. We also find that the removal of SF Express is more obstructive for star, expensive and less-discounted products.

4 - The Armchair Decision: on Queue-length Information When Customers Travel to a Queue

Ricky Roet-Green, University of Rochester, Simon Business School, Rochester, NY, 14627, United States, ricky.roet-green@simon.rochester.edu, Refael Hassin

A common assumption in queueing models is that if a customer decides to join the queue, joining is instantaneous. This assumption does not fit real-life settings, where customers have to travel to a service facility, and while traveling, the queue length might change. Motivated by this realistic setting, we study how queue-length information prior to traveling impacts customers' decision to travel. We compare two models: when customers observe the service-queue state prior to traveling, and when no such information is available. We show that when system congestion is high, the provider can increase throughput by disclosing the queue-length information.

5 - Learning Personalized Product Recommendations with Customer Disengagement

Divya Singhvi, MIT, Cambridge, MA, 02139, United States, Hamsa Bastani, Pavithra Harsha, Georgia Perakis

We consider the problem of personalized product recommendations when customer preferences are unknown and customers decide to stay on the platform based on the quality of recommendations. We prove that bandit learning algorithms over-explore and the greedy policy under-explores in this regime. We propose a new learning algorithm that carefully balances the exploration-exploitation tradeoff in this setting and provably outperforms state-of-art algorithms in this setting.

6 - Decision Forest a Nonparametric Approach to Modeling Irrational Choice

Yi-Chun Chen, UCLA Anderson School of Management, Los Angeles, CA, United States, yi-chun.chen.phd@anderson.ucla.edu, Velibor Misic

An increasing amount of research has revealed that customers are not necessarily rational when making decisions. In this paper, we study a new nonparametric choice model that relaxes assumption of weak rationality. In this model, each customer type is associated with a binary decision tree. Together with a distribution over customer types, the resulting model, called decision forest, can represent any customer choice model, including those inconsistent with weak rationality. We theoretically characterize the depth of the forest needed to fit a data set and propose an efficient estimation method. We further demonstrate the effectiveness of the model on both synthetic and real transaction data.

CC- Room 4C-2

Service Pricing

Contributed Session

Chair: Mustafa Dogan, Carnegie Mellon University, Pittsburgh, PA, 15213, United States

1 - Frills and Product Pricing with Online Reviews

Yao Zhang, Northeastern University, Shenyang, China, yzhang@mail.neu.edu.cn, Cui Zhao

In this paper, we investigate the joint optimization of product pricing and frill decisions for a competitive online retailing market. We develop four game-theoretic models for the constructed frill scenarios, respectively. By comparing the equilibrium decisions under the four scenarios, we determine the optimal product price and frill strategies.

2 - Pricing Ancillary Service Subscriptions

Ruxian Wang, Johns Hopkins University, Carey Business School, Kensington, MD, United States, ruxian.wang@jhu.edu, Maqbool Dada, Ozge Sahin

We investigate heterogeneous customer choice behavior in the presence of main products, ancillary services with options of pay-per-use and subscription, as well as the outside option. Ancillary service subscription can help firms to better price-discriminate heterogeneous customers through different subscription decisions and subsequent purchase behavior.

3 - Strategic Timing and Dynamic Pricing in On-demand Platforms

Mustafa Dogan, Carnegie Mellon University, Pittsburgh, PA, United States, mdogan@andrew.cmu.edu, Alexandre Jacquillat, Vibhanshu Abhishek

We design a dynamic pricing and allocation mechanism for service provision in on-demand platforms facing demand stochasticity, heterogeneity across price-sensitive and time-sensitive customers, and information asymmetry. Time is a strategic device to dynamically manage the demand-capacity imbalances and to provide discriminated service levels. The optimal mechanism depends on the strength of customer heterogeneity and the time preferences of price-sensitive customers. The proposed mechanism increases platform profits as compared to dynamic pricing policies and to static screening menus. We show that optimal prices are not monotonic with demand; higher demand may trigger lower prices.

4 - Pricing Service Maintenance Contracts Using Predictive Analytics

Laurens Deprez, KU Leuven, Leuven, Belgium, Katrien Antonio, Robert Boute

Under a full-service agreement all maintenance costs are covered over a predetermined time horizon in exchange for a fixed premium. The stochastic and machine-dependent nature of the maintenance costs renders the determination of the premium challenging for the service provider. Inspired by insurance pricing, we use predictive analytics to determine the break-even price based on machine-dependent characteristics. We build a simulation engine to mimic the maintenance occurrences and their costs in a real environment and show the economic value of a differentiated pricing strategy.

5 - The Role of Gender and Excessive Financial Behavior in Financial Services

Dominik Piehlmaier, Assistant Professor of Marketing, University of Sussex, Brighton, United Kingdom

This study with more than 9,000 observations assesses the impact of gender on reckless financial behavior. It differentiates between investors who make their decisions independent of others and those who seek outside advice. Within the group of isolated decision-makers, women are equally likely to engage in reckless financial behavior and have a higher propensity to be negatively affected by multiple investment fees compared to men. These female investors are equally likely to believe that their portfolio will outperform the market, have a comparable propensity to make ad-hoc predictions of the average return of the S&P 500 over the course of the next 10 years, and are just as likely to trade on margin.

1 - Free or Fee the Values of Certifications in Online Labor Market

Qiang Gao, Baruch College, City University of New York, New York, NY, 10010, United States, Mingfeng Lin

Many online labor platforms implemented certification mechanism in order to increase worker contract winning probability. However, there is little empirical research on its impact on buyers' contract-awarding decision. Using data from one of the largest online labor markets, we first examine the effects of certification on worker's contract winning probabilities. Cost of certification may be the major factor that affects the effectiveness of certification. A policy change that made the certification test free on the studied platform provides a good opportunity for us to explore this relationship. We finally investigate whether certification reveals the workers' quality.

2 - Carrot or Stick? Check the Weather First: The Effect of Weather on Mobile-based Interventions for Physical Activity

Sanghee Lim, Assistant Professor, Johns Hopkins Carey Business School, Baltimore, MD, 21202, United States, lim.sanghee@jhu.edu, Nakyung Kyung, Byungtae Lee

In this study, we provide the results of a field experiment that examines the effectiveness of different mobile-based interventions (i.e., gain, loss, and neutral framed) in different weather conditions. Our results show the varying effects of gain- and loss-framed intervention depending on the weather: a loss-framed message is more effective on sunny days, while a gain-framed message is more effective on cloudy days. Based on the mood as resource theory, we provide a theoretical discussion that explains our results and advances our

3 - Making the Case: Describing the Value of the Internet of Things in Smart Cities

Joseph Taylor, Assistant Professor, California State University, Sacramento, Sacramento, CA, United States, joseph.taylor@csus.edu, Zafor Ahmed, Sadaf Ashtari, Ramakrishna Dantu, Evren Eryilmaz

The smart city industry is projected to be a $400 billion market by 2020, with 600 cities around the globe expected to generate 60% of the world's GDP by 2025 (Maddox, 2018). Although efficiency, accuracy, automation are often described as the benefits of IoT in smart city interventions, the process of value generation and its theoretical underpinnings are still emerging. This study draws from the organizational information processing view (OIPV) and Sociomaterialism theory to offer a systematic framework to researchers in this emerging area. Our findings and IoT use-cases offer valuable guidelines for policy-makes involved with smart-city initiatives.

Market Design and Societal Concerns

Sponsored: Auction and Market Design

Sponsored Session

Chair: Juba Ziani, Caltech, Pasadena, CA, 91106, United States

Co-Chair: Katrina Ligett

1 - Downstream Effects of Affirmative Action

Juba Ziani, Caltech, Pasadena, CA, 91106, United States, jziani@seas.upenn.edu, Sampath Kannan, Aaron Roth

We study a two-stage model: students are 1) admitted to college on the basis of an entrance exam (a noisy signal about their qualification/type), then 2) students who were admitted to college can be hired by an employer as a function of their college grades (a noisy signal of their type). Students are drawn from one of two populations with different type distributions. We study what kinds of fairness goals can be achieved by the college by setting its admissions rule and grading policy. We show that both goals we consider can be achieved when the college does not report grades. On the other hand, we show that they are impossible to achieve even in isolation when the college uses an informative grading policy.

2 - Incentivizing Fair Data Collection

Rachel Cummings, Georgia Tech, Atlanta, GA, 30332-0205, United States

A surveyor wants to accurately estimate a statistic on a population, but individuals belong to different subpopulations with differing response rates and failing to collect representative data can lead to inaccurate estimation. Alternatively the surveyor may require accurate estimation on every subpopulation, to ensure that minority subpopulations are not ignored. The surveyor can choose an investment level for each subpopulation to increase the response rate, e.g., by expending resources to better sample these people or compensate people for their responses. We study the optimal investment level in each subpopulation, and the corresponding trade-off between budget and fairness/accuracy.

3 - Statistical Fairness in Equilibrium

Christopher Jung, University of Pennsylvania, Philadelphia, PA, United States

We consider the application of machine learning in the criminal justice system and its implications for fairness through a micro-economic lense. We consider a model in which different populations have different distributions over outside options and decide whether or not to commit a crime by evaluating the value of their outside option together with the false positive/negative rates of the criminal justice system. Thus, modifying the system can change the underlying crime rates for both populations and can have unexpected effects on the posterior probability of criminality conditioned on the prediction of the learning algorithm. We study questions both of accuracy and fairness in this model.

4 - A Short-term Intervention for Long-term Fairness

Lily Hu, Harvard University, Cambridge, MA, United States, lilyhu925@gmail.com, Yiling Chen

We show that disparate labor market outcomes between social groups may be immovable even when hiring decisions are bound by an input-output notion of fairness. We construct a dynamic reputational model of the labor market that illustrates the reinforcing nature of asymmetric outcomes resulting from divergent accesses to resources. We adopt a dual labor market composed of a Temporary Labor Market, in which firms must hire to ensure statistical parity of workers granted entry into the pipeline, and a Permanent Labor Market, in which firms hire top performers as desired. This restriction induces an equilibrium that can Pareto-dominate those arising from strategies that employ agroup-blind criterion.

Health Care, Modeling and Optimization IV

Contributed Session

Chair: Nasibeh Zanjirani Farahani, Mayo Clinic, Rochester, MN, 55902, United States

1 - Diabetes Risk Modeling by Copulas Approaches

Hsing Luh, National Cheng Chi University, Taipei, Taiwan, slu@nccu.edu.tw

We derive the distribution of survival time under different risks of diabetes complications. In particular, we study the property of survival copulas and discuss the dependence measures associated with this construction.

2 - A Data Analytics Approach to Characterize Statin Use Among Prediabetic Patients

Alexandra Gentile, University of Arkansas, Fayetteville, AR, United States, amgentil@uark.edu, Shengfan Zhang

Prediabetes is characterized by elevated glucose levels putting patients at risk for Type 2 diabetes. Many patients are also at risk for cardiovascular disease (CVD). An effective treatment for CVD prevention is statin therapy; however, research has linked statins with the development of diabetes, causing controversy in the medical community as to whether prediabetic patients should be prescribed statins for CVD risk. In this study, we employ machine learning techniques using the National Health and Nutrition Examination Survey data to explore the association between patient characteristics and statin prescription for prediabetic patients.

3 - Machine Learning Approach for Building Reliable Integrated Emergency Medical Service Networks for Trauma Patients

Nasibeh Zanjirani Farahani, University of Missouri, Columbia, MO, United States, Moein Enayati, Salman Ahmad, Mihail Popescu, James Noble

Trauma injuries are a leading cause of death in the US, while reliable and efficient Emergency Medical Services (EMS) can increase the survival rate of such patients drastically. This research presents a machine learning approach to reduce the prehospitalization time, in medical transport networks. Innovative on-site evaluation of the trauma patients' health condition along with the performance measure of the trauma centers/intermediate clinics driven from EMS historical data is proposed as the key for better allocation of resources.

4 - An Algorithm of ICD-10-cm Auto-encoding for Inpatients with Comorbidity and Complication

Sheng-I Chen, Assistant Professor, National Chiao Tung University, HsinChu, Taiwan, sichen@nctu.edu.tw, Wei-Ting Hsu, Hsiu-Mei Wei, Ying-Ying Yang, Hao-Min Cheng, Ling-Yu Yang

ICD encoding influences the reimbursement of treatment claimed from healthcare insurance programs. It relies on specialists to reexamine information about the diagnosis and treatments of patients. We aim to facilitate such an operation by developing an algorithm to examine ICD-10-CM codes for multi-disease patients complicated by diabetes mellitus. We formulate the encoding decision as a network optimization problem using the extracting information of the diagnosis report and ICD code definitions. To tackle missing information in the diagnosis report, we develop a procedure to cluster similar diseases and then select to default code to represent ambiguous encoding results.

5 - Using Multi Input Deep Neural Network for Predicting Glucose Level in Diabetes Patients

Chi Wen Chang, UTSA, San Antonio, TX, United States, Adel Alaeddini

Type 2 diabetes (T2DM) is a major health problem that places a heavy burden on patients and the health care system. Using the correlation between diabetes and blood glucose levels, glucose levels and certain metabolic factors of the patients can be used to predict the level of diabetes. In this study, we research the temporal neural network (TCN) to predict the trajectory of glucose levels in multiple patients. Using real-world data sets, we demonstrate the effectiveness of neural networks in providing preventive measures for physicians and patients to reduce potential risks in diagnosis.

Tutorial: Deep Learning in Computer Vision: Methods, Interpretation, Causation and Fairness

Emerging Topic: Tutorials

Emerging Topic Session

1 - Tutorial – Deep Learning in Computer Vision: Methods, Interpretation, Causation and Fairness

Param Vir Singh, Carnegie Mellon University, Pittsburgh, PA, 15215-1437, United States, Nikhil Malik

Deep learning models have succeeded at a variety of human intelligence tasks and are already being used at commercial scale. These models largely rely on the standard gradient descent optimization of parameters W, which maps an input X to an output y =f(X;W). The optimization procedure minimizes the loss (difference) between the model output y and actual output y. As an example, in the cancer detection setting, X is an MRI image, while y is the presence or absence of cancer. Three key ingredients hint at the reason behind deep learning's power. (1) Deep architectures that can better adapt to breaking down complex functions into a composition of simpler abstract parts. (2) Standard gradient descent methods that can attain local minima on a nonconvex Loss(y,y) function that are close enough to the global minima. (3) Learning algorithms that can be executed on parallel computing hardware (e.g., GPUs), thus making the optimization viable over hundreds of millions of observations (X,y). Computer vision tasks, where the input X is a high-dimensional image or video, are particularly suited to deep learning application. Recent advances in deep architectures, i.e., inception modules, attention networks, adversarial networks and DeepRL, have opened up completely new applications that were previously unexplored. However, the breakneck progress to replace human tasks with deep learning comes with caveats. These deep models tend to evade interpretation, lack causal relationships between input X and output y and may inadvertently mimic not just human actions but human biases and stereotypes. In this tutorial, we provide an intuitive explanation of deep learning methods in computer vision as well as limitations in practice.

System Deterrence and Resiliency

Sponsored: Military and Security

Sponsored Session

Chair: Paul L Goethals, United States Military Academy, West Point, NY, 10996, United States

1 - Analyzing System Deterrence Through Attacker-Defender Games under Uncertainty

Sam Chatterjee, Pacific Northwest National Laboratory, Richland, WA, United States, Casey J. Perkins, Nick Betzsold, Robert T. Brigantic

Analyzing effects of defender actions on adaptive adversary behavior in a system security context is a challenging research problem. A defender with limited resources must adopt deterrent strategies to gain advantage against a resourceful adversary. This talk will outline multiple attacker-defender games under uncertainty to reason about deterrence. First, mathematical modeling elements of incomplete information games will be discussed. Then, a deep dive based on varying player perceptions and beliefs will be presented, including equilibrium solution concepts for signaling games and Hypergames.

2 - Operationalizing System Deterrence Through Signaling Games

Nick Betzsold, Data Scientist, Pacific Northwest National Laboratory, Richland, WA, United States, nicholas.betzsold@pnnl.gov

In this talk, we demonstrate an R Shiny app that implements attacker-defender signaling games for optimizing deterrence strategies. Signaling games provide a mathematical framework to reason about deterrence and model varying player beliefs/uncertainties. A key advancement in this research has been the development of an interactive tool that visually evaluates deterrence strategies, identifying favorable outcomes at equilibria. First, we discuss properties of deterrence and signaling games. Next, we present perfect Bayesian equilibria solution strategies. Finally, we showcase the Shiny app's power to assist an analyst and facilitate efficient systems-level deterrence analysis.

3 - Key Features of Effective CSIRT Processes

Prashanth Rajivan, PhD, University of Washington, Seattle, WA, United States, Norbou Buchler, Cleotilde Gonzalez

To counter the growing number of cyber attacks, organizations need high-performing security operation teams. At this point, it is unclear how cyber defense teams are organized in working together to mount and conduct an effective cyber defense. We collected data from Mid-Atlantic Collegiate Cyber Defense Competition using wearable social sensors to assess face-to-face interactions and using a teamwork instrument called OAT (Observational Assessment of Teamwork) to assess teamwork and leadership behaviors in cyber defense. Our results reveal key features of effective team processes defined by outcome measures of scored team success.

4 - A Hybrid Recovery Framework for Resilient Interconnected Network Systems

Nita Yodo, North Dakota State University, Fargo, ND, United States, Paul L. Goethals

To realize system resiliency following a disruption event, there are many recovery approaches that are deemed to be effective in recovering networked systems. The interconnected relationship between networks complicates the recovery process. A meticulously planned recovery approach that works well for a specific network, may lose its effectiveness when applied to interconnected networks. This research proposes a hybrid recovery framework where a set of effective recovery approaches will be fused together to obtain an integrated recovery plan that ensures a target resilience level is achieved.

Conic Optimization in Julia and JuMP

Sponsored: Optimization/Computational Optimization and Software

Sponsored Session

Chair: Juan Pablo Vielma, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States

1 - Complex Semidefinite and Sum-of-squares Optimization with Hypatia.jl

Christopher D. Coey, MIT, Cambridge, MA, 02138, United States, Juan Pablo Vielma, Lea Kapelevich

Motivated by applications in optimal power flow (OPF), we present sum-of-squares-based formulations for polynomial optimization problems over multivariate complex space. Using our new conic interior-point solver Hypatia, which can handle nonsymmetric cones, we solve large complex-SOS problems and perform performance comparisons.

2 - The Hypatia.jl Solver: Conic Interior Point Algorithms and Interfaces

Lea Kapelevich, Massachusetts Institute of Technology, Cambridge, MA, United States, Christopher D. Coey, Juan Pablo Vielma

We present Hypatia.jl, an open-source and highly-configurable conic interior point solver written in Julia. Hypatia is accessible through a native interface or though MathOptInterface (and hence JuMP). We demonstrate the generality of Hypatia's novel primal-dual algorithms for nonsymmetric cone optimization and discuss algorithmic features such as direct or indirect methods for linear systems, dynamical adjustment of numerical precision, and alternative central path proximity measures.

3 - Cutting Planes for Mixed-integer Conic Optimization

Mathieu Tanneau, Polytechnique Montréal, Montreal, QC, Canada, mathieu.tanneau@polymtl.ca, Andrea Lodi, Juan Pablo Vielma

We investigate the separation of disjunctive cuts for mixed-integer conic problems. Leveraging conic duality, we formulate a cut-generating conic program (CGCP) to separate violated disjunctive cuts. In particular, we study how the choice of normalization in CGCP impacts duality failures, thereby exposing challenges that are specific to non-linear settings. Then, we investigate how disjunctive cuts can be strengthened. We propose a geometric which, in a linear setting, reduces to classical monoidal strengthening. Finally, we report preliminary results on the strength of lift-and-project cuts on instances from the CBLIB library.

4 - Proxsdp.jl : Exploiting Low-rank Structure in Semidefinite Programming by Approximate Operator Splitting

Mario Souto, PUC-Rio University, Rio de Janeiro, Brazil, mariohsouto@gmail.com, Joaquim D. Garcia, Álvaro Veiga

ProxSDP is an open source semidefinite programming (SDP) solver developed in Julia language. ProxSDP solves general SDP problems by means of a first order proximal algorithm based on the primal-dual hybrid gradient (PDHG). The main advantage of ProxSDP over other state-of-the-art solvers is the ability of exploit the low-rank property inherent to several SDP problems. This feature allows the PDHG method to efficiently scale to larger instances.

1 - Separation Procedures for Pickup and Delivery Problem with Loading Constraints

Devaraj Radha Krishnan, Oklahoma State University, Stillwater, OK, United States, devaaero10z@gmail.com

In Pickup and Delivery problem (PDP), if multiple shipments are consolidated and placed in a vehicle, then Last-In-First-Out (LIFO) order for pickup and delivery becomes a desirable constraint. In this work, we relax the LIFO constraints and present exact formulations and a branch-and-cut algorithm for PDP with LIFO violation penalties. This is motivated by finding effective trade-off between travel distance and LIFO loading violation. Furthermore, we explore nested integral and fractional separation procedures within our branch-and-cut framework.

2 - Artificial Intelligence, Advanced Learners have Led to Development of New Classes of Systems

Giulia Pedrielli, Arizona State University, Tempe, AZ, United States, Giulia.Pedrielli@asu.edu

Artificial Intelligence, Advanced Learners have led to the development of new classes of Systems posing new challenges for optimal design and control. In this talk, we refer at large to Stochastic Optimization methods, where the focus is on families of algorithms that deliberately inject randomness in the search process. In this context, we try to develop methods to be applied in cases where, (1) there is no homogeneous dynamics of the systems, (2) high effective dimensions need to be considered, and (3) we can construct clever approximations of the system behavior to facilitate the process.

3 - Application of Black-box Global Optimization Techniques for Automatic Test Generation for the Falsification of Highly Complex Cyber-physical Systems

Logan Mathesen, Graduate Research Assistant, Arizona State University, Tempe, AZ, United States, lmathese@asu.edu, Giulia Pedrielli

We focus on developing global optimization techniques for requirements driven search-based test case generation for quickly finding falsifications, unsafe or undesirable behaviors, of Cyber-Physical Systems (CPS). We implement an instance of the Stochastic Optimization with Adaptive Restart (SOAR) black-box optimization framework, that adaptively alternates between an exploitative local search approach and an exploratory global search. This instance of SOAR is applied to the control protocol algorithm for a highly complex real-world Cyber-Physical System. We give insights to global optimization approaches to the falsification problem and give intuition on learned best practices.

4 - Pareto Center Based Parallel Surrogate Optimization Algorithm for Computationally Expensive Nonconvex Mixed-integer Black-box Optimization Problems

Limeng Liu, National University of Singapore, Singapore, Singapore, limeng_liu@u.nus.edu, Christine Shoemaker

This work introduces a parallel surrogate-based optimization method for computationally expensive nonlinear mixed-integer black-box Optimization Problems. The proposed algorithm, SOP-MI combines efficient parallel framework with multiple mixed-integer sampling method, which can solve nonlinear, non-convex mixed-integer problems efficiently. The parallel framework integrated ideas from multi-objective optimization and tabu search. Almost sure convergence is proved for proposed algorithm. In numerical experiments, results show that SOP-MI is significantly better than other compared algorithms especially when the objective function is multi-modal and with many local minimum.

5 - A Convex Optimization Framework for Robustness Analysis of Neural Networks

Mahyar Fazlyab, Postdoctoral Researcher, University of Pennsylvania, Philadelphia, PA, United States

Analyzing the robustness of neural networks against input uncertainties and adversarial attacks has many applications ranging from safety verification and sensitivity analysis to robust training. In this talk, we propose a semidefinite programming (SDP) framework for safety verification and robustness analysis of neural networks with general activation functions. Our main idea is to abstract various properties of activation functions (e.g., monotonicity, bounded slope, bounded values, and repetition across layers) with the formalism of quadratic constraints. We then show how we can analyze various properties of the abstracted network via semidefinite programming (SDP).

6 - 2d Tomography Using a Trans-dimensional Approach

Reetam Biswas, The University of Texas at Austin, Austin, TX, United States, reetam@utexas.edu, Mrinal Kanti Sen, Adrien Arnulf

Full Waveform Inversion (FWI) has become a powerful tool to generate high-resolution subsurface velocity model. FWI attempts to solve a non-linear and non-unique inverse problem and is traditionally based on a local optimization technique and thus quickly get stuck in local minima. To avoid this, FWI requires a good starting model, which in some cases need to be close enough to the true model. Here, we estimate a good starting model solving a first-arrival traveltime tomography of seismic data. We solve using a trans-dimensional approach, based on a Bayesian framework. The number of model parameters is treated as a variable. We use reversible jump MCMC to sample models, and estimate uncertainty.

Combinatorial Optimization

Contributed Session

Chair: Fernando Antonio Medrano, Texas A&M University-Corpus Christi, Corpus Christi, TX, 78412, United States

1 - Online Total Bipartite Matching Problem

Meghan Shanks, University of Illinois at Urbana-Champaign, Urbana, IL, United States, meghans2@illinois.edu, Sheldon H. Jacobson

This paper analyzes a variant of Online Bipartite Matching in which incoming vertices must be matched to some job, even if there are no available edges. A reward is only gained for matchings that are made across some edge. This paper describes lower bounds for the most general version of this problem. It then provides an optimal policy for this problem when the underlying bipartite graph meets certain conditions and identifies the most general conditions under which this policy is guaranteed to be optimal.

2 - Improving Nash Social Welfare Approximations

Peter McGlaughlin, University of Illinois Urbana Champaign, Urbana, IL, United States, mcglghl2@illinois.edu

We consider the fair allocation of indivisible goods among N agents using Nash social welfare (NSW) as our main fairness criterion. It is known that a max NSW allocation also meets multiple other fairness metrics and achieves Pareto optimality. However, existing approximations fail to satisfy all of the remarkable fairness guarantees offered by a max NSW allocation, instead targeting only the specific NSW objective. We address this issue by presenting a 2 max NSW, Prop-1, 1/(2N) MMS, and Pareto optimal allocation in strongly polynomial time.

3 - An Approximation Algorithm of Connected Maximum Coverage Problem for Detecting Mutated Pathways in Cancer

Xu Rao, University of California-Berkeley, Berkeley, CA, United States, Dorit Simona Hochbaum

The maximum k-coverage problem is to select, among subsets of a universal set, k sets the union of which maximizes the number of elements covered. The connected k-coverage problem has an underlying graph where each node is associated with a subset, and the goal is to select a connected subgraph on k nodes that maximizes the number of covered elements. This problem is inspired by mutated pathways detection, where a node represents a gene mutation associated with a set of patients with the mutation, and edges represent gene interactions. We introduce an efficient approximation algorithm for the problem, which improves on the state-of-the-art. This algorithm also applies to monotone submodular function.

4 - Submodular Maximization via Contention Resolution Schemes: A New Polyhedral Viewpoint

Simon Bruggmann, ETH Zurich, Zurich, Switzerland, Rico Zenklusen

Constrained submodular maximization enjoys a wide range of applications from machine learning to sensor placement. A standard way to approach such problem is via relaxation and rounding. Whereas almost problem-independent ways are known to approximately solve strong relaxations, the design of good rounding procedures is highly non-trivial. So-called contention resolution schemes became the most versatile rounding tool in this context. We present a novel, polyhedral viewpoint on how to construct and analyze them, and leverage it to design the currently best contention resolution schemes for matching constraints.

5 - A Model for the Dynamic Stable Set Problem

Christopher Muir, University of Tennessee-Knoxville, Knoxville, TN, 37922, United States, Alejandro Toriello

This work studies a dynamic model of the stable set problem. In this model, the topology of the graph is known probabilistically and information is revealed as vertices are added to the set. We show complexity results suggesting that even for restricted graph classes the problem is intractable. For the general case, we present polyhedral results and develop valid inequalities for the problem. Finally, we demonstrate the computational performance of the inequalities alongside various heuristic methods.

6 - The Complete Vertex P-center Problem: An Exact Set Covering Method with Brute Force Combinatorics

F. Antonio Medrano, Assistant Professor, Texas A&M University, Corpus Christi, Corpus Christi, TX, United States, antonio.medrano@tamucc.edu

The vertex p-Center problem (PCP) consists of locating p facilities that cover all n demands in order to minimize the maximum distance between a demand and the facility that covers it. The complete p-Center problem (CPCP) extends the formulation to solve the for all p-values from 1 to N, where N is the number of nodes to cover. This provides a complete coverage trade-off curve between number of facilities and coverage radius. We propose solving the CPCP using an iterative location set covering approach with selecting only radius values that have the potential to be exact solutions. Experiments find that this set covering method is very fast, especially when combined with brute force combinatorics.

Chair: Henry Lam, Columbia University, NY, United States

1 - A Semidefinite Programming Based Kernel Clustering Algorithm for Gaussian Mixture Models with Outliers

Prateek Raj Srivastava, The University of Texas at Austin, Engineering Training Center II (ETC), Austin, TX, 78712, United States, prateekrs@utexas.edu, Purnamrita Sarkar, Grani A. Hanasusanto

We consider the problem of clustering data points generated from a mixture of Gaussians in the presence of outliers. We propose a semidefinite programming based algorithm that takes the original data as input in the form of a Gaussian kernel matrix, uses the SDP formulation to denoise the data and applies spectral clustering to recover the cluster labels. We obtain theoretical guarantees on the error rate for our algorithm and show that the rate obtained is small provided there is reasonable separation between cluster centers. We compare the performance of our algorithm with existing algorithms like k-means, spectral clustering and other SDP-based formulations on simulated and real world datasets.

2 - Optimistic Likelihood Problems using Geodesically Convex Optimization

Man-Chung Yue, Imperial College London, 1st Floor, 1 Cobbold Road, Shepherds Bush, London, W12 9LA, United Kingdom, Viet Anh Nguyen, Soroosh Shafieezadeh Abadeh, Daniel Kuhn, Wolfram Wiesemann

When evaluating the likelihood of an observation, the nominal distribution for the observation is estimated from data, which makes it susceptible to estimation errors. To alleviate this issue, we propose to replace the nominal distribution with an ambiguity set containing all distributions sufficiently close to the nominal distribution. When this proximity is measured by the Fisher-Rao distance or the KL-divergence, the emerging optimistic likelihood can be calculated efficiently using geodesically or standard convex optimization. We showcase the advantages of our optimistic likelihoods on a classification problem using artificially generated as well as standard benchmark instances.

3 - Exploiting Partial Correlations in Distributionally Robust Optimization

Karthik Natarajan, Singapore University of Technology and Design, Singapore, 439959, Singapore

We identify partial correlation information structures that allow for simpler reformulations in evaluating the maximum expected value of mixed integer linear programs with random objective coefficients. In some cases, this lends itself to efficient representations that result in polynomial-time solvable instances, most notably for the distributionally robust appointment scheduling problem with random job durations as well as for computing tight bounds in PERT networks and linear assignment problems.

4 - Distributional Representation and Optimization under Coordinate-wise Monotonicity

Henry Lam, Columbia University, New York, NY, 10027, United States, henry.lam@columbia.edu

We consider the estimation of performance measures using distributionally robust optimization under coordinate-wise monotonicity of a multivariate density. We explain how this shape information is more robust than other similar candidates in the context of statistical extreme event analysis. We show a mixture representation for such class of densities using a new notion of rectangle embedding sets, and demonstrate how it facilitates the imposition of tractable optimization formulation.

1 - Price Coordination and Demand Learning in Platform Economies

Hongfan Chen, University of Chicago, Chicago, IL, 60615, United States, John R. Birge

This talk addresses the following questions: (i) Should a platform share its proprietary market information to decentralized sellers under demand model uncertainty? (ii) How should a platform design the price coordination mechanism under model uncertainty? We present results that provide answers to each question in a platform setting.

2 - Approximations for Markovian Contextual Bandit Problems

David Brown, Duke University, Fuqua School of Business, Durham, NC, 27708, United States, dbbrown@duke.edu

We study a class of contextual bandit problems; the model allows for both restless arms and stochastic budget constraints. We compare performance bounds based on approximate linear programming and Lagrangian relaxations, and develop a feasible policy based on these approximations. We show that the resulting policy is asymptotically optimal as the number of arms grows. We demonstrate the methods on an application involving a consumer learning about a new set of products through experience.

3 - Non Stationary Streaming PCA

Apurv Shukla, Columbia University, New York, NY, 10025, United States, apurv.shukla@columbia.edu

We consider the problem of streaming principal component analysis (PCA) when the observations are noisy and generated in a non-stationary environment. Given T, p-dimensional noisy observations sampled from a non-stationary variant of the spiked covariance model, our goal is to construct the best linear k-dimensional subspace of the terminal observations. We study the effect of non-stationarity by establishing a lower bound on the performance any algorithm. We establish the convergence behaviour of the noisy power method using a novel proof technique which maybe of independent interest. We conclude that the recovery guarantee of the noisy power method matches the fundamental limit.

4 - Learning Sparse Linear Models with Integer Coefficients

Cynthia Rudin, Duke, LSRC / Box 90129, Durham, NC, 27708, United States

I will present results on learning scoring systems, which are sparse linear models with integer coefficients. This is joint work with Berk Ustun and several medical collaborators.

Chair: Hongcheng Liu, University of Florida, Gainesville, FL, 32606, United States

1 - Stochastic Adaptive Cubic Regularization with Negative Curvature for Nonconvex Optimization

Seonho Park, University of Florida, Gainesville, FL, 32603, United States, seonhopark@ufl.edu, Panayote (Panos) M. Pardalos

In this work, we suggest an algorithm to extend the adaptive cubic regularized Newton method to exploiting negative curvature to update even at an unsuccessful iteration for minimizing nonconvex finite-sum functions. We call this method Stochastic Adaptive cubic regularization with Negative Curvature (SANC). We analyze the convergence guarantee to the second order stationary point. Finally, we provide experimental results including neural networks problems supporting the efficiency of our method.

2 - Global Error Bounds and Linear Convergence for Gradient-based Algorithms for Trend Filtering and Convex Clustering

Tianyi Lin, University of California-Berkeley, Berkeley, CA, 94706, United States, darren_lin@berkeley.edu, Nhat Ho, Michael Jordan

We propose a class of first-order gradient-type algorithms to solve structured filtering-clustering problems, include trend filtering and ℓ_1-convex clustering. Our first main result establishes the linear convergence of deterministic gradient-type algorithms despite the extreme ill-conditioning of the difference operator matrices in these problems. This result is based on a convex-concave saddle point formulation of filtering-clustering problems and the fact that the dual form of the problem admits a global error bound. Empirical results show that the proposed algorithms perform comparable to state-of-the-art algorithms, while presenting advantages for scalability.

3 - A Globally Convergent Algorithm for Tensor PCA

Bo Shen, Virginia Tech, Blacksburg, VA, 24061, United States, Weijun Xie, Zhenyu Kong

As one of important machine learning problems, Tensor PCA has been widely applied in signal processing, manufacturing processes, healthcare, etc. Existing approaches might be effective but often are not convergent. This research fills this gap by developing a globally convergent algorithm for Tensor PCA. Our numerical studies demonstrate that the proposed algorithm can be even more effective than the existing ones.

4 - An FPRAS for Strongly NP-hard Folded Concave Penalized High-Dimensional Generalized Linear Models

Charles David Hernandez, University of Florida, Gainesville, FL, 32603, United States

Please check the mobile app for this abstract.

5 - Nonparametric Stochastic Quasi-gradient Method in Stochastic Programming

Shuotao Diao, University of Southern California, Los Angeles, CA, 90007, United States, sdiao@usc.edu, Suvrajeet Sen

This paper studies a fusion of concepts of stochastic approximation and nonparametric statistical learning methods for predictive stochastic programming, which exploits the power of the predictor-response relationship. Nonparametric stochastic quasi-gradient method (Nonparametric SQG) which is general enough to include kNN estimation (SQG-kNN) as well as kernel estimation (SQG-Kernel) has been built to solve the problems in predictive stochastic programming. Under certain assumptions, the asymptotic convergence of Nonparametric SQG is guaranteed. The computational performance of both SQG-kNN and SQG-Kernel is demonstrated.

1 - Quantifying the Effect of Different Intermodal Terminal Facility Layouts via Simulation

Tyler Dick, U. of Illinois at Urbana-Champaign, Urbana, IL, 61801, United States

To provide industry practitioners with a better understanding of intermodal terminal capacity, this research investigates relationships between various capacity factors and intermodal terminal characteristics via simulation. A simulation model of a domestic intermodal terminal was developed using AnyLogic® software and used to test different facility layouts and operating scenarios.

2 - Testing Intermodal Terminal Optimization Models with Simulation

Patricia Randall, Princeton Consultants, Greenville, SC, 29605, United States, PRandall@princeton.com

Testing optimization models for Intermodal terminal operations requires a realistic, dynamic environment—but doing so in an actual terminal would disrupt operations. Simulation is a viable, robust testing platform for operational software with complex dependencies or for software that would be too costly or risky to test in the field. Simulation's capability to easily model the interaction between entities and incorporate various sources of uncertainty makes it a powerful testing tool for operational software. Highlighting a recent example, we will discuss the basics of simulation software, benefits for using it to test optimization solutions, and tips to get started.

3 - Air-high Speed Rail Intermodal Transport Network Design Problem of China

Dandan Li, Southwest Jiaotong University, Chengdu, 610031, China, 2016210837@my.swjtu.edu.cn, Mi Gan, Mingfei Wang

The rapid growth of e-commerce and the existed idle capacity of high-speed railway in China result in a novel intermodal transport pattern for express delivery, which is air-high speed rail transport(AHSR). In this research, the design of the AHSR network of China is studied. First, we analyze the status quo and feasibility of AHSR. Then, the potential hub city of AHSR network is determined by express demand forecasting and hub city centrality evaluation. Thirdly, the network design model is constructed through macro-planning and micro-operations views, respectively. The models and algorithms are verified by a real case of mainland China.

4 - System-wide Delay Optimizer for Train Schedules at Intermodal Facilities

Di Hoai Nguyen, BNSF, Ft. Worth, TX, United States, Amirali Ghahari

We study a train scheduling problem subject to capacity constraints at major intermodal facilities in a network. Each train carries some number of intermodal shipments (containers/trailers) from their origin facility to their destination facility. At each facility, the train requires processing on the lead tracks and strip tracks, both of which are capacitated. Given a system-wide train schedule which includes planned arrival/departure times for all trains, we formulate an Integer-Program which aims to minimize the system-wide cost of delays, while adhering to each hub's capacity limitations.

Chair: Jonathan Eckstein, Rutgers University, Piscataway, NJ, 02139, United States

1 - Robust Accelerated Gradient Methods

Mert Gurbuzbalaban, Rutgers University, Piscataway, NJ, 02139, United States

We study the trade-offs between convergence rate and robustness to gradient errors in designing a first-order algorithm. We focus on gradient descent and accelerated gradient methods for minimizing strongly convex functions when the gradient has random errors in the form of additive white noise. We define the robustness of an algorithm to noise as the asymptotic expected suboptimality of the iterate sequence to input noise power. We develop a framework that selects parameters of each algorithm to achieve a particular trade-off between rate and robustness. Our framework leads to several algorithms that can perform better than other state-of-the-art methods in the presence of random gradient noise.

2 - Forward-step Projective Splitting Methods for Convex Optimization and Monotone Inclusions

Patrick R. Johnstone, Postdoctoral Associate, Rutgers University, Piscataway, NJ, 08873, United States, patrick.r.johnstone@gmail.com, Jonathan Eckstein

We develop several new variants of the projective splitting method which can use forward steps rather than only resolvents. These results establish symmetries between projective splitting algorithms, the forward-backward splitting method (FB), and the forward-backward-forward method (FBF). Like in FBF, Lipschitz monotone operators require two forward steps within our projective splitting framework. Like in FB, cocoercive operators require one forward step. The stepsize constraints also coincide with the classical methods. Backtracking linesearch variants are also derived. With this progress, projective splitting has become a modern and powerful operator splitting framework.

3 - Rule-enhanced Classification and Regression Models

Ai Kagawa, Brookhaven National Laboratory, Upton, NY, 08854, United States, Jonathan Eckstein, Noam Goldberg

LPBR (LPBoost) and REPR (Rule-Enhanced Penalized Regression) are boosting as well as column generation (CG) methods for classification and regression problems, respectively. Both methods dynamically generate rules in each CG iteration. The combination of the generated rules with margin maximization and regularization can respectively produce robust classification and regression models. Their CG subproblems are the NP-hard RMA (Rectangular Maximum Agreement) problem, solved either heuristically or by exact parallel branch and bound.

4 - A Branch-and-bound Algorithm for Rectangular Maximum Agreement

Jonathan Eckstein, Rutgers University, Piscataway, NJ, 08854, United States, Ai Kagawa

We describe a branch-and-bound procedure for solving an NP-hard problem that arises as a subproblem in several machine learning contexts. Given observations in n-space with signed weights, the problem is to find an axis-parallel "box" set such that the sum of the weights of the observations it contains has maximum absolute value. We first describe a MIP formulation for this problem, which turns out to be difficult to solve. Next we describe an alternative, combinatorial branch-and-bound procedure and the various data structures and implementation techniques needed to make it practical. The algorithm has been implemented using PEBBL.

Chair: Somayeh Moazeni, Stevens Institute of Technology, Hoboken, NJ, 07030, United States

1 - Parametric Analysis of Semidefinite Optimization

Tamas Terlaky, Lehigh University, Bethlehem, PA, United States, Ali Mohammad Nezhad

We study parametric analysis of SDO problems w.r.t. the perturbation of the objective function. We study the behavior of the optimal partition and optimal set mapping in a so-called nonlinearity interval, and investigate the sensitivity of the approximation of the optimal partition in a nonlinearity interval. The approximation of the optimal partition is obtained from a bounded sequence of interior solutions on, or in a neighborhood of the central path. An upper bound on the distance between the approximations of the optimal partitions of the original and perturbed problems is presented.

2 - Low Order Complexity SDP/SOS Methods for Polynomial Optimization

Motakuri V. Ramana, Research Scientist and Consultant, Warangal, India

Polynomial optimization problems, i.e. optimization, feasibility and related problems involving polynomial functions where we seek globally optimal solutions or exact certifications, are very central and useful, as well as very hard class of NP-Hard problems. A class of Semidefinite Programming (or equivalently Sums of Squares) methods of single-exponential complexity for feasibility as well as general polynomial optimization problems will be presented, that are, to the contributor's knowledge, first known of that complexity order.

3 - Scaled Diagonally Dominant Tensors in Polynomial Optimization

Xin Shi, Lehigh University, Bethlehem, PA, United States, xis316@lehigh.edu, Luis F. Zuluaga

Diagonally dominate (DD) matrices and scaled diagonally dominant (SDD) matrices have been used in characterizing two subclasses of sum of squares polynomials (SOS). In our work, we construct two subclasses of positive semidefinite polynomials (PSD) which are based on DD tensors and SDD tensors. With the new subclasses, SOS programs and PSD programs may be relaxed to alternative LP programs and SOCP programs than the ones obtained from DD and SDD matrices. We characterize different relationships between these relaxations.

4 - Towards Efficient Approximation of P-cones

Yuriy Zinchenko, University of Calgary, University of Calgary, MS446, 2500 University Drive Nw, Calgary, AB, T2N 1N4, Canada

The second-order cone (SOC) has gained wide applicability in optimization. SOC may be effectively handled by interior-point methods and is well approximated with polyhedra. Ben-Tal and Nemirovski constructed an elegant 'optimal' approximation scheme where the number of linear inequalities grows logarithmically with approximation precision. In contrast, the situation with SOC extensions to p- cones remained dramatically different. Neither there are dimension-invariant SC-barriers for such cones, nor has one been able to approximate these cones efficiently. We describe a novel approximation approach and provide evidence that an efficient polyhedral approximation is within reach.

Sponsored Session

Chair: Kory Hedman

1 - ARPA-E Grid Optimization Competition: Challenge 1 Overview

Kory W. Hedman, Program Director, ARPA-E, US DOE, Washington, DC, United States, Kory.Hedman@hq.doe.gov

This discussion will focus on Challenge 1 of ARPA-E's Grid Optimization (GO) Competition. The GO Competition has been a year-long algorithm competition to solve security-constrained optimal power flow (SCOPF), a nonconvex network optimization problem that must be solved in real-time operations by utilities and ISOs. APRA-E has challenged competitors to build and execute new SCOPF algorithms that provide minimum cost operating solutions while maintaining grid reliability. This talk will provide an overview of the first year of the competition, including challenges and lessons learned.

2 - ARPA-E Grid Optimization Competition: Challenge 1 Top Performers

Ashley Arigoni, Lead Scientist, ARPA-E/QS-2, Denver, CO, United States, ashley.arigoni@qs-2.com

ARPA-E will invite top performing teams in Challenge 1 of the Grid Optimization (GO) Competition to present their successful algorithms and strategies. This talk will highlight innovative and transformative methodologies which are expected to improve upon grid software presently used in real-time operations. The top performers in Challenge 1 will showcase approaches that will be representative of the software evolution required by industry to feasibly accommodate and optimally dispatch a modern electric grid consisting heavily of distributed and intermittent resources.

3 - ARPA-E Grid Optimization Competition: Challenge 1 Results

Jesse T. Holzer, Pacific Northwest National Laboratory, Richland, WA, United States, jesse.holzer@pnnl.gov, Stephen T. Elbert

We have results from the ARPA-E Grid Optimization Competition Challenge 1! Over 20 teams of researchers, from across the U.S. and around the world, brought together expertise in power systems, optimization, and software engineering to develop innovative solution methods for a challenging security constrained AC optimal power flow problem. We've put their algorithms to the test in our HPC environment on a suite hundreds of problem instances over a range of sizes and difficulties. We'll share some highlights and welcome the top solvers to tell us about their approaches.

4 - ARPA-E Grid Optimization Competition: Challenge 1 Methodologies

Carleton Coffrin, Los Alamos National Laboratory, Los Alamos, NM, United States

The security-constrained optimal power flow (SCOPF) problem is a non-convex mixed integer program that plays a critical role in the daily operations of modern power systems. Industrial SCOPF instances are large-scale, featuring thousands to millions of decisions variables, and need to be solved very quickly, on the order of minutes. Together these real-world requirements present a formidable optimization challenge. This presentation provides an overview of the key approaches to exploiting the structure of the SCOPF problem to solve industrial-scale instances and investigates the quality-performance trade offs of different solution methodologies.

Recent Advances in Non-Convex Optimization

Sponsored: Computing

Sponsored Session

Chair: Andres Gomez, University of Pittsburgh, Pittsburgh, PA, 15217, United States

1 - Polyhedral Results for Tree Ensembles Optimization

Jongeun Kim, Bijan Taslimi, Mohit Tawarmalani, Piscataway, NJ, 02139, United States, Jean-Philippe P. Richard

Tree ensemble models are often used as regression functions to predict the effect of input variables. Recently, optimization of tree ensembles has been introduced as a tool for making optimal decisions that maximize profit or minimize cost. In this talk, we propose a new mixed-integer programming formulation for this problem that uses a combination of the reformulation-linearization technique and graph-theoretical concepts.

2 - Approximation Algorithms for the Maximum Entropy Sampling Problem

Yongchun Li, Virginia Tech, Blacksburg, VA, United States, liyc@vt.edu, Weijun Xie

This paper studies the maximum entropy sampling problem (MESP), which selects the most informative principal submatrix of a given size from a positive semidefinite matrix. We first derive a new convex integer programming formulation for MESP. Using the convex relaxation solution, we propose a sampling algorithm and its deterministic implementation, which improves the best known approximation bound. We also analyze the commonly used local search algorithm for MESP and prove its first known approximation bound. Finally, we extend our analyses to other selection criteria.

3 - Exact Guarantees on the Absence of Spurious Local Minima for Non-negative Robust Principal Component Analysis

Salar Fattahi, University of California-Berkeley, Berkeley, CA, United States, fattahi@berkeley.edu, Somayeh Sojoudi

This work is concerned with the non-negative robust principal component analysis (PCA), where the goal is to recover the non-negative principal component of a data matrix precisely, where some measurements could be corrupted with sparse noise. Most of the techniques for the robust PCA rely on convex relaxation methods, which significantly increase the number of variables. In contrast, the Burer-Monteiro approach can be used to cast the robust PCA as a non-convex l-1 optimization problem with a significantly smaller number of variables. In this work, we show that this formulation of the positive robust PCA has no spurious local minima and its global minimum coincides with the true component.

4 - Worst-case Iteration Bounds for Log Barrier Methods for Problems with Nonconvex Constraints

Oliver Hinder, Stanford University, Stanford, CA, United States, Yinyu Ye

Interior point methods (IPMs) that handle nonconvex constraints such as IPOPT, KNITRO and LOQO have had enormous practical success. Unfortunately, current analyses of log barrier methods with general constraints implicitly prove guarantees with exponential dependencies on $1/\mu$ where μ is the barrier penalty parameter. We provide an IPM that finds a μ-approximate Fritz John point by solving $\mathcal{O}(\mu^{-7/4})$ trust-region subproblems when the objective and constraints have Lipschitz first and second derivatives.

5 - Naive Feature Selection: Sparsity and Robustness in Naive Bayes

Armin Askari, UC Berkeley, Berkeley, CA, United States, aaskari@berkeley.edu, Laurent El Ghaoui, Alexandre d'Aspremont

Naive Bayes remains an attractive classification method, especially in very large-scale settings. We propose a cardinality-constrained version of naive Bayes, which can be used for feature selection. This leads to a combinatorial maximum-likelihood problem, for which we provide an exact solution in the case of binary data, or a bound in the multinomial case which becomes tight as the sparsity level increases. We then consider the case when the data is not exactly known, and develop robust maximum likelihood (max-min) counterparts. Numerical experiments show that our model is competitive with other feature selection methods, while being orders of magnitude faster to train.

New Discrete Optimization Approaches for Machine Learning

Sponsored: Computing

Sponsored Session

Chair: Cong Han Lim, Georgia Institute of Technology, Atlanta, GA, United States

1 - Rank-one Convexification for Sparse Regression

Alper Atamturk, University of California-Berkeley, Industrial Eng. & Operations Research, Berkeley, CA, 94720-1777, United States, Andres Gomez

We derive new strong convex relaxations for sparse regression based on the convex-hull formulations for rank-one quadratic terms with indicator variables. The new relaxations can be be formulated as semidefinite optimization problems. The proposed rank-one strengthening can be interpreted as a non-separable, non-convex sparsity-inducing regularizer, dynamically adjusting its penalty according to the shape of the error function. In our computational experiments with benchmark datasets, the proposed conic formulations are solved within seconds and result in near-optimal solutions with high prediction accuracy and good interpretability for non-convex L0 problems.

2 - An Approximation Algorithm for Training One Node RELU Neural Network

Guanyi Wang, Georgia Institute of Technology, Atlanta, GA, 30332, United States, gwang93@gatech.edu

Training a ReLU regression is a fundamental optimization problem in deep learning. Starting with the NP-hard result of training a ReLU regression, we present an approximation algorithm and analyze the performance of this algorithm under two settings. (1) Given any arbitrary sample points, the approximation algorithm guarantees a n/k approximation ratio. (2) Assume an underlying statistical model, the same algorithm gives an approximation ratio independent of n asymptotically. In practice, the approximation algorithm works better than gradient-descent type (GDT) methods in some cases, and the solution of the approximation algorithm can be used as a starting point of GDT methods.

3 - Conic Subspace Clustering: Paradigm, Algorithms, and Applications

Amin Jalali, Self, Palo Alto, CA, United States, Rebecca Willett

Given samples lying on a few unknown subspaces, subspace clustering amounts to identifying a partition of samples consistent with the corresponding subspace memberships. Many subspace clustering methods first solve a convex optimization problem, based on the so-called self-expressiveness paradigm, to derive a graph embedding, and then feed these affinities into a graph clustering procedure. Conic Subspace Clustering (CSC) is a new paradigm that makes use of the underlying geometry of normalized samples to derive the graph embedding. We will cover important aspects of this new paradigm and how they lead to fast novel algorithms for new regimes of subspace clustering with provable guarantees.

4 - An Efficient Pruning Approach for Robust Isotonic Regression

Cong Han Lim, Georgia Institute of Technology, Atlanta, GA, 30328, United States, clim31@gatech.edu

We study a variant of the classic isotonic regression problem where we use separable robust estimators in the objective function. One can use a simple dynamic program to solve this to within -accuracy (of the global minimum) in O(n/) steps. This approach ignores any inherent properties of the estimators. We combine techniques from the convex case with branch-and-bound ideas, leading to a novel algorithm where the complexity scales with the shape of the functions. This achieves the best known bounds for both the convex (O(nlog(1/)) and the general nonconvex cases. Experiments show that our approach can perform much faster than the DP approach, especially as the desired accuracy increases.

1 - Scaling Up Quasi-newton Algorithms: Communication Efficient Distributed SR1

Majid Jahani, Lehigh University, Kehigh University, Bethlehem, PA, United States, maj316@lehigh.edu, Reza Nazari, Albert Solomon Berahas, Sergey Rusakov, Martin Takac

In this paper, we present a scalable distributed implementation of the S-LSR1 algorithm [1]. First, we show that a naive implementation of S-LSR1 requires multiple rounds of expensive communications at every iteration and thus is inefficient. We then propose DS-LSR1, a communication-efficient variant of the S-LSR1 method, that drastically reduces the amount of data communicated at every iteration, that has favorable work-load balancing across nodes and that is matrix-free and inverse-free. Our method scales well in terms of both the dimension of the problem and the number of data points. [1]Berahas, A. S., Jahani, M., & Taká , M. Quasi-Newton Methods for Deep Learning: Forget the Past, Just Sample

2 - The Proximal Primal-dual Algorithm for Fast Distributed Nonconvex Optimization and Learning Over Networks

Davood Hajinezhad, SAS Institute, Cary, NC, 27707, United States, dhajinezhad@gmail.com, Mingyi Hong, Ming-Min Zhao

In this paper we consider nonconvex optimization and learning over a network of distributed nodes. We develop a Proximal Primal-Dual Algorithm (Prox-PDA), which enables the network nodes to distributedly and collectively compute the set of first-order stationary solutions in a global sublinear manner. To the best of our knowledge, this is the first algorithm that enables distributed nonconvex optimization with global sublinear rate guarantees.

3 - Fast Distributed Optimization via Anderson Accelerated Douglas Rachford Splitting

Junzi Zhang, Stanford University, Stanford, CA, United States, Anqi Fu, Stephen P. Boyd

We consider the problem of finite-sum non-smooth convex optimization with general linear constraints, where the objective function summands are only accessible through their proximal operators. To solve it, we propose an Anderson accelerated Douglas-Rachford splitting (A2DR) algorithm, which combines the scalability of Douglas-Rachford splitting and the fast convergence of Anderson acceleration. We show that A2DR either globally converges or provides a certificate of infeasibility/unboundedness under very mild conditions. We describe an open-source implementation (https://github.com/cvxgrp/a2dr) and demonstrate its outstanding performance on a wide range of examples.

4 - Robust Distributed Optimization for Machine Learning: Efficient Algorithms and Challenges

Zachary Charles, Google, Madison, WI, United States, Hongyi Wang, Shashank Rajput, Dimitris Papailiopoulos

In order to scale training of large machine-learning models, we often employ distributed optimization techniques. As these distributed systems grow in size, so too does the probability that a compute node experiences some kind of failure, including hardware failures, software bugs, or the presence of an adversary governing the output of the node. In order to guarantee the reliability of distributed training systems, recent work has proposed training methods that are robust to arbitrary node failures. To improve robustness, recent work generally employs robust aggregation techniques or algorithmic redundancy techniques. While the former suffers from high computation costs, the latter can only tolerate a small number of failures. In this work, we present DETOX, a framework for robust distributed training that combines robust aggregation with algorithmic redundancy. DETOX is designed to be used in tandem with robust aggregation methods, and we show theoretically that this leads to substantial increases in robustness and efficiency. We provide extensive experiments over real distributed setups across a variety of large-scale machine learning tasks, showing that DETOX leads to orders of magnitude accuracy and speedup improvements over many state-of-the-art robust training methods. If time permits, we will discuss some challenges and open problems.

Joint Session TSL/ITS/Practice Curated: Data Driven Approaches for Travel Demand and Mobility Analysis

Sponsored: Transportation Science & Logistics/Intelligent Transportation Systems (ITS)

Sponsored Session

1 - Characterizing Data Falsification Effects on Connected Autonomous Vehicle Platoons Using a Forced Vibration Equation

Xiaozheng He, Rensselaer Polytechnic Institute, Troy, NY, United States, hex6@rpi.edu, Pengcheng Wang, Xinkai Wu

The similarity between traffic flow oscillation and mechanical vibration inspires us to model the connected autonomous vehicles (CAVs) dynamics under data falsification attack using a forced vibration equation, where the attack is regarded as an external force to the system. The proposed model facilitates us to derive inherent oscillation properties of the CAV stream and analyze the effects of data falsification attack on CAVs dynamics. Based on the derived properties, we investigate the oscillation severity of CAV streams under the data falsification attack through simulation.

2 - Accounting Latent Information Search in Choice Modeling: A Search Action Model

Yifei Xie, Massachusetts Institute of Technology, Cambridge, MA, United States, yifeix@mit.edu, Mazen Danaf, Angelo Guevara, Arun Akkipenally Prakash, Moshe Ben-Akiva

This paper proposes a choice model that incorporates the information search behavior. Existing models for this purpose often assume that the search process is observed, which is rarely the case in real-world applications. We address this issue by modeling the search decisions as latent. The framework is broadly applicable and of great relevance for travel behavior modeling where real-time travel information is readily available but not always considered in decision-making. The framework is illustrated through Monte Carlo experiments, where model identification and parameter recovery are validated. It is also shown that ignoring unobserved search leads to biased estimates and poor prediction.

3 - Inverse Reinforcement Learning in Improving Driver's Safety

Qiong Hu, Auburn University, Auburn, AL, United States, qzh0011@auburn.edu, Amir Mehdizadeh, Alexander Vinel, Fadel Mounir Megahed

To improve the driver's safety, an MDP model has been developed to find the optimal policy to minimize the risk considering the weather and traffic conditions. The traditional way is to apply data analysis to estimate the relationship between factors and the risk. Our model is to use inverse reinforcement learning to obtain the reward function and help the driver make a better decision during the route such as the time of rest stop or choosing the speed level.

4 - Evaluation of Road Safety Using Machine Learning Methods Incorporating with Visualization Techniques.

Amir Mehdizadeh, Auburn University, Auburn, AL, United States, Azm0127@auburn.edu, Qiong Hu, Alexander Vinel, Fadel Megahed

Traffic, weather and road geometry are the main external factors which impact the crash probability. The interaction between these factors is complex and can potentially increases the crash probability. We first use three unsupervised learning methods (K- means and Hierarchical clustering and Principle Component Analysis) incorporating with different visualization techniques in order to identify different traffic states considering weather condition and road geometry. Then, using crash data, the risk associated with each traffic state is obtained by utilizing different statistical models. Finally, based on the results a set of general rules which impact the road safety is proposed.

5 - Evaluating the Impacts of Real-time Travel Information on Driver Physiology

Shubham Agrawal, Purdue University, West Lafayette, IN, United States, shubham@purdue.edu, Irina Benedyk, Srinivas Peeta

Real-time travel information can help drivers to make informed travel choices, but also distracts them from the primary driving task during information perception and processing. Hence, there is the need for a comprehensive understanding of information impacts on driver cognition. This study analyzes driver's brain electrical activity patterns collected using electroencephalogram (EEG) to assess driver cognition using neurophysiology. Data is collected in a network-level driving simulator environment that simulates realistic route choice decisions under real-time travel information provision.

6 - An Optimization Model for Bike-sharing Inventory Allocation in Competitive Environment

Chenyi Fu, Tianjin University, Tianjin, China, Ning Zhu, Shoufeng Ma

The bike-sharing firm of interests needs to consider whether they can survive the vehement competition with the local monopoly providers when entering into the new areas. This study adopts a multi-stage max-min-max framework to consider the worst-case profit. A myopic method embedded with a constraint-and-column generation approach is presented to obtain an approximate solution. The numerical studies display that when the bikes of the competitor are plentiful, distributing them uniformly can already have great influence on the profit of the firm of interests. Then the algorithm is effective and will generally depend on the number of bikes of two firm and less on the number of OD pairs.

Vehicle Routing I

Contributed Session

Chair: Yasel Costa, Fundacion Zaragoza Logistics Center, Wehrgrabengasse 1-3, Steyr, 4400, Australia

1 - GNN-based Path Prediction for Vehicle Routing Problem

Pan Gu, Zhejiang Cainiao Supply Chain Management Co., Hangzhou, China, gupan.gp@cainiao.com, Jian-Ya Ding, Chao Zhang, Lei Shen, Shengyin Li, Bing Wang, Yinghui Xu

Vehicle routing is a classical yet active research area. It is difficult to obtain a satisfactory routing plan by OR model without a deep knowledge on various restrictions. But implicit constraints are difficult to model. In this paper, we propose a deep neural-network method to predict promising paths for the vehicles. We combine supervised GraphSAGE and LSTM as the deep neural networks part, embedding graphs to a low dimensional vector space. The prediction result is integrated in a novel "Vehicle-Trip-Pattern" (VTP) algorithm in Cainiao. Offline experiments show that the prediction model can capture some of the implicit constraints and reduce the number of candidate trips significantly.

2 - Operational Constraints for Real World VRP

Shubhada Kshirsagar, ESRI, Redlands, CA, United States, skshirsagar@esri.com

Solving a standard Vehicle Routing Problem (VRP) to optimality is a difficult challenge. However, the optimal solution is often unrealistic and infeasible in the real world. Additional constraints must be considered to make the solution operationalizable. In this presentation, we examine qualitative constraints like clustering routes; balancing workloads yet being reasonably efficient; sequencing orders on a "Neighborhood" basis; and prioritizing high revenue orders but visiting lower priority ones if possible. We will look at ways these can be defined quantitatively to fit business rules. Though hard to define, these types of constraints are critical for producing an operational solution.

3 - A Novel Process Systems Approach for Vehicle Routing Optimization

Nooshin Nekoiemehr, Optimization Specialist, Hatch Ltd., Mississauga, ON, Canada, nooshin.nekoiemehr@hatch.com, Danielle Zyngier, Hao Li

A novel formulation is proposed to solve vehicle routing problem with pickup and delivery time windows using Process Systems Engineering technology. This framework enables modeling consistency and full integration across value chain systems (production-transportation-distribution). The resulting model can reroute a fleet of vehicles to accommodate new passengers in real-time while still guaranteeing promised delivery times for existing passengers. The efficiency of the method is illustrated through realistic case studies.

4 - Variable Neighborhood Search for the Electric Multi-trip Vehicle Routing Problem with Backhauls, Time Windows and Recharging Stations

Qian Hu, Associate Professor, Nanjing University, Nanjing, China, huqian@nju.edu.cn

Delivery companies now consider electric vehicles in green logistics. We study an electric vehicle routing problem with backhauls, time windows and recharging stations; it also allows heterogeneous electric vehicles and multi-trips. The problem is to find a set of feasible routes to serve all customers and minimize the total cost related to travel distance, waiting and recharging. We propose a hybrid heuristic based on variable neighborhood search with preprocessing, route operators and recharging operations. Computational results show that the heuristic is competent to find good feasible solutions for test instances with up to 1500 customers and 100 recharging stations.

5 - The Hilly Topography Vehicle Routing Problem: A Comprehensive Study for Urban Transportation Planning

Yasel Costa, Fundacion Zaragoza Logistics Center, Zaragoza, Spain, ycosta@zlc.edu.es, Victor Suarez, William Sarache, Tom Van Woensel

The effect of road gradient on fuel consumption has recently attracted much interest. Some scientific contributions have demonstrated that a shortest distance route is not necessary the best solution in terms of green performance (less CO2 emissions). In addition to the above, this paper proposes a new mathematical model for optimizing the fuel consumption equation that considers the topographic profile of transportation routes. Our proposal not only includes a novel formulation for fuel consumption but also address route security issues using the model constraints. Aimed to demonstrate our model validity, we have designed and solved 105 instances of Hilly Topography Vehicle Routing Problem.

Sponsored Session

Chair: Sandra D. Eksioglu, Clemson University, Clemson, SC, 29634, United States

1 - Coordination Arrangements in Intermodal Transportation: Game Theoretic Analysis

Irina Benedyk, Purdue, West Lafayette, IN, 47906, United States, Srinivas Peeta

This study uses a game theoretic framework that models competitive behaviors of two types of agents (maritime carriers and intermodal terminals), to understand how carriers and terminals can enhance their efficiency through four coordination arrangements (incentives, alliances, change of scope, and collective actions). The analysis of agents' behavioral responses on coordination arrangements is presented. The study findings can be used by the public sector to estimate possible impacts of policies aiming to foster intermodal transportation coordination.

2 - Mitigation Strategies Against Supply Disruption Risk

Ece Sanci, University of Michigan, Ann Arbor, MI, United States Mark Stephen Daskin

The economic impact of disruptions can be enormous when the supply chain design is optimized to perform well under normal circumstances. In this study, we provide a decision support framework based on a multistage stochastic programming model to choose the best mitigation strategy against supply disruption risk. We consider a variety of feasible strategies including improving the reliability of the primary supplier through backup capacity, reserving capacity from a secondary supplier, and increasing inventory levels. Our results show that the payoff of investing in mitigation strategies can be large, in particular, when the adverse effects of the disruption cannot be eliminated for a long time.

3 - Day-to-day Load Planning Strategies in Less-than-truckload Service Networks

Yassine Ridouane, Georgia Institute of Technology, Atlanta, GA, United States, yridouane@gatech.edu, Ian Hodara Herszteg, Natashia Boland, Alan Erera, Martin W.P. Savelsbergh

We propose new strategies for helping dispatchers in their daily decision process for operational load planning in LTL service networks. The freight volume that actually appears during a day of operations does not generally match the daily demand that was forecasted by load planners a week ahead. This renders the service guarantee of shipments hard to meet as the capacity on planned paths may not be enough. We use a time expanded network representation of the problem and present heuristics to solve it in a reasonably acceptable time. We applied these methodologies to realistic instances and the results show a substantial improvement over a set of chosen metrics as compared to a baseline approach.

4 - Exploring K- Best Solutions for the Capacitated Facility Location Problems in the Context of Network Design Decision-making

Claudio B. da Cunha, University of Sao Paulo, Sao Paulo, Brazil, Caue S. Guazzelli

We explore K alternative solutions to a facility location problem that usually arises in Supply Chain Network Design problems. The results on two well-known benchmark instances have shown that for all instances the gaps between the optimal solutions and the 20-best alternative ones were, on average, less than 1%. More surprisingly, 64% of all these alternative solutions had a gap smaller than 0.5%. This suggests that our approach may be used to identify whether near-optimal alternative solutions can yield to a better overall solution from the point of view of the decision-maker that have to consider other aspects, oftentimes qualitative, that cannot be explicitly modeled.

1 - Application of Learning Classifier Systems in Microscopic Traffic Simulation

Bekir Bartin, Associate Professor, Altinbas University, Istanbul, Turkey

This paper presents the application of XCS learning algorithm in simulating drivers' lane selection behavior in microscopic simulation models of toll plazas. XCS is a machine learning technique that ties reinforcement learning and genetic algorithm. The proposed formulation translates an agent's lane selection decision into a learning problem, assuming that its ultimate objective is to reduce delay and crash risk. The agent is simulated within a hypothetical toll plaza simulation network without any notion of the outcome of its decisions. Through multiple learning episodes and the outcome of its actions i.e., delay and crash risk, it learns the best policy for choosing a toll lane.

2 - An Intersection Control Strategy Based on Transferable Utility for Connected Vehicles

Dianchao Lin, New York University, NYUAD, Saadiyat Island, Abu Dhabi, 129188, United Arab Emirates, dl3404@nyu.edu, Saif Eddin G. Jabari

We present an intersection traffic management scheme that employs transferable utility games. Payoffs to individual vehicles are modeled as travel time savings weighted by value of time. Vehicles at the intersection are divided into two groups based on whether they benefit from applying a system payoff maximizing control scheme every time a new vehicle arrives to the system. The losers are compensated by the winners and the payoff maximizing scheme is applied. We test the effect of increased penetration rates of vehicles involved in the game. We also perform comparisons against other widely used control schemes. Our results demonstrate the viability of the proposed control scheme.

3 - Simulating CAVs on Urban Transportation Networks

Xuegang Ban, University of Washington, Seattle, WA, United States, banx@uw.edu, Yiran Zhang, Qiangqiang Guo

We develop a SUMO simulation model for a urban transportation network. The simulation model is used to simulate mixed traffic flow of CAVs and human driven vehicles, and CAVs with lower level automation.

4 - Connected and Automated Vehicles Impacts Assessment in New York

Camille Kamga, Associate Professor, City College of New York / UTRC, New York, NY, United States, Sandeep Mudigonda, Justin Collombet, Rodrigue Tchamna

The transformative potential of connected and automated (CAV) mobility needs to be assessed considering a wide-range of impacts enhanced safety via collision avoidance, better mobility through signal-vehicle coordination, platooning, etc. and also associated environmental benefits of reduced fuel consumption and greenhouse gas emissions and also significant financial impact. Employing a range of simulation and data sources, these impacts are analyzed for various vehicles and trips in New York. A microscopic, open-source simulation testbed developed in SUMO is being used to assess safety and mobility impacts and benefits to agencies as a part of the NYC CV pilot from CV applications.

5 - Use of Vehicle Trajectory Data-based Calibration of Microscopic Simulation Models for Evaluating Connected Vehicle Technologies

Abdullah Kurkcu, New York University, Brooklyn, NY, United States, ak4728@nyu.edu, Kaan Ozbay

As part of the CV Pilot safety performance evaluation plan, analysis will be conducted using micro-simulation modeling techniques instead of direct field observations. A pure before and after comparison under identical circumstances can be conducted using microscopic traffic simulation tools. Simulation calibration can be viewed as a process of minimizing the difference between simulated and observed traffic measures. Traditionally, only operational measures, such as traffic counts, travel time are used. But to conduct safety oriented analysis, it is essential that safety-related measures, such as safety indicators, to be included in the calibration process.

Chair: Rakesh Nagi, U. of Illinois at Urbana-Champaign, Urbana, IL, 61801, United States

1 - Analysis of Workload Inbalance and Mean Response Time of U-shaped Production Line

Yu Zhou, University at Buffalo (SUNY), Buffalo, NY, United States, yzhou67@buffalo.edu, Rajan Batta

A spatial queuing model is applied to analyze a U-shaped production line. Workload imbalance and mean response time from workers are two key points de- rived from the hypercube model. Different types of task assignments are analyzed to minimize workload imbalance and mean response time. Numerical results will be presented.

2 - Achieving Design Flexibility in Crossdock Facilities by Finding Alternative Solutions of Interest

Monique Guignard, University of Pennsylvania, Bala Cynwyd, PA, United States, Steven Orla Kimbrough

For some optimization problems, assuming maximization and <= constraints, a "good" solution may have different characteristics: A. feasible, with high objective function value, B. feasible, with some high slack values, and acceptable objective value, or C. Slightly infeasible, with some high slack values and high objective value. Standard optimization only produces type A solutions. We compare two approaches for assigning trucks to doors in a rectangular crossdock facility in terms of ease of generation and attractiveness of the "good" solutions.

3 - Formulation and Solution of a Master Production Planning Problem

Sunderesh S. Heragu, Regents Professor, Head, Humphreys Chair, Oklahoma State University, 322 Engineering North, School of Industrial Engineering & Management, Stillwater, OK, United States, sunderesh.heragu@okstate.edu, Baski Balasundaram, Austin Buchanan, Yajun Lu, Hosseinali Salemi, Hao Pan

We present an analytical approach for master production planning of pickle products at a top 10 private label food and beverage company. A linear programming model is formulated that maximizes economic profit and customer service levels by taking a combination of time-varying raw material costs, transportation/inventory costs, monthly production costs at each across multiple manufacturing plants, and revenues at the SKU-level into account. The mathematical model is implemented in Python along with commercial optimization solver Gurobi. The master planning model can also be extended to estimate crop intake needs for strategic planning.

1 - Airport Capacity Management Towards a Slot Allocation Modelling Approach Compliant with IATA Rules

Nuno Ribeiro, Singapore University of Technology and Design, Singapore

Air traffic demand has grown to exceed available capacity during extended parts of each day at many of the busiest airports in the world. Absent opportunities for capacity expansion, this may require the use of demand management measures to restore the balance between scheduled traffic and available capacity. We develop an original modelling approach aimed to advance existing slot allocation tools and procedures at the largest airports in the world. For that purpose, we formulate a novel integer programing model of slot allocation fully compliant with the WSG rules. The model - named Priority-based Slot Allocation Model (PSAM) - develops an original and efficient mathematical formulation that enables its implementation using exact optimization methods at airports at least with twice the size as previously considered.

2 - A Stochastic Integer Programming Approach to Air Traffic Scheduling and Operations

Kai Wang, MIT Sloan School of Management, Cambridge, MA

This paper provides an original integrated approach that jointly optimizes scheduling interventions in the strategic level and ground-holding operations in the tactical level across airports networks, under operating uncertainty. It is formulated as a two-stage stochastic integer program. We develop new exact solution algorithms based on dual integer cuts and neighborhood search, which are shown to provide optimal, or near-optimal solutions in reasonable computational times. Case study results identify opportunities in network demand management.

3 - Airline Timetable Development and Fleet Assignment Incorporating Passenger Choice

Keji Wei, Dartmouth College, Hanover, NH

We introduce an original integrated optimization approach to comprehensive timetabling and fleet assignment under endogenous passenger choice. An original multi-phase solution approach and several acceleration heuristics are proposed. Our solution approach significantly outperforms direct implementation using a commercial solver. Computational results using a major airline's network suggest that our overall modeling and computational approach results in significant profit improvements within a realistic computational budget. We present several extensions for strategic decision-making.

4 - Runway Scheduling during Winter Operations

Maximilian Pohl, TU Munich, Munich, Germany

We present an optimization model for the runway scheduling problem considering winter operations. During periods of snowfall, runways have to be intermittently closed in order to clear them from snow, ice, and slush. We propose an integrated optimization model to simultaneously schedule snow removals and aircraft on multiple runways. To improve computational times, we develop pruning rules and valid inequalities. A computational study based on real-world data shows that our approach significantly reduces weighted aircraft delay and computes high quality runway schedules within a few seconds.

Approximation Algorithms for Dynamic Pricing and Assortment Problems

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Antoine Desir

1 - Multi-product Dynamic Pricing with Limited Inventories under a Cascade Click Model

Stefanus Jasin, University of Michigan, 2836 Barclay Way, Ann Arbor, MI, United States, sjasin@umich.edu, Sajjad Najafi, Izak Duenyas, Joline Uichanco

We consider a dynamic pricing problem where products are displayed on a list and have limited inventories. Upon arrival, customers start browsing from the top of the list, deciding at each step whether to buy, not buy, leave the system, or continue browsing. This is the popular Cascade Click model in the literature. We study the property of the optimal price policy. We also study a deterministic approximation of the problem, develop heuristic policies and show that they are asymptotically optimal.

2 - Assortment Optimization under the Paired Combinatorial Logit Model

Heng Zhang, University of Southern California, San Gabriel, CA, United States, hengzhang24@gmail.com, Paat Rusmevichientong, Huseyin Topaloglu

We consider uncapacitated and capacitated assortment problems under the paired combinatorial logit model, where the goal is to find a set of products to maximize the expected revenue obtained from a customer. In the uncapacitated setting, we can offer any set of products, whereas in the capacitated setting, there is an upper bound on the number of products that we can offer. Even the uncapacitated assortment problem is strongly NP-hard. To develop an approximation framework for our assortment problems, we transform the assortment problem into an equivalent problem of finding the fixed point of a function but computing the value of this function at any point requires solving a nonlinear integer program.

3 - An Approximation Algorithm for Network Revenue Management under Nonstationary Arrivals

Mika Sumida, Cornell Tech, New York, NY, 10128, United States, ms3268@cornell.edu, Paat Rusmevichientong, Huseyin Topaloglu

We provide an approximation algorithm for network revenue management problems. In our approximation algorithm, we construct an approximate policy using value function approximations that are expressed as linear combinations of basis functions. We use a backward recursion to compute the coefficients of the basis functions in the linear combinations. If each product uses at most L resources, then the total expected revenue obtained by our approximate policy is at least 1/(1+L) of the optimal total expected revenue. In many network revenue management settings, although the number of resources and products can become large, the number of resources used by a product remains bounded.

4 - Bifurcating Constraints to Improve Approximation Ratios for Online (reusable) Resource Allocation

Jackie Baek, MIT, Cambridge, MA, United States, baek@mit.edu, Will Ma

We improve approximation ratios in online resource allocation problems by bifurcating constraints into matroid constraints and graph constraints. Our work applies to both reusable resources and network revenue management.

1 - Joint Inventory Allocation and Price Optimization Problem

Andrew Vakhutinsky, Oracle Labs, Burlington, MA, United States, andrew.vakhutinsky@oracle.com, Kiran V. Panchamgam, Su-Ming Wu

We examine a retail profit maximization problem with two sets of decision variables: location-specific pricing to sell the merchandise inventory and the amount of inventory allocated from multiple supply centers at potentially different costs. We propose a general iterative approach to solving the problem similar to gradient descent and show its convergence to optimality and describe some special cases commonly encountered in practice. We conclude our presentation by discussing the results of our computational experiments using the data of the Oracle fashion retail customer and share our experience of productizing the algorithm as part of Oracle Retail Price Optimization software product.

2 - Ensemble Methods in Dynamic Pricing

Dirk Sierag, PROS, Houston, TX, United States

In this case study a scalable dynamic pricing method is applied to several datasets. The goal is two-fold: (1) improve forecast accuracy, and (2) optimize prices. The method exploits ensemble techniques to estimate parameters and price-sensitivity functions, which are subsequently used to optimize prices. Along with performance results of our method, we will discuss the impact of feature selection/engineering on these datasets and the relationship between forecasting accuracy and price optimization.

3 - Adding Flights for the Super Bowl? Airline Revenue Management with Price-freeze Options

Xiyuan Ge, University of Washington, Seattle, WA, 98195, United States, xiyuange@uw.edu, Ovunc Yilmaz, Daewon Sun

Mega sporting events such as the Super Bowl are played at neutral locations rather than in one of the competing teams' host city. In this paper, we study the pricing and capacity decisions for an airline selling tickets for the neutral location from the cities with semi-final teams. We propose a novel pricing mechanism called "price-freeze options" where customers can pay a fee to reserve the right (and obligation) to purchase an airline ticket at the pre-semi-final price if their team qualifies for the final game.

4 - Dynamic Pricing of Fashionable Products with C2c Marketplaces and Strategic Consumers

Mingcheng Wei, University at Buffalo, 326C Jacobs Management Center, Buffalo, NY, 14260, United States, mcwei@buffalo.edu, Michelle Wu

This paper studies the influence of C2C resale marketplaces on pricing decisions and revenue performance of a capacitated seller selling high-tech or fashion products. We identify conditions under which the resale marketplace could benefit the seller.

Joint Session RMP/Practice Curated: Pricing and Revenue Management Applications at Amazon

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Robert L. Phillips, Amazon, Palo Alto, CA, 94306, United States

1 - Amazon Lockers: Improved Customer Experience with Machine Learning and Mathematical Optimization

Samyukta Sethuraman, Senior Research Scientist, Amazon, Palo Alto, CA, United States, samyukts@amazon.com

Amazon's focus on customer obsession has led to the installment of Amazon lockers, where customers can pick up packages and drop off returns. To manage unknown package dwell times and rising locker delivery rates, Amazon developed a hybrid model for this novel yield management application. The model combines machine learning and mathematical optimization to maximize package deliveries, reduce rejections and improve customer satisfaction. This model resulted in a 9% increase in locker throughput worldwide during the peak holiday season in 2018.

2 - Dynamic Freight Pricing at Amazon

Roger Lederman, Amazon, Seattle, WA, United States

We discuss how automated truckload pricing models helped Amazon extend its supply of carriers, replacing a primarily manual process of negotiating for loads at the last minute. Our pricing algorithm supports one-click tendering for carriers at competitive prices, and allows planners to predict spot capacity costs to create a more efficient schedule of loads. Removing the need for negotiations has created a faster, more convenient process, with transparency to rates for all carriers. The algorithm has been essential to this shift by providing guaranteed rates that consistently reflect the current market, giving carriers the confidence to quickly accept new work when it matches their capabilities.

3 - Dual Sourcing and Pricing for Seasonal Products

Alvaro Maggiar, Amazon.com, New York, NY, United States, maggiara@amazon.com, Alp Muharremoglu, Ali Sadighian

We present a procurement model for highly seasonal products, such as toys or fashion products, which are usually purchased through a combination of import and domestic buys, months ahead of typical vendor lead times. This procurement process differs significantly from more common just-in-time buying, and the decision to split orders between import and domestic channels reflects a trade-off between cost and information gain. We present a dynamic programming approach to the problem that captures the value of information gain by modelling the evolution of forecasts through the Martingale Method of Forecast Evolution, and incorporate pricing decisions during the selling season.

1 - Joint Pricing and Routing in a Network

Pornpawee Bumpensanti, Georgia Institute of Technology, H. Milton Stewart School of Industrial & Sys, Atlanta, GA, United States, Martin Savelsbergh, He Wang

The joint pricing and routing problem considers a transportation network represented by a directed graph, where each edge has a capacity and a linear transportation cost. The decision maker sets price for each origin-destination pair (which determines the amount of flow that needs to be served) and split flow among multiple paths in the network given capacity constraints. The objective is to maximize revenues from serving flows minus transportation costs. We propose two algorithms for this problem: a Frank-Wolfe type algorithm, and a primal-dual algorithm using online learning technique.

2 - On Revenue Management with Strategic Customers Choosing When and What to Buy

Yiwei Chen, University of Cincinnati, Cincinnati, OH, 487372, United States, Nikolaos Trichakis

We consider a network revenue management model with customers who strategically decide when to purchase and which product to purchase. Customers have heterogeneous arrival times, product valuations and value decay rates. The seller aims at finding a pricing policy that maximizes the expected total revenue. We reformulate the problem as a multi-dimensional mechanism design problem. We establish an upper bound by relaxing this problem into a series of one-dimensional problems. We show that a simple fixed price policy achieves a constant competitive ratio relative to this upper bound. Our numerical study shows that our policy is nearly optimal.

3 - Low-regret Online Decision-making via the Bellman Inequalities

Alberto Vera, Cornell University, Ithaca, NY, United States, aav39@cornell.edu, Siddhartha Banerjee, Itai Gurvich

We introduce a framework to construct re-solving policies with the first constant regret guarantees (i.e., additive optimality-loss that is constant in the horizon and resource budgets) for a wide variety of problems, including online resource-allocation, dynamic pricing with discrete price levels, online budgeted probing, and contextual bandits. All our policies are built out of a meta-algorithm, where we first construct a tractable offline benchmark that satisfies a notion we refer to as the Bellman inequalities, and then use this benchmark with re-solving to construct a feasible online policy.

4 - A Primal-dual Learning Algorithm for Personalized Dynamic Pricing with an Inventory Constraint

Ningyuan Chen, Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong, Guillermo Gallego

A firm is selling a product to different types of customers over a finite season with non-replenishable inventory. The type label of an arriving customer can be observed but the demand function associated with each type is initially unknown. The firm sets personalized prices dynamically for each type and attempts to maximize the revenue over the season. We provide a near-optimal learning algorithm when the demand and capacity scale in proportion. The algorithm utilizes the primal-dual formulation and learns the dual optimal solution explicitly. It allows the algorithm to overcome the curse of dimensionality and sheds light on novel algorithmic designs for learning problems with resource constraints.

Emerging Topics in Emergency Medical Services

Sponsored: Public Sector OR

Sponsored Session

Chair: Marla Lavanya

1 - Identifying Trade Offs in Equity and Efficiency for Simultaneously Optimizing Location and Multipriority Dispatch of Ambulances

Shakiba Enayati, State University of New York, Plattsburgh, Plattsburgh, NY, United States, senay002@plattsburgh.edu, Maria Esther Mayorga, Hector Toro Diaz, Laura Albert

Emergency medical service (EMS) systems provide acute care and possibly transportation to hospitals to patients experiencing medical emergencies. The community expects equitable service from EMS systems. We provide a multicriteria optimization approach aimed at identifying good solutions for several equity and efficiency measures together, based on a joint modeling approach for location and dispatching policy decisions, while considering multiple levels of call priority. We apply our approach to a real world data set. We show that the joint approach provides better solutions than using the common assignment of the closest available ambulance, in particular for the equity criteria.

2 - Contract Design with Information Asymmetry in Emergency Stroke Care Systems

Ruijiu Mao, Purdue University, West Lafayette, IN, United States, mao95@purdue.edu, Nan Kong, Paul Griffin

Stroke treatment is time sensitive and dependent on stroke type. Sending emergency stroke patients to an appropriate care facility level can save time and increase their survival. The stroke type can only be confirmed after a CT scan from primary stroke centers or stroke capable hospitals. We consider a set of contracting mechanisms for coordinating stroke care between the government (Medicaid/Medicare), hospital, and EMS system within a principal-agent framework. EMS decides the corresponding facility level by following its policy set a priori, which can lead to over- or under-treatment. We illustrate how appropriate contract choice varies by factors such as urbanicity.

3 - Optimizing Regional Trauma Network via Bilevel Integer Programming

Shaonan Liu, Dalian University of Technology, China, Dalian, China, hua.zheng.kai@mail.dlut.edu.cn, Nan Kong, Mingzheng Wang, Pratik J. Parikh

In this talk, we consider a problem of optimizing a regional trauma network that minimizes the negative effects of under-triage (to improve social well-being) and over-triage (to reduce spending) errors in the presence of two decision-makers, the government and the hospital system. We present a novel bilevel subsidized network redesign problem and design a branch-and-bound algorithm with an enhanced cut to solve the resultant bilevel integer programming. The numerical experiments with randomly generated instances demonstrate the superiority of our algorithm for medium- to large-sized bilevel integer programming. We also present a case study based on the real data from a Midwest U.S. state.

4 - Optimizing the Coordination of Emergency Medical System and Drone-delivered Automated External Defibrillators Operated by Random Bystanders

Jungeun Shin, University of Illinois Urbana-Champaign, Urbana, IL, United States, jungeun4@illinois.edu, Lavanya Marla, Justin James Boutilier

Drone-delivered automated external defibrillators (AED) are emerging technology for emergency care of out-of-hospital arrest due to its mobility for quick response to emergency requests. However, AED cannot be properly used unless any bystander is available at the scene. In this study, we consider adding drone-delivered AED to the existing ambulance services and develop an optimization framework to minimize additional required drones while the ambulance-drone cooperative EMS system guarantees a required response time when bystanders' availability is stochastic.

IE/OR for Health and Education Policy

Emerging Topic: Policy & Government

Emerging Topic Session

Chair: Sze-chuan Suen, University of Southern California, Los Angeles, CA, 90089-0193, United States

1 - Investing in Performance: Information and Merit-based Incentives in K-12 Education

Vanitha Virudachalam, University of Illinois at Urbana-Champaign, Urbana-Champaign, IL, United States, vanitha@wharton.upenn.edu, Sergei Savin, Matthew Steinberg

We study the relationship between information on student performance and monetary incentives for teachers using a two-period principal-agent model, where the school district (principal) chooses whether to invest in interim assessments and how much merit-based compensation to offer to teachers, while the teachers (agents) decide on the level of effort to exert in each period. Two-state Markovian dynamics describe the evolution of student performance. We establish that there are some settings where the provision of additional information about the student mid-year performance has a demotivating effect on teachers.

2 - Diversion Programs for Drug Offenders: Health Outcomes and Cost-effectiveness

Margaret L. Brandeau, Stanford University, Management Science and Engineering, Stanford, CA, United States, brandeau@stanford.edu, Cora Bernard

Diversion programs aim to divert low-level drug offenders toward community care resources, avoiding criminal justice costs and disruptions in treatment for HIV, HCV, and drug abuse. We assessed the health benefits and cost-effectiveness of a jail diversion program for low-level drug offenders. We find that such a program will reduce HIV and HCV incidence, overdose deaths among people who inject drugs, and jail population size. Moreover, such a program is likely to be cost-effective, generating savings in the criminal justice system while only moderately increasing healthcare costs.

3 - Cost-effectiveness Analysis of Pre-art Drug Resistance Testing for HIV-infected Children in Kenya

Mutita Siriruchatanon, University of Washington, Seattle, WA, United States, siriruc@uw.edu, Shan Liu, Horacio A. Duarte

WHO guidelines recommend empiric efavirenz-based antiretroviral therapy (ART) for HIV-infected children initiating treatment at ≥ 3 years old. However, the prevalence of efavirenz-associated pretreatment drug resistance (PDR) is high in this population. We developed and calibrated a model that simulates natural disease progression and treatment for HIV-infected children in Kenya. We simulated three care strategies for PDR testing among children ≥ 3 years old: 1) no testing; 2) testing with oligonucleotide ligation assay (OLA), a low-cost point-of-care test; and 3) testing with consensus sequencing (CS). PDR testing with OLA is a cost-effective alternative to PDR testing with CS.

4 - Cost-effectiveness of a Vaccines under Development

David W. Hutton, University of Michigan, Ann Arbor, MI, 48105, United States, dwhutton@umich.edu

Various vaccines are under development. When they become available, organizations like the Advisory Committee on Immunization Practices will want to be ready to make recommendations about who should receive these vaccines (if anyone). We discuss the approach of using mathematical models to evaluate the cost-effectiveness of newly-developed vaccines in various populations with different risks. We discuss how models can be useful to evaluate under what conditions (vaccine price and efficacy) vaccines would be considered cost-effective. We show this with examples of norovirus and respiratory syncytial virus.

5 - Introduction of Store Choice in India's Food Security Program – Implications on Demand Distribution, Replenishment Policy and Welfare Enhancement

Maya Ganesh, Student, Indian School of Business, Hyderabad, India, Maya_Ganesh@isb.edu, Sarang Deo, Sripad K. Devalkar

India's food security program has traditionally suffered from poor service levels due to local monopoly of retail stores. Advances in technology have enabled introduction of store choice to empower beneficiaries. However, absence of data before implementation makes it difficult to evaluate impact of choice on program performance. We develop a structural model of beneficiaries' store choice, use its estimates to construct baseline scenario (no choice) & evaluate impact of choice. Further, we demonstrate empirically that this impact is mediated by demand variability at store level. Based on this insight, we establish the need for complementary supply side changes for an effective intervention.

4:30-5:15 Litic Software / 5:15-6:00 Optimization Firm

Vendor Tutorial

1 - LITIC, the Next Generation Decision Analytics Platform

John Poppelaars, Litic Software, Berendrecht, Netherlands

LITIC is a new, cloud based, decision analytics platform that will increase your productivity as an Operations Research consultant significantly. It supports you throughout the model development cycle, starting from data all the way through delivery of the decision support app, without the need to switch to other tools. It will let you bypass the coding hurdles you encounter every day and lets you fulfill customer requirements without the need to become an advanced application developer. During the tutorial John Poppelaars, OR consultant with over 30 years of practical experience and a 2012 Edelman laureate, will demonstrate the use of LITIC in solving client challenges, also touching upon best practices of OR consulting. Using examples from his own practice John will illustrate how LITIC has made a difference in supporting his clients. John will touch upon data analysis, interactive modelling support of LITIC, scenario and sensitivity analysis and app development, illustrating the speedup LITIC can bring to decision analytics in practice.

2 - ALAMO for Data Analytics and Machine Learning

Yash P. Puranik, Carnegie Mellon University, 5000 Forbes Avenue, Doherty Hall, Pittsburgh, PA, 15213, United States, Nick Sahinidis

The Optimization Firm will present a tutorial on the new ALAMO software for building models from data. ALAMO's innovative optimization and sampling technology uses data from experiments or simulations to generate interpretable models. ALAMO ensures that the models are as simple and accurate as possible while also satisfying physical constraints on the response variables. This tutorial will describe ALAMO's biggest features that make it uniquely suited for machine learning and analytics. We'll also present results comparing ALAMO to standard machine learning methods. Everyone has free access to ALAMO before its commercial launch.

Special Session: Gaussian Processes: A Discussion on Theory and Applications in Machine Learning and Computer Experiments

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Raed Al Kontar, University of Michigan, Ann Arbor, MI, 48109, United States

Co-Chair: Rui Tuo, College Station, TX, 77845, United States

1 - Gaussian Processes: A Discussion on Theory and Applications

Raed Al Kontar, University of Michigan, IOE 2769, Ann Arbor, MI, 48109, United States, alkontar@umich.edu

In this talk, we discuss recent methodological advances in Gaussian process regression for computer experiments.

2 - Gaussian Processes from a Computer Experiments Perspective

Rui Tuo, Texas A&M University, College Station, TX, United States, ruituo@tamu.edu

Data science in computer experiments mainly focuses on data collection, surrogate modeling, statistical inference, and decision making for complex computer simulation problems. Gaussian process regression serves as an important type of surrogate models in computer experiments. Besides using the usual kriging methods, we will discuss the following specific problems: 1) design of experiments; 2) non-stationary Gaussian process models; 3) approximation theory for Gaussian process regression.

Risk Analysis I

Contributed Session

Chair: Navid Ahmadian, University of Houston, Houston, TX, United States

1 - Research on Construction Risk Early Warning of High-speed Railway in Hard and Dangerous Mountainous Areas Based on Extension Theory

Junxiang Xu, South West Jiaotong University, Chengdu, China, 1933348984@qq.com, Jin Zhang, Hui Dong

Based on the analysis of the research status of risk assessment methods for railway construction in mountainous areas at home and abroad, this paper establishes the index system of risk early warning for high-speed railway construction, formulates the criteria of risk early warning classification, constructs a risk early warning model based on extension theory, gives weight value by using combination assignment method, and obtains the correlation function value of early warning object and early warning grade. Taking Sichuan-Tibet railway key tunnel construction project as an example, the applicability of the model and calculation method is verified.

2 - Heterogeneous Risk Preferences in Community-based Electricity Markets

Fabio Moret, Technical University of Denmark (DTU), Lyngby, Denmark, fmoret@elektro.dtu.dk, Pierre Pinson, Athanasios Papakonstantinou

Clearing decentralized electricity markets where agents can negotiate their energy procurement individually, is a complex process further complicated by the uncertainty associated with distributed energy sources. Each agent has subjective criteria in how they appraise risk, leading to heterogeneous risk attitudes that can impact market outcomes and the corresponding payments. We introduce a notion of fairness and build upon it to develop risk hedging mechanisms in the form of financial contracts in order to mitigate the impact of risk. We then evaluate their impact on market equilibrium and show that by trading financial products, more fair market equilibria are achieved.

3 - Perceived Environmental Risk and Strategic Changes: Moderating Effects of TMT Heterogeneity

Rui Wang, University of Science and Technology of China, Hefei, China, wangrr@mail.ustc.edu.cn

Analyzing data from 182 publicly listed firms in China from 2012 to 2018, we find that perceived environment risk complexity plays a positive role to strategic changes, while perceived environment risk dynamism diminishes it. We also find that the negative effect of perceived environment risk complexity is weakened when its dynamism is high, or accentuated when TMT functional background heterogeneity is large. In addition, the positive effect of perceived environment risk dynamism is attenuated when the TMT functional background heterogeneity is high. We discuss our contributions to research on corporate external risk sensing, dynamic management capability and corporate strategic behavior.

4 - A New Perspective on Supplier Risk Mitigation Strategies

Vishwakant Malladi, Indian School of Business, Mohali, Punjab, India, vishwakant_malladi@isb.edu

Frequency and duration are two disparate dimensions of supplier risk. Risk mitigation investments can be directed to improve either of them. In this paper, we consider the two dimensions independently and study the impact of each of these dimensions on the supply chain. We show that a retailer is more concerned with the duration of disruptions than with the frequency. Moreover, we also show that the supplier and retailer have conflicting interests with respect to risk mitigation investments. Finally, we also investigate the impact of supplier risk dependence on the supply chain.

5 - Optimized Certainty Equivalent Risk Measures as Parameterized Risk Families and Their Decomposition Into CVaR and Density Estimation

Alexander Mafusalov, FedEx Express, Memphis, TN, United States, sasha.mafusalov@gmail.com

This paper considers a general convex regret/error/utility measure, under a condition of asymptotic linearity. A parametric 0-1 family of risk quadrangles corresponds to that measure. It is proved that there exists a probability distribution mapping, mean-preserving under certain conditions, such that the described family of risk quadrangles for a random variable coincides with the family of quantile-based quadrangles for the mapped distribution. Additional functionals (buffered probability, Lorenz curve, shortfall risk), interconnections, and particular cases studied. This research draws a strong connection between risk minimization and density estimation.

6 - A Unified Approach for Network Resiliency Quantification Assessment and Improvement

Navid Ahmadian, University of Houston, Houston, TX, United States, nahmadian@uh.edu, Gino J. Lim, Jaeyoung Cho

We propose a quantitative approach for measuring the resiliency of network components and the network itself. First, the component resiliency is defined as a function of criticality, disruption frequency, disruption impact, and recovery time. The component resiliency reflects the effect of component disruption on the network. Then, the network resiliency is measured by the resiliency of the weakest component in the network. Hence, enhancing the network resiliency is possible through reinforcing weakest components in the network.

Sponsored Session

Chair: Hui Yang

Co-Chair: Bianca Maria Colosimo, Politecnico di Milano, Milan, I-20156, Italy

Co-Chair: Arman Sabbaghi, Purdue University, West Lafayette, IN, United States

1 - Spectral Autoencoder for Anomaly Detection in Attributed Networks

Yuening Li, Texas A&M University, College Station, TX, United States, Xiao Huang, Jundong Li, Mengnan Du, Na Zou

We propose a spectral convolution and deconvolution based framework - SpecAE, to project the attributed network into a tailored space to detect global and community anomalies. SpecAE leverages Laplacian sharpening to amplify the distances between representations of anomalies and the ones of the majority.

2 - Identifying the Influential Inputs for Network Output Variance Using Sparse Polynomial Chaos Expansion

Zhanlin Liu, University of Washington, Seattle, WA, United States, Ashis G. Banerjee, Youngjun Choe

We propose a novel model to identify the process inputs that influence the process output's variance significantly for a class of processes represented as directed acyclic networks. Theoretical analysis proves the convergence of model prediction. The model's superior efficiency over a benchmark method is empirically validated on two manufacturing processes.

3 - Collusion Detection and Ground Truth Inference in Crowdsourcing for Labeling Tasks

Changyue Song, University of Wisconsin-Madison, Rm 3221, Mechanical Engineering Building, 1513 University Ave, Madison, WI, 53715, United States, Kaibo Liu, Xi Zhang

This paper aims at inferring the ground true labels based on worker-generated noisy labels under worker collusion in crowdsourcing systems. Specifically, we propose a penalized pairwise profile likelihood method with the adaptive LASSO penalty for collusion detection. Theoretical properties are investigated that guarantee the asymptotic performance of the proposed method.

4 - Transfer Learning using Informative Structure Priors in Ordered Graphical Models

Chao Wang, University of Wisconsin-Madison, Madison, WI, 53706, United States, Xiaojin Zhu, Shiyu Zhou, Yingqing Zhou

In this paper, a structure learning framework for ordered block model with limited data samples is proposed. The method constructs an informative structure prior to rigorously reveal commonalities among heterogeneous data from different processes to benefit the learning in complex systems. The method is validated with real car assembly processes.

Maintenance and Reliability Models for Technical Systems

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Cristiano Alexandre Virginio Cavalcante

1 - A Hybrid Maintenance Policy Based on Operation Time and Shocks Counting for Protection Systems

Alexandre Alberti, UFPE - Universidade Federal de Pernambuco, -, Brazil, alexandre.emc091@gmail.com, Cristiano Cavalcante, Shaomin Wu

We consider a protection system that presents an inherent deterioration process and over which demands act as shocks, which can result in a sudden increase in the failure or defect rate, which is a realistic scenario. We propose a hybrid inspection and preventive replacement policy that considers decision variables related to the operating time and the number of shocks observed, and present an application in the context of electrical energy substations. We also investigate the effects of imperfect maintenance.

2 - Integrated Preventive Maintenance and Quality Control Inspection in an Imperfect Production System

Rodrigo Sampaio Lopes, Assistant Professor, Federal University of Pernambuco, Caruaru, PE, Brazil, rodrigoengep@gmail.com, Cristiano Cavalcante

In this study, the influence of a quality inspection policy on an imperfect production system is modelled. The inspection policy is imperfect, permitting type I and type II errors. After each production cycle, preventive maintenance is performed. In case of failure in the production process before the cycle's end, a minimal repair is indicated. The model is formulated with the objective of minimizing the total cost expected per item while considering an average outgoing quality constraint. The results indicate that the probability of type I and type II inspection errors has a significant impact on optimal production and the percentage of items inspected.

3 - A Study of the Effect of Quality of Maintenance in Opportunistic Maintenance Models.

Cristiano Cavalcante, Universidade Federal de Pernambuco, Rua Antonio de Castro N. 61, Apartment 701, Recife Pernambuco, 52070-080, Brazil, cristianogesm@gmail.com, Mônica Marsaro, Alexandre Alberti

The maintenance has being recognized as a strategical function inside the organizations. This is because provide effective maintenance planning, meeting the appropriated level of quality of this maintenance is become challenging. Therefore, Opportunistic maintenance is a way to increase the performance of a system, finding a moment where this action will not reverberate in downtime. We proposed two maintenance models that consider opportunistic maintenance and errors in inspections. Model 1 considers if the component is indicated be defective (false or true positive) it will be renewed, while in Model 2 the component will only be replaced in a double check structure.

4 - A Framework for Building Multicriteria Decision Models in Reliability and Maintenance Context

Adiel Teixeira De Almeida, Universidade Federal de Pernambuco, Cx Postal 7462, Recife PE, 50630-970, Brazil, adielta@gmail.com, Lucia R. Roselli

Considering the role Reliability and Maintenance (RM) may play in any organization, the decision-making process is relevant for the strategic success. Building decision models for RM context is an important issue, particularly those with multiple objectives. This paper presents a framework for building multicriteria decision models in the RM Context. Classification of multicriteria (MCDM/A) methods is given, with concerns related to choosing a method, considering the DM's compensatory and non-compensatory rationality, and including Multi-Attribute Utility Theory (MAUT) and outranking methods (ELECTRE and PROMETHEE). The framework is presented with some applications already done.

Stochastic Models in Healthcare

Sponsored: Health Applications

Sponsored Session

Chair: Oguzhan Alagoz, University of Wisconsin-Madison, Madison, WI, 53706, United States

Chair: Liz Scaria

1 - Cholesterol Follow-up Policy in the Context of Preventive Treatment of Cardiovascular Disease

Daniel Felipe Otero Leon, PhD Student, University of Michigan, Ann Arbor, MI, United States, dfotero@umich.edu, Brian T. Denton, Mariel Sofia Lavieri

Preventing chronic diseases is an essential aspect of medical care for healthy patients, but deciding when to collect information, such as the patient's cholesterol levels, is difficult. Measuring too frequently may be unnecessary and costly; on the other hand, measuring too infrequently means the patient may forgo needed treatment and experience adverse events related to the disease. We present results from estimating a stochastic model based on longitudinal data for cholesterol in a large cohort of patients seen in the national Veterans Affairs health system. We further use this model to study policies for when to collect measurements to assess the need for cholesterol lowering medications.

2 - Accommodating Demand Surges via Proactive Staff-Planning in the Emergency Department

David Rea, University of Cincinnati, Cincinnati, OH, 45220, United States, readj@mail.uc.edu, Craig Froehle

While most services can influence the timing of demand (e.g., via appointment systems or pricing), Emergency Departments (EDs) need to accommodate all patients on arrival. While relative rare, demand surges (a sudden rise in patient-care needs) are known to result in long-lasting operational bottlenecks. This research conceptualizes demand surges as observations in the tail of a distributional forecast. The activation of additional (back-up) staff in anticipation of demand surges is suggested as a strategy for combating ED crowding. Using substantial primary data, we test the hypothesis that this proactive activation of backup will result in consistently lower patient waiting times.

3 - Cost Effectiveness of Depression Screening for General Adult Population

F.Melike Yildirim, Georgia Institute of Technology, Atlanta, GA, United States, fmyildirim@gatech.edu, Pinar Keskinocak, Julie L. Swann

U.S. Preventive Services Task Force (USPSTF) did not find enough evidence about the optimal depression screening intervals for general adults in primary care. However, undiagnosed and untreated depression decrease the quality of life and increased the risk of suicide, therefore the routine screening has potential impact on improvement of progression of disease. In this study, we evaluate age and gender specific depression screening intervals for US adult population. The cost-effectiveness of screening can lead to policy makers and insurance companies to expand the coverage for depression screening in primary care.

4 - An Agent-based Simulation of Hospital Acquired Clostridioides Difficile Infection

Elizabeth Scaria, University of Wisconsin-Madison, University of Wisconsin, Madison, WI, United States, scaria@wisc.edu, Oguzhan Alagoz, Nasia Safdar

Clostridioides difficile infection (CDI) is one of the most common healthcare associated infections. Preventing CDI transmission in healthcare settings involves system-level behavioral interventions, such as environmental disinfection, hand hygiene, and antibiotic stewardship, implemented in bundles. Incomplete knowledge of CDI transmission dynamics hinders decision makers' ability to select optimal interventions. We develop an agent-based simulation model of CDI transmission to assess and compare the relative effectiveness of infection control interventions. Our model provides data for decision makers to select optimal infection control interventions.

5 - Dynamic Patient Routing with Nurse Workload Considerations

Siddhartha Nambiar, North Carolina State University, Raleigh, NC, 27603, United States, snambia@ncsu.edu, Maria Esther Mayorga

While nursing workload has been studied extensively in human factors and other fields, there's a gap (and lack of consensus) in analytics and decision science regarding how to objectively quantify workload and how to use it effectively in an analytic framework. To this end, we develop a multi-class, multi-server queueing model that routes incoming patients to one of several different server pools in an Emergency Department (ED) setting. The routing is performed such that the total time spent by the patient in the system is minimized and the workload experienced by the servers (nurses) is efficiently managed.

HAS- Health IT and Operations Management

Sponsored: Health Applications

Sponsored Session

Chair: Susan F Lu, Purdue University, West Lafayette, IN, United States

1 - The Zocdoc Effect: How Does Online Information Impact Appointment Availability in Outpatient Care?

Yuqian Xu, University of Illinois at Urbana-Champaign, Champaign, IL, United States, Mor Armony

With the rapid development of online technology, patients are now exposed to a lot of information about doctors before making appointments. This increasing availability of information raises questions regarding the impact of online channels on patients' valuation and doctors' service incentives. In this paper, we propose a queueing model to study the impact of online information on patients and doctor's decisions.

2 - The Impact of Information Technology and Communication on Medical Malpractice Lawsuits

Sharma Luv, University of Southern California, Columbia, SC, United States, Luv.Sharma@moore.sc.edu, Carrie Queenan

Health care organizations have substantially invested in Health Information Technology (HIT) as part of an effort to improve quality. However, many hospitals fail to generate positive returns on this significant investment, based on reimbursements for quality measures through the Affordable Care Act (ACA). Given the high cost of lawsuits, we investigate if HIT adoption reduces lawsuits, and their attendant costs, as another consideration in HIT payoffs.

3 - Does underuse Variation in Test-ordering Practice Relate to Higher Subsequent Care-delivery Cost?

Seokjun Youn, The University of Arizona, Tucson, AZ, United States, syoun@email.arizona.edu, Gregory R. Heim, Subodha Kumar, Chelliah Sriskandarajah

To examine how variation in clinical practice relates to hospital operational performance, we propose a novel measure of practice variation using inpatient discharge data. We find that hospitals may be improperly rewarded for quality improvements if practice variation is ignored, implying that incentives/penalties for hospital operations should be designed to account for such effects. Further, we find differential impacts of underuse variation in test-ordering practice on test-ordering cost and subsequent care-delivery cost. Restrictive reimbursement rules on test-ordering practice are undesirous, as they may result in even higher eventual total care-delivery spending.

4 - The Value of Health It Interoperability: Evidence from Interhospital Transfer of Heart Attack Patients

Yao Li, Tsinghua University, Beijing, China, liy36.15@sem.tsinghua.edu.cn, Lauren Xiaoyuan Lu, Susan F. Lu, Jian Chen

We empirically investigate the effects of health IT interoperability and health information exchange on the interhospital transfer of heart attack patients. Using the NY State ED and Inpatient Databases and HIMSS Database, we characterize the effects in terms of the speed of the transfer process and the health outcome and service utilization of transferred patients.

Empirical Research in Various Healthcare Operations

Sponsored: Health Applications

Sponsored Session

Chair: Rachna Shah, University of Minnesota, Minneapolis, MN, 55455, United States

1 - Evaluating the Profit Quality Link in Nursing Homes

Alison Clement, University of Minnesota, Minneapolis, MN, United States, cleme558@umn.edu, Kevin W. Linderman, Rachna Shah

The health economics literature has repeatedly investigated the link between a nursing homes profit status (for profit or not for profit) and quality. These studies have had inconsistent results, demonstrated that there is not a significant difference in profit margin between for profit and not for profit nursing homes, and assumed that nursing homes are rational profit maximizers. I draw on the behavioral theory of the firm to propose that the link between profit and quality depends not only on the profit status but also the expected performance compared to aspirations.

2 - Diminishing Effects of EHR in USA Hospitals

David Dobrzykowski, University of Arkansas, Fayetteville, AR, United States, dddobrzy@uark.edu, Bogdan C. Bichescu, Randy V. Bradley, Kang Lee, Renee Pratt, Antoinette Smith

Most hospitals in the USA have now adopted some form of electronic health records (EHR) while reporting varying degrees of success. Our study examines how EMR adoption influences individual measures of patient experience over time as hospitals adopt increasingly sophisticated applications. We reveal important curvilinear relationships and tipping points when hospital leaders might expect diminishing returns of patient experience.

3 - Drivers of Emergency Department Boarding

Arshya Feizi, Boston University, Boston, MA, United States, afeizi@bu.edu, Jillian Berry Jaeker, William E. Baker

One of the key reasons for emergency department (ED) overcrowding is boarding patients. Boarding occurs when admitted patients must wait for prolonged periods of time the ED pending their transfer. We investigate the systematic and behavioral causes of boarding empirically.

4 - Quality Healthcare: Patient Flows with Queue Limitation

Richard J. Schonberger, Seattle, WA, 98004, United States

This presentation advocates broad application of queue-limitation (QUEL) methodologies for enabling quick, queue-less response along the multiple flow paths leading to and involving patients. They apply virtually throughout the healthcare organization: wait-free availability/fetching of records, meds, instruments, supplies, imaging, blood, and so on—with key methodologies focused on quick, queue-limited response and patient safety.

5 - How Continuity in Service Impacts Process Control: Evidence from a Primary Care Setting.

Vishal Ahuja, Southern Methodist University, Cox School of Business, Dallas, TX, United States, vahuja@smu.edu, Bradley R. Staats, Carlos Alvarez

In service operations where customers have repeated interactions with service providers, it is critical to understand the importance of maintaining continuity of service, whether customer-types with complex needs need to be prioritized and can there be too much continuity. We study these questions in the context of healthcare - in particular, we study the impact of continuity of service on process control as measured by coefficient of variation of lab measures.

Design of Healthcare Strategies under Population Heterogeneity

Emerging Topic: Personalized Health

Emerging Topic Session

Chair: Hadi El-Amine, George Mason University, Fairfax, VA, 22030, United States

1 - A Reinforced Learning Framework for Dynamic Prediction and Management of Type 2 Diabetes Patients

Syed Hasib Akhter Faruqui, University of Texas-San Antonio, San Antonio, TX, United States, Adel Alaeddini, Jing Wang

Type 2 diabetes mellitus (T2DM) is a major health problem. Self-management of lifestyle is essential for glycemic control, and to prevent diabetes complications. Mobile-based health data can play an important role in lifestyle management and control of T2DM. We propose a Reinforcement learning model (agent) that monitors daily lifestyle data of a patient including diet, physical activity, weight, and glucose level and provides an optimal individualized self-management regiment. The model also alerts patients of lifestyle choices that may hinder their progress in attaining weight and glucose level control thus helps patients better adhere to a self-management lifestyle for control of T2DM.

2 - Learning Curve Effects and Cost Effectiveness Analysis in Precision Medicine

Manuel A. Nunez, Associate Professor, University of Connecticut, Vernon, CT, United States, mnunez@business.uconn.edu, Yucheng Chen

Precision medicine is a high-cost complex medical procedure that provides targeted treatments according to individual characteristics of each patient. We present a cost-effectiveness dynamic model to assess learning curve effects in cost reduction through interaction with centralized database repositories. We also consider public policy consequences.

3 - Optimal Clustering of Frequency Data with Application to Disease Risk Categorization

Hadi El-Amine, George Mason University, Fairfax, VA, 22030, United States, helamine@gmu.edu, Hrayer Aprahamian

We provide a novel clustering procedure for a special type of data, known as frequency data. Our interpretation of the data set as a discrete distribution allows us to extract statistical information which we embed within an optimization framework. Our analytical results of the resulting difficult combinatorial optimization problem allow us to construct exact algorithms that converge to the optimal solution in quadratic time. In addition, in order to handle larger data sets, we provide two hierarchical heuristic algorithms that run in linear time. Our case study on HIV risk categorization demonstrates substantial benefits of our proposed clustering scheme over current practices such as k-means.

4 - Optimal Test Selection for the Screening of Heterogeneous Populations

Hrayer Aprahamian, Texas A&M University, College Station, TX, United States, hrayer@tamu.edu, Hadi El-Amine

We study the design of large-scale group testing schemes under a heterogeneous population, and with the availability of multiple tests. The objective is to classify the population as efficiently and accurately as possible. Our approach examines components often neglected in the literature, such as group size dependent costs, and the possibility of no testing. By developing key structural properties of the resulting problem, we are able to reduce it to a network flow problem. We then provide results that facilitate the construction of the graph and provide a polynomial time algorithm. Our case study, on the screening of HIV in the US, demonstrates the substantial benefits of the proposed approach.

1 - Training Generative Networks Using Random Discriminators

Babak Barazandeh, University of Southern California, Los Angeles, CA, United States, barazand@usc.edu, Meisam Razaviyayn, Maziar Sanjabi

Generative Adversarial Networks (GANs) have drawn a lot of attention for learning the underlying distribution of data. Despite their wide applicability, training GANs is notoriously difficult. This difficulty is due to the min-max structure of the problem and the lack of proper tools of solving general min-max problems. In this work, we try to alleviate this problem by proposing a new generative networks that relies on the use of random discriminators instead of adversarial design. This design helps us to avoid the min-max structure and leads to an optimization problem that is stable and could be solved efficiently. The performance of the proposed method is evaluated using both synthetic and real data.

2 - Time for Devopts – Mathematical Optimization in the Age of Agile, Devops. and Cloud Infrastructure

Andrea Cassioli, Maersk Line, Fruebjergvej 3, Symbion Science Park, Copenhagen, 2100, Denmark, Stefan Guericke

In the last years, the gap between solution methods in literature and optimizations running in production has increased. Agile development practices, DevOps and modern cloud-based infrastructure call for a revisit of how optimization software is developed. We review the state-of-the-art, propose a development framework that can be applied across different programming languages and modelling frameworks and test it with an optimization use-case. The framework enables OR experts to continue focusing on solution methods but having the tools to deploy a scalable and reusable optimization application using the latest technologies and thus, increase the acceptance in industry.

3 - An Image-based Approach to Detecting Structural Similarity Among Mixed Integer Programs

Zachary James Steever, University at Buffalo, Buffalo, NY, United States, zjsteeve@buffalo.edu, Chase Murray, Mark Henry Karwan

Operations researchers have long drawn insight from the structure of a mixed integer program's (MIP) coefficient matrix. We propose a new question - can coefficient matrix structure be used to identify similarities between different MIPs? We treat these matrices as pixel map images, and employ computer vision techniques to detect latent structural features therein. These feature vectors are used to measure similarity between images, and consequently, MIP instances. For this introductory analysis, we used the collection of instances in the MIPLIB 2017 (an online repository for MIP instances) as our data set. Results indicate that this may be a promising approach for identifying related models.

4 - Mosel 5: Next Generation Modelling and Application Design Features for Optimization Projects

Susanne Heipcke, Principal Engineer, FICO, Birmingham, United Kingdom, susanneheipcke@fico.com

FICO Xpress Mosel 5 builds out its support of a dynamic and modular structure in the implementation of optimization projects, thus facilitating the collaboration of larger teams (often working in a distributed setting) in the development and maintenance of end-user applications. New features include dynamic handling of packages and the introduction of namespaces, also supported by enhancements to the development environment Xpress Workbench. Considerable performance improvements in the handling of large-scale data have been achieved through new data structures that are presented via examples.

5 - Leveraging Cloud Computing for Solving Large Scale Optimization Problems Using Scaleable Algorithms

Baykal Hafizoglu, FICO, Kennesaw, GA, United States, baykalhafizoglu@fico.com

Large scale optimization problems often cannot be solved using standard mathematical modeling methods (linear/mixed integer programs) due to excessive run times and hardware requirements. In this study, we first demonstrate a generic methodology to develop optimization algorithms, which can scale with additional hardware to reach desired solution quality and run time. We next provide examples of how FICO Xpress-Mosel leverages cloud computing to orchestrate these algorithms.

6 - Joint Predictive and Prescriptive Analytics

Mehmet Kolcu, Wayne State University, Detroit, MI, United States, fl4915@wayne.edu, Alper E. Murat

In traditional learning algorithms, the degree of closeness between true and predicted values generally measures prediction quality. However, these learning algorithms do not consider decision problems where the predictions will be used as uncertain parameters. In other words, standard approaches using point estimates as input in optimization problems miss the connection between predictive and prescriptive algorithms. We propose a new framework evaluating quality of predictions based on the decisions by integrating machine learning algorithms with optimization problems. We aim to find the parameters of learning algorithms within decision problems through bilevel optimization.

SOLA Student Best Paper Award

Sponsored: Location Analysis

Sponsored Session

Chair: Ismail Capar, Texas A&M University, College Station, TX, United States

1 - A Cyclic Allocation Model for the Inventory-Modulated Capacitated Location Problem

Kayse Lee Maass, Northeastern University, Boston, MA, 02115, United States

Hard capacity constraints have been used for decades in facility location modeling. Yet, in reality, many facilities are able to extend capacity for short periods of time. To address this, we present a cyclic, day-specific allocation approach to assigning demand sites to processing facilities that accounts for short term capacity flexibility. In particular, unprocessed demand in excess of the daily processing capacity is held and processed at the beginning of the following day. We demonstrate that this cyclic allocation and flexible capacity approach reveals cost effective operating policies that take advantage of spatial and temporal correlations in demand and capacity.

2 - Exact Robust Solutions for the Combined Facility Location and Network Design Problem in Hazardous Materials Transportation

Xufei Liu, University of South Florida, Tampa, FL, United States

We consider a bi-level leader-follower problem that simultaneously optimizes facility locations and network design in hazardous materials transportation. The leader intends to reduce facility setup cost and hazmat exposure risk by choosing facility locations and closing road segments. When making such decisions, the leader anticipates the response of the followers who aim to minimize transportation costs. A robust optimization method is used to deal with uncertain hazmat risk and transport demand. We devise an exact algorithm that combines a cutting plane algorithm with Benders decomposition.

3 - Exact Solution of Several Families of Location Arc Routing Problems

Jessica Rodriguez-Pereira, Technical University of Catalonia, Catalonia, Spain

We model and solve several families of location-arc routing problems. The aim is to select the facility locations and to construct a set of routes traversing the required edges, where each route starts and ends at the same facility. The models differ in the objective function and if capacity constraint are included. Alternative formulations with only binary variables are presented and solved by branch and cut. Despite the difficulty of the problems, the numerical results demonstrate the good performance of the algorithm, solving to optimality instances with up to 200 vertices.

4 - Benders Decomposition for Profit Maximizing Hub Location Problems with Capacity Allocation

Gita Taherkhani, University of Waterloo, Waterloo, ON, Canada

We model and solve several families of location-arc routing problems. The aim is to select the facility locations and to construct a set of routes traversing the required edges, where each route starts and ends at the same facility. The models differ in the objective function and if capacity constraint are included. Alternative formulations with only binary variables are presented and solved by branch and cut. Despite the difficulty of the problems, the numerical results demonstrate the good performance of the algorithm, solving to optimality instances with up to 200 vertices.

Joint Session MSOM/HC/Practice Curated: Empirical Healthcare Operations: Improving Quality and Process Outcomes

Sponsored: Manufacturing & Service Oper. Mgmt/Healthcare Operations

Sponsored Session

Chair: Mehmet U.S. Ayvaci, The University of Texas at Dallas, Richardson, TX, United States

Co-Chair: Ozalp Ozer, The University of Texas at Dallas, Richardson, TX, 7United States

1 - Matching Patients to Providers: A Field Experiment

Diwas S. Kc, Emory University, Goizueta Business School, Atlanta, GA, United States, Kunpeng Zhang

To examine how patients select providers, we conduct a series of field experiments in which the patient sees different characteristics of the provider. This allows us to assess what patients value most in selecting providers. We also examine the resulting effects on the quality of care.

2 - Quality Improvement Spillovers: Evidence from the Hospital Readmissions Reduction Program

Mohamad Soltani, University of Wisconsin-Madison, Madison, WI, 53706, United States, mohamad.soltani@wisc.edu, Robert Batt, Hessam Bavafa

Financial incentives are commonly used to encourage improvements in quality. However, the presence of spillovers can make managing these incentives difficult. We study the spillover effects of a national healthcare quality improvement policy, the Hospital Readmissions Reduction Program (HRRP), on patients and metrics not targeted by the policy. Whereas prior work has shown limited spillover of quality improvement initiatives in manufacturing settings, we find that in the healthcare setting, HRRP led to improvements in the target metric for non-targeted patients. We also find significant improvements in non-targeted measures such as 31-60-day readmissions, length of stay and cost.

3 - Saving Lives with Algorithm-enabled Process Innovation: The Case of Sepsis

Mehmet U.S. Ayvaci, University of Texas at Dallas, Richardson, TX, 75080-3021, United States, mehmet.ayvaci@utdallas.edu, Idris Adjerid, Ozalp Ozer

We study whether and how algorithm-enabled process innovation (AEPI) creates value in the context of an AEPI effort focused on early identification and treatment of a deadly clinical condition known as sepsis. Using a rich set of clinical and nonclinical data from a hospital system, we examine the relationship between sepsis AEPI and patient mortality. Overall, we demonstrate that sepsis AEPI is effective in reducing mortality and it does so through timely diagnostic (i.e., lactates) and therapeutic (i.e., antibiotics) interventions. As time goes by, however, the timeliness of these interventions partially lapses and so does the sepsis AEPI's reduction impact on mortality.

IS Research on Digital Platforms

Sponsored: EBusiness

Sponsored Session

Chair: Marios Kokkodis, Boston College, Chestnut Hill, MA, 02215, United States

1 - Do Corporate Contributions Spur Innovative Activity in Online Crowdsourced Goods? Evidence From the Linux Kernel

Mike Horia Teodorescu, Assistant Professor, Boston College, Chestnut Hill, MA, 02903-4370, United States, teodores@bc.edu, Do Yoon Kim

Despite significant advances in our understanding of the factors that affect corporate provision of digital public goods, the converse question of how corporate participation affects innovation in digital public goods is less understood. In this paper, we test how increased corporate participation affects source code contributions and follow-on innovation in a large open source project. We test whether corporate contributions increase non-corporate contributions or whether they "crowd out" non-corporate contributions. We find that while corporate contributions attract more contributions overall, they also lead to less follow-on innovation.

2 - On the Timing of Registration Request: A Randomized Field Experiment

Ni Huang, Arizona State University, Arizona, Gilbert, AZ, 85233, United States, Probal Mojumder, Tianshu Sun, Jinchi Lv, Joseph Golden

Online commerce websites often request user to register in the online shopping process. Recognizing the challenges of user registration, many websites opt to delay their registration request until the end of conversion funnel (ex-post registration request). Grounding on the nudge theory, our study explores an alternative approach by asking users to register with the website at the beginning of their shopping journey (ex-ante registration request). We conducted a large-scale randomized field experiment in partnership with an online retailer in the U.S. to examine how the ex-ante request affects users' registration decision, as well as short-term conversion and long-term purchase behavior.

3 - Monetary Incentives and Knowledge Spillover: Evidence from a Natural Experiment

Jing Wang, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, Gen Li, Kai-Lung Hui

Knowledge sharing is common on the Internet. In this paper, we study the effect of introducing monetary incentives for holding live talks on users' contribution to non-rewarded activity of answering questions on the same online question-and-answer platform. Using a combination of coarsened exact matching and difference-in-differences estimation techniques, we find that introducing paid program creates a positive spillover effect on the hosts' free contributions, specifically, 9.4%-40.8% more answers, in the short run when compared with non-hosts. The paid feature did not result in any significant change in the quality of answers. We suggest reputation building is likely the mechanism underlying the spillover and provide direct evidence that our finding persists in view of competing mechanisms and explanations, such as explicit advertising, reciprocity, and time spillover. Additional analyses reveal that the spillover effect in the long run is negative for short-lived hosts and positive for long-lived hosts, the latter effect gradually tapered off over time. We draw related research and managerial implications.

4 - Can (S)he Code? Gender Bias in an Open Source Software Community

Tingting Nian, University of California, Stern School of Business, Irvine, CA, 10012, United States, tnian@uci.edu

It is well-documented that women are underrepresented across all STEM fields and particularly in computing. Amongst the many factors that impact women's lack of participation in computer science-related fields, previous research identifies the negative stereotype about women's abilities is one of the leading reason. In order to scientifically examine the issue of gender bias in online open source software communities, our study investigates whether and to what extent there exists a gender bias on Stack Overflow. Our results reveal a 10.2% reduction in monthly votes after a female user reveals her gender, statistically significant at the one percent level.

Experiments in Supply Chain Contracting

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Andrew M. Davis, Cornell University, Ithaca, NY, 14853, United States

1 - Managing Multilocation Demand in Supply Chains: An Experimental Investigation

Rihuan Huang, Cornell University, Ithaca, NY, 14853, United States, rh567@cornell.edu, Andrew M. Davis, Douglas J. Thomas

We experimentally investigate managing multilocation demand from a supply chain perspective. Specifically, we consider a two-echelon supply chain consisting of one manufacturer and two retailers. We compare ex ante and ex post demand aggregation strategies. Experimental results show that the ex post strategy when the manufacturer has more pricing power outperforms the ex ante strategy.

2 - Team Decision Making in Operations Management

Jiawei Li, University of Michigan, Ann Arbor, MI, United States

We consider team decision-making in two canonical operations settings: standalone Newsvendor inventory decisions (tactical decision-making) and Newsvendor under information sharing (strategic decision-making). We find that teams perform worse than individuals when making Newsvendor decisions, and exhibit a stronger pull-to-center bias. In the information sharing setting, team retailers are less trustworthy while team suppliers are just as trusting as individual suppliers. We leverage a novel aspect of our experiment: subject teams can text chat to facilitate decision making, and provide evidence for a team-decision making framework that can organize these findings.

3 - Increased Transparency in Procurement: The Role of Peer Effects

Ruth Beer, Indiana University, Kelley School of Business, Bloomington, IN, 47404-5180, United States, ruthbeer@indiana.edu, Daniela Saban, Ignacio Rios

We study the effects of increased transparency in a setting where purchasing decisions are delegated to individual employees as opposed to being centrally managed by an organization. We develop a theoretical model which incorporates peer effects resulting from transparency and we show that there exists a spillover region where an employee is more likely to choose the expensive supplier when he observes that his peer did so. We confirm this finding with a laboratory experiment. We also find that employees whose decisions are observed are less likely to choose the expensive supplier, in line with what the social norm of appropriate behavior prescribes.

4 - The Role of Trust in Aligning Capacity Decisions in Supply Chains

Kyle Hyndman, University of Texas at Dallas, Richardson, TX, 75080, United States, Sara Benetti, Jose Lopez, Florian Federspiel, Santiago Kraiselburd

We study behavior in a series of two-player supply chain game experiments. We focus on the differences in behavior under fixed and random matching. We will measure ex ante, and ex post trust and how it interacts with outcomes and decisions.

1 - A Fuzzy Rough Based Algorithm for Automated Decisions in Blockchain Based Supply Chain

Amit Karamchandani, IIM Lucknow, Lucknow, India, fpm17013@iiml.ac.in, Samir K. Srivastava, Akhil Srivastava

Blockchain can enable the availability of all the supply chain data on a single platform. This study aims at developing an algorithm to enable the generation of automated optimized decisions in a blockchain-based supply chain.

2 - Privacy Concerns with Blackchain-based Electonic Health Records

Jingquan Li, Hofstra University, Hempstead, NY, United States, Jingquan.Li@hofstra.edu

Blockchain provides a shared, immutable and transparent history of all the transactions to build electronic health records (EHRs) with trust, accountability and transparency. The very useful features of Blockchain may also raise major privacy issues that may discourage usage. This paper examines major privacy concerns with blackchain-based EHR systems and presents our perspectives on the design of private and trustable blackchain-based EHR systems. This study first discusses how blockchain technology could help data sharing between patients and healthcare providers. It then examines the major privacy concerns. Finally, it proposes a privacy protection architecture for the blockchain.

3 - Development of an Instrument to Measure the Patient Satisfaction for Improving Adherence of Obstructive Sleep Apnea Treatment

Dursun Delen, Oklahoma State University, Tulsa, OK, United States, dursun.delen@okstate.edu, Rupesh Agrawal, Bruce Benjamin

Patient-centric health outcome is the new emphasis to develop targeted treatment for each patient. A homogenous survey instrument is absent, to measure patient satisfaction, experience, expectations, and perceptions. The goal of this study is to conduct exploratory, confirmatory factor analysis to investigate items, construct for survey instrument for patient satisfaction, explicitly for patients with obstructive sleep apnea disorder. The study will lay the foundation for the development of the survey instrument for patient satisfaction, experience, expectations, and perceptions.

4 - Become Friends with Customers: Enterprises Participate in Social Activities in Online Health Communities

Wanxin Qiao, Beijing Institute of Technology, Beijing, China, Zhijun Yan, Junwei Kuang, Fei Peng

The behavior of enterprises participating in social networks is an important operational strategy in marketing and an effective means to increase their stickiness with customers. Most literature has focused on the impacts of the behavior of individual joining social network, but little research has investigated the behavior of enterprises participation in that. Thus, this study examines the relationship between the use of "Friends", a mode with social attributes in online health communities, and customer satisfaction or customer sharing behavior. The results show that enterprises use "Friends" behavior will positively affect customer satisfaction and customer sharing behavior.

1 - Distributionally Robust Optimization with Shape Information

Ruiwei Jiang, University of Michigan, Ann Arbor, MI, 48109, United States, Yuanyuan Guo

Incorporating shape information (e.g., unimodality, log-concavity, etc.) into distributionally robust optimization (DRO) models can reduce conservatism. Unfortunately, such incorporation often makes DRO models computationally intractable. This paper investigates a general framework and shows that the corresponding DRO model can be recast as a stochastic program with respect to an unambiguous probability distribution. This facilitates efficient solution algorithms (e.g., sample average approximation) for DRO models with shape information.

2 - Why is Maximum Clique Often Easy in Practice?

Jose Luis Walteros, 1983, Buffalo, NY, United States, Austin Buchanan

To this day, the maximum clique problem remains a computationally challenging problem. Indeed, despite researchers' best efforts, there exist unsolved benchmark instances with one thousand vertices. However, real-life instances with millions of vertices can be solved in a few seconds. Why is this the case? In this paper, we provide a rigorous explanation for this phenomenon based on a graph parameter which we call the clique-core gap. When this graph parameter can be treated as a constant, as is often the case for real-life graphs, the maximum clique problem can be solved in time O(m^1.5).

3 - A Model of Queue-Scalping

Luyi Yang, Johns Hopkins University, Baltimore, MD, 21202, United States, Zhongbin Wang, Shiliang Cui

Recent years have witnessed the rise of queue-scalping in congestion-prone service systems. A queue-scalper has no material interest in the primary service but proactively enters the queue in hopes of selling his spot later. This paper develops a queueing-game-theoretic model of queue-scalping and examines its implications for the service system. Contrary to conventional wisdom, we find that queues with an intermediate demand volume can be most susceptible to scalping, rather than queues with either very small or very large demand volume. This result implies that an effort to mitigate scalping through capacity expansion may only lead to the presence of more scalpers.

Joint Session OMS/Practice Curated: Contemporary Scheduling

Emerging Topic: Project Management & Scheduling

Emerging Topic Session

Chair: Emrah Cimren, Starbucks, Seattle, WA, 98134, United States

1 - Forecasting Project Delays with Contextual Task Information and Machine Learning

Xiaojia Guo, University College London, International Hall, Lansdowne Terrace, London, WC1N 1AS, United Kingdom, x.guo.11@ucl.ac.uk, Yael Grushka-Cockayne, Bert De Reyck

Forecasting project durations, costs, and resources is a critical process of any project. Inaccurate forecast of these quantities is a major source of risk in project management. We propose a new method of forecasting project durations based on past schedules and actual timelines. We apply text mining and nature language processing techniques to extract characteristics from the name and description of a task. These characteristics, together with those of the task's predecessors, successors and parallel tasks, are used as predictors to forecast the distribution of task durations. We show that our method is more accurate than existing benchmarks in predicting task durations and project durations.

2 - Network Design with Routing Consideration

Emrah Cimren, Starbucks, Seattle, WA, 98134, United States, Joe Caven, Lecoeuche Renaud, Michael Chun

As a result of growing customer demand, companies may need to redesign their distribution network by adding new locations and expanding capacity of distribution centers. In this work, we develop a network design methodology which provides new distribution center locations and facility types in consideration of vehicle routings for efficient transportation activities. The methodology is applied on Starbuck's Consolidated Distribution Center Network.

3 - Detailed Simulation as Means for Scheduling Inventory Movements in a Retail Environment

Cameron Bartok, Starbucks, Seattle, WA, 98134, United States, Thomas Gartner, Renaud Lecoeuche

Today's retail environments must deal with inventory in multiple states; frozen, thawing, fresh etc. To enable business, inventory must be cycled through these states at the right time. This requires balancing the risk of waste given short shelf life of fresh items and the need to have fresh inventory for customers to purchase. In this work we investigate the use of detailed simulation to understand the opportunity and risk of scheduling when and how much inventory to prepare for sale.

4 - Approximation Schemes for Minimizing the Maximum Lateness on a Single Machine with Release Times under Non-availability or Deadline Constraints

Hans Kellerer, Universitat Graz, Graz, Austria, hans.kellerer@uni-graz.at, Imed Kacem

We consider four single-machine scheduling problems with release times, with the aim of minimizing the maximum lateness. In the first problem we have a common deadline for all the jobs. The second problem looks for the Pareto frontier with respect to the two objective functions maximum lateness and makespan. The third problem is associated with a non-availability constraint. In the fourth one, the non-availability interval is related to the operator who is organizing the execution of jobs on the machine. For each of the four problems, we establish the existence of a polynomial time approximation scheme (PTAS).

Product and Business Model Innovation

Emerging Topic: New Product Development

Emerging Topic Session

Chair: Niyazi Taneri, National University of Singapore, Singapore, 119245, Singapore

1 - Drivers of Food Waste in Commercial Kitchens: An Empirical Analysis

Varun Karamshetty, INSEAD, Boulevard de Constance, Fontainebleau, 77300, Singapore, Varun.Karamshetty@insead.edu, Elena Belavina

Kitchens are wasting as much on food waste as they make in profits. With an estimated $1 trillion in food being wasted every year, food waste is not only a huge economic loss, but also has a major impact on our environment accounting for nearly 15% of global GHG emissions. We analyze proprietary data, collected using a novel IoT technology based electronic monitoring system, to understand key drivers of food wastage in commercial kitchens. We identify the controllable factors, and quantify the impact of each of them. We then propose changes in their operations that minimize wastage while maintaining their service quality and bottom-line.

2 - Designing Resource Competitions for Research Projects

Wenqi Lian, Singapore Management University, Singapore, wenqilian.2015@pbs.smu.edu.sg, Pascale Crama

University-administered research funds (UARF) at major research universities are an important source of early bridge funding for academic research, often the first step in the journey to secure the necessary government funding. Our model investigates how the UARF's objectives and funding rules affect social welfare outcomes by influencing the novelty and quality of projects being funded by the government. We observe that a UARF funding rule that focuses on novel projects provides the highest social welfare, regardless of the UARF's objective. Finally, we present a non-threshold funding rule that can outperform various threshold-based rules by allocating funds to marginal projects.

3 - Managing Public-private Partnerships for the Development of Drugs for Neglected Diseases

Rongrong Luo, Singapore University of Technology and Design, Singapore, 485999, Singapore, rongrong_luo@mymail.sutd.edu.sg, Shantanu Bhattacharya, Niyazi Taneri, Ying Xu

Although neglected diseases seriously impair people' lives, biopharmaceutical firms lack financial incentives to develop drugs for them. The prevalent solution is to build R&D collaboration between an NGO and the firms. We analyze such a contractual relationship and see how the NGO balances the cost of incentivizing the firms and the social welfare achieved by developing the drug for the neglected disease.

Economic Growth, Environment and Climate

Emerging Topic: Sustainable Growth

Emerging Topic Session

Chair: Yongyang Cai, Ohio State University, Columbus, OH, 43210, United States

1 - Regional Sustainable Economic Development under Risks

Ziqian Gong, The Ohio State University, Columbus, OH, United States, gong.286@osu.edu, Yongyang Cai, Brian Cultice, Ziyu Guo, Shaohui Tang, Yaoping Wang, Jeffrey Bielicki, Alan Randall, Ian Sheldon, Elena Irwin

We develop a Dynamic Regional Food, Energy, Water Systems (DRFEWS) model to analyze the environmental sustainability and individual well-being resulting from shifts in complex economic and environmental systems. Our DRFEWS model uses a dynamic general equilibrium framework to represent the interactions between local, regional, national, and global systems across time and space as well as sectors including households, farming, manufacturing, food, energy, and ecosystem. We apply our model to evaluate the sustainability of Great Lakes (GL) regional economic practices, and then help decision-makers maximize the potential of the GL economy and environment to benefit its citizens.

2 - Assessing the Economic and Environmental Efficiency of the Ukrainian Power Generation Sector

Javier Inon, World Bank Group, Washington DC, CO, United States, javier.inon@gmail.com, Jevgenijs Steinbuks, Debabrata Chattopadhyay

This study seeks to assess the efficiency of the Ukrainian power generation under physical, regulatory and environmental constraints. Using a novel dataset on electricity generation for each utility-scale power plant from 2012 to 2018, we optimize the generators' dispatch accounting for zonal transmissions caps and fuel, import and operational limits. The cost-efficiency gap is calculated between the observed allocations and prices to the least-cost solutions. Sensitivity and econometric analyses are performed to account for uncertainties in transmission constraints, fuel supply limits and environmental mandates, and determining key factors affecting the calculated efficiency gap.

3 - Optimal Timber Management Decisions in the Face of Future Uncertainties

Alla Golub, Purdue University, West Lafayette, IN, 95032, United States, golub@purdue.edu, Brent Sohngen, Yongyang Cai, Thomas Hertel, John Kim

The goal of this study is to examine the impacts of uncertainty in future climate, income and population, as portrayed in the IPCC's Shared Socio-Economic Pathways, on optimal timer management decisions. The analysis is based on a dynamic forward looking model of global land use with biome specific competition for land, representation of timber sector, and climate impacts. A min-max-regret analysis is conducted to determine a robust path of timber management investments that factors in key uncertainties. The results suggest that, while climate change can have important consequences for forests, economic growth has the strongest impact on forested ecosystems in the future.

4 - Climate Policy with Carbon Removal and Storage in a Dynamic Stochastic Economy

Yongyang Cai, Ohio State University, Columbus, OH, 43210, United States, cai.619@osu.edu, Kenneth Judd

We build a dynamic stochastic integrated model of the climate and economy to incorporate elements such as carbon removal and storage, economic risks, recursive preference, and climate target constraints (e.g., the global average atmospheric temperature increase does not exceed 2 or 1.5 Celsius). We solve it numerically using parallel value function iteration for the high-dimensional dynamic stochastic programming problem. We find that the climate target constraints significantly increase the social cost of carbon (SCC), and the technology improvement in carbon removal and storage can significantly reduce the SCC.

Innovation and Entrepreneurial Operations

Emerging Topic: Technology, Innovation Management & Entrepreneurship

Emerging Topic Session

Chair: Karthik Ramachandran, Georgia Institute of Technology, Atlanta, GA, 30308, United States

1 - Inventory, Speculators and Initial Coin Offerings

Rowena J. Gan, The Wharton School, Philadelphia, PA, 19103, United States, ganj@wharton.upenn.edu, Gerry Tsoukalas, Serguei Netessine

Initial Coin Offerings (ICOs) are an emerging form of fundraising for Blockchain-based startups. We propose a simple model of matching supply with demand with ICOs by companies involved in production of physical products. We examine how ICOs should be designed in the presence of product demand uncertainty, make predictions on ICO failure, and discuss the implications on firm operational decisions and profits.

2 - Dueling Innovation Contests

Konstantinos Stouras, UCD Smurfit, Stillorgan, Ireland, konstantinos.stouras@ucd.ie, Sanjiv Erat, Casey Lichtendahl

In a crowdsourcing platform, firms design competing innovation contests and solvers self-select which contest to exert effort into. We study equilibria among competing budget allocations. We show that there is a unique dominant strategy for each firm to reward multiple identical rewards. In contrast, when firms' objectives are sufficiently close to ideation contests, a single first reward is the unique equilibrium allocation. Our theory predicts that observed variation in reward provision can be explained by different objectives of competing firms.

3 - Sequential Product Development and Introduction by Cash-constrained Start-ups

Sreekumar R. Bhaskaran, Southern Methodist University, Cox School of Business, Dallas, TX, 75275, United States, Sinan Erzurumlu, Karthik Ramachandran

For startups, introduction of an on-hand product can generate additional funds to support the development of an advanced product. However, the lower performance of the on-hand product can negatively impact the perceptionof the firm's future products—i.e., cannibalize the payoffs of the advanced product—and lower future profitability. We study this trade-off between revenues that an on-hand product generates for R&D funding and the cannibalization effect it has on future products. We characterize the optimal introduction timing of the on-hand product as a function of the financial resource constraints, the interdependence between these sequential products and the cost of development.

4 - The Learning-financing Tradeoff At Lean Startups

Onesun Steve Yoo, University College London, School of Management, London, E14 5AB, United Kingdom, onesun.yoo@ucl.ac.uk, K. Sudhir

The lean startup methodology advocates an iterative and adaptive product development and testing approach that maximizes the startup's likelihood of market success. However, the entrepreneur faces an important tradeoff between product development and testing choices that optimizes learning for the startup's market success against observable signals for investors who decide on whether to finance the startup and the terms of financing. We characterize the learning-financing tradeoff and the extent of its effects in a startup's product development choices.

Forestry IV: Models and Methods for Forest Planning under Risk

Sponsored: Energy, Natural Res & the Environment/Forestry

Sponsored Session

Chair: Andres P Weintraub, Universidad de Chile, Santiago, Chile

Co-Chair: Cristóbal Pais, UC Berkeley, Berkeley, CA, United States

1 - Downstream Protection Value: A Firesmart Fuel Management Decision Support System for Reducing Landscape Wildfire Risk

Cristóbal Pais, M. Sc, UC Berkeley, Berkeley, CA, United States, j.garcia@ctfc.es

Please check the mobile app for this abstract.

2 - A Simulation Based Heuristic Approach to Support Decision to Support Decisions in Forest Fires Fuel Management

Andrés P. Weintraub, Professor, Universidad de Chile, Santiago de Chile, Chile

How to incorporate protection of valuable forest areas from future firesinto management plans is a complex problem, in particular given the spatial andhigh uncertainty characteristics of fires. We make use of a stochastic firespread simulator to evaluate different harvesting strategies throughcarrying out a high number of simulations.

3 - Cell2fire: A New Stochastic Cell-based Fire Growth Model for Forest Management

Jaime Adrián Carrasco Barra, PhD Student, Universidad de Chile, Santiago de Chile, Chile

Cell2Fire is a new cell-based forest and wildland landscape fire growth simulator. The fire environment is characterized by partitioning the landscape into a large number of homogeneous cells and specifying the fuel, weather, fuel moisture and topography attributes of each cell. Fire spread within each cell is assumed to be elliptical and governed by spread rates predicted by different fuel models. In particular, the BehavePlus Fire Modeling, Canadian Forest Fire Behavior Prediction, and Kitral Chilean Systems are included in Cell2Fire. We validated Cell2Fire by using it to predict the growth of real fires and compared our predictions with those produced by existing state-of-the-art simulators.

4 - A Parallel Progressive Hedging Algorithm for Stochastic Harvest Scheduling under Climate Change

Martin B. Bagaram, PhD Student, University of Washington, Seattle, WA, United States, martb@uw.edu, Sandor F. Toth, Weikko S. Jaross, Andres P. Weintraub

To account for climate change, in forest harvest scheduling, we discretize the potential distribution of forest growth under different climate scenarios and solve the resulting stochastic mixed integer program. Increasing the number of scenarios allows to better approximate the entire probability space of future forest growth but at the computational expense. We propose to solve in parallel the scenario-based sub-problems using parallel computing. We fix the variables (starting from the root-node) upon satisfaction of their relevant non-anticpativity constraints. Once all variables from a node are fixed, the model can be separated into sub-problems that are recursively solvable in parallel

Joint Session ENRE/Elec/Practice Curated: Computational Frontier in Power Systems

Sponsored: Energy, Natural Res & the Environment/Electricity

Sponsored Session

Chair: Feng Qiu, Argonne National Laboratory, Lemont, IL, 60439, United States

Co-Chair: Alinson Xavier, Argonne National Laboratory, Argonne, IL, 60439, United States

1 - New Formulation of Transmission Constraints for Decentralized Power Systems Optimization

Alinson Santos Xavier, Argonne National Laboratory, Argonne, IL, 60439, United States, axavier@anl.gov, Feng Qiu, Santanu Subhas Dey

The DC power flow formulations most commonly used in the industry, based on injection shift factors, have dense and unstructured constraints, which makes them unsuitable for decentralized studies. In this work, we propose a new DC power flow formulation which has a decomposable block-diagonal structure, scales well for large systems, and can handle N-1 security requirements. The formulation can also be used to determine optimal energy exchange prices between neighboring zones. Benchmarks on Multi-Zonal Security-Constrained Unit Commitment show that it can reliably solve instances with up to 6,515 buses, with no convergence or numerical issues.

2 - Spatial and Topological Interdiction for Transmission Systems

Russell Bent, Los Alamos National Laboratory, Los Alamos, NM, 87545, United States, Kaarthik Sundar, Sidhant Misra, Feng Pan

This talk models two new classes of N-k attacks in power transmission system: (i) Spatial N-k attacks where the attack is constrained to be within a specified distance of a bus chosen by an attacker and (ii) Topological N-k attacks where the attack is constrained to connected components. Each of these problems is formulated as bilevel, max-min optimization problems algorithms to solve these formulations will be presented. Detailed case studies analyzing the behavior of these interdiction problems and comparing them to the traditional worst-case N-k interdiction problem will also also presented.

3 - HIPPO – Numerical Experiments for Solving Unit Commitment

Feng Pan, Pacific Northwest National Laboratory, Richland, WA, 99352, United States, Yonghong Chen, Jesse Holzer, Ed Rothberg, Arun Veeramany

HIPPO is a software library developed to solve security constrained unit commitment (SCUC) problems. The size of SCUC can be large for ISO-size day-ahead market and SCUC model can have a wide-range performance on different market cases. In this talk, we will discuss the numerical experimental results from solving SCUC on MISO cases.

4 - Machine Learning for Improving Power System Optimization Performance

Feng Qiu, Argonne National Laboratory, Lemont, IL, 60439, United States, Alinson Santos Xavier, Shabbir Ahmed, Xiaoyi Gu, Santanu S. Dey

Machine learning has been used in various areas in energy sector, e.g., forecasting and detection. In this talk, we focus on using machine learning techniques to improve the computational performance of a number of fundamental mixed-integer programming optimization problems in power systems. Machine learning is used to extract information from historical instances (e.g., input data, solutions, solver information) to improve the computational performance of MILP solvers when solving similar instances in the future. Computational results show that the proposed machine learning approaches can effectively improve the performance.

Enhancing Renewable Energy Integration through Optimization Techniques

Sponsored: Energy, Natural Res & the Environment/Electricity

Sponsored Session

Chair: Neng Fan, University of Arizona, Tucson, AZ, 85721, United States

Co-Chair: Jose Ruiz Duarte, University of Arizona, Tucson, AZ, 85721, United States

1 - Operations Management for a Vertical Farm with Onsite Renewable Energy Integration and Demand Response

Jose Luis Ruiz Duarte, University of Arizona, Tucson, AZ, 85721, United States, jlruizduarte@email.arizona.edu, Neng Fan

Food security is one of the main issues addressed by international community. Controlled environment agriculture increases the productivity of food systems at the cost of being highly energy intensive due to the control mechanisms to simulate an ideal environment for crops. In this presentation, the development of an optimization model for the energy-related operations of a controlled environment greenhouse with onsite energy storage systems and renewable energy sources with uncertain power output and operating under demand-side management policies is shown. A sensitivity analysis is performed under different scenarios and growing policies.

2 - A Co-optimization Scheme of Distributed Joint Market with Microgrids

Yiwei Wu, University of Houston, Houston, TX, 77004, United States, ywu41@uh.edu, Gino J. Lim, Jian Shi

The microgrid (MG) is becoming the most promising platform to incorporate distributed energy resources. However, the potential for microgrids to provide ancillary services (AS) to support the distribution system (DS) operation has not been well explored. Besides, the interaction procedures between MGs and DS become more complicated with both power delivery and AS. In this work, we proposed a decentralized joint DS market structure where the MGs can conduct power delivery and AS scheduling. The problem is formulated as a bi-level programming model where the upper level is a DS management problem and the lower level presents MG optimal scheduling problem and solved using an efficient algorithm.

3 - Behavior of Storage Capacities in Response to Market Prices

Mehrdad Pirnia, University of Waterloo, Waterloo, ON, N2L3G1, Canada, mpirnia@uwaterloo.ca, John David Fuller, Hassan Shavandi

We present an analytical research to study the behavior of electric storage capacities in response to electricity market prices, when renewable generation with and without uncertainty is integrated into the grid. Our study considers both deterministic and stochastic models when the storage capacity participates in reserve market and when it operates as only an energy market. To model the stochastic models we use chance constraints. We use the findings of this research to estimate the service life of batteries based on their cycles.

4 - N-1-1 Contingency-Constrained Unit Commitment with Renewable Integration and Corrective Actions

Daniel A. Zuniga Vazquez, University of Arizona, Tucson, AZ, 85721, United States, danielzunigav@email.arizona.edu, Jose L. Ruiz Duarte, Neng Fan, Feng Qiu, Jianhui Wang

Achieving an N-1-1 reliable power system is crucial. The complexity is increased for the unit commitment problem when contemplating renewable energies, due to their intermittent behavior. This research presents a power system unit commitment problem attaining the N-1-1 reliability standards defined by NERC with corrective actions, as well as operations compliance check on economic dispatch, power flows under contingency states, and worst case renewable energy generation. For an efficient solution, a variation of the nested Column-and-Constraint-Generation (C&CG) algorithm is presented. The model and algorithm are evaluated on modified versions of several IEEE test systems.

Optimization in Energy and Power Grids

Sponsored: Energy, Natural Res & the Environment/Energy

Sponsored Session

Chair: Shenyinying (Ruby) Tu, Northwestern University

1 - A Two-Stage Decomposition Approach for AC Optimal Power Flow

Shenyinying Tu, Northwestern University, Hampton Pkwy, Evanston, IL, 60201, United States, Andreas Waechter, Ermin Wei

This paper proposes a decomposition approach to solve ACOPF problems. The power network is decomposed into a master network and a set of subnetworks. We formulate the problem as a two-stage optimization problem and require only a small amount of communication between the master network and subnetworks. The key contribution is a novel smoothing technique that renders the response of a subnetwork differentiable with respect to the input from the master problem. Speedup can be obtained by processing the subnetworks in parallel. Numerical results show favorable convergence results and illustrate the scalability of the algorithm.

2 - Finding Solutions to Security-constrained ACOPF Problems

Daniel Bienstock, Columbia University, New York, NY, United States, dano@columbia.edu

We discuss methodologies used to address the security-constrained ACOPF problem in the recent GO competition. Joint work with R. Waltz, S. Mourait and J. Nocedal.

3 - Optimal Power Flow with Sequential Convex Restriction - Identifying a Feasible Path

Line Roald, University of Wisconsin-Madison, Madison, WI, 87544, United States

Due to the non-convexity of the AC optimal power flow, it is unclear whether there exists a sequence of control actions which can drive the system from our current to the new, optimal operating point without violating any operational constraints. Here, we describe a method to identify such a feasible path by solving a sequence of convex quadratic programs, where each program corresponds to a convex inner approximation of the AC feasible region. Due to the properties of convex sets, there is a guaranteed feasible path between the operating points identified in each iteration. Extensive numerical studies on IEEE test cases show that the method arrives at a high-quality solution in few iterations.

4 - Grid-Aware versus Grid-Agnostic Distribution System Control: A Method for Certifying Engineering Constraint Satisfaction

Daniel K. Molzahn, Assistant Professor, Georgia Institute of Technology, Atlanta, GA, 60605, United States, molzahn@gatech.edu, Line Roald

Distributed energy resource (DER) controllers may be grid-agnostic or grid-aware, depending on whether distribution network constraints are considered. Grid-agnostic controllers do not need network models or system measurements, but may cause dangerous constraint violations. We consider the potential impacts of DER controllers with respect to network constraint violations. Specifically, we describe an optimization-based method that certifies when any grid-agnostic controller can be applied without concern regarding network constraint violations, or, conversely, when grid-aware control may be needed to maintain distribution grid security.

Advanced Analytics for Local Energy Markets and Aggregator Business Models

Sponsored: Energy, Natural Res & the Environment/Energy

Sponsored Session

Chair: Anthony Papavasiliou, CORE, UCL, Voie du Roman Pays 34, L1.03.01, Office b.114, Louvain la Neuve, 1348, Belgium

Co-Chair: Yuting Mou, Universite Catholique de Louvain

1 - A Bi-Level Optimization Formulation of Multilevel Demand Subscription Pricing

Yuting Mou, Universite Catholique de Louvain, Louvain, Belgium, Anthony Papavasiliou, Philippe Chevalier

In this study, we revisit multilevel demand subscription pricing (MDSP) for electric power, in which a price plan to assign different reliability combined with duration for a slice of power is offered. We formulate the menu design as a Stackelberg game where an aggregator moves first with a menu, and residential consumers react by selecting menu options. The Stackelberg game is modelled as a bi-level optimization problem, and then reformulated as an MIP. Using our approach, we can integrate the menu design problem into a day-ahead market model and mobilize residential flexibility.

2 - Private Versus Public Information and Mechanism Design for Aggregating Customers in the Electricity System

Alberto J. Lamadrid, Lehigh University, Bethlehem, PA, 18015-3120, United States, Tim Mount

We present a market structure for hierarchical exchanges between an electric transmission system operator and independent aggregators controlling distributed storage, in the form of deferrable demand. The objective of these aggregators is to minimize the expected payments for electric energy, subject to meeting the energy needs of their customers, while submitting bids into the wholesale market as an interface with the system operator. This structure represents an alternative to, e.g., extending the logic of nodal pricing to individual customers or adding markets for new products such as VARs.

3 - Negotiation Mechanisms for Local Energy Markets

Thomas Morstyn, University of Oxford, Oxford, OX1 1HG, United Kingdom

Local energy markets offer the new opportunity to incentivise coordination between owners of distributed energy resources, so that their flexibility can be integrated into power system operations. Recently proposed mechanisms for negotiating transactions in local energy markets are presented, including profit sharing based on cooperative game theory; deferred acceptance from matching market theory; distributed optimisation; and unidirectional locational marginal pricing. These mechanisms are compared in terms of trade-offs offered for market objectives including economic efficiency, game theoretic stability, computational burden and addressing network constraints.

4 - Operate a Local Energy Market (LEM) Based on Market Clearing Algorithms – N-SIDE and Centrica Present their Pioneering Platform

Damien Denayer, N-SIDE, Louvain, Belgium, Olivier Devolder

To help system operators (SO), N-SIDE and Centrica are developing an innovative Local Energy Market (LEM) platform. Its purpose is to unlock the potential of flexibility at low voltage level and to provide alternatives to grid reinforcement or long term contracts. It includes a market clearing algorithm matching bids and offers, ensuring transparent solutions, maximizing the gains for the flexibility owners and minimizing the costs for SO. The market is being tested in a project in the UK. N-SIDE and Centrica will demonstrate the different features of the LEM, its benefits and the first results.

Regional Modeling of Energy Systems

Sponsored: Energy, Natural Res & the Environment/Energy

Sponsored Session

Chair: Gokul Iyer, Pacific Northwest National Laboratory, College Park, MD, 20740, United States

Co-Chair: Felipe A Feijoo, Chile

Co-Chair: Zarrar Khan, Pacific Northwest National Laboratory, College Park, MD, 20740, United States

1 - Climate Variability Impacts on US Power System Capacity and Operations

Gokul Iyer, Pacific Northwest National Laboratory, College Park, MD, 20740, United States, gokul.iyer@pnnl.gov, Zarrar Khan, Pralit Patel, Marshall Wise, Mohamad Hejazi, Sonny Kim

Electricity demand is expected to grow over the coming decades creating a need for long-term power sector planning to ensure an adequate and reliable power system capable of adapting to changes in demand profiles within a multi-sectoral framework. Existing power sector models capture the complexities of electricity supply and demand but often ignore the broader system. In contrast, multi-sector human-earth system models capture complex relationships across sectors and systems but represent power sector dynamics at fairly aggregate levels. In this study we enhance GCAM-USA, an existing multi-sector model to capture sub-annual electricity demand dynamics in response to changing temperatures.

2 - Energy Transitions for Reaching Climate Targets: The Case of 1.5c Energy-water-food Nexus in Latin America

Felipe A. Feijoo, Pontificia Universidad Catolica de Valparaiso, Av. Brasil 2241, Office 6-8, Valparaiso, Chile, felipe.feijoo@pucv.cl, Andrea Arriet

We study the energy, food, water nexus in Latin American countries under scenarios consistent with the Paris agreement of making efforts to keep global warming to 1.5C by the end of the century. For this research, we developed and used a detailed version of the Global Change Assessment Model (GCAM) develop for Latin America. The benefits of using a detailed version of GCAM (GCAM-LAC) are also discussed.

3 - Regional Energy Deployment System 2.0 – An Open Access Capacity Expansion Model

Maxwell Brown, National Renewable Energy Laboratory, Golden, CO, United States

This presentation focuses on the re-development of the Regional Energy Deployment System (ReEDS 2.0), a detailed capacity expansion model of the continental US. Specific topics addressed are the motivation behind and challenges in redeveloping the model as well as considerations for future development.

4 - Electrification Scenarios for New York State's Low Carbon Energy Future

Delavane Diaz, Electric Power Research Institute, Washington, DC, 20005, United States

This paper describes an enhanced version of EPRI's innovative US-REGEN energy-sector model to capture the integrated nature of New York's electric and non-electric energy systems with high structural, temporal, and spatial resolution. We develop and compare a range of policy and technology scenarios to evaluate the potential role of electric technologies to meet energy needs, and resulting impacts on modeled energy system and environmental outcomes through 2050 in New York State.

5 - Achieving Climate-land-energy-water Sustainable Development Goals in the Indus Basin and the Role of Cross-border Cooperation

Adriano Vinca, International Institute for Applied Systems Analysis, Laxenburg, Austria
Adriano Vinca, University of Victoria, Victoria, BC, Canada, Simon Parkinson, Ansir Ilyas

The Indus Basin, a highly densely irrigated area home to about 300-million people, has expected growing demands for water, energy and food in the coming decades. With no abundant surface water left in the basin and accelerating use of groundwater, long-term strategic and integrated management of water and its interlinked sectors (water-energy-land) is fundamental for the sustainable development of the region. We show a scenario-based analysis using numerical models (The Nexus Solution Tool) where we link local issues and policies to the Sustainable Development Goals, showing synergies and conflicts among different objectives and the value of international cooperation to achieve such goals.

Monday, 8:00AM - 9:30AM

Joint Session DM/Practice Curated: Data Analytics for Retailers

Sponsored: Data Mining

Sponsored Session

Chair: Chloe Glaeser

1 - The Value of Pop-up Stores on Retailing Platforms: Evidence from a Field Experiment with Alibaba

Dennis Zhang, Washington University in St Louis, St Louis, MO, 63130, United States, denniszhang@wustl.edu, Hengchen Dai, Lingxiu Dong

Omni-channel retailing has become an essential strategy in modern-age retailing. We study the value of short-lived and experiential-oriented pop-up stores, a popular type of omni-channel retail strategy, on both retailers that participate in pop-up store events and retailing platforms that host these retailers. We conducted a large-scale randomized field experiment with Alibaba Group involving approximately 800,000 customers and used advanced Wi-Fi technology to track every customer's visit to a pop-up store—a missing component from past research that commonly relies on point-of-sales data.

2 - How to Find Your Most Valuable Service Outlets: Measuring Influence Using Network Analysis

Qiuping Yu, Georgia Institute of Technology, Atlanta, GA, 47405-1701, United States, Shawn Mankad, Masha Shunko

Consider a network of stores operating under the same brand, for example, a chain of coffee shops (Starbucks). Improving quality and increasing sales at one store may have different impact on the other stores: from negative impact as a result of potential cannibalization, to positive impact from improved brand reputation and knowledge spillover. In this paper, we propose a methodology to causally identify the network effects that stores have on each other and the total influence of each store on the entire network at a large scale. By applying our method to a large dataset from a major national restaurant chain in the US, we provide insights in effectively managing the network of the brand.

3 - Personalizing Retail Promotions Through a Dag-based Representation of Customer Preferences

Srikanth Jagabathula, NYU Stern School of Business, New York, NY, 10012, United States, sjagabat@stern.nyu.edu, Dmitry Mitrofanov, Gustavo J. Vulcano

We propose a new method to personalize promotions in the retail setting. Our method relies on a new representation of customer preferences in the form of a directed graph. A directed edge A -> B from brand A to brand B in the graph indicates that the customer strongly prefers brand A over brand B, and this preference remains stable over time. We assume that these preferences are acyclic, so our representation will become a directed acyclic graph (DAG). We propose techniques using which a retailer can infer the DAG representation of each customer from observed purchase transactions. We demonstrate the efficacy of our approach on data from a collection of grocery retailers.

4 - Predictive and Prescriptive Analytics for Location Selection of Add-on Retail Products

Teng Huang, University of Connecticut, Storrs, CT, United States, teng.huang@uconn.edu, David Bergman, Ram Gopal

We study an analytical approach to selecting expansion locations for retailers selling add-on products. In our context, both base and add-on products could be subject to spatial autocorrelation. Using data from an industrial partner, we build predictive models for understanding the derived demand of the add-on product and establish an optimization framework for automating expansion decisions to maximize expected sales. Spatial autocorrelation and the complexity of the predictive model impact the complexity and the structure of the prescriptive optimization model. Using the optimization framework can result in substantial increases in expected sales over baseline policies.

Data Analytics in Developing Quality Management Theory

Sponsored: Data Mining

Sponsored Session

Chair: Richard Peng

Co-Chair: Heng Xie, University of North Texas - College of Business, Denton, TX, 76203-5017, United States

1 - Multiple Methods Analysis for Quality Management Theory Development

Heng (John) Xie, University of North Texas, 1155 Union Circle #311277, 304C, Denton, TX, 76203-5017, United States, Heng.Xie@unt.edu, Xianghui (Richard) Peng, Victor R. Prybutok

This study uses meta-analysis and text mining to compare the gaps between academic literature and industry practice in quality management. We analyze the findings from the literature by using meta-analysis. We utilize confirmatory semantic analysis to examine the Baldrige winners. The results reassess the relationship between quality management practices and performance. This study contributes to quality management theory development.

2 - Investigating the Dynamics of Quality Management Theory Evolution Through Text Analytics

Benjamin T. George, Assistant Professor of Business Analytics, University of South Dakota, Sioux Falls, SD, 57106, United States, Bartlomiej Hanus, Rebecca Scott

Quality Management Theory (QMT) is an ever-evolving paradigm driven by changes in both technology and emerging applications for quality. The chief chronicler of this growth is the academic journals within the field. The goal of this study is to examine whether the underlying concepts of quality theory are presented differently through Application-driven and Technical-driven quality publications. We scraped data from respective abstracts of two competing academic quality-focused journals. Text mining techniques are then applied to investigate the underlying characteristics to determine similarities and differences.

3 - A Meta-analysis of Technology Acceptance in Healthcare

Xinyu Wei, University of North Texas, Denton, TX, 76201, United States, xinyu.wei@unt.edu, Victor R. Prybutok, Xianghui (Richard) Peng

The study of healthcare technology acceptance from a consumer's perspective generates increasing interest in both academia and industry. In the current study, we synthesize relevant findings from previous empirical studies to extend and refine the existing technology acceptance theories in healthcare context using meta-analysis techniques. Insights for practitioners and contributions to academia, especially quality management, are discussed.

Sponsored Session

Chair: Feng Qiu

1 - Mining Utility Data for Enhancing Distribution Grid Observability and Resilience

Zhaoyu Wang, Iowa State University, Ames, IA, 50011, United States, wzy@iastate.edu

This talk will present our research on enhancing power distribution grid observability and resilience using real utility data and machine learning techniques. We have archived a large amount of smart meter, PMU and SCADA data and associated grid circuit models from collaborating utilities. By leveraging the smart meter data, we can infer hourly consumption patterns of unobservable customers using only their monthly billing information. In addition, we have used multi-year data from outage management systems to model distribution grid resilience curves and characterize resilience features.

2 - An Online Mechanism Design to Elicit Multi-Dimensional Flexibilities from Electric Vehicles

Bo Sun, the Hong Kong University of Science and Technology, Hong Kong, Hong Kong, bsunaa@connect.ust.hk, Xiaoqi Tan, Danny Tsang

Electric vehicles (EVs) have been well-recognized as a deferrable load in demand-side management programs. To better integrate an increasing number of EVs into power systems reliably and economically, we identify and exploit two novel and promising flexibilities, namely, energy-flexibility and deadline flexibility, beyond the deferrable properties of EVs. We have designed a priced-based online mechanism to elicit those multi-dimensional flexibilities from EVs to maximize the social welfare. Our proposed mechanism is proved to have a bounded competitive ratio theoretically, and can achieve competitive empirical results in numerical tests based on real-world traces of taxi vehicles.

3 - Methods for Behind-the-Meter Solar Estimation and Forecasting

Yingchen Zhang, NREL

Distributed photovoltaic (PV) generation often occurs “behind the meter”: a distribution grid operator can only observe the aggregate load, the sum of the true, masked load and the PV generation. This lack of observability poses a challenge to distribution grid management strategies, which typically require real-time or near-future disaggregated estimates of load and PV generation. In this presentation I will discuss use of local solar irradiance measurements to estimate and forecast solar power, to disaggregate the summed PV generation and true load signals.

4 - Classification of Imbalanced Structured Data Using Convolutional Neural Network

Yoon Sang Lee, Columbus State University, Columbus, GA, United States, yslee211@gmail.com

This study proposed a technique mitigating imbalance class problem of structured data. The technique proposed in the study combines the label encoding, discretization, the conversion of instance to image files, and the use of CNN for the classification of the image files. For the performance evaluation, we used five data sets from UCI repository. For each data set, we created different data sets encoded by different preprocessing steps respectively, and each created data set is classified by five different classifiers. The result of the experiment shows that the CNN with the discretization and label encoding provides the best performance in all combinations of preprocessing steps and classifiers.

Co-Chair: John F. Betak, Collaborative Solutions LLC, Albuquerque, NM, 87122, United States

1 - Statistical Estimation on Infrastructure Networks

Robert Bassett, Navel Postgraduate School, Monterey, CA, United States

This talk will introduce new developments in statistical estimation on networks. We will focus on Fused Density Estimation, a technique for constructing density estimates from observations which occur along the edges of a network. We will address computational challenges and provide theoretical support for the use of the Fused Density Estimation. Lastly, we review applications of the technique to infrastructure networks, demonstrating the efficacy of the technique with a number of real-world examples.

2 - SME Miner: Utilizing Specialized Corpus Choices by Text Mining Application

Christie Nelson, Rutgers University, Princeton, NJ, 08540, United States, cnelson@dimacs.rutgers.edu, Trefor Williams, John F. Betak, Alex Nguyen, Kartheek Reddy Mondeddu, Ivan Mera, Jon McGuire

A tool, SME Miner, has been created to analyze free-text fields in a somewhat novel manner: extracting subject matter expert (SME) identified keywords and utilizing the count of these keywords per instance as an additional attribute in traditional machine learning methods. SME Miner automates the process of extracting SME-identified dictionary words from free-text, bins them by category, and creates a count-per-instance. We will show a proof-of-concept utilizing a railroad company's maintenance log along with how one might do a second application utilizing a government agency's background check data.

3 - Identifying Themes in British and American Railroad Accident Reports Using LDA

Trefor Williams, Rutgers University, Piscataway, NJ, 08540, United States, tpw@rci.rutgers.edu

Topic modeling, a type of text mining was used to analyze themes in railroad accident investigations conducted by the Railroad Accident Investigation Board (RAIB) in the United Kingdom. Latent Dirichlet Allocation was used to automatically generate 15 topics. The major themes found from the RAIB reports included accidents involving maintenance crews and track possession, accidents involving train doors, and accidents involving level crossings. A comparison of the RAIB topics with those found from the accident reports of the National Transportation Safety Board in the United States showed that common accident themes were level crossing accidents, bridges, switching, and signals.

Sponsored Session

Chair: Yan Xu

1 - Wasserstein Distributionally Robust Inverse Multiobjective Optimization

Bo Zeng, University of Pittsburgh, Benedum Hall, Pittsburgh, PA, 15260, United States, bzeng@pitt.edu, Chaosheng Dong

We present a distributionally robust approach to inverse multiobjective optimization. Specifically, we study the problem of learning the objective functions or constraints of a multiobjective decision making model, based on a set of observed decisions. We use the Wasserstein metric to construct the uncertainty set centered at the empirical distribution of these decisions. We show that this framework has statistical performance guarantees. Also, an algorithm is developed to solve the resulting formulation and prove its finite convergence. Numerical results demonstrate the performance of the distributionally robust approach to inverse multiobjective optimization.

2 - Quasi-Newton Trust-Region Methods for Machine Learning Problems

Riadh Omheni, SAS Institute, Cary, NC, United States, Jennifer Erway, Joshua Griffin, Roummel Marcia

Machine learning (ML) problems are often posed as highly nonlinear and nonconvex unconstrained optimization problems. Methods for solving ML problems based on stochastic gradient descent generally requires fine-tuning many hyper-parameters. In this talk we present alternative approaches for solving ML problems based on a quasi-Newton trust-region framework. Numerical experiments showing the efficiency of this approach will be presented.

3 - Improving Chronic Disease Forecasting with Synthetically Augmented Datasets

Matthew Baucum, University of Tennessee-Knoxville, Knoxville, TN, United States, Anahita Khojandi, Robeto Fernandez

Deep learning is a powerful tool for healthcare analytics, but because of the paucity of longitudinal data, it may not show great performance when used to forecast patient disease progression with small sample sizes. In this study, we build two disease forecasting models with a small dataset of Alzheimer's patients (a neural network and recurrent neural network). We then use hidden Markov models and variational autoencoders to augment the training data with synthetic patient profiles. Synthetic data from the variational autoencoder significantly improved the forecasting model's accuracy; we discuss insights from the models and implications for future work.

4 - Constrained Multi-Objective Optimization for Automated Machine Learning

Yan Xu, SAS Institute, Inc., Cary, NC, 27519, United States, yan.xu@sas.com

Automated machine learning has gained a lot of attention recently. Building and selecting the right machine learning models is often a multi-objective optimization problem. General purpose machine learning software that simultaneously supports multiple objectives and constraints is scant, though the potential benefits are great. In this work, we present a framework called Autotune that effectively handles multiple objectives and constraints that arise in machine learning problems.

Debiasing Decision Making – Ethical Data Mining and Eliminating Algorithmic Bias

Sponsored: Data Mining

Sponsored Session

Chair: Heidi Livingston Eisips, MBA, San Jose State University, San Jose, CA, United States

1 - Debiasing Decision Making – Ethical Data Mining and Eliminating Algorithmic Bias

Heidi L. Eisips, Adjunct Faculty, San Jose State University, San Jose, CA, 95111, United States, heidi.eisips@sjsu.edu

Data Mining and Data Analytics have provided modern society with fantastic benefits and productivity gains. Data is everywhere, and some posit that data is the new currency of the digital economy. And yet we know that human biases and machine-learned biases can have enormous costs: negative social impacts, financial losses, and sometimes even catastrophic loss of life. This panel will explore ways that we can develop the social awareness, engineering know-how, business processes, and legal instruments necessary to better reap the benefits of big data while harnessing an ethical framework and mitigating the risks introduced by human and algorithmic bias.

Financial Statistics and Applications

Sponsored: Finance

Sponsored Session

Chair: Markus Pelger, Stanford University, Stanford, CA, 94305, United States

1 - Crowding and Liquidity Provision in Factor Investing

Victor DeMiguel, London Business School, Management Science and Operations, Regents Park, London, NW1 4SA, United Kingdom, avmiguel@london.edu, Alberto Martin-Utrera, Raman Uppal

Smart-beta providers exploit characteristics such as size, value, and momentum, while other financial institutions provide liquidity for smart-beta trades. We study the effect of competition between smart-beta and liquidity providers. A liquidity provider competing with a single smart-beta provider reduces liquidity by half compared to the centralized setting. However, competition amongst smart-beta providers restores liquidity almost to that in the centralized setting, transferring profits to liquidity providers. Thus, a regulator concerned with the quality of smart-beta products available to retail investors should limit excessive competition amongst smart-beta providers.

2 - The Network of Firms Implied by the News

Hannan Zheng, PhD Candidate, Boston University, Boston, MA, United States, zhannan@bu.edu, Gustavo Schwenkler

We show that the news reports about distressed links between firms that facilitate contagion in financial markets. News-implied contagion generally flows from a smaller to a larger linked firm and generates predictability in stock returns and bond spreads. We show that the degree of connectivity in the news-implied network of firms is related to measures of financial uncertainty and contagion, and is predictive of adverse macro-economic outcomes. To obtain our results, we develop a machine learning methodology that takes text data as input and outputs a network of firm links implied by the data. These results enable the accurate estimation of firm-level and aggregate risks.

3 - Large Dimensional Latent Factor Modeling with Missing Observations and Applications to Causal Inference

Ruoxuan Xiong, Stanford University, Stanford, CA, 94305, United States, rxiong@stanford.edu, Markus Pelger

This paper develops the inferential theory for latent factor models estimated from large dimensional panel data with missing observations. We propose to estimate the latent factor model by principal component analysis of an adjusted covariance matrix estimated from the partially observed panel data. We derive the asymptotic distribution for the estimated factors, loadings and imputed values under a general approximate factor model. One key application is to estimate counterfactual outcomes and test for individual treatment effects at any time. We study the effect of academic publications on the risk premium of anomaly returns and find that around 15% is significantly reduced by the publication.

4 - Deep Learning for Predicting Asset Returns

Guanhao Feng, City University of Hong Kong, Hong Kong, China, He Jingyu, Nicholas Polson

Deep learning is useful to stock return prediction and requires a large sample for model training. We find out, the commonly used pooled model training in deep learning fits well with large variance stocks (low market equity) but underfits small variance stocks (high market equity). Inspired by Bayesian hierarchical modeling and seemingly unrelated regressions (SUR), we propose a deep learning SUR approach (DL-SUR) that shares information across different stocks while train each stock separately. We create a two-pass neural network to combine pooled modeling and individual time-series modeling with the ``warm starting". In a comprehensive empirical study, we compare pooled, time-series, and DL-SUR model prediction performances for U.S. equity returns. Lastly, our proposed method achieves better performance for small variance stocks and higher Sharpe ratio in value-weighted portfolios.

CC- Room 211

Recent Advances in Nonconvex Programming for Machine Learning

Emerging Topic: Artificial Intelligence & Machine Learning

Emerging Topic Session

Chair: Miju Ahn

1 - Estimation of Shape Constrained Index Models

Ying Cui, University of Southern California, Los Angeles, CA, United States, yingcui@usc.edu

Index models are very popular in econometrics and statistics. Most methods that have been proposed in the literature use kernel smoothing to estimate these models, which are not computationally efficient for high dimensional problems. In this paper, we show that a simple assumption of convexity or difference-of-convexity of the regression function enables one to fit such models by modern optimization techniques. A majorization-minimization method to solve the resulting nonconvex constrained nonsmooth optimization problems, where the convex subproblems are solved by a nonsmooth-Newton based augmented Lagrangian method.

2 - Risk Measures and Machine Learning: New Approaches and Algorithms

Matthew Norton, Naval Postgraduate School, Monterey, CA, United States

We discuss some recent developments in Risk Management that have helped to improve and interpret ML algorithms. We first look at a suite of new performance metrics for regression and classification derived from Buffered Probability of Exceedance. We show that these new metrics are simple to optimize, lead to efficiently solvable classification/regression problems, and provide new interpretations of SVM's. Next, we see that new developments have also reached into Deep Learning, with new risk measures giving rise to Generalized Batch Normalization, a new layer in Deep Neural Network architectures that can help increase speed of convergence and improve predictive performance.

3 - Efficient Individualized Decision Rules Estimation Using Bi-level Optimization

Yifan Cui, Wharton School of the University of Pennsylvania, Philadelphia, PA, United States, cuiy@wharton.upenn.edu, Ying Cui, Zhengling Qi

In many applications such as precision medicine, people are interested in learning individualized decision rules (IDRs) from observational studies. This problem becomes very challenging when both the propensity score cannot be consistently estimated and a large number of baseline covariates exist. In this paper, relying on the linearity assumption on the outcome model, we develop a $\sqrt{n}$-efficient learning procedure for optimal IDRs under high-dimensional settings without estimating the propensity score. By leveraging bi-level optimization techniques, the proposed learning procedure performs the evaluation and search of IDRs simultaneously.

4 - Robust Training of Neural Networks: A Game Formulation with Convergence Guarantees

Tianjian Huang, University of Southern California, Los Angeles, CA, United States, tianjian@usc.edu

Recent adversarial attacks on neural networks raise significant concerns about the reliability of these models in critical applications. In this work, we introduce a novel algorithm for training neural networks which are robust against adversarial attacks. The proposed algorithm is based on a game formulation where each adversary player attempts to change the label to a particular target label. Our numerical experiments demonstrate that the proposed algorithm achieves the state-of-the-art performance. In addition, the proposed method have theoretical convergence guarantees. It is scalable, and does not require heavy parameter tuning.

Business Value of Crowd Intelligence

Sponsored: Artificial Intelligence

Sponsored Session

Chair: Xuan Wei, University of Arizona, Tucson, AZ, 85721, United States

Co-Chair: Zhengchao Yang, University of Arizona, Tucson, AZ, 85281, United States

1 - Does Crowdsourced Content Contribute to Public Benefits? Its Effectiveness in Relieving Traffic Congestion around Urban Areas

Tae Hun Kim, Baylor University, Waco, TX, 76798, United States, taehun_kim@baylor.edu, Chenhui Guo, Vallabh Sambamurthy

We address how real-time content, crowdsourced by Waze users, impacts traffic congestion around urban areas. We utilize large-scale data on hour-by-hour content production activities and locations of Waze users in New York City (NYC) and apply the spatial panel data approach to estimate the contribution of content production to traffic mobility around NYC. Our findings reveal that the crowdsourced content creates public benefits by reducing the duration of traffic congestion: although a minority of drivers use Waze and crowdsource the traffic-related content, the benefits from the content in the form of reduced duration of traffic congestion eventually extend to the majority of drivers in NYC.

2 - When E-government Meets Crowd Intelligence: Literature Review and Research Prospection

Xiaoyang Chen, Tsinghua University, Beijing, China, chenxiaoyang111@outlook.com, Nan Zhang, Qingguo Meng

Crowd intelligence, also mentioned as collective intelligence or swarm intelligence in the prior literature, is defined as a blend of "information, technology and participants" to produce better decisions for responding to complex social problems. For understanding and exploring the public value of crowd intelligence, some theoretical considering from public management and politics could seem as another dimension besides technological capacities, as the same as e-government. In this paper, we will review the related literature from the different research areas, and propose some future orientations about crowd intelligence in public administration based on the literature.

3 - The Dark Side of Images: The Effect of Customer Generated Images on Product Ratings

Yue Guan, Tsinghua University, Beijing, China, Yong Tan, Qiang Wei, Guoqing Chen

Customer Generated Image (CGI) on e-commerce platforms has been widely recognized as a marketing tool to persuade customers into purchases. Despite its wide application, the effect of CGI on post purchase satisfaction has seldom been examined in academia. This study draws upon consumer psychology theory, employs a difference in differences model with propensity score matching method and finds that CGIs could lead to lower subsequent product review ratings compared with those not exposed to CGIs. Additional analysis indicates that this negative effect could depend on factors such as review ratings, human faces, or the quality of CGI.

4 - Crowd-Powered False News Detection in Social Media

Xuan Wei, University of Arizona, Tucson, AZ, 85721, United States, weix@email.arizona.edu, Zhu Zhang, Dajun Daniel Zeng

We investigate false news, a global concern attracting significant attention lately. The prevalence of false news in social media has severe consequences in many areas. Human knowledge and intelligence hold great potential to complement machine-based methods. Yet, they are largely under-explored in current false news detection research. We observe that the crowd contributes to the challenging task of assessing the veracity of news by posting responses or reporting. Through application of appropriate analytical techniques such as the proposed framework as reported in this manuscript, crowd intelligence can be fruitfully integrated with machine intelligence to tackle false news detection.

5 - The Impacts of Social Focus of Crowds on Hotelpopularity

Yiyang Bian, Nanjing University, Nanjing, China, Jianwei Liu

We explore how social focus and linguistic style in online customers' discussion contents influence hotel popularity. Few studies investigated differential effects of narrative style and social focus orientation on hotel popularity. This study generalizes the systematic-related and heuristic-related characteristics from the discussion contents in online tourism forum. Drawing on Heuristic-Systematic Persuasion Model, we investigate how these two types of cues influence hotel's popularity degree and online reputation.

1 - Impending Revolution in Talent Management that put the Data Scientist FIRST

Lance Kallaman, President, DataPrime, Los Angeles, CA, United States

Companies often can't fill Data Science jobs fast enough because of the shortage of talent. That doesn't mean they can't acquire the types of skills data scientists typically possess. It takes creative thinking, persistence, and a new approach. Hiring the right Data Scientist is hard! Hiring managers need more accurate assessments of data science skills required of the role they are hiring and to have Data Science candidates presented with capabilities and strengths highlighted. Data Scientists want an accurate understanding of the role, culture, and career value of the opportunity and an understanding of their skills in relation to the opportunity and Data Science community at large. Meeting the needs of the market requires a revolution in how Data Science talent is identified, assessed, hired, incentivized, developed, and retained. Lance will share how this revolution in Data Science talent management can be delivered through Talent Agency, Job Placement, and Career Development services.

2 - Approaches in Building Machine Learning Products and Teams

Andrew Musselman, Owner & Director, BetaSoftware, Seattle, WA, United States

The fervor of Artificial Intelligence and Machine Learning, and Analytics have led to a bumper crop of education, training, tools, methods, and promised results. This presentation will cut through the hype and will share case studies of how commercial programs have achieved actual, documented, and enduring results in the development of their analytics programs. Best practices for developing elite teams will be shared along with business practices and techniques for optimizing the delivery of world-class talent, projects, and products.

Analysis and Control of Stochastic Systems

Sponsored: Applied Probability

Sponsored Session

Chair: Jiheng Zhang, Hong Kong University of Science and Technology, Sai Kung, Hong Kong

1 - Sizing Flexible Resources in Large-scale Service Systems

Jinsheng Chen, Columbia University, New York, NY, United States, jc4823@columbia.edu, Jing Dong

Service systems typically involve multiple classes of customers, each requiring a different type of service. Flexible (multi-skilled) servers can improve system performance as they can help an overloaded pool during queue imbalances. However, they may be more costly than dedicated (single-skilled) servers, or work at a slower rate. We analytically determine the optimal staffing levels of flexible and dedicated resources using an asymptotic approach. We find that the optimal staffing levels and the behavior of the system depend critically on which of two regimes the system parameters fall under.

2 - On-demand Matching in a Spatial Model with Abandonment and Cancellation

Guangju Wang, Hong Kong University of Science and Technology, Hong Kong, Hong Kong, gwangal@ust.hk, Hailun Zhang, Jiheng Zhang

Car-hailing platforms have a profound impact on the way people travel and commute. As an intermediary between passengers and drivers, a platform gathers location information from both sides and makes on-demand matchings upon passengers' requests. Optimization of such matching decisions is challenging because of the complex system dynamics. We first propose a spatial model to approximate the pick-up distance of a matching and analyze the queueing dynamics, where the platform can control the matching process according to the pick-up distance. Based on the fluid approximation of the system, we find a simple optimal condition and propose a self-adaptive policy to find the optimal pick-up distance.

3 - Control of Fork-join Processing Networks with Multiple Job Types and Parallel Shared Resources

Erhun Ozkan, Koç University, College of Admisnitrative Sciences, Istanbul, 34450, Turkey, erhozkan@ku.edu.tr

A fork-join processing network is a queueing network in which tasks associated with a job can be processed simultaneously. Fork-join processing networks are prevalent in computer systems, healthcare, manufacturing, project management, justice system, etc. In a fork-join processing network, jobs arriving in the system fork into arbitrary number of tasks, then those tasks are processed in parallel, and then they join and leave the network. There are shared resources processing multiple job types. We study the scheduling problem for those shared resources (that is, which type of job to prioritize at any given time) and propose an asymptotically optimal scheduling policy in diffusion scale.

4 - Dynamic Scheduling of Multiclass Many-server Queues with Abandonment: The Generalized Gc /h Rule

Hailun Zhang, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, Hong Kong, hzhangaq@connect.ust.hk, Zhenghua Long, Nahum Shimkin, Jiheng Zhang

We consider the problem of server scheduling in a G/M/n+GI queue with multiple customer classes based on the analysis of the associated fluid model.For the purpose of minimizing the long-run average queue length costs and abandon penalties, we first introduce the target-allocation policy and prove its optimality for any general queue length cost functions and patience time distributions.The Gc /h rule, which extends the well-known Gc rule by taking abandonment into account, is shown to be optimal for the case of convex queue length costs and nonincreasing hazard rates of patience. Numerical experiments show that this hybrid policy performs satisfactorily.

Experimentation, Learning, and Estimation

Sponsored: Applied Probability

Sponsored Session

Chair: Mohammad Rasouli, Stanford University, Palo Alto, CA, 94306, United States

1 - Experimenting in Equilibrium

Kuang Xu, Stanford Graduate School of Business, Stanford, CA, 94305, United States, Stefan Wager

We study experimental design in large-scale stochastic systems with substantial uncertainty and structured cross-unit interference. We consider the problem of a platform that seeks to optimize supply-side payments p in a centralized marketplace where different suppliers interact via their effects on the overall supply-demand equilibrium, and propose a class of local experimentation schemes that can be used to optimize these payments without perturbing the overall market equilibrium. We show that, as the system size grows, our scheme can estimate the gradient of the platform's utility with respect to p while perturbing the overall market equilibrium by only a vanishingly small amount.

2 - Generalization Error and Estimate Consistency

Assaf Zeevi, Columbia University, New York, NY, 10027, United States

We present some observations that connect classical asymptotic estimation theory and modern finite sample approaches, and allow a better characterization and understanding of the generalization error in statistical learning. In particular, we investigate simple structural conditions on the loss function under which finite sample generalization bounds are valid, and show that estimator consistency implies ``fast rates" of convergence for the excess risk, as well as asymptotically optimal finite sample bounds. These results substantially improve generalization bounds of many important problems.

3 - Prepivoting in Finite Population Causal Inference

Colin B. Fogarty, Massachusetts Institute of Technology, Cambridge, MA, United States

In finite population causal inference, randomization alone can be employed as a basis for statistical inference. In this framework exact tests facilitated through randomization-based inference are generally justified only under sharp null hypotheses - null hypotheses that specify the potential outcomes. That said, inference is often desired for the average of the treatment effects while leaving the particular pattern of effect heterogeneity unspecified. We present a broadly applicable testing procedure that is finite sample exact for sharp null hypotheses while retaining asymptotic validity under weak nulls by employing a bootstrap prepivoted test statistic.

4 - Adaptive Experimental Design with Temporal Interference

Mohammad Rasouli, Stanford University, Palo Alto, CA, 94306, United States, rasoulim@stanford.edu, Peter W. Glynn, Ramesh Johari

In experimenting dynamic systems, treatment and control can change the state of the system (e.g. pricing algorithm of a ridesharing system, matching algorithm of a delivery system, or reserve price in ad auctions) resulting in temporal interference. We model it as estimating the difference of the steady state reward between two different policies in a Markov chain with unknown transitions and rewards that depend on the actions (treatment or control). We characterize the adaptive experimental design and estimator that are consist and efficient. For practical implementation, we propose alternative estimators and corresponding optimal policies, and study the efficiency gap of these designs.

1 - Managing Capacity Utilization in Service Platforms

Marcelo Olivares, Associate Professor, Universidad de Chile, Beaucheff 851, Of 624, Santiago, Chile, molivares@uchile.cl

In service systems with variable demand capacity decisions require making a trade-off between the responsiveness to customers versus operating costs of labor. To break this trade-off, the service system can operate as a platform with access to a large pool of employees with flexible working hours that are compensated through piece-rates. In this setting a new trade-off emerges between capacity utilization and worker turnover. We analyze this trade-off using data from an outbound call-center that operates with a pool of flexible agents working remotely.

2 - Waiting in Queues: Predictions and Decisions

Gad Allon, University of Pennsylvania, Philadelphia, PA, 19104, United States, gadallon@wharton.upenn.edu, Mirko Kremer, Achal Bassamboo

We study how customers form beliefs while waiting in line in a lab setting. In particular, we study the impact of these beliefs formation processes about decision-making and the impact of the prospect of making a decision on the quality of the predictions.

3 - On Withholding Capacity from Strategic Patients

Mor Armony, New York University, New York, NY, 10012, United States, marmony@stern.nyu.edu, Yunchao Xu, Nan Liu

Common wisdom suggests that everything else being equal, seeing patients sooner rather than later is preferable. In particular, health outcomes improve with reduced delay and so does patient satisfaction. At the same time, if the delay in access to care is reduced, patients may be more inclined not to show up for their appointments given that rescheduling will not result in excessive wait. We investigate how an outpatient care provider should manage capacity in the presence of such strategic behavior of patients. We find that under some circumstances, it is optimal for the service provider to withhold capacity from patients in order to elicit them to show up for their scheduled appointments.

4 - Nudging Patient Choice: Evidence from a Field Experiment

Jiayi Liu, Emory University, Atlanta, GA, United States, Diwas S. Kc

To examine the drivers of patient no-shows at outpatient clinics, we conduct a series of field experiments where the messaging regarding their upcoming appointment is randomly assigned. We find that the type of messaging has a significant effect on the queuing behavior of individuals, most notably their no-show behavior.

Behavioral Dynamics in Various Contexts

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Dayoung Kim, California State University-Fullerton, Fullerton, CA, 92831, United States

1 - Gamesmanship Behavior in Supply Chain Competition

Mohsen Ahmadian, PhD Student, University of Massachusetts-Boston, Boston, MA, 02215, United States, mohsen.ahmadian001@umb.edu, Ehsan Elahi, Roger H. Blake

In the context of simultaneous competition, this paper investigates decision-makers' tendency to focus on exceeding their competitors' payoffs rather than maximizing their own payoff. Considering this tendency, we introduce a new type of competition equilibrium, which assumes each decision-maker's objective is to maximize the difference between his own and his competitors' payoff in his favor. We term this equilibrium gamesmanship equilibrium and introduce its general formulation. We then use controlled laboratory experiments to investigate how well the gamesmanship equilibrium fares in explaining the subjects' behavior under three different outsourcing competition setups.

2 - Nudging Organizations: Evidence from Three Large-scale Field Experiments

James Fan, Naval Postgraduate School, Monterey, CA, 93940, United States, james.fan@nps.edu, Paul Ferraro, Kent Messer, Collin Weigel

Nudges and changes to choice architecture can affect individual behaviors. However, whether the same interventions are equally effective in changing the behaviors of groups of individuals acting as organizations is an open question. In three natural field experiments, local organizations make decisions about whether to contribute financially to a national coordinating organization. We test the efficacy of five behavioral nudges. Compared to the estimated treatment effects of similar interventions among individuals, our estimated effects on organizations are dramatically smaller and of the opposite sign.

3 - Taxi Drivers Minimize on Waiting Time Because of its Salience Rather Than on Earnings Resulting in Adverse Economic and Environmental Impacts

Lawrence Jin, National University of Singapore, Singapore, Singapore

We analyze more than 140,000 decisions by 3,000 taxi drivers at Singapore's Changi airport and find that information saliency causes drivers to make suboptimal decisions. Taxi drivers minimize the waiting time for their next passenger, and overlook the significantly higher fares that they can earn from the airport compared to other locations. As a result, many taxis do not wait at the airport for passengers. Correcting this mistake would increase taxis' earnings by SG$1.8 million per year in Singapore. Taxis would also drive 2.8 million fewer kilometers per year, which translate into an annual saving of SG$800,000 in maintenance plus fuel costs and reduce air pollution.

4 - Effect of Experiential Learning in Teaching Process Management

Naser Nikandish, California State University, Fullerton, CA, 92831, United States, Dayoung Kim

This project examines effectiveness of outside class experiential learning exercise on teaching process management topics in an undergraduate level operations management course. We conduct this experiment in two classes of different sizes. After teaching process management topics in the form of traditional theoretical presentation, students are offered an optional exercise outside the classroom to analyze a real process. Then we measure students understanding in a follow up midterm exam. We found out that the students who conducted the outside classroom experiential learning exercise performed significantly better than students who did not participate in this exercise.

5 - The Behavioral Traps in Making Multiple, Simultaneous, Newsvendor Decisions

Shan Li, Baruch College, City University of New York, Baruch College, New York, NY, 10010, United States, shan.li@baruch.cuny.edu, Kay-Yut Chen

This paper conducted an experimental study to explore behaviors of newsvendors who make order decisions for two products simultaneously. Our study has implication on how multiple products should be grouped and managed.

Data Driven Research in Supply Chains

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: David Simchi-Levi, Massachusetts Institute of Technology, Dept of Civil and Environmental Engineering, Cambridge, MA, 02139, United States

1 - Phase Transitions and Cyclic Phenomena in Bandits with Switching Constraints

David Simchi-Levi, Massachusetts Institute of Technology, Institute for Data, Systems, and Society, Cambridge, MA, 02139, United States

We consider the classical stochastic multi-armed bandit (MAB) problem with a constraint on the total cost incurred by switching between actions. The model is motivated by an industry collaboration, where the online retailer applies dynamic pricing with demand learning but limits the number of price changes. We prove matching upper and lower bounds on regret and provide near-optimal algorithms for this problem. Surprisingly, we discover phase transitions and cyclic phenomena of the optimal regret. That is, we show that there are phases defined by the number of arms and switching costs, where the regret upper and lower bounds in each phase remain the same and drop significantly between phases.

1 - Fair Lending to Small Farmers

Deeksha Sinha, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, deeksha@mit.edu, Vivek Farias, Disha Bhanot

In this work, we build a fair credit scoring mechanism that can be used for financing small farmers. Small farmers constitute the majority of farmers in developing countries. These farmers rely heavily on loans for growing crops. A credit scoring mechanism which appropriately captures their willingness to pay and does not penalize them for factors beyond their control like weather conditions, crop prices is desired. These accurate risk estimates can then be used to design loans which satisfy the farmers' needs at an interest rate matching their credit-worthiness. We have partnered with a large public sector bank in India which has a strong presence in the agricultural lending sector.

2 - Product Quality in a Supply Chain with Social Learning

Dongwook Shin, HKUST Business School, Lee Shau Kee Building, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, dwshin@ust.hk, Assaf Zeevi

This paper investigates the manufacturer's incentive to improve quality, which sells its product to customers via an online retailer. The online retailer provides a product review system where customers can share their experience of the product. The manufacturer may not have full information about customer demand. In contrast to conventional knowledge, we show that the presence of online reviews may deteriorate the product quality in online markets.

3 - Can Two Competing On-demand Service Platforms Both Be Profitable?

Jiaru Bai, Wake Forest University, Winston Salem, NC, United States, baij@wfu.edu, Christopher S. Tang

As venture capital firms are financing on-demand service platforms, we wonder how many startups of this kind can survive in a competitive market. To examine this question, we present a model in which two on-demand service platforms compete in both the provider and customer markets.

4 - Bayesian Dynamic Pricing and Subscription Period Selection with Unknown Customer Utility

Yuan-Mao Kao, Duke University, Durham, NC, 27705, United States, yuan.mao.kao@duke.edu, N. Bora Keskin, Kevin Shang

We consider a firm that aims to determine the price and service duration for a subscription service. The firm faces uncertainty regarding its customers' preferences and can accumulate information through sales and usage observations over time. We derive an efficient method to obtain the firm's optimal policy in the presence of perfect information on customer preferences. We also construct and analyze a near-optimal policy for the case of imperfect information.

Sponsored: Manufacturing & Service Oper. Mgmt/Service Operations

Sponsored Session

Chair: Chiara Farronato, Harvard Business School, Boston, MA, 02163, United States

1 - Online Reviews as Barriers to Entry

Chiara Farronato, Harvard Business School, Soldiers Field Road, Morgan Hall 412, Boston, MA, 02163, United States

We explore entry barriers induced by online reputation systems. We first provide descriptive evidence from an online platform that new sellers have increasing difficulty in making their first sales. The interval between entry and first sale increases over time and is longer in categories where a larger share of sellers have high ratings or for categories with longer histories. We plan to test whether barriers to entry are induced by the design of online review systems by conducting an experiment. In particular, we plan to test whether adding recent seller ratings to the information disclosed to consumers increases buyers' propensity to choose new suppliers relative to older and established suppliers.

2 - The Role of Feedback in Dynamic Crowdsourcing Contests: A Structural Empirical Analysis

Zoey Jiang, University of Michigan-Ann Arbor, Ann Arbor, MI, 48104, United States, jiangzh@umich.edu, Yan Huang, Damian Beil

We empirically examine the impact of feedback on the outcome of crowdsourcing contests. We develop and estimate a dynamic structural model using a rich data set about online logo design contests. The model captures key features of the crowdsourcing context, including a large participant pool, new entries throughout the contest, and the participants' strategic choice among entry, exploration, and exploitation decisions in a dynamic game. We compare alternative feedback policies using counter-factual simulations, and find providing feedback throughout the contest may not be optimal.

3 - The Impact of IPOs on Peer-to-peer Lending Platforms

Maxime Cohen, McGill University, Montreal, QC, 10012, Canada, maxccohen@gmail.com, Kevin Jiao

In this paper, we use a comprehensive dataset from two large peer-to-peer lending platforms. We are facing an interesting situation where one platform went public by filing an IPO, whereas the other platform still remained privately held. We exploit this empirical environment to carefully infer the causal effect of IPOs on peer-to-peer lending platforms.

4 - The Re-design of Framework Agreements Markets in Chile

Marcelo Olivares, Universidad de Chile, Beaucheff 851, Of 624, Santiago, Chile, Eduardo Lara, Daniela Saban, Gabriel Weintraub

Framework Agreements (FAs) are a common procurement mechanism used by governments and large organizations. They are based on an auction-type design to select an assortment of products from multiple suppliers with posted prices, from which organizations can then buy. The Chilean government acquires US$2 billion in goods and services per year using FAs. In this talk, we discuss how we collaborated re-designing the food FA, one of the largest FAs run by the Chilean government. The new FA auction prices decreased by around 25% (in real terms) on average compared to the previous food FA auction that was run before the re-design several years ago.

Emerging Topics in Sustainable Operations

Sponsored: Manufacturing & Service Oper. Mgmt/Supply Chain

Sponsored Session

Chair: Somya Singhvi, MIT, Cambridge, MA, 02139, United States

1 - Unifying Agricultural Wholesale Markets: Impact on Farmers' Income

Somya Singhvi, MIT, Cambridge, MA, 02139, United States, ssinghvi@mit.edu, Retsef Levi, Manoj Rajan, Yanchong Zheng

In order to improve farmer welfare, Government of Karnataka in India started integrating all its regulated markets through an online platform (UMP) in 2014. In this work, we empirically examine the impact of UMP on wholesale prices and find that while UMP had a significant impact on farmers' profit margins for some commodities, it had no impact for others. Utilizing proprietary auction data, we provide evidence that systemic supply chain logistics and process design considerations that affect trades in the physical markets are important factors influencing the impact of UMP. We discuss several policy insights related to the design of similar agri-platforms in developing countries.

2 - Improved Crop Yields Through Optimized Planting Schedules

Ying (Maggie) Zhang, Clemson University, Clemson, SC, 29634, United States, ying6@clemson.edu, Jayashankar M. Swaminathan

In this paper, we develop a model to determine the optimal seeding policy under rainfall uncertainty using a finite-horizon stochastic dynamic program. We show that the optimal planting policy is a time dependent threshold-type policy where the farmer should plant when the seed amount on hand is above the optimal threshold. Utilizing field weather data from Southern Africa, in a real size large-scale problem, we demonstrate significant relative yield advantage of the optimal planting schedule over commonly used heuristics in practice.

3 - Process Standardization for Remanufacturing

Cerag Pince, Quinlan School of Business, Loyola University Chicago, Schreiber Center 425, Chicago, IL, 60611, United States, Atalay Atasu, Beril L. Toktay

Remanufacturing is a labor-intensive process. Motivated by a third-party remanufacturer (3PR) of consumer products, we study workforce capacity investment problem in the context of product recovery operations. We analyze how a remanufacturing firm should determine the quantity and type (skilled vs. unskilled) of its workforce when both the number and complexity of units to be processed are random. We characterize the optimal solution along with the conditions when using only one type of workforce dominates the other.

4 - Mechanism Design for Supply Chain Certification Programs

Pia Ramchandani, Wharton School of Business, Philadelphia, PA, United States, piar2@wharton.upenn.edu, Hamsa Sridhar Bastani, Kenneth Moon

Existing certification programs (e.g. Fair Trade, Utz, etc.) that seek to improve human rights and sustainable production may be reaching a plateau in adoption and possibly losing traction, leaving opportunities for mechanism design improvement. Through an empirical analysis on the coffee market, we seek to verify or disprove a series of commonly cited barriers associated with growth of certification programs. We also identify potential targets of certification adoption and investigate their incentives to suggest enhancements for mechanism design.

Joint Session MSOM/SC/Practice Curated: Learning to Optimize

Sponsored: Manufacturing & Service Oper. Mgmt/Supply Chain

Sponsored Session

Chair: Max Shen, JD.com, Santa Clara, CA, 95054, United States

Co-Chair: Junyu Cao, Albany, CA, 94706, United States

1 - Online Learning Algorithms for Stochastic Inventory Systems

Cong Shi, University of Michigan, 2257 Woodhaven Ct, Ann Arbor, MI, 48105, United States, Hao Yuan

We consider several periodic-review inventory systems under censored demand. We assume the firm does not know the demand distribution a priori, and makes adaptive inventory ordering decision in each period based only on the past sales (a.k.a. censored demand) data. We develop several nonparametric learning algorithms that combine the powers of stochastic gradient descent, bandit controls, and simulation-based methods. We establish tight or nearly tight regret bounds for the developed algorithms and demonstrate their numerical performance.

2 - Sequential Choice Bandits: Learning with Marketing Fatigue

Junyu Cao, University of California, Berkeley, Berkeley, CA, 94706, United States, jycao@berkeley.edu, Wei Sun, Zuo-Jun Max Shen

Motivated by the observation that overexposure to unwanted marketing activities leads to user dissatisfaction, we consider a setting where a platform offers a sequence of messages and is penalized when users abandon the platform due to marketing fatigue. Based on user feedback, the platform dynamically learns users' tolerance and their valuations of messages to determine the optimal length and the order of the messages, while maximizing the cumulative payoff. We refer to this online learning task as the sequential choice bandit problem, and characterize the regret bound of our proposed algorithm. Lastly, we evaluate the performance of our algorithms with both synthetic and real-world datasets.

3 - Optimization of Tree Ensembles

Velibor Misic, UCLA Anderson School of Management, Los Angeles, CA, 90095, United States, velibor.misic@anderson.ucla.edu

Tree ensemble models such as random forests and boosted trees are often used to predict the effect of different decisions. While such models are widely used for predictions, little is known about how to use them for effective decisions. In this talk, we consider the problem of finding a decision that is optimal with respect to a tree ensemble model. We formulate this problem as a mixed-integer optimization model and present theoretical results on its structure. We test our method on real data sets, including two case studies in drug design and customized pricing, and show that it can efficiently solve large-scale instances to near or full optimality, outperforming heuristic solutions.

4 - A Dimension-free Algorithm for the Contextual Continuum-armed Bandit Problem

Ningyuan Chen, University of Toronto, Clear Water Bay, Toronto, ON, Canada, Jeff Hong, WENHAO LI

In multi-armed bandit problems, when the contextual information and the decision variable are both continuous and high-dimensional, it is known that the optimal rate of regret scales exponentially with both dimensions. In this project, we show that when the objective function is globally concave in the decision variable, we can alleviate the curse of dimensionality.

Joint Session INFORMed/Practice Curated: Activities in the Classroom

Sponsored: Education

Sponsored Session

Chair: Michael J Racer, University of Memphis, Memphis, TN, 38152, United States

1 - Developing a Blog for High School Calculus Students

Michael J. Racer, University of Memphis, 302 Fogelman College of Business, Memphis, TN, 38152, United States, Anne Papakonstantinou

We want to introduce an activity they we are starting in the INFORMS to help high school students become better at developing calculus models. We are created a sample blog and want to show it to members of Informs. Then will developing a list of teachers at high schools and on a regular basis send them these examples to use in their classrooms. We just want to generate as much support as we can from the Informs community

2 - OR and Computational Science in the UG Curriculum

Allen Holder, Rose-Hulman Institute of Technology, Department of Mathematics, Terre Haute, IN, 47803, United States

Operations research and computational science combine nicely in the undergraduate arena to help prepare students for technical careers and continued education. We will review coursework that has been developed in support of a computational science degree at the Rose-Hulman Institute of Technology. The curriculum combines topics from optimization, statistics, numerical analysis, and computer science, and it supports applications that span science and engineering. The focus is on computational savvy, with material being supported mathematically and discussed algorithmically.

3 - Experiential Learning and Applying OR in Healthcare

Amy Cohn, University of Michigan, Department of IOE, Ann Arbor, MI, 48109, United States

Much of my research is focused on developing, implementing, and applying Operations Research-based decision support tools to solve complex, multi-criteria optimization problems in healthcare. Specifically, I solve personnel scheduling problems such as the assignment of residents to training rotations or attending physicians to clinical unit. This applied research has also presented me with the opportunity to provide experiential learning opportunities to a large number of undegraduates and masters students. They not only learn to address the technical challenges of a complex combinatorial optimization problem, but gain training in multi-disciplinary team work, in problem scoping, in communicating across different fields, and in tackling the practical challenges of implementing a theoretical solution in real-world practice. I will present my experience in working with a large and diverse group of students in such a learning environment and share lessons learned along the way.

4 - Flipping the intro to OR Course

Susan E. Martonosi, Harvey Mudd College, Department of Mathematics, Claremont, CA, 91711, United States

After participating in a semester-long active learning fellowship, I took the plunge and "flipped" my long-standing Intro to OR course. This talk will describe the structure of the course, what went well, and what will be improved in the future. I'll reflect on the importance of space and classroom infrastructure in contributing to the experiment. I'll also describe the ways in which a collaborative and supportive learning community emerged in the course, and how that is important for broadening the participation of underrepresented groups in our profession.

iFORM Emerging Research

Sponsored: Manufacturing & Service Oper. Mgmt/iFORM

Sponsored Session

Chair: William Schmidt, Cornell University, Ithaca, NY, 14850, United States

1 - Financing Inventory under Bank Capital Regulation and Seller Orchestration

Yuxuan Zhang, Tsinghua University, Beijing, 100084, China, zhangyux14@mails.tsinghua.edu.cn, Simin Huang, S. Alex Yang

This study examines the value of information updating in a milesteon-based supply chain finance scheme. We find that the value of information increases as the trade process becomes more reliable, and as the value of the traded goods increases signicantly as the order successfully passes the rst milestone. The value of information becomes also higher as the bank's cost of equity increases.

2 - The Linkage Between Primary and Secondary Markets for Eurozone Sovereign Debt: Free Flow or Bottleneck?

Nikolay Osadchiy, Emory University, Atlanta, GA, 30322, United States, Alexander Eisl, Christian Ochs, Marti Subrahmanyam

We investigate the consequences of interlinked sovereign bond markets in the Eurozone for the transmission of yields, liquidity and market conditions, specifically, the impact of sovereign bond auctions on secondary markets and the sovereign's cost of debt. We develop a model of financially constrained primary dealers operating in both primary and secondary bond markets. Our model produces optimal inventory levels for existing- and newly issued bonds that can be related to predictable price movements around new sovereign bond issuance. We find an empirical support for the model and estimate the impact of financial constraints on the cost of debt.

3 - Dynamic Contracting in Multi-level Organizations

Ruiting Zuo, National University of Singapore, Singapore, 138601, Singapore, ruitingz@u.nus.edu, Jussi Keppo, Nizar Touzi

In typical contracting problems, a principal designs a contract and then an agent decides whether to accept it and take corresponding actions or to reject it. We investigate incentive contracts under dynamic actions and a simple organizational structure with an owner of an organization, a manager, and a worker. The owner cannot perfectly observe the manager and worker's actions, and similarly, the manager cannot perfectly observe the worker's actions. We show how the actions of the participants and the costs of their actions interact. We then extend the model to a case with an owner, a manager, and multiple workers.

4 - Operational Disruptions, Firm Risk, and Control Systems

William Schmidt, Cornell University, Ithaca, NY, 14850, United States, Ananth Raman

We empirically examine whether implementing and credibly attesting to having effective internal control systems moderates the impact of operational disruptions on the disrupted firm's risk. We show that firms with such credible control systems experience a materially smaller increase in their risk and a smaller decrease in their market value.

1 - Integrated Optimization of Fertilization Application, Cultivation and Harvesting

Yangfang (Helen) Zhou, Singapore Management University, Singapore, Singapore, Onur Boyabatli

Motivated by the fresh produce industry, this paper studies the decisions faced by a farmer growing one single crop: fertilizer application, cultivation and harvesting. We develop a two-stage stochastic program capturing uncertainties in both yield and harvesting labor cost as well as the effect where yield in the second stage is stochastically increasing in the fertilizer application quantity in the first stage. We characterize the farmer's optimal decisions as well as the impact of these two uncertainties on the farmer's optimal decisions and profitability.

2 - Batching for Perishable Products

Arzum E. Akkas, Boston University, Boston, MA, 02142, United States, aakkas@bu.edu, Erol Pekoz

Batching is beneficial in manufacturing systems since it reduces production changeovers and, thus, unit production cost. However, a negative consequence of batching is that it increases inventory which, in particular, can be detrimental for perishable products, because excess inventory erodes shelf lives and, thus, increases expiration levels in the supply chain. In this work, we analyze batching decisions of a manufacturing firm and find that, under a reasonable model, the total inventory cost is 13% higher when expiration in downstream supply chain is ignored, which usually is the case in practice. Our work leverages real inventory data from a food manufacturer.

3 - Food Waste in Agricultural Supply Chains

Elena Belavina, Associate Professor, Cornell University, Ithaca, NY, United States, belavina@cornell.edu

Emission from food waste are a major contributor to global warming. In this talk we will explore how changes in the supply chain impact food waste of each part of the supply chain and resulting overall impact on the emissions.

4 - Analysis of One-Europe Type Policies on Agribusinesses

Shivam Gupta, University of Nebraska Lincoln, COB 511K, Lincoln, NE, 68588, United States, Saurabh Bansal

Market-integrating policies such as the One-Europe policies remove import-export barriers. We discuss how this change of regime affects the prices, focusing on agribusiness domain.

Decision Framing & Problem Formulation

Sponsored: Decision Analysis

Sponsored Session

Chair: Andrea Hupman, University of Missouri-St. Louis, St Louis, MO, 63121, United States

1 - Finding the Right Problem Frame to Manage the Change

Edward Cook, President, The Change Decision, Richmond, VA, United States, ed.cook@thechangedecision.com

Framing a decision problem is not necessarily obvious. A decision analyst may need to explore the placement of the correct frame with the group of stakeholders because often "the problem" presented is not the real problem. In this presentation, we will explore the employment of theory and technique in the pursuit of not only getting to a useful frame for the decision but also the psychology of preparing the group of stakeholders to manage the change. This presentation will include examples the presenter has driven from Fortune 100 companies to small firms to nation-building activities in Iraq.

2 - Improving Counterfactual Forecasting Using Relevance Diagrams

Lucas J. Haravitch, University of Southern California, Los Angeles, CA, United States, lharavit@usc.edu, Ali E. Abbas

To overcome the cognitive complexity associated with counterfactual thinking, we propose relevance diagrams to capture and organize disparate information about the workings of a system. This research considers methods to simplify relevance diagrams by using a Gaussian copula structure of variable dependencies and by exploring approximation methods for eliciting dependencies from forecasters.

3 - A Simulation Approach to Compare Decision Quality of Multiattribute Models with Incomplete Attribute Sets

Sarah A. Kusumastuti, University of Southern California, Los Angeles, CA, United States, kusumast@usc.edu

Empirical evidence suggests that decision makers are ill-equipped to identify all relevant objectives (consequently attributes) in a multiattribute decision problem. The effect of incomplete objective sets is examined using a Monte Carlo simulation by comparing the decision made by a baseline model with a reduced model incorporating only a subset of its attributes. The simulations measure the performance of reduced additive multiattribute models under various characteristics of a decision problem, such as number of objectives, proportion of missing objectives, number of alternatives, intercorrelations among objectives, and use of weight approximation methods (equal or ROC weights).

4 - Sensitivity Analysis to Value Specification and Measurement

Andrea Hupman, University of Missouri-St. Louis, St Louis, MO, 63121, United States, hupmana@umsl.edu, Mitchell A. Millstein

A high quality decision analysis requires careful attention to the specification of values and the measurement(s) used to represent each of the values. In this talk, we consider multi-criteria methods to aggregate a set of values into a total value measure and examine how the inclusion of different criteria affects the ranking of the total value measures. We conduct sensitivity analysis on data from a company that implemented a multi-criteria method to value its customers to inform decisions within the company. The analysis highlights the implications of value inclusion for decision analysis.

MCDM and Medicine / Healthcare: A Mutually Beneficial Relationship- I

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Evangelos Triantaphyllou, Louisiana State University, Baton Rouge, LA, 70803, United States

Co-Chair: Juri Yanase, Complete Decisions, LLC, Baton Rouge, LA, 70810, United States

1 - A Unified Framework for Preventive Healthcare Service Design: Patient-Physician Collaboration

M Gabriela Sava, Clemson University, College of Business, Clemson, SC, 29634, United States, msava@clemson.edu, Jerrold H. May, Luis G. Vargas, Jennifer Shang, James G. Dolan

As patients are increasingly becoming active participants in making their medical decisions, healthcare providers are increasing their focus on patient-centered care. We propose a new service design for shared decision-making, which incorporates analytically both patients' preferences and physicians' expertise into a joint patient-physician model to assess, aggregate, and synthesize preferences.

2 - Clinical Decision Support System Using MCDM Technique: A Non-invasive Diagnostic Mechanism in Assessing Malignant Potentiality

Debjani Chakraborty, Indian Institute of Technology, Kharagpur, India, Kharagpur, India, drdebjanic@yahoo.co.in

In spite of significant amount of technological advances in cancer research over the past few decades malignancy has potentially raised the death toll across the world owing to its low survival rate. Minimal or non-invasive patient-comfort centric mechanism is popular in early diagnosis of malignancy. A clinical decision support system is proposed which will not only improve diagnostic decisions but also enable doctors to design an improved time saving therapeutic plan of action with minimum subjectivity. The whole process is based on multi-scale data with knowledge fusion of human cognition (experience based subjective impressions of pathologists) and its mathematical representation as MCDM.

3 - A Multi-criteria Ranking Algorithm for Determining Patient-tailored Breast Cancer Therapy

Mostafa Hasan, Wichita State University, Wichita, KS, United States, hasan.bbc@gmail.com, Esra Buyuktahtakin Toy, Elshami Elamin

In this study, we determine a comprehensive set of criteria for selecting the best breast cancer therapy by interviewing medical oncologists. We then present two analytical hierarchy process (AHP) models for quantifying the weights of criteria for breast cancer treatment. Using the weights of criteria from the AHP model, we propose a new multi-criteria ranking algorithm (MCRA), which evaluates a large variety of patient scenarios and provides the best patient-tailored breast cancer treatment alternatives based on the input of nine medical oncologists. The MCRA could be used as an accessible decision-support tool to aid oncologists and educate breast cancer patients.

4 - Optimization of Intensity-modulated Proton Therapy Considering the Biological Effect

Gino J. Lim, University of Houston, Dept of Industrial Engineering, Houston, TX, 77204, United States, ginolim@uh.edu, Xuemin Bai, Wenhua Cao

Linear energy transfer (LET) guided methods have been applied to intensity-modulated proton therapy to achieve a higher biological. It's noticed that using LET as a surrogate will increase the model complexity and ignore the difference between dose and LET distribution, which is a more fundamental property. This study focuses on the potential benefits of LET keep going up after the physical dose Bragg Peak to avoid high values of LET in critical structures located within or near the target and increase LET in the tumor area, without compromising the target coverage.

Disaster Preparedness and Response through Optimization

Emerging Topic: Humanitarian and NotforProfit Operations

Emerging Topic Session

Chair: Elise Miller-Hooks, George Mason University, Silver Spring, MD, 20905, United States

1 - A Multi-stage Stochastic Programming Model for Relief Distribution Considering the State of Road Network

Zhijie Dong, Texas State University, San Marcos, TX, 78640, United States, sasha.dong@txstate.edu, Shaolong Hu

As an important aspect in disaster operations management, relief distribution has been challenged by many factors. A multi-stage stochastic programming model is developed for disaster relief distribution with consideration of multiple types of vehicles, fluctuation of rental, and the state of road network. The state of road network is characterized using uncertain and dynamic road capacity. The scenario tree is employed to represent the uncertain and dynamic road capacity, and demonstrate the decision process of relief distribution. A progressive hedging algorithm (PHA) is proposed to solve the proposed model in large-scale size with an application in Ya'an earthquake in China.

2 - Management of Interdependent Infrastructure Networks under Disaster Related Uncertainties

Tugce Canbilen, Middle East Technical University, Universiteler Mah. Dumlupinar, Bul. ODTU Kampusu Endustri, Ankara, 06800, Turkey, canbilen@metu.edu.tr, Sakine Batun, Melih Celik

After a disaster, multiple infrastructures have disruptions in their services. During the restoration of these services, we need to consider the operational and restoration independencies among these infrastructures. In this study, the problem under consideration is Interdependent Infrastructure Restoration with disaster related uncertainties. We propose a two-stage program for this problem. In the presentation, we will present how the network reinforcement decisions change according to the network interdependency and uncertainty.

3 - Post-disaster Inspection and Restoration Prioritization in Roadway Networks

Bahar Shahverdi, George Mason University, 4738 Forestdale Dr, Fairfax, VA, 22032, United States, bshahver@masonlive.gmu.edu, Elise Miller-Hooks, Hsi-Hsien Wei

We present mathematical techniques to prioritize post-disaster inspection and roadway restoration activities to mitigate the event's effects on the performance of traffic and other lifelines while maximizing opportunities for completing repairs in a timely manner.

4 - Managing Humanitarian Logistics Through Public-private Partnership: A Collaborative Decision-making Approach to the Pre-positioning of Hurricane Relief Kits

Yue Ge, Assistant Professor, University of Central Florida, Orlando, FL, United States, yue.ge@ucf.edu, Sara Iman, Joseph Szmerekovsky

Business participation in disaster relief pre-positioning and procurement planning is crucial but understudied. This study examines the current pattern of public-private partnerships contributing to humanitarian logistics in hurricane relief efforts in Florida. A dynamic framework is proposed for collaborative decision-making among government, businesses, and other stakeholders that support disaster relief efforts. It is expected that building collaborative emergency preparedness will lead to the reduction of the socioeconomic costs in managing disaster response and the improvement of emergency management performance. A pilot study of Hurricane Irma response is included.

5 - Fuel Distribution Planning for Islands

Vahid Eghbal Akhlaghi, University of Iowa, Iowa City, IA, United States, vahid-eghbalakhlaghi@uiowa.edu, Ann Melissa Campbell, Renato E. de Matta

In this study, we propose an optimization approach for the storage and distribution problem of fuel for disaster recovery on islands under a variety of possible disaster scenarios. We examine Puerto Rico's fuel reserves and how their storage locations may have influenced the recovery from different hurricanes. We develop a mixed integer program to determine an efficient delivery scheme. This model involves evaluating the tradeoff between risk level and transportation costs and ensuring equity and fairness in allocating fuel to affected areas.

1 - What Can Images Tell Us: A Predication Study Based on Facial Analysis

Hongfei Li, School of Business, University of Connecticut, School of Business, 2100 Hillside Road, Storrs, CT, 06269, United States, hongfei.li@uconn.edu, Fangda Han, Shun-Yang Lee, Jing Peng

Cosmetic surgery is a type of highly risky service and consumers usually suffer from an unsatisfying consequence after taking surgery. In this paper, we manage to predict consumers' post-surgery appearance based on other consumers' cases by deep learning. Specifically, we utilize generative neural networks (GANs), one type of generative model to automatically generate the post-surgery face given the pre-surgery face image. We design experiments to show that our method can increase consumers' purchase intention. Cosmetic surgery platform or service provider (i.e., hospitals) can leverage our technique to predict consumers' post-surgery images when they are making their purchase decision.

2 - Extending Discrete Choice Model Using Deep Learning

Yixuan Ma, UC Irvine, Irvine, CA, 92617, United States
Yixuan Ma, Beijing Jiaotong University, Beijing, China, Zhenji Zhang, Alexander Ihler

Human choice is hard to predict since the utility of individual depends on alternatives in a complex way. Classical discrete choice models, in particular conditional logit model (CLM), use simple linear utility function, which might not hold in reality. We extend CLM using convolutional neural networks, recurrent neural networks, and residual neural networks to deal with utility nonlinearity. Our methods combine the strengths of deep learning methods, such as flexible representations and improved accuracy, with those of choice models, such as ability to handle variable pool sizes. We test the models on three datasets. Results show that extended choice models outperforms the CLM.

3 - Decision Model in Earthquake Emergency Rescue Based on Deep Belief Network

Rui Fan, Beijing Jiaotong University, Beijing, China

The lack of information after the earthquake has made it difficult for policy makers to make timely decisions, resulting unnecessary losses and damages. In this study, we firstly analyzed the components and extracted a series of visual data of earthquake emergency rescue decision-making process. Then we used Deep Belief Network to deal with data mining problem and established a seismic emergency rescue case library. We improved the similarity evaluation function by combining the traditional Case-Based Reasoning technology with the Deep Belief Network (DBN-CBR). The proposed model was verified using actual data of Yushu earthquake.

4 - Ontology-based Knowledge Base Construction for Public Emergencies in Beijing

Haoyu Gui, Student, Beijing Jiaotong University, Beijing, China, 17120610@bjtu.edu.cn, Dan Chang

Facing with a series of unexpected incidents with complex reasons, it is difficult to propose a reasonable decision accurately based on traditional database. The knowledge base can be seen as a useful tool to store massive data, semantic analysis of the corresponding data, propose an optimal decision-making scheme, and improve the accuracy of emergency decision-making. In this study, based on historical emergency cases, we used ontology technology to represent terms and knowledge in a structured shared conceptual system, established the emergency knowledge base for public emergencies, and gave a practical application of improving the use of knowledge in emergency process in Beijing.

Economics of Information Systems

Sponsored: Service Science

Sponsored Session

Chair: Fengmei Gong, University of La Verne, La Verne, CA, 91750, United States

1 - Impacts of Social Systems on User Retention: The Case of Guild System and Friends System in Online Game

Insung Hwang, McGill University, Montreal, QC, Canada, Insung.hwang@mail.mcgill.ca, Kunsoo Han, BeomSeok Kim

User retention in a game is critical because it is strongly correlated with the game's success. In this study, we investigate the impacts of two social systems - guild system and friends system - on user retention in massively multiplayer online role-playing games (MMORPG) by drawing on the prior literature on the motivating effects of social relatedness. We estimate the impacts of these systems by using 1,204 users' data and a stratified Cox Proportional Hazard model. We found that while both systems positively affect user retention, the impact of guild system is stronger than that of friends system. This result contributes to the literature on social interaction and user retention in online games.

2 - The Impact of Information Technology on Firm Costs

Vaarun Vijairaghavan, University of Calgary, 2500 University Drive NW, Calgary, AB, T2N 1N4, Canada, vvijaira@ucalgary.ca, Barrie R. Nault

We evaluate the mechanics of IT productivity, by analyzing the channels through which IT improves firm productivity. Viewing firm productivity as a standard Cobb-Douglas function, we disentangle the effects of IT on each of the major cost components of a firm. Our theoretical contribution is the development of a Cobb-Douglas based methodology to analyze the effect of IT investments on firm-reported costs.

3 - Coopetition in Ride Sharing Economy

Chenglong Zhang, PhD Candidate, University of Texas at Dallas, Richardson, TX, United States, Chenglong.Zhang@utdallas.edu, Jianqing Chen, Srinivasan Raghunathan

Ride sharing platforms (e.g., Uber, Lyft) face great uncertainties on supply side (drivers). Given the vehicle issue faced by drivers, ride sharing platforms cooperate with rental firms (e.g., Hertz) in order for potential drivers accessing vehicles. Given the competition for riders between the platform and the rental firm, we study their incentives to engage in such coopetition (competition and cooperation) relationship. We find that the cooperation on supply side intensifies their competition on demand side. Although the intensified price competition always decreases total revenue of the two firms from riders, cost reduction from the cooperation could dominate the effect of reduced revenue.

4 - Interdependence of IT investment in Supply Chains

Fengmei Gong, University of La Verne, La Verne, CA, 91750, United States, fgong@laverne.edu, Zhuo (June) Cheng, Barrie R. Nault, David Zhang

Information technology (IT), being the enabler of the supply chain integration, requires mutual investment from the business partners and can't be adopted or used unilaterally. As supply chain partners invest in IT, firms need to make similar investments in order to better collaborate with their partners. The purpose of this paper is to investigate the interdependence of IT investment in the supply chain networks at the industry level. We identify the supply chain networks by utilizing the industry level input-output tables. Spatial econometrics methodology is used as the estimation technique to estimate the influence of supply chain neighbors on each other's IT investment.

Procurement Design

Sponsored: Auction and Market Design

Sponsored Session

Chair: Nicolas Fugger, Mannheim, 68161, Germany

1 - The Role of Commitment in Auctions

Philippe Gillen, ZEW Mannheim, L7,1, Mannheim, 68161, Germany, gillen@zew.de

We study the role of commitment in a first-price auction environment. We devise a simple two stage model in which bidders first submit an initial offer that the auctioneer can observe and then makes a counter offer. There is no commitment on the auctioneer's side to accept an offer as is or even to choose the lowest bidder. We compare this setting to a standard first-price auction both theoretically and experimentally. While theory suggests a clear revenue ranking and a difference in bidding behavior, we cannot confirm these hypothesis in the experiment.

2 - Suppliers Cutting Corners: Can Excessive Competition Compromise Quality?

Aadhaar Chaturvedi, Assistant Professor, University of Namur, Namur, Belgium, aadhaar.chaturvedi@unamur.be

Supplier(s) cutting corners by downgrading product quality is an ever present problem for a buyer. Product testing and supplier screening are typically limited in detecting it and penalties are non-credible for small entrant suppliers. We investigate the impact that increasing competition would have on supplier(s) decision to cut corners. We model a reverse auction in which the winning supplier(s) decides (ex-post) to cut corners and look at the impact that either number of participating bidders or dual sourcing (level of competition) would have on supplier(s) likelihood (ex-ante) to cut corners. We then characterize buyer's decision on the number of suppliers to invite and to dual source.

3 - Drug Procurement Auctions and Supply Uncertainty

Nicolas Fugger, ZEW Mannheim, L7, 1, Mannheim, 68161, Germany, Ulrich Laitenberger

Supply uncertainty because of shortages is a common problem in drug procurement auctions. Multi-unit auctions to contract multiple firms are a possible solution to decrease supply uncertainty. We use a theoretical model and data from generic drug procurement auctions by German health insurers to study the motives for offering multiple contracts and their effects on auction outcomes. Our model shows that increasing the number of contracts can at the same time decrease supply uncertainty and increase competitive pressure on bidders.

4 - Debarment and Collusion in Procurement Auctions

Yoan Hermstrüwer, Max Planck Institute for Research on Collective Goods, Bonn, Germany, hermstruewer@coll.mpg.de, Claudia Cerrone, Pedro Robalo

This paper explores the impact of debarment as a deterrent of collusion in first-price procurement auctions. We develop a procurement auction model where bidders can form bidding rings, and derive the bidding and collusive behavior under no sanction, debarment and fines. The model's predictions are tested in a lab experiment. We find that debarment and fines both reduce collusion and bids. The deterrent effect of debarment increases in its length. However, the debarment of colluding bidders reduces efficiency and increases the bids of non-debarred bidders. The latter suggests that the market size reduction resulting from debarment may trigger tacit collusion.

Health Care, Modeling and Optimization V

Contributed Session

Chair: Mahboubeh Madadi, San Jose State University, College of Engineering and Science, Ruston, LA, 71272, United States

1 - Adjusting for Time Varying Confounding in Adaptive Interdisciplinary Pain Management Program

Ashkan Farahani, UT-Arlington, Arlington, TX, United States

Interdisciplinary pain management programs involve diverse medical professionals to administer a mix of analgesic and cognitive treatments to improve quality of life in patients suffering from chronic pain. The observational nature of the data along with treatments administered over time lead to time varying confounding between treatments and patient's state variables and pain outcomes. This induces bias in the state transition and outcome model employed in this framework. This presentation discusses the inverse probability of treatment weighting framework to address time varying confounding in estimating causal effects of treatments.

2 - Analysis on Coordination Mechanism of the Referral System between Healthcare Institutions with Different Hierarchy

Sen Yang, Southeast University, Nanjing, China, elvinyang_seu@126.com, Haiyan Wang

The demand for high quality medical resources in China leads to the imbalance of patients in the major hospitals and community healthcare centers. An effective referral system between major hospitals and community healthcare centers is one of the ways to solve this problem. We analyze the competitive equilibrium of different institutions under different objectives using an integrated model of queuing and game theory, considered the effects of different incentives on the choice of primary care institution. The result shows that the subsidy mechanism can effectively coordinate the referral system.

3 - The Strategy of Revenue Sharing in Two-way Referral Mechanism for Healthcare Alliances

Jie Deng, Jiangnan University, Wuxi, China, chiechteng@hotmail.com

Since the limited medical resources in China, establishing the healthcare alliance and developing the two-way referral mechanism have becoming the inevitable choice to promote the rational use of health resources and reducing the waiting time and cost of patients. The study develops an analytical framework for a revenue sharing mechanism between healthcare alliance, where tertiary hospitals and community hospitals retaining its own objective function, we investigated the revenue sharing under various scenarios and found when the agreement is more likely to reached, and its effects on balance their busy between the tertiary-community hospitals, and finally analyze its benefits for patients.

4 - Pain Management via Opiods: Incorporating Pain Sensitivity into Prescription Decisions

Abdullah H. Gokcinar, The University of Texas at Dallas, Richardson, TX, United States, abdullahhalit.gokcinar@utdallas.edu, Metin Cakanyildirim

Use of opioids in pain management constitutes a significant challenge in healthcare. Underprescription of opioids yields inadequate pain-relief, while overprescription leads to serious side effects. Furthermore, opioids can paradoxically induce even higher pain, rather than reducing it. These make correct prescription decisions vital and difficult to obtain. We study the optimum opioid-use decisions in an analytical (probabilistic) model under various prescription / treatment policies. To the best of our knowledge, this work is the first application of optimization theory to the pain management context, and provides us and medical professionals with a novel pain model.

5 - Adaptive Joint Scheduling and Vehicle Routing Problem for Community-based Healthcare Delivery

Samira Fazel Anvaryazdi, Washington University in Saint Louis, St. Louis, MO, 71270, United States, Mahboubeh Madadi

In this study, an adaptive joint scheduling and vehicle routing scheme is proposed for community-based healthcare delivery. The goal is to maximize community-level health outcomes over a finite time horizon. We seek to derive optimal policies to deliver care to heterogeneous patients (with varying risk factors) located in different regions. A mobile health clinic visits patients whose demand might be known a prior or stochastic.

Chair: Natalie M Scala, Towson University, Towson, MD, 21252, United States

Co-Chair: James P. Howard, Johns Hopkins Applied Physics Laboratory, Columbia, MD, 21045, United States

1 - Military Workforce Planning and Manpower Modeling

Nathaniel D. Bastian, Operations Research Scientist | Assistant Professo, Army Cyber Institute, U.S. Military Academy, West Point, NY, 10918, United States, nathaniel.bastian@westpoint.edu, Andrew Oscar Hall

Military workforce planning and manpower modeling employs operations research tools and techniques to address problems of creating jobs and positions, as well as finding and assigning people to these positions. We provide an overview of military workforce planning and manpower modeling as it pertains to the military operations research practitioner and researcher. We review previous work in the domain, and we describe the four main classes of operations research methods. We also discuss multi-disciplinary research supporting retention and talent management, along with two real-world case studies to highlight applications in practice.

2 - Threatcasting in a Military Setting

Natalie Vanatta, U.S. Army, Ft Meade, MD, United States, Brian D. Johnson

The intersection of digital and physical security is critical to the future security of our military and national defense. Coming technological advances widen the attack plain over the next decade enhancing vulnerabilities. Helping to understand and plan for the future operating environment is the basis of a research effort known as Threatcasting. This analytic technique focuses on the intersection between cyber and physical domains and how it can revolutionize or paralyze the future. This session will use the weaponization of artificial intelligence as a case study to explain the research technique and results.

3 - Simulation Optimization of a Missile Attack Plan

Brian M. Wade, Director, US Army TRADOC Analysis Center - Monterey, Monterey, CA, United States, brian.wade@nps.edu, Shane N. Hall, Benjamin G. Thengvall

This paper discusses the importance of simulation optimization in military applications, and a brief overview of the simulation optimization literature applied to military applications is also included. Next, a relevant, real-world military problem of planning ballistic and cruise missile plans to maximize damage to an airfield is presented. Simulation optimization using three discrete-event simulations and an optimization metaheuristic program is used to analyze and solve this military problem. Finally, solutions that trade-off runway damage with the destruction of aircraft and fuel sites are discussed.

1 - Daily Tutor Scheduling Support at Hopeful Journeys Educational Center

Matthew D. Bailey, Bucknell University, Freeman College of Management, Taylor Hall, Lewisburg, PA, 17837, United States, Lucas A. Waddell

Hopeful Journeys Educational Center is a non-profit school providing full-day one-on-one tutoring for students with autism. The hourly assignments of tutors to students are subject to numerous constraints and preference such as student need and availability, teacher availability, qualifications, and team assignments. Working closely with the school-wide scheduler and under a limited budget, we developed a cost-effective, optimization-based daily scheduling support system. The system has become an integral part of their scheduling process saving hours of work each day. In the course of its development and deployment, it provided some interesting modeling and computational challenges.

2 - Empowering Denver Public Schools System to Optimize School Bus Operations

Amanda Chu, Georgia Tech-ISYE, Atlanta, GA, 30332, United States, Pinar Keskinocak, Monica Villarreal

Over 25 million students take advantage of school bus services according to the U.S. National Center for Education Statistics. School bus transportation is an integral service to students and their families. This collaborative project between Denver Public Schools (DPS) and Georgia Tech focused on creating bus route assignments to minimize objectives such as buses used, lateness, and reposition miles. We incorporated models into a decision-support (DS) tool, which enables users to create and analyze school bus route assignments. The methods and tool have been successfully used by DPS routers and analysts in the 2018-2019 academic year resulting in positive impact across multiple dimensions.

3 - Pricing Analytics for Rotable Spare Parts

Adam N. Elmachtoub, Columbia University, New York, NY, United States, Omar Besbes, Yunjie Sun

We describe a comprehensive approach to pricing analytics for reusable resources in the context of rotable spare parts, which are parts that can be repeatedly repaired and resold. Pricing rotable spare parts presents unique challenges ranging from limited data availability, minimal demand information, and complex inventory dynamics. Working in collaboration with a major aircraft manufacturer, we develop a novel pricing analytics approach that tackles all of these challenges, and describe a large-scale implementation which resulted in 3.9% improvement in profit over a ten-month period.

Financial Engineering I

Contributed Session

Chair: Qi Zhao, University of Illinois-Urbana-Champaign, Champaign, IL, 61820, United States

1 - Cracking the Black Box: A Neural Network Based Option Valuation Model

Yi Cao, Lecturer in Management Science, University of Edinburgh, Edinburgh, United Kingdom, jason.caoyi@gmail.com, Xiaoquan Liu, Jia Zhai

We develop a novel hybrid gated neural network based option valuation model. We start from the no-arbitrage option pricing theory, design a multiplicative structured hidden layers to maintain its differentiability, and select the slope and weights of input layers to satisfy the constraints. A separate neural network is constructed for predicting implied volatility. By offering economic interpretation our model extends the machine learning literature that predominantly focuses on complex algorithms to enhance mapping performance. It also contributes to the option valuation literature by offering neural network based analytical Greek letters. Empirical evidences are on S&P 500 options.

2 - Systemic Risk Quantification via Shock Amplification in Financial Networks

Dohyun Ahn, The Chinese University of Hong Kong, Shatin, N.T., Hong Kong, dohyun.ahn@cuhk.edu.hk, Nan Chen, Kyoung-Kuk Kim

We focus on systemic risk quantification under the Eisenberg-Noe network model with random shocks. In particular, we address the issue of incomplete network information by characterizing shock amplification due to the network structure. We obtain robust bounds and asymptotic behaviors of default probabilities when only partial network information is available, and we observe that the link structure of the network contains crucial information. Furthermore, we apply these results to the computation of systemic risk capital and its robust version using chance-constrained optimization.

3 - Assessing the Value of Retrofitting Carbon Capture and Storage to Natural Gas-fired Power Plants

Liping Fang, Ryerson University, Toronto, ON, Canada, lfang@ryerson.ca, R.S. Elias, M.I.M. Wahab

A real-options approach to ascertain the value of retrofitting carbon capture and storage technology to existing natural gas-fired power plants is presented. A plant is valued based on clean spark spread options. Uncertainties of electricity and natural gas prices are modeled using mean-reverting processes. Two carbon capture and storage technologies, post-combustion and oxy-fuel combustion, are considered. Whether to retrofit and at what carbon price to retrofit are analyzed and sensitivity analyses based on different costs, prices, and volatility parameters are carried out.

4 - Top-down Valuation Framework for Employee Stock Options

Yang Zhou, University of Washington, Seattle, WA, United States, yzhou7@uw.edu, Tim Leung

We propose a new valuation framework for employee stock options (ESOs). Our approach accounts for vesting period, multiple early exercises, and sudden job termination. To compute the ESO costs, we develop several numerical methods to solve the associated systems of PDEs. We implement and compare different numerical methods, and examine the effects of various contractual features.

5 - Financial Distress Prediction in Colombian Infrastructure Firms Using Logistic Regression and Support Vector Machines

Carlos A. Caro, Universidad de los Andes, Bogotá, Colombia, ca.caro10@uniandes.edu.co

Bankruptcy describes the condition in which a business cannot repay their debts, which forces them to follow legal and financial liquidation processes. Bankruptcies incur severe consequences to shareholders, creditors, and employees. Advanced statistics and machine learning techniques have been used in the past years to predict many business failure cases. Such models have been of great use for investors, creditors, auditors, banks and government policymakers. In this study, logistic regression and support vector machine models are used with the aim of predicting the financial distress risk of firms belonging to the construction industry in Colombia, one-year prior of its occurrence.

6 - Empirical Study of Fractional Stochastic Volatility

Qi Zhao, University of Illinois, Urbana-Champaign, Urbana, IL, United States, qiz2@illinois.edu, Alexandra Chronopoulou

The Hurst index is a vital parameter in a fractional stochastic volatility model that determines whether the model is long-range dependent (exhibits long memory) or antipersistent (rough). In our work, using options data we extract the stock's volatility via a regression method which we then use to estimate the Hurst index by applying a variations-based semi-parametric technique. When the method is applied to an S&P 500 dataset, we compute the Hurst index to be around 0.18, and conclude that the volatility is rough.

Chair: Georgina Hall, INSEAD, Fontainebleau, 77300, France

1 - Partial Recovery in the Graph Alignment Problem

Georgina Hall, INSEAD, Boulevard de Constance, Fontainebleau, 77300, France

We consider two adjacency matrices A and B, obtained by generating two correlated (n,q,s) Erdos-Renyi graphs A1 and A2, and taking A=A1 and B=Pi^*TA2Pi^*, where Pi^* is a permutation matrix. We present conditions on n, q, and s under which one can recover, both theoretically and computationally, a permutation matrix whose overlap with Pi^* is larger than a fixed fraction of the nodes. We also present conditions on n, q and s under which recovery is impossible. Joint work with Laurent Massoulie.

2 - An Optimal-Storage Approach to Semidefinite Programming using Approximate Complementarity

Madeleine Udell, Assistant Professor, Cornell University, New York, Ithaca, NY, 14850, United States, udell@cornell.edu

This talk develops new storage-optimal algorithms that provably solve generic semidefinite programs (SDPs) in standard form. The methods are particularly effective for weakly constrained SDPs. The key idea is to formulate an approximate complementarity principle: Given an approximate solution to the dual SDP, the primal SDP has an approximate solution whose range is contained in the null space of the dual slack matrix. For weakly constrained SDPs, this null space has very low dimension, so this observation significantly reduces the search space for the primal solution.

3 - Achieving Acceleration in Distributed Stochastic Optimization

Mert Gurbuzbalaban, Rutgers University, 100 Rockafeller Rd, Piscataway, Piscataway, NJ, 08854, United States, mg1366@business.rutgers.edu

We study distributed stochastic multi-agent optimization problems defined over a network where each agent possesses a local cost function that is strongly convex and smooth where only stochastic estimates of the gradient are available. We show that a momentum variant of distributed stochastic gradient converges to a neighborhood of the optimum with the accelerated linear rate while being communication-wise efficient. Building on this result, we develop optimal stochastic gradient algorithms that can achieve the lower bounds up to log factors and illustrate their performance in practice.

4 - Towards understanding Random and Deterministic Order in ADMM and Coordinate Descent

Ruoyu Sun, University of Illinois Urbana-Champaign, Minneapolis, MN, 55414, United States

Since the recent finding that multi-block ADMM (Gauss-Seidel order) does not converge, people have found three variants of ADMM that converge in practice: Gaussian-back substitution ADMM (GBS-ADMM), symmetric Gauss-Seidel ADMM (sGS-ADMM), randomly permuted ADMM (RP-ADMM). The first two are deterministic, and the third is random. We prove that in the worst-case, the two deterministic orders can be O(n^2) times slower than randomized order for solving unconstrained problems. In addition, we show that for RP order the gap is at most O(n), based on the proof of a weak matrix AM-GM inequality.

1 - Optimization of Out-of-Hours Schedules for Pharmacies

Arie M. Koster, Professor of Discrete Optimization, RWTH Aachen University, Pontdriesch 14-16, Aachen, 52056, Germany, koster@math2.rwth-aachen.de, Christina Büsing, Timo Gersing

The supply of pharmaceuticals is a critical component of a functioning health care system. To guarantee a 24/7 supply, all pharmacies in Germany have to participate in an out-of-hours schedule. To minimize the total number of services, we simultaneously have to deal with covering, packing and coloring constraints. In this talk, we present an integer programming formulation to obtain a recurring schedule of services. Furthermore, combinatorial insights for the problem are derived from this model and computational results for real-life cases are presented.

2 - Recent Computational Advances for Solving the Multi-item Capacitated Lot-sizing Problem

Esra Buyuktahtakin Toy, Associate Professor, New Jersey Institute of Technology, Newark, NJ, United States, esratoy@njit.edu, Ning Liu, Cole Smith, Joseph C. Hartman

In this talk, we will review recent computational progress regarding the multi-item capacitated lot-sizing, which is a core production and inventory planning problem. Our approaches vary from DP-based and partial objective function inequalities to approximate dynamic programming in order to tackle this highly complex NP-hard problem in a tractable solution time.

3 - Improving Column Generation via Random Coloring and Parallelization for Vehicle Routing Problems

Miao Yu, University of Michigan, Ann Arbor, MI, United States, miaoyu@umich.edu, Viswanath Nagarajan, Siqian Shen

Vehicle routing problems arise in a variety of applications including the emerging shared-mobility-based pickup and delivery problem and home medical care delivery. We consider a VRP where each customer has a unit demand. To efficiently solve the pricing problem in the column generation, we propose two parallel algorithms for the elementary shortest path problem with resource constraints: an extension of the pulse algorithm first proposed by Lozano et al. and a random coloring algorithm based on the color-coding of Alon et al. We conduct numerical experiments to evaluate the proposed algorithms on classic VRP benchmark, as well as instances of medical home care delivery problem.

4 - Exact Algorithms for Lot-sizing Problem with Multiple Capacities, Piecewise Concave Costs, and Subcontracting

Kartik Kulkarni, Virginia Tech, Blacksburg, VA, 24060, United States, kartikrf@vt.edu, Manish Bansal

We present an exact algorithm for a generalized lot-sizing problem with the following features: (a) the total production capacity in each time period is the summation of binary multiples of n capacities of different sizes, (b) subcontracting option; and (c) concave costs. We also study lot-sizing problem with piecewise concave production costs and concave holding costs. Our computational results show that these algorithms are computationally efficient.

1 - A Reliable Facility Location Problem with Wasserstein Ambiguity Set

Kanglin Liu, Tsinghua University, Beijing, China, lkl15@mails.tsinghua.edu.cn, Ruiwei Jiang, Zhihai Zhang

Supply chain disruption will cost severe damgae to the entire system. To improve efficiency and effectiveness, we consider a reliable uncapacitated facility location problem, where the probability of facility failure lives in a Wasserstein ball centered at the empirical disruption distribution. The original distributionally robust model is formulated as a two-stage stochastic program with the objective of minimizing fixed cost and worst-case expected transportation cost. We reformulate the original min-max-min problem as an entire minimization linear program by proving totally unimodularity.

2 - Stochastic Optimization of Unimodular Functions

Lawrence Thul, Graduate Student, Princeton University, Princeton, NJ, United States, lathul@princeton.edu, Warren Powell

We propose a derivative-free method for optimizing a stochastic unimodular function in a finite, one-dimensional domain. In nonconvex stochastic optimization problems, stepsize tuning can be one of the most challenging and time consuming tasks. This stochastic line search method can be applicable to solving for the best stepsize in each iteration of gradient descent on stochastic functions.

3 - Geometric Evaluation of Robustness of Stochastic Optimization Solutions

Jorge Vera, Professor, Pontificia Universidad Catolica de Chile, Dept. Industrial and System Engineering, Universidad Catolica de Chile, Santiago, 7820436, Chile, jvera@ing.puc.cl

2-stage models attempt to make "good" decisions, considering the impact of those decisions in an uncertain future using the expected cost of the second stage as a measure of that impact. In this work we explore the effect of first stage decisions on the geometry of the optimization problem of the second stage. A problem with good geometry might be less sensible to perturbations in the data and, hence, more robust to the risk of uncertainty. We show how to formulate a 2-stage problem that tries to optimize the balance between cost and a suitable geometric measure of the second stage and illustrate the idea in some simulated experiments as well as a real industrial application.

4 - Distributionally Robust Combinatorial Optimization

Ruiwei Jiang, University of Michigan, Ann Arbor, MI, 48109, United States, ruiwei@umich.edu, Shabbir Ahmed, Mohit Singh

We study distributionally robust analogs of combinatorial optimization problem with uncertain objective coefficients. We provide equivalent deterministic reformulations of such problems under several types of ambiguity sets, and discuss corresponding solution approaches.

5 - Efficient Algorithms for Discrete Distributionally Robust Stochastic Program

Zhe Zhang, Georgia Tech, Atlanta, GA, 30318, United States, Shabbir Ahmed, Guanghui Lan

Recently, there has been a growing interest in distributionally robust optimization as a principled approach to data-driven optimization. In this paper, we consider the two-stage distributionally robust stochastic program with discrete scenario support. For continuous scenario support problem, while much research effort has been devoted to exact tractable reformulations, but one often has to resort to solving a discretized approximation when such reformulations are unavailable. Despite the problem's importance, few algorithms are developed, and most of them can neither handle the non-smooth second stage cost function nor the large number of scenarios K effectively. We fill the gap by developing two O(1/epsilon) algorithms whose iteration complexity only mildly depend on K. Moreover, the major computations involved in each iteration of these algorithms can be conducted in parallel if necessary. Finally, for the most important Kantorvich ball ambiguity set, we propose a slight modification of our algorithms to overcome the demanding computation of the distribution projection.

Data Driven Optimization and Applications

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Andrew Lim, National University of Singapore, Singapore, 119245, Singapore

1 - A Robust Approach to Uncertainty in Games with Applications to a Cournot Model

Giovanni P. Crespi, Professor, Universita' degli studi dell'Insubria, Varese, Italy, giovanni.crespi@uninsubria.it, Matteo Rocca, Davide Radi

Introducing uncertainty and ambiguity averse players on a game, we study the notion of robust-optimization equilibria (ROE), proving they can be represented as Nash equilibria of a "nominal" game. We provide deeper insight in the notion of -Nash Equilibria, as a characterization of ROE and we show the ROEs may be qualitatively different from Nash-Equilibria in the nominal counterpart. For example, multiple and asymmetric ROEs can exist for a robust game such that its nominal counterpart is a simple symmetric game with only a symmetric Nash-equilibrium. With a learning mechanism in a duopoly game, we show also the convergence properties to an equilibrium differ.

2 - Enhance Principal Components Analysis by Using the Most Robust Solution as the Groundwork

Long Zhao, National University of Singapore, CBA 5.334 B, Singapore, 78712-1277, Singapore, Rui Gao

Instead of carefully designing uncertainty sets, we propose a new way to utilize RO or DRO to obtain a fantastic on-average performance. We take the most robust solution, i.e., the solution with infinity size uncertainty set, as the groundwork and use the well-estimated information to build upon it. To showcase the power of this simple idea, we apply it to enhance the PCA because the top PCs are good estimations. Although the new method uses a much fewer number of PCs, it can at least matches the best possible PCA method across all datasets we tried with five different objectives. We also provide theoretical evidence and simulation results to show the importance of the most robust solution.

3 - Forecasting Demand for New Products

Shanshan Huang, National University of Singapore, National University of Singapore, BIZ2 B1-01, Singapore, 117592, Singapore, shanshanhuang@u.nus.edu, Andrew Lim, Tong Wang

We develop an innovative forecasting methodology for estimating the demand for new products. The key challenge is that there are no historical sales for new products. One approach is to fit a regression or machine learning method to the sales and covariates data for existing products. However, it ignores the key substitution effects. We develop a blending of choice models to account for potential substitution patterns. Our method reduces the prediction error by 50% compared to benchmarks such as regression and machine learning methods.

4 - Approximating the Gittins Index in a Bayesian Bandit

Andrew Lim, National University of Singapore, 15 Kent Ridge Drive, Mochtar Riady Building, Singapore, 119245, Singapore, andrewlim@nus.edu.sg

While the optimal policy for the Gittins-Whittle formulation of the multi-armed bandit is fully characterized in terms of the Gittins index, the Gittins index is notoriously difficult to compute for high dimensional Bayesian bandits. We develop a method for approximating the dynamics of the posterior and show how it can be used to approximate the Gittins index for high-dimensional Bayesian bandits. Comparisons of the Gittins-Whittle framework to Thompson sampling and the Upper Confidence Bound approach will be discussed, and applications of our approximation to Bayesian bandits where the rewards are mixtures will also be presented.

Advances in Sequential Decision-Making Algorithms

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Daniel Jiang, University of Pittsburgh, Pittsburgh, PA, 15261, United States

1 - Lookahead-bounded Q-learning

Ibrahim El Shar, PhD Student, University of Pittsburgh, Pittsburgh, PA, United States, ije8@pitt.edu, Daniel Jiang

Lookahead-bounded Q-learning (LBQL) introduced in this work is a new convergent variant of Q-learning which addresses the problem of sample efficiency in the standard Q-learning algorithm. LBQL uses the collected experience and the current action-values as a Q-based dual feasible penalty to create the so-called information relaxation dual dynamic programs. These are then used to enhance the performance of the standard Q-learning algorithm by providing lower and upper bounds on its iterates. We show that LBQL converges to the optimum action-values with probability 1. Numerical experiments confirm the quick convergence of LBQL as compared to standard Q-learning algorithm.

2 - New Empirical Algorithms and Convergence Analysis for Approximate Dynamic Programming

William Haskell, Purdue University, West Lafayette, IN, 01945, United States

In this talk, we consider empirical methods for doing large-scale dynamic programming that we call ‘empirical dynamic programming’ (EDP). EDP is easily implementable, and naturally supports function approximation for handling large or continuous state spaces. Our convergence analysis of EDP is based on iteration of random operators. As one of our key contributions, we develop a new method for convergence analysis of iteration of random operators, and we show that this method has broad applicability to many types of approximate dynamic programming algorithms. We also demonstrate the favorable performance of EDP in numerical tests.

3 - Leveraging Networks in Approximate Linear Programming

Selvaprabu Nadarajah, College of Business, University of Illinois at Chicago, Chicago, IL, 60607, United States, selvan@uic.edu, Andre Augusto Cire

We consider a hierarchy of approximate linear programs (ALPs) for solving a general class of discrete optimization problems based on network approximations of a value function. We show how the burden of solving these network ALPs can be overcome by restricting their feasible set using a construction that leverages chordal graphs. Our network ALPs and their restrictions have quality guarantees and exhibit promising performance on two challenging applications.

4 - Feedback-based Tree Search for Reinforcement Learning

Daniel Jiang, University of Pittsburgh, Pittsburgh, PA, 15261, United States, drjiang@pitt.edu, Emmanuel Ekwedike, Han Liu

Inspired by recent successes of Monte-Carlo tree search (MCTS) in a number of application domains, we propose a reinforcement learning (RL) technique that iteratively applies MCTS on batches of small, finite-horizon versions of the original infinite-horizon Markov decision process. The terminal condition of the finite-horizon problems, or the leaf-node evaluator of the decision tree generated by MCTS, is specified using a combination of an estimated value function and an estimated policy function. The recommendations generated by the MCTS procedure are then provided as feedback in order to refine, through classification and regression, the leaf-node evaluator for the next iteration.

Joint Session RAS/Practice Curated: Precision Scheduled Railroading

Sponsored: Railway Applications

Sponsored Session

Chair: Carl D. Van Dyke, TransNetOpt, West Windsor, NJ, 08550, United States

1 - Principles of Precision Scheduled Railroading

David T. Hunt, Director, Oliver Wyman, One University Square, Suite 100, Princeton, NJ, 08540, United States, david.hunt@oliverwyman.com

Shippers are tightening supply chains by continually demanding faster and more reliable transportation. To better adapt in this highly competitive environment, railroads are implementing Precision Schedule Railroading (PSR). This presentation will provide an overview of PSR, including why PSR is necessary to railroad operations today, what are the pros and cons of PSR, and how operations research and analytics can better enable successful PSR operations.

2 - Precision Scheduled Railroading at Norfolk Southern: Overall Process and Optimization Tools

Clark Cheng, Sr. Director Operations Res & Chief Data Scientist, Norfolk Southern Corporation, 3 Commercial Place, Atlanta, GA, 23510, United States, Clark.Cheng@nscorp.com, Yudi Pranoto

Norfolk Southern has adopted the precision scheduled railroading (PSR) principles as it develops new operating plan, TOP21. In this talk, we will first describe the overall process, and then focus on how OR models, including both simulation and optimization, have been leveraged to support this process.

3 - Precision Scheduled Railroading at CSX

Michael Swain, CSX. Transportation, 500 Water Street, 13th Floor - J300, Jacksonville, FL, 32202, United States

Scheduled railroading is transforming CSX into a more efficient and reliable railroad. Based on five guiding principles — safety, service, cost control, asset utilization and people — scheduled railroading is both an operating model and a shared commitment to excellence. We will discuss the various aspects of PSR and what they mean at CSX.

4 - Role of OR, Modeling and Analytics in Precision Scheduled Railroading

Carl D. Van Dyke, TransNetOpt, 6 Snowbird Court, West Windsor, NJ, 08550, United States, carl@cvdzone.com

Precision scheduled railroading (PSR) is viewed as a management strategy for getting the most out of a freight railway. These results are generally observed in metrics such as increased asset velocity, better on-time performance of shipments, reduced loco fleet sizes, higher service reliability, etc. Associated with this is a shift in how cars are handled, the roles of specific yards, and a rethink of the capital investment process. While much of this is often achieved through “smart railroading,” analytics, modelling and OR can play a key role to test the impact of potential changes, identify opportunities, and monitor system performance, all of which will be explored in this talk.

1 - On Acceleration with Noise-corrupted Gradients

Jelena Diakonikolas, University of California-Berkeley, University of California-Berkeley, 475 Evans Hall, Berkeley, CA, 94720, United States, Michael B. Cohen, Lorenzo Orecchia

We study the stability of accelerated algorithms in the setting of noise-corrupted gradients and provide two main technical contributions: (i) a new accelerated method AGD+ that generalizes Nesterov’s AGD and improves on the recent method AXGD, and (ii) a theoretical study of accelerated algorithms under noisy and inexact gradient oracles. This study leverages the simplicity of AGD+ and its analysis to clarify the interaction between noise and acceleration and to suggest modifications to the algorithm that reduce the mean and variance of the error incurred due to the gradient noise.

2 - A Universally Optimal Multistage Accelerated Stochastic Gradient Method

Alireza Fallah, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, afallah@mit.edu, Necdet Serhat Aybat, Mert Gurbuzbalaban, Asuman Ozdaglar

We study the problem of minimizing a strongly convex and smooth function when we have noisy estimates of its gradient. We propose a novel multistage accelerated algorithm that is universally optimal in the sense that it achieves the optimal rate both in the deterministic and stochastic case and operates without knowledge of noise characteristics. The algorithm consists of stages that use a stochastic version of Nesterov’s accelerated algorithm with a specific restart and parameters selected to achieve the fastest reduction in the bias-variance terms in the convergence rate bounds.

3 - A Unified Approach to Algorithm Analysis

Laurent Lessard, University of Wisconsin-Madison, Madison, WI, United States, laurent.lessard@wisc.edu

Even within the family of first order methods, there is tremendous variety. These include fast/accelerated methods, operator-splitting methods, proximal variants, quasi-newton methods, and more. This talk will present a unified control-theoretic framework for representing and analyzing algorithms. Algorithms are viewed as interconnections of simple components (linear dynamical systems, random noise, or adversarial disturbances), which allows us to leverage tools from robust and nonlinear control. In particular, we can derive bounds on worst-case convergence rates in an automated fashion, which leads to a natural energy dissipation interpretation and an associated Lyapunov function.

4 - Bregman Augmented Lagrangian Method and its Acceleration

Niao He, University of Illinois Urbana-Champaign, Urbana, IL, 61801, United States, niaohe@illinois.edu

We study a family of Bregman proximal augmented Lagrangian methods to solve linearly constrained convex optimization problems. The algorithm includes the classical method of multipliers as a special case. By exploiting the domain knowledge and special structures of the dual problem, it could lead to easier sub-problems. We establish convergence rates of the algorithm in the general convex and strongly convex settings. We further demonstrate how the algorithm can be applied problems related to Markov decision processes, and reveal connections with existing reinforcement learning algorithms.

Conic Optimization II

Contributed Session

Chair: Michael Rotkowitz, University of Maryland, Dept. of ECE, A.V. Williams Bldg., College Park, MD, 20742, United States

1 - Working in Reverse: Inverse Optimization Methods for Pyomo in Online Settings

Stephanie Allen, University of Maryland, College Park, College Park, MD, United States

Two recent papers by Dong, Chen, & Zeng and Barmann, Martin, Pokutta, & Schneider extend work from the online convex optimization field to parameterize an objective function in real time, meaning that a researcher must attempt to parameterize the objective function as parameters in the feasible region change and as the observed optimal solution also changes. We create a Python class (with help from the Pyomo optimization package) with online capabilities to implement these methods for a subset of convex optimization problems. We plan to use the class to replicate computational experiments from the papers.

2 - Discrete Choice Prox Functions on the Simplex

Vladimir Shikhman, Chemnitz University of Technology, Reichenhainer Str. 41, Chemnitz, 09119, Germany, vladimir.shikhman@mathematik.tu-chemnitz.de, David Müller, Yurii Nesterov

We derive new prox-functions on the simplex from additive random utility models of discrete choice. They are convex conjugates of the corresponding surplus functions. We explicitly derive the convexity parameter of discrete choice prox-functions associated with generalized extreme value models, and specifically with generalized nested logit models. Incorporated into subgradient schemes, discrete choice prox-functions lead to natural probabilistic interpretations of the iteration steps. As illustration we discuss an economic application of discrete choice prox-functions in consumption cycle.

3 - Upper Bounds for the Minimization of a Particular Singular Value

Michael C. Rotkowitz, Lyft, San Francisco, CA, United States, University of Maryland, College Park, MD, United States

We consider the problem of minimizing a particular singular value of a matrix variable, neither the largest nor the smallest, which is then subject to some convex constraints. This arises in the computation of the controllability of decentralized systems, and similar issues arise for vector order statistics. In this talk, we discuss the relatively easier issue of finding upper bounds for this problem. Some counter-intuitive results are presented on the best convex heuristic for this problem from a family of Ky Fan norms. We further show how expressing the singular value as a difference of Ky Fan norms, and using semidefinite representations of each, can be used to derive sequential convex procedures.

4 - Lower Bounds for the Minimization of a Particular Singular Value

Michael C. Rotkowitz, Lyft, San Francisco, CA, United States, University of Maryland, College Park, MD, United States

We consider the problem of minimizing a particular singular value of a matrix variable, neither the largest nor the smallest, which is then subject to some convex constraints. This arises in the computation of the controllability of decentralized systems, and similar issues arise for vector order statistics. In this talk, we discuss the more difficult issue of finding lower bounds for this problem. We discuss the formulation of the problem as a polynomial optimization (PO), such that sum-of-squares (SOS) techniques can be used to determine lower bounds. We further show how the Courant-Fischer characterization of the singular value can be used to derive a sampling technique to produce much smaller POs.

Challenges in Energy Systems Network Optimization

Sponsored: Optimization/Network Optimization

Sponsored Session

Chair: Kory Hedman

1 - Simulated Coordinated Scheduling and Operation of Electric and Natural Gas Networks

Aleksandr Rudkevich, President, Newton Energy Group LLC, Boston, MA, United States, Anatoly Zlotnik, Evgeniy Goldis, Russ Philbrick, Pablo Ruiz, Aleksandr Beylin, Xindi Li, Richard D. Tabors, Rafael Castro

We simulate a concurrent operation of the electric and natural gas networks. Electric network is modeled by a rolling horizon multi-cycle MIP-based SCUC and SCED optimization emulating day-ahead and real-time markets. A rolling horizon transient optimization of compressors and gas flows is used to clear the intra-day market on a pipeline network. Gas-fired generators are represented as gas and electric market participants. Coordination of gas and electric scheduling is achieved through the exchange of shadow prices, physical requirements and limitations between two markets. We present results comparing alternative coordination mechanisms using data for real markets in the Northeaster US.

2 - Challenges and Successes of Large Scale Power Network Optimization in Julia

Carleton Coffrin, Los Alamos National Laboratory, Los Alamos, NM, United States

The recent programming language Julia promises to combine the simplicity of high-level languages like python and Matlab with the performance of low-level languages like C and C++. If successful in its ambitions, Julia would drastically reduce the time required to transform prototype algorithms into production solutions. In this work we explore the viability of using Julia for solving large-scale non-convex mixed-integer optimization problems faced by power network operators, such as security-constrained optimal power flow. The underlying computational challenges are presented and the performance of Julia-based algorithms are compared to established high-performance alternatives.

3 - Optimization-based Approaches to Spatial Disaggregation of Virtual Batteries Over Power Networks

Mads R. Almassalkhi, University of Vermont, Burlington, VT, United States, malmassa@uvm.edu

Distributed energy resources (DERs) are often aggregated and coordinated as a single bulk resource or virtual battery (VB) that interfaces directly with market-based signals. However, a VB is often not aware of the physical location of the underlying DERs in the power network. This means that VB dispatch signals can lead to violations of local network limits, which can reduce grid reliability. This talk discusses recent convex optimization-based approaches to disaggregate a VB dispatch signal over an AC power networks to ensure network-admissible coordination of DERs during dynamic operating conditions.

4 - Large-scale Grid Models: Synthetic Data & Co-simulation

Bryan Palmintier, NREL, Golden, CO, United States, Tarek Elgindy

Power grid modernization and wide-spread distributed energy resource (DER) integration are driving an explosion of interest in advanced algorithms and new optimization schemes. However, there has historically been a lack of open-access realistically sized and detailed datasets—particularly for the distribution system—and simulation tools able to model these systems. This talk will present recent advances with very large-scale (>>1M nodes) distribution data sets and the use of co-simulation to tractably model large integrated transmission-distribution grids and their interactions with new controls/optimization.

5 - Challenges with Distributed Energy Resource Aggregation

Yonghong Chen, Consulting Advisor, MISO, Carmel, IN, United States, ychen@misoenergy.org

Distributed energy resources can potentially introduce significant challenges on market design and market operations. This talk will discuss several MISO R&D studies on DER modeling and integration. First of all, large amount of small resources can introduce significant computational challenges. Secondly, DER aggregation across multiple locations may introduce dispatch and pricing issues and the possibility of oscillation. It'll also require coordination between transmission and distribution. Thirdly, both participants and system operators will require better tools and processes to manage uncertainties.

Recent Advances in Learning and Distributionally Robust Optimization I

Sponsored: Computing

Sponsored Session

Chair: Hamed Rahimian, Northwestern University, Evanston, IL, 60208, United States

1 - Wasserstein Distributional Robustness, Regularization, and Generalization

Rui Gao, University of Texas at Austin, Austin, TX, 78712, United States, rgao32@gmail.com

In this talk, we consider Wasserstein distributionally robust optimization that aims to find a solution that hedges against a set of distributions that are close to some nominal distribution in Wasserstein metric. We discuss the connection between this framework and regularization problems in statistical learning, and study its generalization error bound.

2 - Distributionally Robust Reformulations of Discrete Probability Distributions

Ihsan Yanikoglu, Ozyegin University, Istanbul, Turkey, ihsan.yanikoglu@ozyegin.edu.tr

This talk focuses on robust reformulations of ambiguous chance constraints when the underlying family of distributions is discrete and supported in a so-called ``p-box”, ``p-ellipsoidal”, or phi-divergence uncertainty set. Using the robust optimization paradigm, the deterministic counterparts of the ambiguous chance constraints are reformulated as mixed-integer or convex optimization problems which can be tackled by commercial solvers for moderate sized instances. For larger sized instances, we propose a safe approximation algorithm that is computationally efficient and yields high quality solutions.

3 - Efficient Algorithms for Distributionally Robust Machine Learning

Soumyadip Ghosh, IBM TJ Watson Research Center, Yorktown Heights, NY, 10598, United States, ghoshs@us.ibm.com, Mark S. Squillante

We consider a new stochastic gradient descent algorithm for efficiently solving general min-max optimization problems that arise naturally in distributionally robust learning. By focusing on the entire dataset, current approaches do not scale well. We address this issue by initially focusing on a subset of the data and progressively increasing this support to statistically cover the entire dataset.

5 - Prescriptive Static Stochastic Programming

Hamed Rahimian, Postdoctoral Fellow, Northwestern University, Evanston, IL, 60208, United States, hamed@northwestern.edu, Bernardo Kulnig Pagnoncelli

Classical stochastic programming models (e.g., two-stage stochastic program and chance-constrained program) are often described by the random parameters. However, in many settings, random parameters depend on multidimensional features. We study stochastic programming models to prescribe an optimal decision in a framework that the random parameters need to be learned from a set of data. We demonstrate our framework using a variety of kernel smoothing functions, borrowed from the statistical learning, and we show the convergence properties of the resulting models. We also compare the results with the classical models that ignore the features information.

Navigating the Review Process – Recently Accepted Papers in Empirical Healthcare OM

Sponsored: Manufacturing & Service Oper. Mgmt/Healthcare Operations

Sponsored Session

Chair: Fernanda Bravo, UCLA Anderson School of Management, Los Angeles, CA, 90024, United States

Co-Chair: Song-Hee Kim, University of Southern California, Los Angeles, CA, 90089, United States

1 - Separate and Concentrate: Accounting for Patient Complexity in General Hospitals

Sandra Sülz, Erasmus University Rotterdam, Rotterdam, Netherlands, sulz@eshpm.eur.nl, Ludwig M. Kuntz, Stefan Scholtes

Scholars have recently suggested the reorganization of general hospitals into organizationally separate divisions for routine and non-routine services. We provide empirical evidence for this proposal from a quality perspective. Disentangling the effects of high absolute and relative hospital volumes in a disease group, our analysis suggests that both routine and complex patients would benefit from a hospital with a multi-specialty hub for emergency and non-routine elective services at its core, complemented by separate disease-focused hospitals-within-hospitals for routine services, and by adopting a disease-based departmental routing strategy for newly arriving complex patients.

2 - Using Patient-Centric Quality Information to Unlock Hidden Health Care Capabilities

Wallace J. Hopp, University of Michigan, Herrick Professor of Business, Ross School of Business, Ann Arbor, MI, 48109-1234, United States, Guihua Wang, Jun Li

We use mitral valve surgery outcome data to compute patient-centric information and evaluate the potential health benefits from using the information to guide patients to surgeons. We estimate total societal benefits from using patient-centric information are comparable to those achievable by enabling the best surgeons to treat 10-40% more patients.

3 - The Impact of Delay Announcements on Hospital Network Coordination and Waiting Times

Jing Dong, Columbia University, New York, NY, 60208, United States, Elad Yom-Tov, Galit Bracha Yom-Tov

We investigate the impact of delay announcements on the coordination within hospital networks using a combination of empirical observations and numerical experiments. We offer empirical evidence that patients take delay information into account when choosing emergency service providers and that such information can help increase coordination in the network. Our numerical results indicate that the level of coordination that can be achieved is limited by the patients’ sensitivity to waiting, the load of the system, the heterogeneity among hospitals and, importantly, the method hospitals use to estimate delays.

4 - Patient Prioritization in Emergency Department Triage Systems: an Empirical Study of the Canadian Triage and Acuity Scale (ctas)

Eric Park, University of Hong Kong, Hong Kong, ericpark@hku.hk, Yichuan Ding, Mahesh Nagarajan, Eric Grafstein

Emergency departments (EDs) typically use a triage system to classify patients into priority levels. Most triage systems do not specify how exactly to route patients across and within the assigned triage levels. Decision makers in EDs often have to use their own discretion to route patients. Also, how patient waiting is perceived and accounted for in ED operations is not clearly understood. Using patient-level ED visit data from 4 EDs in the metro Vancouver, BC, area, we structurally estimate the waiting cost structure of ED patients as perceived by the decision makers who make ED patient routing decisions. We derive policy implications and make suggestions for improving triage systems.

Distributed Optimization for Machine Learning

Sponsored: Optimization/Nonlinear Programming

Sponsored Session

Chair: Mert Gurbuzbalaban, Rutgers University, Piscataway, NJ, 08854, United States

Co-Chair: Bugra Can, Rutgers University, Newark, NJ, 07102, United States

1 - GNSD: A Gradient based Nonconvex Stochastic Algorithm for Decentralized Optimization

Mingyi Hong, University of Minnesota, Keller Hall, Minneapolis, MN, 55455, United States, Songtao Lu, Haoran Sun

In this paper, we propose a gradient-tracking based nonconvex stochastic decentralized (GNSD) algorithm for solving nonconvex optimization problems, where the data is partitioned into multiple parts and processed by the local computational resource. Through exchanging the parameters at each node over a network, GNSD is able to find the first-order stationary points (FOSP) efficiently. From the theoretical analysis, it is guaranteed that the convergence rate of GNSD to FOSPs matches the well-known convergence rate O(1/sqrt{T}) of stochastic gradient descent by shrinking the step-size.

2 - On Maintaining Linear Convergence of Distributed Learning and Optimization under Limited Communication

Na Li, Thomas D. Cabot Associate Professor, Harvard University, Cambridge, MA, 02138, United States, nali@seas.harvard.edu, Sindri Magnusson, Hossein Shokri Ghadikolaei

In parallel and distributed machine learning processors need to compress important algorithm information to bits so they can communicate and coordinate to solve large problems. We consider a general class of linearly convergent parallel/distributed algorithms and illustrate how we can design quantizers compressing the communicated information to few bits while still preserving the linear convergence. We illustrate our results on learning algorithms using different communication structures, such as decentralized algorithms where a single master coordinates information from many workers and fully distributed algorithms where only neighbors in a communication graph can communicate.

3 - An Inexact Penalty for Convex Problems with Linear Constraints

Angelia Nedich, ASU, Tempe, AZ, 85281, United States, Angelia.Nedich@asu.edu, Tatiana Tatarenko

In this work, we consider a constrained convex problem with linear inequalities and provide an inexact penalty re-formulation of the problem. The novelty is in the choice of the penalty functions, which are smooth and can induce a non-zero penalty over some points in feasible region of the original constrained problem. The resulting unconstrained penalized problem is parametrized by two penalty parameters which control the slope and the curvature of the penalty function. With a suitable selection of these penalty parameters, we show that the solutions of the resulting penalized unconstrained problem are feasible for the original constrained problem, under some assumptions.

4 - A Tight Convergence Analysis for Stochastic Gradient Descent with Delayed Updates

Yossi Arjevani, NYU, New York, NY, United States, yossi.arjevani@gmail.com, Ohad Shamir, Nathan Srebro

Gradient-based optimization methods are widely used in machine learning and other large-scale applications. However, in their standard formulation, they are also strongly synchronous in nature. In this work, we provide tight finite-time convergence bounds for stochastic gradient descent on quadratic functions, when the gradients are delayed and reflect iterates from a number of rounds ago. First, we show that without stochastic noise, delays strongly affect the attainable optimization error. In sharp contrast, we quantify how stochastic noise makes the effect of delays negligible, improving on previous work which only showed this phenomenon asymptotically or for much smaller delays.

5 - Decentralized Computation of Effective Resistances and Acceleration of Distributed Optimization Algorithms

Bugra Can, Rutgers University, Newark, NJ, 07102, United States, bc600@scarletmail.rutgers.edu

The effective resistance between a pair of nodes in a weighted undirected graph is defined as the potential difference induced between them when a unit current is injected at the first node and extracted at the second node. We develop an efficient provably linearly convergent distributed algorithm for computing effective resistances and use our algorithm to design an efficient communication matrix for consensus optimization. Our framework can accelerate many state-of-the-art distributed optimization algorithms including the EXTRA and DPGA methods on a variety of networks.

Network Models and Routing Algorithms I

Sponsored: Transportation Science & Logistics/Intelligent Transportation Systems (ITS)

Sponsored Session

Chair: Yufeng Zhang, University of Minnesota, Minneapolis, MN, 55455, United States

1 - Optimal Traffic Metering Locations and Levels in Urban Transportation Networks

Rasool Mohebifard, Washington State University, Pullman, WA, 99163, United States, Rasool.Mohebifard@wsu.edu, Ali Hajbabaie

Existing perimeter control methods regulate traffic flow at predefined gate locations. This study incorporates gate location decisions in perimeter control in an integrated Mixed-Integer Nonlinear Program (MINLP) and presents a customized methodology to solve it. The methodology divides the feasible region of the problem into several sub-regions based on gate locations, constructs two significantly less computationally complex MINLPs, decomposes them into primal and master problems, and finds solutions by solving them iteratively. Numerical analysis show that the integrated program reduces travel times by 8.5% to 8.8% compared to the case of perimeter control with fixed gate locations.

2 - A Linear Programming-based Algorithm for Traffic Assignment Problem with Link Interaction

Yufeng Zhang, University of Minnesota, Minneapolis, MN, 55455, United States, Alireza Khani

Traffic assignment algorithms play an important role in transportation-related studies. Classic traffic assignment algorithms set some restrictions on travel cost functions. We studied the traffic assignment problem for user equilibrium with link interactions and formulated it as Variational Inequalities. Using the Benders Decomposition technique, the problem was converted to a linear program and we further constructed the dual problem. We proposed an algorithm that only involves solving standard traffic assignment problems and linear programs for the problem. Some decent properties to the formulation were explored. Computational results were given to show the efficacy and efficiency of the algorithm.

3 - Learning Activities in Operations Research Course to Teach TSP and CVRP Problem

Evelyn Arrey, Universidad Catolica del Norte, Manuel Verbal 1333, Antofagasta, 1240000, Chile, evelyn.arrey@ucn.cl, Carlos Olivos, Hernan Caceres

We propose two learning activities in the course of Operations Research at Universidad Católica del Norte, Chile. The first one is focused in the Traveling Salesman Problem where the students have to represent it in a cork board using pins, and with a thread, they must determine the tour, using as little as possible. The other learning activity is based on the Capacitated Vehicle Routing Problem. The students must represent in real life the vehicle with capacity, and then they have to determine the best routes in order to minimize the attending cost to each demand point. With these activities, students learn about combinatorial complexity. Both activities will be presented to show the methodology results.

4 - Convergence Behavior for Network Characterization Metrics for Traffic Assignment

Priyadarshan Patil, University of Texas at Austin, Austin, TX, United States, Katherine Ross, Stephen Boyles

Traffic assignment (TA) is used for infrastructure planning, based on metrics like total system travel time (TSTT), vehicle miles traveled (VMT) or link flows. These metrics show different behaviors for a common network convergence state. This study presents formulations, computational analysis, and daily TA simulations for 14 networks at varying demands, comparing key metrics across convergence levels. Results show that VMT and TSTT stabilize far earlier (~1e-4 gap) than link flows (~1e-5), which stabilize slightly before used most likely path set and most likely path flows (~1e-6).

5 - Computational Performance of Constraint Programming for Routing Problems

Tiantian Zhu, Nanyang Technological University, 50 Nanyang Avenue, Singapore, 639798, Singapore, Stephen Boyles

Constraint programming (CP) has been applied to a variety of combinatorial optimization problems, most notably in scheduling applications. In other problems CP has also established itself as a competitor to state-of-art mixed-integer linear programming solvers. This work presents a comparison between these two approaches of their performance in solving routing problems, such as TSP, VRP and other variants of them. The paper explores the converging time and solution optimality of both approaches based on the test of numerous instances selected from the open-source TSPLIB and VRPLIB dataset.

CC- Room 616

Vehicle Routing II

Contributed Session

Chair: Wei Zhang, The Hong Kong Polytech University, MN037, Hung Hom, Hong Kong, China

1 - The Heuristic Algorithm for Etruck Traveling Salesman Problem with Battery Recuperation

Sungho Kang, Korea University, Seoul, Korea, Republic of, ght2game@korea.ac.kr, Taesu Cheong

When operating electric trucks, one of concerns is the limitation of the travel distance due to the limit of battery capacity. This issue can be relieved by the battery recuperation that is a technique of converting the position energy of the eTruck into the electric energy of the battery using the regenerative braking system. In this study, we study routing problem of eTruck with battery swapping stations and battery recuperation. This problem can be solved by replacing it with asymmetric TSP over energy TSP graph. This can be modeled by using a dynamic programming. However, due to the increased computational complexity, we propose a heuristic based methodology to address the concomitant problem.

2 - Determination of Optimum Irrigation Route for the Maintenance of Mine Roads

Camilo Gamboa, Universidad Catolica del Norte, Antofagasta, Chile

The unpaved routes of mine are extensive and cover a highly variable traffic flow. The maintenance management of these routes is carried out by a cargo vehicle, which stores a liquid mineral and irrigates all road networks to reduce the emission of dust into the environment. This management is carried out suboptimally since the irrigation process is carried out regularly throughout the system without preference or need criteria. The purpose of the work is to determine the network of optimal routes that the vehicle must travel to carry out irrigation in critical zones of high pollution rate, minimizing the costs of using liquid and fuel.

3 - Pricing Tax Return for Students that Opt-out from Using School Bus, the Case for Multiple Schools

Hernan Caceres, Department Chair, Universidad Catolica del Norte, Antofagasta, Chile, hcaceres@ucn.cl, Macarena Duran, Carlos Olivos, Rajan Batta

School districts are often mandated to provide transportation but can encounter ridership that varies between 22-72 percent. Consequently, buses run with unused capacity over long routes. We explore the scenario where students are compensated for giving up the option to ride a bus, to reduce the overall cost of the system. We explore the effect of applying either of two policies across all the schools of one district in Western New York. Mathematical formulations for this problem are developed and analyzed. Results from a case study along with algorithmic computational results will be presented.

4 - Dial-a-ride Problem with Floating Targets

Wei Zhang, The Hong Kong Polytechnic University, Kowloon, Hong Kong, wei.sz.zhang@connect.polyu.hk, Alexandre Jacquillat, Kai Wang, Shuaian Wang

This problem takes inputs as a batch of customer orders, each requesting travel from a given origin to a given destination by a given deadline. We optimizes sequences of stops visited by vehicles to pick up and drop off passengers. Unlike the traditional dial-a-ride problem, the pick-up locations can differ from the customers' origins, within a maximum walking distance. We determine the timings and the locations of the vehicle's stops, thus coordinating vehicle operations and customer pick-ups. We propose a mixed-integer second-order cone program with valid inequalities, and a dynamic programming-based algorithm to generate solutions in fast computational times.

Innovations in Urban Delivery

Sponsored: Transportation Science & Logistics/Freight Transportation & Logistics

Sponsored Session

Chair: Sara Reed, University of Iowa, Iowa City, IA, United States

1 - The Multi-visit Drone Routing Problem

Stefan Poikonen, University of Colorado Denver, Denver, CO, 80202, United States, Bruce L. Golden, Adriano Masone

The Multi-visit Drone Routing Problem is a truck-and-drone routing problem that seeks to minimize total route duration to service a predefined set of customers. In this problem, the energy dissipation rate of the drone is a user-defined function and the drone may be able to carry more than one package simultaneously. The definition of feasible locations to launch or retrieve a drone may be defined independently of the customer locations. We propose a heuristic that routes first, transforms the network graph second, and solves a shortest path thirdly. Extensions to launching along an edge may be presented.

2 - Last Mile Delivery using Autonomous Vehicles

Sara Reed, University of Iowa, University of Iowa, Iowa City, IA, United States, sara-j-reed@uiowa.edu, Ann Melissa Campbell, Barrett Thomas

An autonomous vehicle has the flexibility to remain in continuous use with or without the delivery person on board eliminating the need to park the vehicle. The Capacitated Autonomous Vehicle Assisted Delivery Problem (CAVADP) uses an autonomous vehicle as a mobile depot to support a delivery person in serving customers. We provide valid inequalities to the general model as well as results on general geographies of customers. We will show the value of using autonomous vehicles relative to standard delivery with parking.

3 - The Multiple Flying Sidekicks Traveling Salesman Problem with Variable Drone Speeds

Ritwik Raj, University at Buffalo, Amherst, NY, 14216, United States, r28@buffalo.edu, Chase Murray

This research studies the impact of unmanned aerial vehicle (UAV) speed in a system in which a truck combines with a fleet of UAVs for last-mile deliveries. Studies have shown that UAV power consumption increases nonlinearly with speed. Consequently, for a fixed battery capacity, UAV endurance decreases with speed. Also, depending on the parcel weight, the speeds at which UAVs can travel the maximum distance may vary. We leverage these properties to provide a three-phased algorithm that dynamically modifies speeds to achieve superior UAV performance, with the goal of minimizing the delivery makespan. Results indicate that total makespan can be decreased by operating UAVs at submaximal speeds.

4 - Splitting Shopping and Delivery Tasks in a Personal Shopper Service

Mathias A. Klapp, Assistant Professor, P. Universidad Catolica de Chile, Santiago, 7820436, Chile, maklapp@ing.puc.cl, Alp Arslan, Niels Agatz

We study an online personal shopper service, a type of last-mile delivery service operating as intermediary between customers and brick and mortar stores. This service receives and accepts orders dynamically over time, each defined by a list of items potentially required from multiple stores. For each accepted order, a shopper has to collect all items requested and deliver these to the customer location before a short deadline. We estimate the benefits of splitting customer requests into multiple tasks served by different shoppers in parallel and re-consolidating tasks of multiple requests having common collection points into one shopper.

On-demand Public Transit

Sponsored: Transportation Science & Logistics/Urban Transportation

Sponsored Session

Chair: Ankur Mani, University of Minnesota, Saint Louis, MO, 63108-2432, United States

Co-Chair: Varun Gupta

1 - A Markov-based Continuous Approximation Model for On-demand Public Transportation Systems

Alexander Vinel, Auburn University, Auburn, AL, 36832, United States, alexander.vinel@auburn.edu, Daniel F. Silva

We consider a family of models for on-demand public transportation systems that combine a continuous approximation approach with a Markov process. Our goal is to develop a simple way to evaluate system performance, which can then be used in capital planning (eg., fleet sizing, contracting, driver assignment, etc). We will present the analytical solution for the case of first- and last-mile operation. We then also demonstrate how this theoretical result compares with data collected from a real-world pilot project in a major US city.

2 - A Pricing Framework for the Multi-modal Mobility Marketplace

Ragavendran Gopalakrishnan, Assistant Professor, Queen's University, Department of Civil and Environmental Engg., Kingston, ON, 14853, Canada, Chamsi Hssaine, Siddhartha Banerjee, Samitha Samaranayake

We study the problem of designing an efficient mobility marketplace: a centralized platform where private on-demand mobility providers and public transit can jointly offer hybrid multi-modal trips to commuters. Pricing such trips to maximize social welfare, while ensuring that both commuters and mobility providers enjoy weak Pareto improvement (compared to the status quo), is a hard problem. Our general approach is based on formulating a "shaded" welfare maximization program and yields a pricing policy with a constant-factor approximation guarantee, under an intuitive structural condition based on a notion of the "efficiency gains" from introducing multi-modal trips.

3 - Dynamic on Demand Ride-sharing Trip-vehicle Matching with Pricing

Saeid Rasulkhani, New York University, New York, NY, United States, saeid@nyu.edu, Joseph Y.J. Chow

In this study we design a trip-vehicle matching problem for an on demand ridesharing systems. Using a stochastic process and stability principle, we define an online ticket pricing scheme for the system. A trip is set of pick up and drop off points of passengers with some feasibility constraints such as capacity and timing and so on. We match the trips to vehicles in a way that maximum payoff get generated. Once the matching problem is solved, the pricing ensures that none of passengers or drivers have incentive to deviate from their current matching pair.

4 - Integrated Optimization of Charging Facility Deployment and Vehicle Management for Electric Car-Sharing Systems

Yang Liu, National University of Singapore, Department of Industrial & Systems Engineering, Singapore, 117576, Singapore

Electric car-sharing systems are expected to be a promising alternative for sustainable urban mobility. We investigate an integrated optimization problem which determines the long-term facility deployment plan at the strategic level, while the operational decisions in the short term are also optimized. A two-stage stochastic integer program is formulated to capture the demand uncertainty, and a multi-layer time-space-battery network flow model is constructed for tracking battery states. We propose a two-phase benders decomposition algorithm. Numerical results reveal that the deployment of both fast charging and normal charging infrastructure can improve system performance.

Reliable Facility Location Against Disruptions

Sponsored: Transportation Science & Logistics/Facility Logistics

Sponsored Session

Chair: Xin Wang, University of Wisconsin-Madison, Middleton, WI, 53562-4278, United States

1 - Reliable Hub Location Model for Air Transportation Networks under Random Disruptions

Yong Liang, Tsinghua University, Beijing, China, Hao Shen, Zuo-Jun Max Shen

The popular hub-and-spoke network designs of major airlines can trigger cascading e ects under disruption events and lead to further losses. In this work, we present a path-based reliable hub location model that assigns to each origin-destination pair a primary path and a backup path to hedge against disruption risks. While most previous studies on reliable hub-and-spoke network design assume independent disruptions, our model allows disruptions to be correlated. We validate numerically the value of using backup paths, especially for inter-regional networks, where the results also demonstrate the importance of incorporating disruption correlations.

2 - Reliable Location of First Responder Stations for Cooperative Response to Disasters

Zhoutong Jiang, Master Student, University of Illinois at Urbana-Champaign, Champaign, IL, Champaign, United States, Yanfeng Ouyang

Major emergency incidents often require cooperative service from multiple types of responders; service effectiveness might suffer from probabilistic disruptions of the service stations themselves. We developed a reliable facility location model to optimally deploy emergency response resources such that the quality of emergency service (often from multiple jurisdictions) is maximized under the risk of disruptions. Numerical experiments are used to demonstrate the applicability of the model and to draw managerial insights.

3 - Emergency Power Planning for an Electric Transit System

Zhiwei Chen, University of South Florida, Tampa, FL, 33617, United States, zhiweic@mail.usf.edu, Xiaopeng Li

Transit systems have been through a transition to electric vehicle (EV) fleets. The main power charging system from the power grid may be disrupted during emergency and thus needs to be complemented by emergency power systems from alternative power systems (e.g., solar panels or generators). This study proposes a mathematical model for network planning of the emergency power system for an EV transit system.

Joint Session AAS/TSL Air: Air Traffic Flow Management

Sponsored: Aviation Applications

Sponsored Session

Chair: James Calvin Jones, MIT Lincoln Laboratory, Cambridge, MA, 02140, United States

1 - Assessing the Impact of Weather and Traffic Management Initiatives to the En Route Performance in the National Airspace System

Yulin Liu, University of California-Berkeley, University of California-Berkeley, Berkeley, CA, 94709, United States, Mark M. Hansen, Michael O. Ball, David J. Lovell

En route inefficiency is measured in terms of extra distance flown by aircraft, above the theoretical shortest distance route. We apply both trajectory clustering method and statistical models to quantify the impact of three major factors - convective weather, wind, and Traffic Management Initiatives (TMIs) including Miles-In-Trail (MIT) and Airspace Flow Program (AFP) - to the flight en route inefficiency. Statistical models indicate that weather is the most influential factor in seeming to cause flights to deviate from the great circle route. Winds and TMIs are also important for some origin-destination pairs, but less significant than convective weather.

2 - Rerouting Aircraft During Space Launches Using Adaptive Spatial Discretization

Rachael E. Tompa, Research Assistant, Stanford University, Stanford, CA, United States, Mykel John Kochenderfer

To ensure safety during space launches, the FAA restricts a large column of airspace that aircraft are rerouted around. With the increase of space launches, airlines are often penalized with rerouting expenses. Recent research has focused on making these restrictions smaller and dynamic. The problem has been modeled as a Markov decision process and solved using dynamic programming. A major challenge with this formulation is its computational tractability. This talk uses an adaptive spatial discretization method, to increase computational tractability while providing a finer state space discretization. This scalable method results in less disruption in the airspace while reducing risk.

3 - A Spectral Approach Towards Analyzing Air Traffic Network Disruptions

Max Z. Li, PhD Candidate, Massachusetts Institute of Technology, Cambridge, MA, 02140, United States, maxli@mit.edu, Karthik Gopalakrishnan, Kristyn Pantoja, Hamsa Balakrishnan

The networked nature of the air transportation system leads to system-wide delays due to disruptions at an airport. A comprehensive analysis of system performance requires understanding the inherent interdependencies between airports in order to characterize off-nominal disruptions and to aid in recovery. In this work, we apply Graph Signal Processing to the analysis of airport delay networks. We characterize different patterns of delay distributions using 10 years worth of operational data from major US airports. We show that attributes of the resultant eigenvector modes and energy contributions are useful metrics to characterize disruptions caused by specific off-nominal events.

4 - Reinforcement Methods for Air Traffic Management

James Jones, MIT Lincoln Laboratory, Cambridge, MA, 02140, United States, Yan Glina, Kendrick Cancio

In this talk we discuss the use of a set of reinforcement learning methods for controlling the planned rates of aircraft on a set of Traffic Management Initiatives across the Northeast United States. The work is validated through the use of a fast-time air traffic management simulation.

Choice-Modeling and Price Optimization

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Ovunc Yilmaz, University of Notre Dame, South Bend, IN, 46617, United States

Co-Chair: Alper Arslan, Queen’s University, Kingston, ON, Canada

1 - Capacitated and Bounded Pricing under Multinomial Logit Choices and Applications in the Hotel Business

Gwangjae Yu, Arizona State University, Tempe, AZ, 85281, United States, gjyu@asu.edu, Hongmin Li, Scott Webster

We consider a capacitated pricing problem in which a firm determines prices of multiple substitutable products when the supply or capacity of the products are constrained and prices are bounded. This problem applies broadly to many industries; we illustrate an application in the hotel business.

2 - Price Equilibrium under Heteroscedastic Exponomial Choice

Aydin Alptekinoglu, The Pennsylvania State University, University Park, PA, 16802, United States, aydin@psu.edu, John H. Semple

We analyze the price equilibrium among an oligopoly of single-product firms under Heteroscedastic Exponomial Choice. Of theoretical interest is the impact of heteroscedasticity on equilibrium prices, which is new to the discrete choice literature. We find that the individual and collective incentives differ in equilibrium: Firms individually want lower error variability for their own product, but collectively prefer higher error variability for all products - including their own - because higher error variability softens the price competition. Of empirical interest, the equilibrium is unique and it can be very easily computed.

3 - A Comparative Empirical Study of Discrete Choice Models in Retail Operations

Gustavo J. Vulcano, Universidad Torcuato di Tella, Av Figueroa Alcorta 7350, Suite 405, Buenos Aires, 1428, Argentina, gvulcano@utdt.edu, Gerardo Berbeglia, Agustin Garassino

Demand estimation is a fundamental task in retail operations and revenue management. In addition to the classical multinomial logit (MNL) model and its variants, new demand models have been proposed (e.g., the Markov chain model) and others have been revisited (e.g., the rank-based and exponomial models). At the same time, new computational approaches were developed to ease the estimation function (e.g., column generation, EM algorithms). In this work, we conduct a systematic, empirical study of different demand models and estimation algorithms, and characterize operational environments suitable for different implementations.

4 - Football Ticket Pricing for Multiple Sale Channels with Heterogeneous Customers

Hayri Alper Arslan, Queen's University, Kingston, ON, Canada, arslan.alper@econ.queensu.ca, Ovunc Yilmaz, Robert Easley, Ruxian Wang

Football teams face a pricing problem different than baseball, basketball, and hockey teams partly due to fewer home games per season and more season tickets sold. Dynamic pricing which focuses on single-game ticket pricing has limited value in this setting, therefore most football teams use variable pricing where they charge different prices for (i) different seat categories and (ii) different games. In this paper, we develop a data-driven framework to study a price optimization problem for multiple sales channels (i.e., season tickets and single-game tickets) with game demands given by a discrete mixed multinomial logit (MMNL) model.

Innovative Pricing Strategies

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Pnina Feldman, Boston University, Boston, MA, 02215, United States

1 - Pricing Capacity Over Time and Recourse Strategies: Facilitate Reselling, Offer Refunds, or Overbook?

Pnina Feldman, Boston University, Questrom School of Business, 595 Commonwealth Avenue, Boston, MA, 02215, United States, pninaf@bu.edu

Perishable capacity is often sold before it is used which creates the opportunity to include in the pricing mechanism a recourse strategy, such as resale, refunds and overbooking. We investigate alternative recourse strategies and the implication for firm's profit and social welfare.

2 - Fake Reviews

Chen Jin, National University of Singapore, Singapore, 117417, Singapore, Luyi Yang

We study fake reviews in a competitive online environment.

3 - Experiential Retailing and Pricing Implications

Nevin Mutlu, Eindhoven University of Technology, UCLA Anderson School of Management, Operations and Technology Management, Eindhoven, 90095-1481, Netherlands, Hadi El-Amine, Ozge Sahin

Fueled largely by the millennial generation, consumer preference for spending goes more to experiences over objects. In this paper, our goal is to study the impact of offering experiential services in brick and mortar stores on retailers' prices and profits. We identify cases where retailers and consumers benefit from augmented retail experiences.

4 - Online Learning and Decision-making under Generalized Linear Model with High-dimensional Data

Xue Wang, Pennsylvania State University, , University Park, PA, 16802, United States, wxie91@gmail.com, Mingcheng Wei, Tao Yao

In this study, we consider the online learning and decision-making problem with high-dimensional covariates. We penalize the bandit model with Minimax Concave Penalty (MCP-bandit) to handle the high-dimensional issue. Under epsilon-decay sampling scheme, we show the cumulative regret of MCP-bandit is upper bound O(s^3log d log T), where s is the sparsity level, d is the total dimension and T is the time length.

Dynamics in Online Platforms

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Yonatan Gur, Stanford University, Stanford, CA, 94305, United States

Co-Chair: Daniela Saban, Stanford University, Palo Alto, CA, 94305, United States

1 - Sequential Procurement with Contractual and Experimental Learning

Gregory Macnamara, Stanford University, Stanford, CA, United States, Yonatan Gur, Daniela Saban

We study the design of sequential procurement strategies that integrate stochastic and strategic information. We consider a buyer who repeatedly demands one unit of the same good and cannot commit to long-term contracts. In each time period, the buyer makes a price offer to a seller who has private, persistent information regarding his cost and quality. If the offer is accepted, the seller provides the good with a stochastic quality that is not contractible; otherwise, the buyer sources the good from a known outside option. The buyer can learn from observations of the strategic acceptance decisions taken by the seller, and from evaluations of the stochastic quality delivered whenever a purchase occurs.

2 - The Impact of Service Experience on Engagement: Empirical Evidence from Ride-sharing

Baek Jung Kim, New York University, New York, NY, United States, bkim2@stern.nyu.edu, Maxime Cohen

When experiencing a low-service quality, customers may stop using the service and switch to a competitor. In the context of ride-sharing, we study how different quality dimensions affect customers' usage. Using a rich dataset including detailed rides information of 5,269,413 rides, we show evidence that low-service quality has a negative impact on usage. We then build and estimate a structural demand model of riders, including dynamic effects of service quality and its inter-temporal dependence via the goodwill-stock framework to quantify the economic value of each service -quality dimension.

3 - Learning Customer Preferences from Personalized Assortments

Yifan Feng, University of Chicago, Chicago, IL, 60637, United States, yifan.feng@chicagobooth.edu, Rene A. Caldentey, Christopher Ryan

A company wishes to commercialize the best version of a product out of a menu of available alternatives. The company does not know customers' preferences over the set of alternatives and relies on a voting system that allows potential buyers to vote for their preferred version. Under a general ranking-based choice model framework, we study how to dynamically customize each individual voter's choice set, so as to identify the top-ranked alternative with a fixed probabilistic confidence level, while using a minimal number of votes.

4 - Substitutes or Complements: Consumption of News, Fake News and Fact-checks.

Senthil Veeraraghavan, University of Pennsylvania, Wharton School OPIM Department, Philadelphia, PA, 19104, United States, senthilv@wharton.upenn.edu, Jiding Zhang, Ken Moon

Fake news reduces quality of factual coverage, affects the political stability and informedness of citizenry. In this paper, using an individual-level panel data, we study the demand and consumption patterns of news from mainstream publications, fake articles and fact-checking websites. We disentangle the possible mechanisms of consuming fake news: idiosyncratic preference, event-driven utility shocks, and complementarity. We show that in general fake news complement with fact-checking, but there is a negative correlation between the idiosyncratic utility of fake news and fact checking.

Revenue Management and Market Analytics III

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Gabriel Weintraub, Stanford Graduate School of Business, Stanford, CA, 94304, United States

1 - Information Disclosure in Online Platforms: Optimizing for Supply

Yiangos Papanastasiou, University of California Berkeley, Haas School of Business, 2220 Piedmont Ave, Berkeley, CA, 94720, United States, yiangos@haas.berkeley.edu

This paper studies the interaction between information disclosure in two-sided online platforms and the composition (quantity and quality) of service providers active in the platform.

2 - Autonomous Vehicle Market Design

Garrett van Ryzin, Head of Marketplace Labs, Lyft, New York, NY, United States, Zhen Lian

We analyze a model of autonomous vehicle (AV) ride hailing markets in in which uncertain aggregate market demand can be served using a combination of a fixed fleet of AVs and human driver contractors. We compare the equilibrium profits of a ride hailing firm under the pure-AV and mixed AV-human-driver service models and examine the impact of a consolidated vs. separate dispatch market designs.

3 - Quality Selection in Two-sided Markets

Bar Light, Stanford, Stanford, Stanford, CA, United States, Ramesh Johari, Gabriel Weintraub

In two-sided markets, platforms acquire information about both buyers and sellers. Platforms use this information to increase their revenue and to enhance the welfare of the platform's participants. For example, platforms such as Amazon Marketplace, Upwork, and eBay suspend or ban low quality sellers from participating in their platforms, and provide information to buyers about the sellers that participate in their respective platforms. In this paper we examine how much information a platform should share in order to maximize its revenue.

4 - Persuasion in Networks: Public Signals and K-cores

Ozan Candogan, University of Chicago, Booth School of Business, Chicago, IL, 27708, United States, ozan.candogan@chicagobooth.edu

We consider a setting where agents in a social network take binary actions, which exhibit local strategic complementarities. Agents are a priori uninformed about a payoff-relevant state. An information designer chooses a public signaling mechanism that sends informative signals about the state to maximize the expected number of agents who take action 1. We characterize the structure of optimal public signaling mechanisms. We show that the optimal mechanism (i) publicly reveals which core of the network should take action 1 in an incentive compatible way, and (ii) admits a novel 2-interval structure.

Topics in Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Stefanus Jasin, University of Michigan, Ann Arbor, MI, 48105-9461, United States

Co-Chair: Sheng Liu, University of California-Berkeley, Berkeley, CA, 94709, United States

1 - Is Model Misspecification Detrimental for the Data-driven Newsvendor?

Gah-Yi Ban, London Business School, Regent's Park, London, NW1 4SA, United Kingdom, gban@london.edu, Zhenyu Gao, Fabian Taigel

We compare solving the data-driven newsvendor problem under three well-known paradigms: Bayesian, Frequentist Parametric and Nonparametric. For the Bayesian and Frequentist Parametric approaches, we consider the effects of model mis-specficiation. We make comparisons analytically, using tools from asymptotic statistics, and empirically, on simulated data and on a real-life data set from a large fresh food chain.

2 - Dynamic Inventory Allocation with Demand Learning for Seasonal Goods

He Wang, Georgia Institute of Technology, H. Milton Stewart School of Industrial & Sys, Atlanta, GA, 30332-0205, United States, Milashini Nambiar, David Simchi-Levi

We propose a dynamic learning approach to allocating seasonal goods to retail stores in one-warehouse multiple-retailer setting. At the start of the selling season, a fixed amount of inventory is available at the warehouse, with no additional replenishment. In each period, the decision maker can allocate inventory from the warehouse to the retailers. The allocation decision must be non-anticipating, in that it can only depend on demand forecasts and demand realizations seen at the retailers thus far.

3 - Multiproduct Pricing under the Generalized Extreme Value Models with Homogeneous Price Sensitivities

Heng Zhang, University of Southern California, Los Angeles, CA, 91776, United States, Paat Rusmevichientiong, Huseyin Topaloglu

We consider unconstrained and constrained multiproduct pricing problems under an arbitrary GEV model when products have the same price sensitivity parameter. We show that the optimal prices of the different products have a constant markup in the unconstrained problem. In the constrained one, we assume the expected sales of the products are constrained to lie in a convex set. We give an equivalent market-share-based formulation, where the purchase probabilities of the products are the decision variables. We show that this is a convex program, and the gradient of its objective function can be computed efficiently. We can recover the optimal prices for the products by using the optimal market shares.

4 - Dynamic Joint Assortment and Pricing Optimization with Demand Learning

Sentao Miao, University of Michigan-Ann Arbor, Ann Arbor, MI, 48104, United States, semiao@umich.edu

We consider a joint pricing and assortment selection problem where customers arrive sequentially and make purchasing decisions following a multinomial logit (MNL) choice model. Not knowing the customers' choice parameters a priori and subjecting to a display capacity constraint, we dynamically determine the subset of products for display and the selling prices to maximize the expected total revenue over a selling horizon. We design an algorithm which uses the method of random sampling, and an instance-independent upper bound for the Bayesian regret of our algorithm is obtained. Numerical results show that it performs very well.

5 - Urban Consolidation Center or Peer-to-Peer Platform? The Solution to Urban Last-Mile Delivery

Yun Fong Lim, Singapore Management University, Lee Kong Chian School of Business, 50 Stamford Road, 04-001, Singapore, 178899, Singapore, yflim@smu.edu.sg, Qiyuan Deng, Xin Fang

The growth of urban population and e-commerce activities increases the demand for urban last-mile delivery. To reduce traffic congestion, an urban consolidation center (UCC) bundles shipments from multiple carriers before delivering them to a city center. Despite the potential benefits, the adoption rate of UCCs in practice is low. In contrast, a notable number of peer-to-peer platforms have been established recently to share delivery capacity. We compare the performance of these two business models. We study a game-theoretical model involving a consolidator, who operates a UCC or a capacity sharing platform, and multiple carriers, who choose whether to use the consolidator's service.

Location and Logistics

Sponsored: Location Analysis

Sponsored Session

Chair: Sibel Alumur Alev, University of Waterloo, Waterloo, ON, N2L 3G1, Canada

1 - A New Approach for Modeling and Solving Refueling Station Location Problem with Routing

Omer Burak Kinay, University of Waterloo, Waterloo, ON, Canada, obkinay@uwaterloo.ca, Fatma Gzara, Sibel Alumur Alev

In this study, we address charging infrastructure planning for electric vehicles and propose the full coverage approach for refueling station location problem with routing. The aim is to minimize the total fixed cost of establishing charging stations as well as the total recharge to complete every origin-destination trip. We take drivers' willingness to deviate from their shortest paths into account and consider the routing aspect of the problem by finding the optimal deviation paths. In order to tackle real-life instances of the problem, a Benders decomposition algorithm is proposed.

2 - Covering Vehicle Routing Problem: Applications for Refugee Related Services

Bahar Yetis Kara, Bilkent University, Department of Industrial Engr., Ankara, 06800, Turkey, bkara@bilkent.edu.tr, Elfe Buluc

Providing "Child Friendly Spaces (CFS)" to vulnerable refugee children are addressed in this study. The mobile CFS problem is determining the stay-over points for the trucks while maximizing the number of children reached and the routes of the trucks while minimizing the total distance travelled. The studied problems are categorized as Covering Vehicle Routing Problem with and without Integrated Tours both of which are new to the location and routing literature. Mathematical models and optimization based heuristics for different versions of the problems are introduced. The proposed solutions are applied to a real life case of city Kilis.

3 - Stochastic Districting Models

Stefan Nickel, Karlsruhe Insitute of Technology, Institute for Operations Research, Karlsruhe, 76131, Germany, stefan.nickel@kit.edu, Antonio Diglio, Francisco Saldanha-da-Gama

Districting Problems (DPs) aim at partitioning a set of basic geographic areas, named Territorial Units (TUs), into a set of larger clusters, called districts, according to some planning criteria. The latter typically refer to balancing, contiguity and compactness. In this paper, we introduce a Stochastic Districting Problem with Recourse (SDPR) whose aim is to partition a given set of TUs into a prefixed number of clusters in order to maximize the overall compactness and to meet balancing constraints, expressed in terms of average demand per district. Demands associated to each TU are modeled as random variables. The problem is formulated as a two-stage stochastic program with recourse.

4 - Store Location with Multipurpose Shopping Trips and Discrete Choice

Vladimir Marianov, Pontificia Universidad Catolica de Chile, Department of Electrical Engineering, Vicuna Mackenna 4860, Santiago, 782-0436, Chile, marianov@ing.puc.cl
Vladimir Marianov, Complex Engineering Systems Institute, Santiago, Chile, marianov@ing.puc.cl, Armin Lüer-Villagra, H.A. Eiselt

Nearly all store location models assume that customers make single purpose trips. In practice, consumers purchase more than one product during a trip. Recently, the issue was included in a model for the location of commercial facilities, in which a customer purchased one or two products in a trip depending on the perceived utility. The rule for choosing what trip to engage in was deterministic. We introduce a discrete-choice model, and allow the entrant firm to find the best price for its product. We provide preliminary test results.

Law and Fairness in OR

Emerging Topic: Policy & Government

Emerging Topic Session

Chair: Swati Gupta

1 - Fairness in School Matching

Xuan Zhang, Columbia University, New York, NY, 10025, United States, Yuri Faenza, Swati Gupta

The Gale-Shapley stable matchings model is widely used in school admissions. Under this model, schools are required to rank students in their order of preference. However, the way in which students are evaluated may be subject to unintended bias due to various factors. We study the problem by mathematically modeling “perceived bias”. In particular, we assume students’ true potential follows a certain continuous distribution but some students’ evaluated potentials are scaled down by a discount factor (<1) due to biases. We investigate the impact of this bias on students as well as on the schools. We propose multiple solutions to alleviate the adverse effects of bias in school admissions.

2 - Infrastructure Impacts of Fairness in Electricity Policy

Valerie Thomas

Please check the mobile app for this abstract.

3 - Preference Elicitation for Participatory Budgeting

Gerdus Benade, Carnegie Mellon University, Pittsburgh, PA, United States, Ariel Procaccia, Swaprava Nath, Nisarg Shah

Participatory budgeting enables the allocation of public funds by collecting and aggregating individual preferences. Making the most of this new paradigm requires a rethinking of some of the basics of computational social choice, including the very way in which individuals express their preferences. We analytically compare four preference elicitation methods, knapsack votes, rankings by value or value for money, and threshold approval votes, through the lens of implicit utilitarian voting, and find that threshold approval votes are qualitatively superior. This conclusion is supported by experiments using data from real participatory budgeting elections and a user study.

4 - Learning Optimal and Fair Decision Trees for Non Discriminative Decision Making

Sina Aghaei, University of Southern California, Los Angeles, CA, United States, saghaei@usc.edu, MohammadJavad Azizi, Phebe Vayanos

Recently, automated data-driven decision-support tools are increasingly being used in socially sensitive settings. Yet, they may result in discriminative decisions in that they may treat individuals from a specific group unfairly, resulting in disparate treatment and/or impact and violating moral or ethical standards. In this paper, we unify unfairness definitions across classification and regression and propose a mixed integer optimization framework for learning optimal and fair decision trees to prevent disparity. We conduct extensive computational studies that show that our framework yields non-discriminative decisions at lower cost to overall accuracy than other approaches.

Vendor Tutorial

1 - Nonlinear Optimization Using Artelys Knitro with Julia/JuMP

Richard Waltz, Artelys, 6932 W. 85th Street, Los Angeles, CA, 90045-2603, United States

Artelys Knitro is the premier solver for nonlinear optimization problems. Julia is a free, open-source, high-level programming language for technical computing that also comes with an optimization modeling language JuMP. This software demonstration will highlight the newly released Knitro interface to Julia/JuMP. This interface leverages the new C API in Knitro to exploit problem structures such as quadratic and conic constraints. The Knitro C API can be called directory through Julia to access all Knitro features. Alternatively, Knitro may be used through the JuMP modeling language, which provides automatic differentiation for nonlinear functions. We will demonstrate both approaches as well as benchmarking features provided through this interface.

2 - Deploying Models with GAMS MIRO

Lutz Westermann, GAMS, 1217 Potomac Street NW, Washington, DC, 20007, United States, Michael Bussieck, Steven Dirkse

Are you a model developer wanting to run your GAMS application from within a web browser, with convenient visualization of input and output data? Or an enterprise requiring a graphical user interface so that planners can work more productively, leveraging the full potential optimization brings? During this tutorial, we will introduce GAMS MIRO, a web interface for your GAMS models. We will start explaining the fundamental concepts of GAMS and the advantages of using GAMS to build optimization-based decision support applications. We will continue with the various options to connect GAMS models to other application and briefly cover some recent developments. The central part of the tutorial will be about GAMS MIRO. It has tight connections to the GAMS modeling system that allow you to perform data manipulation, scenario management, graphical evaluation of the results and much more from within the web browser by adding very few annotations to your model. You specify which input and output datasets you want to visualize, and the result is a fully functional GUI that can be launched directly from the new GAMS Studio or via a shortcut on your Desktop. GAMS MIRO also facilitates the generation, organization, and sensitivity analysis of multiple scenarios of an optimization model. A server version will support additional features: managing multiple optimization models for concurrent users with access management, load balancing, batch configuration and much more.

Data Mining I

Contributed Session

Chair: Samuel Davis, Northeastern University, Boston,MA, United States

1 - Towards Interpretable and Actionable Random Forest Classification Models

Abdelaziz Berrado, University Mohammed V. in Rabat, Rabat, Morocco, berrado@emi.ac.ma

The lack of interpretability of random Forest models is the main driver of this research. Our objective in this work is to expose avenues for demystifying the predictive structure of random forest classification models. We present the state of the art related to this pending research issue and present our suggested approach to prune and thereafter understand random Forest classification models.

2 - Exploring Accident Path from Incident Narratives Using Active Learning Based Text Classification

Kritika Singh, Indian Institute of Technology, Kharagpur, India, kritika.swati@gmail.com, Harshawardhan Mahajan, Rohan Singhade, J. Maiti

Literature lack effort in exploration of complete accident path from incident narratives which can be achieved with text classification (TC) model. However, it will require huge annotated data. This can be dealt by using Active Learning (AL). AL is a semi-supervised iterative technique where only most informative records are queried to human annotator for labels and remaining unlabeled records are labeled using TC algorithm In this work we have developed an AL model using SVM, which was applied on 612 process incident reports and 190 accident paths were obtained. The proposed method outperformed other TC algorithms (SVM, Naïve Bayes and k-Nearest Neighbor).

3 - Matched Forest: Supervised Learning for High-dimensional Matched Case-control Studies

Nooshin Shomalzadeh, Arizona State University, Tempe, AZ, United States

Matched case-control analysis is widely used in biomedical studies to identify exposure variables associated with health conditions. Matching is used to improve the efficiency by enforcing cases and controls to have the same distribution of confounding variables. Existing variable selection and classification methods for matched case-control studies are challenged in high-dimensional settings where interactions among variables are also important. We describe a quite different method for analyzing high-dimensional matched case-control data set which is not only flexible regarding the number of matching and exposure variables and but also able to detect interaction effects.

4 - Systematic Examination of Pruned and Aggregated Leaves Improves Decision Tree Accuracy

Samuel R. Davis, Northeastern University, Boston, MA, United States, davis.sam@husky.neu.edu, Sara Nourazari, Nasser S. Fard

Decision trees (DTs) often suffer from two issues: small leaves are prone to over-fitting training data, and impure leaves have significant prediction error. Pruning balances these objectives by merging shared-parent leaves, whereas separate-and-conquer approaches cover the feature space using rules. Systematic examination of pruned and aggregated leaves (SEPAL) eliminates the shared-parentage constraint, thus simultaneously pruning and aggregating leaves that are statistically similar by iteratively reducing and re-modeling the training data. Results demonstrate consistent improvement upon the classification and regression tree (CART) methodology of inducing decision trees.

1 - Optimal Sequential Subspace Change-point Detection

Liyan Xie, Georgia Institute of Technology, Atlanta, GA, United States, Yao Xie, George V. Moustakides, George V. Moustakides

We present a novel Subspace-CUSUM procedure for a fundamental problem, to detect changes with an unknown low-dimensional subspace structure, which is manifested as a spiked covariance matrix. We show our computationally efficient Subspace-CUSUM procedure is first-order asymptotically optimal and demonstrate its competitive performance using numerical and real-data examples.

2 - An Active Learning Methodology for Efficient Estimation of Noisy Black-Box Functions using Gaussian Process Regression

Rajitha Meka, University of Texas-San Antonio, San Antonio, TX, 78230, United States, Adel Alaeddini

In many real-world problems, we encounter situations to approximate black-box functions which are expensive to evaluate. To efficiently estimate these functions using Gaussian processes, we propose an active learning methodology based on integration of Laplacian regularization, and maximum mean squared error method.

3 - Heterogeneous Information Learning in Large-Scale Networks

Xiao Huang, Texas A&M University, College Station, TX, United States, Jundong Li

Network analysis has been widely adopted in many industrial applications such as targeted marketing. Real-world nodes are often abundantly accompanied with other types of meaningful information such as node attributes. We propose a general framework to incorporate this heterogeneous information into network embedding to learn better node vector representations.

4 - Image-Based Process Control Using Tensor Analysis

Zhen Zhong, Georgia Institute of Technology, Atlanta, GA, United States, Kamran Paynabar, Jianjun Shi

High-dimensional process control strategies should be deployed to ensure on-target quality in many applications. To address this, we propose a novel tensor-based process control approach by incorporating the tensor time series and regression techniques. Simulation and case studies show that our proposed method is more effective than the benchmark.

Data Science for Quality and Reliability Assurance

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Jianguo Wu, Peking University, Beijing, 100080, China

Co-Chair: Mingyang Li, Tampa, FL, 33647, United States

1 - Gaussian Process Model with Non-vectorial Inputs and its Application to Design of Printed Antennas

Xi Chen, University of Arizona, Tucson, AZ, 85721, United States, xic@email.arizona.edu, Qiang Zhou

The conventional Gaussian Process (GP) model setting deals only with a scalar output and input in a vector form, i.e. a list of parameters. However, many modern engineering simulations take inputs of 2D/3D part designs where the spatial information matters, thus cannot be well described by a simple vector. We proposed in this paper a general GP-based surrogate modeling framework with spatially structured input and applied it to the design of printed antennas.

2 - Multi-objective Optimal Design for Multi-state Reliability Demonstration Tests

Suiyao Chen, University of South Florida, Tampa, FL, 33617, United States, suiyaochen@mail.usf.edu, Lu Lu, Mingyang Li

Reliability demonstration tests (RDTs) are important reliability assurance activities to safeguard product reliability. Conventional designs of RDTs often consider a single objective (e.g., consumer's risk) and/or a single failure state. This work proposes an optimal design framework for multi-state RDTs by simultaneously investigating multiple and potential conflicting objectives, such as consumer's risk, producer's risk and warranty service cost. A Pareto Front approach is also employed to select the optimal test plans. A comprehensive case study is further provided to illustrate the proposed work and demonstrate its effectiveness with design insights obtained.

3 - Optimal Maintenance Management for Co-located Deteriorating Water and Transportation Systems with Interdependencies

Hung Nguyen, University of South Florida, Tampa, FL, 33613, United States, nqh@mail.usf.edu, Noha Abdel-Mottaleb, Shihab Uddin, Qing Lu, Qiong Zhang, Mingyang Li

Maintenance and rehabilitation of transportation infrastructure (TI) and water infrastructure (WI) systems are critical to nation's security and prosperity. Existing maintenance approaches often considered TI and WI separately. Due to their co-location and spatial proximity, TI and WI are physically and/or operationally interdependent. This work proposes an optimal maintenance management framework for joint maintenance prioritization and planning of interdependent TI and WI systems with a large number of co-located roads and pipes. A case study is further provided to demonstrate the cost-effectiveness of the proposed work over conventional maintenance approaches.

4 - A Functional Neural Network for Data Fusion and RUL Prediction

Yuxin Wen, University of Texas at El Paso, El Paso, TX, 79902, United States, Jianguo Wu, Bill Tseng

Accurate Remaining useful life prediction plays a critical role for effective implementation of condition-based maintenance. In this work, an effective two-stage prognostic framework is proposed to predict the remaining useful life (RUL) for individual units. Under the framework, a functional neural network that integrates multi-sensor degradation signals and time-to-event data is developed for data fusion and RUL prediction. The effectiveness of the proposed method is demonstrated through case studies.

5 - A Neural Data Fusion Model for Condition Monitoring and Residual Life Prediction

Zhen Li, Peking University, Beijing, 100871, China, zhen.li@pku.edu.cn, Jianguo Wu

Multi-sensor signals are now readily available for condition monitoring and residual life prediction. Composite health indices can be constructed by fusing these signals to better capture the health condition. However, most of the existing methods fuse signals linearly, which may not be sufficient to characterize the health condition. To address such issue, this paper develops a novel neural data fusion model for health index construction. Three loss functions are formulated by considering the monotonicity of the health index and variability at the failure point. The superiority of the proposed method is demonstrated through numerical and case studies.

Joint Session HAS/Practice Curated: Data Analytics in Healthcare Operations

Sponsored: Health Applications

Sponsored Session

Chair: Retsef Levi, MIT, Cambridge, MA, 02142, United States

1 - Machine Learning to Address Hospital Capacity: Predicting Discharges and Identifying Barriers to Discharge

Taghi Khaniyev, MIT Sloan School of Management, Cambridge, MA, 02142, United States, khaniyev@mit.edu, Kyan Safavi, Ana Cecilia Zenteno, Jonathan Zanger, Mark Seelen, Martin S. Copenhaver, Bethany Daily, Peter Dunn, Retsef Levi

Hospital congestion is caused among other factors by an imbalance of the timing of patient admissions and discharges. We trained a neural network model to predict next-day's surgical patient discharges based on previous patients' recovery care paths at a large academic medical center. Further, we analyzed mismatches between predicted and actual discharges to identify areas for improvement in the discharge process and to enhance the accuracy of the tool. The model had an AUC of 0.89. Mismatches occurred without clinical reason 45% of the time and were due to clinical practice variation 25% of the time.

2 - Optimization of Public Access Defibrillators Compared to Guidelines-based Deployment

Christopher Sun, Massachusetts Institute of Technology, Cambridge, MA, M5G 2R2, United States, clfsun@mit.edu, Timothy Chan

Public defibrillators can be used by bystanders with no prior training to resuscitate cardiac arrest victims. Optimization has been shown to improve defibrillator location decisions by maximizing cardiac arrest coverage, a measure of spatial proximity and temporal accessibility of defibrillators to cardiac arrests, but has not been compared to established guidelines. We present a comparison of optimal defibrillator placements against guideline-based placements over a nine year study period using real patient data. Optimized locations increased cardiac arrest coverage by 50.7%-117.2% over guideline-based locations and significantly improved estimated patient outcomes.

3 - A New Patient Trajectory Simulation Method for Staffing in Care Coordination Programs

Hari Balasubramanian, Univ of Massachusetts-Amherst, Amherst, MA, 01003, United States, hbalasubraman@ecs.umass.edu, Ekin Koker, Aaron Truchil

Care Coordination programs intended to improve outcomes and lower cost of care for patients with complex health and social needs have proliferated in recent years. Staff encounters with patients in these programs can be modeled as a trajectory, each encounter marked with a staff type, duration and a timestamp from enrollment date. Using encounter data from a care coordination program, we simulate different realizations by sampling patient trajectories randomly without replacement, allowing for a constant and a Poisson patient arrival rate. We present our findings and offer insights for healthcare organizations looking to start care coordination programs.

4 - Measuring Physician Work Using Electronic Health Records

Michael Hu, MIT, Cambridge, MA, 02130, United States, hum@mit.edu, Stephanie Eisenstat, Retsef Levi, Walter O'Donnell

As electronic health records (EHRs) have become more prevalent, physicians are spending substantial time completing EHR-related work. Observational studies indicate that half of physicians' office time is spent on EHR work. Furthermore, many physicians report they are forced to complete EHR work after hours, which has significantly contributed to physician burnout. In this work we achieve the following: (1) establish a rigorous methodology for accurately measuring physician time spent on EHR tasks using click-level EHR data; and (2) explore how EHR work is distributed temporally and across different types of patients.

5 - Mixing it Up: Operational Impact of Hospitalist Workload

Masoud Kamalahmadi, Indiana University, Bloomington, IN, 47405, United States, maskamal@iu.edu, Alex Mills, Jonathan Helm, Kurt M. Bretthauer

Hospitalists are physicians that specialize in caring for hospital inpatients, replacing a primary care physician who may only make rounds once per day and thereby reducing delays. Given a limited number of hospitalists in a hospital, we seek to determine their optimal service mix (workload and patient types).

Data & Simulation Modeling in Opioid Research

Sponsored: Health Applications

Sponsored Session

Chair: Mohammad Jalali

1 - Physician Patient-sharing Network of Chronic Opioid Users

Toyya A. Pujol, Georgia Institute of Technology, Atlanta, GA, United States, pujol@gatech.edu, Nicoleta Serban

Opioid dependence has become a US public health concern due to the increasing rates over the last 10 years; resulting in a four-fold increase in opioid related deaths from 2013 to 2016. To better understand chronic users, i.e. those most at risk for addiction, we need to know about their healthcare system and the social influence of their providers among each other. In this study, we will utilize Medicaid claims data to identify 2013 and 2014 Medicaid-insured chronic opioid users and their healthcare providers. We will create a social network in which edges represent if two physicians share a patient. The results will include analysis on the topology of the network and the initial findings.

2 - Cost-effectiveness of Treatments for Opioid Use Disorder in Veterans Affairs Patients

Michael Fairley, Stanford University, Stanford, CA, 94304, United States, mfairley@stanford.edu, Margaret L. Brandeau, Doug Owens

In the Veterans Affairs Health System (VA), which is the largest provider of healthcare in the US, the rate of fatal drug overdose among patients is twice that of the general US population and the prevalence of opioid use disorder is 7 times higher than for patients in commercial health plans. We develop a microsimulation model to evaluate the cost-effectiveness of treatments and portfolios of treatments for opioid use disorder in VA patients. We consider the following treatments: medication-assisted therapy with methadone and buprenorphine, opioid antagonist therapy with naltrexone, overdose education and distribution of naloxone, cognitive behavioral therapy and contingency management.

3 - Social Signal in the Opioid Crisis: Text Mining the Physician Review Sites

Stanislav Mamonov, Associate Professor, Montclair State University, Montclair, NJ, United States, stanislav.mamonov@montclair.edu

Overprescription of opioid pain relievers is a known contributor to the growing opioid epidemic. Identification of medical practices that engage in overprescription has proven challenging. We examine the utility of physician review websites (PRWs) as potential sources of data that may help identify overprescribing physicians. We leverage text mining techniques to identify linguistic cues that are associated with known cases of overprescription. We find that patients flag potentially problematic medical practices in their reviews and suggest that an intervention by authorities is warranted.

4 - The Unintended Consequences of Health Policy: An Empirical Analysis of Opioid Prescribing Behavior

Justin Kistler, University of South Carolina, Columbia, SC, 29212, United States, justin.kistler@grad.moore.sc.edu, Luv Sharma

As a critical component of the Patient Protection and Affordable Care Act, the Value Based Purchasing program was designed to incentivize healthcare organizations and providers to improve the safety and quality of patient care. While considerable improvement has been made in several performance domains, our empirical analysis of opioid prescription rates over a seven-year period indicates an unintended increase in opioid prescribing immediately following the implementation of the Value Based Purchasing program. Our findings also indicate the moderating impact of prescriber workload on opioid prescription rates.

5 - A Predictive Analytics Model for Opioid Treatment Completion

Hyojung Kang, University of Illinois at Urbana-Champaign, Champaign, IL, United States, hyokang@illinois.edu, Seokgi Lee

The opioid epidemic is a public health emergency in the U.S. While the number of patients attending opioid treatment has increased over the years, the rate of treatment completion has been low. To better understand characteristics of patients who complete or do not complete opioid treatments, we analyze national data sets including treatment episodes and implement a predictive analytics model based on the logical analysis data (LAD) approach.

Joint Session HAS/Practice Curated: Queueing Models in Hospital Operations

Sponsored: Health Applications

Sponsored Session

Chair: Yichuan Ding, University of British Columbia, Vancouver, BC, V6T 1C3, Canada

Co-Chair: Opher Baron, University of Toronto, Toronto, ON, M5S 1L7, Canada

1 - Improving Patient Flow in Emergency Departments: A Question of Life or Death

Marko Duic, Southlake Regional Health Centre, Newmarket, ON, Canada

The flow of customers in any enterprise is an important challenge to get right, but in Emergency Departments bad flow actually kills patients. Getting flow right is a challenge because of conflicting incentives throughout the health system. Many providers make extensive use of “dams” and “reservoirs” to obstruct flow. An entire mythology exists in healthcare to confuse inefficiency with safety, and flow with risk. The way forward is to transform culture and incentives – a tall order in any system, let alone a safety-conscious, conservative one like healthcare. The talk will draw on examples from 20+ years of successfully leading change in Emergency Departments in Canada and the UK.

2 - The Impact of Consults on LOS in Emergency Department: North York General Hospital

Dmitry Krass, University of Toronto, Rotman School of Management, 105 St George Street, Toronto, ON, M5S 3E6, Canada, Opher Baron, Tianshu Lu, Zhoupeng Jack Zhang, Marco Duic

We empirically investigate the impact of an Emergency Department redesign project on the patients’ waiting time until initial assessment and their length of stay (LOS). We construct a system of time series models to reflect the interactions among different waiting phases throughout a patient’s LOS, as well as the interplay between the hospital’s overall service performance and the number of patients. We use a modified Multistage least square method to estimate our model. We conduct an iterative counterfactual study to evaluate the ‘net’ impacts of the project on key variables and the significance of these impacts.

3 - When System Characteristics Override Clinical Priority: An Empirical Investigation of MRI Scheduling and Service Delivery

Hossein Abouee Mehrizi, University of Waterloo, Waterloo, ON, Canada, haboueemehrizi@uwaterloo.ca, Somayeh Sadat

We conduct an empirical analysis of MRI scheduling and service delivery based on over a million records from Ontario, Canada. We show that certain system characteristics override clinical priority in patient’s access time to care, namely whether the patient’s procedure is batched with similar procedures, whether the procedure is expected to be short in duration, and overall system congestion. We also demonstrate that the duration of the MRI scan is impacted by system characteristics such as the shift the procedure takes place in, the case mix of proceeding patients, and overall clinic congestion. Our research has implications for health policy makers monitoring access to care and quality of care.

4 - Local Adjustment of Physician Schedule in Emergency Department

Yiwen Jin, University of British Columbia, Vancouver, BC, V6T1Z4, Canada, Yichuan Ding

In this paper we optimize Emergency Department (ED) physicians’ staffing by locally adjusting the shift schedule in order to minimize patients’ total waiting cost. With a local adjustment, we move the shift with high granularity instead of globally setting the staffing requirement. We consider two types of cost, the queueing backlog and patients’ total waiting cost with a piecewise linear marginal cost function. We provide two indices where we find that the essence of this problem lies in comparing busy periods. We characterize our adjustment policy through pathwise analysis of the historical data and offer instructions of implementation in a local ED.

Personalized Medicine I

Emerging Topic: Personalized Health

Emerging Topic Session

Chair: Brian T Denton, University of Michigan, Ann Arbor, MI, 48109-2117, United States

Co-Chair: Weiyu Li, IOE Department, University of Michigan, IOE Department, Ann Arbor, MI, 48105, United States

1 - Optimal Intervention for Women with Hypertensive Disorders of Pregnancy

Esma S. Gel, Associate Professor, Arizona State University, School of Computing, Informatics and, Decision Systems Engineering, Tempe, AZ, 85287-8809, United States, esma.gel@asu.edu, Aysegul Demirtas

Hypertensive disorders of pregnancy (HDP) affect up to 10% of pregnancies around the globe. We consider the decision problem of timing of delivery for women with HDP. We formulate a discrete-time Markov decision process (MDP) model and a robust MDP model that minimize the risks of maternal and neonatal adverse outcomes, and assess their results within a probabilistic sensitivity analysis (PSA). In PSA, we evaluate the performance of candidate delivery policies based on problem instances constructed with the orders between model parameters to incorporate physicians’ intuition.

2 - Personalized Treatment for Chronic Depression with Individual Treatment Effect Estimation

Mutita Siriruchatanon, University of Washington, Seattle, WA, 98105, United States, siriruc@uw.edu, Shan Liu

In a data-rich environment, information on population and individual patient history can be used in predicting their health outcomes, which leads to early detection of ineffective treatment. To develop a computerized decision support tool for mental health care providers, we formulate an optimal treatment selection problem for chronic depression and estimate the individual treatment effects on disease transitions leveraging the subgroup progression patterns and its treatment effect distribution using simulated data. The new optimal treatment policies are obtained from an exploration of several methods on individual treatment effect estimation.

3 - A Data-driven POMDP for Optimizing Individualized Surveillance Strategies for Prostate Cancer

Weiyu Li, University of Michigan, Ann Arbor, MI, 48105, United States, weiyuli@umich.edu, Brian T. Denton

Active surveillance (AS) is a strategy that involves regular clinical examinations, biomarker tests, and biopsies to monitor patients diagnosed with low-risk prostate cancer. The ideal strategy must strike a balance between the burden of testing and the benefit of early detection of progression to high-risk prostate cancer. We propose a hidden Markov model (HMM) to estimate the progression rate of cancer, and the sensitivity and specificity of the biomarker tests using longitudinal data from a large surveillance study. We use the HMM as the basis for a partially observable Markov decision process (POMDP) and present results for optimal strategies.

4 - Effective Preventive Care Management of Multiple Chronic Conditions

Ali Hajjar, University of Wisconsin-Madison, Madison, WI, 53706, United States, hjaar@wisc.edu, Oguzhan Alagoz, Vincent Cryns

Clinical practice guidelines are poor at addressing the needs of patients with multiple chronic conditions (MCC). We develop a stochastic optimization modeling framework to personalize the management of MCC. We provide an exact solution algorithm to optimally solve the modeling framework. We demonstrate how our modeling framework can be used to personalize breast cancer screening for women with diabetes. We find some important policy insights, that were not recognized by the medical community before.

Advances in Input Uncertainty Quantification

Sponsored: Simulation

Sponsored Session

Chair: Eunhye Song, Penn State University, University Park, PA, 16802, United States

1 - Efficient Input Uncertainty Quantification via Green Simulation Using Sample Path Likelihood Ratios

Ben Feng, University of Waterloo, Waterloo, ON, N2J 4Y3, Canada, ben.feng@uwaterloo.ca, Eunhye Song

Input uncertainty is caused by the finite-sample estimation error in the input models, which inflates the uncertainty in simulation outputs. Typical bootstrap-based procedures have a nested simulation structure that requires BR simulation runs: the outer loop bootstraps B input distributions, each of which requires R inner simulation runs. In this work, we propose an efficient green simulation input uncertainty quantification procedure that reuses the same R inner sample paths in all outer loops using appropriately defined likelihood ratios. The procedure produces asymptotically valid confidence intervals and significant efficiency gains are demonstrated in our numerical experiments.

2 - Computationally Efficient Quantification of Simulation Input Uncertainty

Huajie Qian, Columbia University, New York, NY, 10027, United States, hq2157@columbia.edu, Henry Lam

Quantifying the input uncertainty of stochastic simulation, based on variance estimation or confidence interval construction, often entails substantial simulation costs due to the nested sampling requirements of the quantification schemes. We present several related approaches to reduce these costs, utilizing optimization, subsampling, and random perturbation respectively. We explain the statistical mechanisms of these approaches and why they need significantly less simulation efforts than some previous methods. We also compare them in terms of the ease of implementation and empirical performances.

3 - Online Quantification of Input Uncertainty for Parametric Models

Tianyi Liu, Georgia Institute of Technology, Atlanta, GA, United States, tianyiliu@gatech.edu, Enlu Zhou

Quantification of Input Uncertainty has been well studied for the batch data setting where data is given and fixed. However, there lack methods to process online data. We propose an online quantification algorithm for parametric models based on a two-layer importance sampling technique, which enables assimilating online data in real-time by reusing old simulation results. Our method is proved to achieve a uniform-in-time convergence. We further show that under the same simulation budget, our new algorithm works strictly better than the direct extension of the offline Bayesian quantification method.

4 - Input Uncertainty Quantification with Empirical Dependence Information

Taeho Kim, Korea Advanced Institute of Science & Technology, Dept of Industrial & Systems Engineering, 291 Daehak-Ro, Daejeon, 305-701, Korea, Republic of, thk5594@kaist.ac.kr, Kyoung-Kuk Kim

In this work, a data-driven input modeling in multiple dimensions is proposed. By utilizing empirical copula for the dependence structure, the separate estimation of marginal and joint distributions is feasible. Then we quantify the input uncertainty by resampling methods. Under certain regularity conditions, we prove the asymptotic normality of the target estimator and the consistency of resampling-based input uncertainty quantification. This approach also allows us to decompose the input variance into the sum of the variances induced by marginal and dependence information.

Crowdsourcing Platforms

Emerging Topic: Sharing Economy & Crowdsourcing

Emerging Topic Session

Chair: Michael R Wagner, University of Washington, Seattle, WA, 98195, United States

Co-Chair: Soraya Fatehi, University of Washington, Seattle, WA, 98195-3200, United States

1 - The Impact of the Gig-economy on Financial Hardship Among Low-income Families

Kaitlin Daniels, Olin Business School, Washington University in St. Louis, St. Louis, MO, United States, Michal Grinstein-Weiss

We empirically measure the impact of Uber's entrance into a market on the financial health of workers. We find that low-income workers are more likely to fail to meet regular, short-term financial obligations (e.g. monthly bills) following Uber entry. We explore mechanisms and illustrate the robustness of our findings. Analysis elucidates the role of gigs like Uber within the broader economy.

2 - Courteous or Crude? understanding and Shaping User Behavior in Ride-hailing

Yunke Mai, University of Kentucky, Lexington, KY, United States, yunke.mai@duke.edu, Bin Hu, Sasa Pekec, Yuhao Hu, Zikong Zou

We build an evolutionary game theory model to investigate how riders' and drivers' behavior evolves in response to a ride-hailing platform's operational decisions. We identify two sustainable asymptotically stable equilibria of the dynamic system of the platform, one resembling a traditional taxi service while the other resembling a successful ride-hailing platform. Using this characterization, we then show how the platform could leverage operational tools at its disposal to optimize its performance. Finally, we establish that a platform can generally improve social welfare and may achieve the socially optimal state by prioritizing high-rating riders in matching under supply shortage.

3 - Analysis of Public Attitude Towards Bikeshare Using Crowdsourcing Data

Xiaodong Qian, University of California-Davis, Davis, CA, United States, xdqian@ucdavis.edu

Bikesharing system is a convenient and environmental-friendly way to finish short-distance trips. However, there always exists access barriers for people to enjoy this convenient transportation model. Bikeshare system planners want to cover more and more potential users with a certain amount of bikeshare stations because of limited budgets. Currently, there are multiple online crowdsourcing data showing people's attitude towards bikeshare and providing suggestions for potential bikeshare stations. This research is aimed at analyzing these crowdsourcing data using natural language processing technology and developing a location optimization model based on crowdsourcing data.

4 - Crowdsourcing Last-mile Deliveries

Soraya Fatehi, University of Washington, Michael G. Foster School of Business, University of Washington, Seattle, WA, 98195-3200, United States, sfatehi@uw.edu, Michael R. Wagner

We study labor planning and pricing for crowdsourced last-mile delivery systems that are utilized to deliver on-demand orders. We develop our model by combining crowdsourcing, robust queuing, and robust routing theory, which allows for capturing uncertainties, trend and seasonality in: customer demands, crowd availability, service times, and traffic patterns. For a given delivery time window and a guarantee level to deliver on-time, we analytically derive the optimal delivery assignments to available independent crowd drivers and compute their optimal hourly wages. Amazon, Postmates, and UberEATS are among the companies that are utilizing crowdsourcing for last-mile deliveries.

SpORts Analytics I

Sponsored: SpORts

Sponsored Session

Chair: Keith A Willoughby, University of Saskatchewan, Saskatoon, SK, S7N 5A7, Canada

1 - Evaluating Player Dominance and Game Outcome: The Case of Curling

Keith A. Willoughby, University of Saskatchewan, Department of Finance and Mangement Science, Saskatoon, SK, S7N 5A7, Canada, willoughby@edwards.usask.ca, Kent Kostuk

Curling is a winter team sport popular in Canada, Europe, the northern United States and the Pacific Rim. Typically, curling teams are comprised of four players (lead, second, third and skip). Team members slide 45-pound circular disks of polished granite down a sheet of ice. A scorer evaluates the success of each shot on a 4-point scale. Using data from Canadian national championships, we compare the percentage score differences between each team's corresponding players and evaluate its impact on the game outcome.

2 - Patterns of Game Play in Irish (Gaelic) Football – A Social Network Analysis Approach

Vincent Hargaden, Associate Professor, University College Dublin, School of Mechanical & Materials Engineering, Engineering & Materials Science Centre, Belfield, D04 V1W8, Ireland, vincent.hargaden@ucd.ie

Irish (Gaelic) football is a 15-a-side field sport played through a combination of hand and foot passing. Each year from May through September, the elite teams compete in a series of conference and play-off games to determine the championship winner. Similar to many team sports (e.g. basketball, soccer etc.) it is of interest to analyse the players' interaction and cooperation from a network perspective. Using hand and foot passing data between players from games involving the four-in-a-row title winning team (2015-2018), we take a social network analysis approach to identify players' interactions and the team style of play.

3 - Dynamically Scheduling NFL Games to Reduce Strength of Schedule Variability

Ben Grannan, Furman University, Greenville, SC, 29617-7908, United States, Elizabeth Bouzarth, Andrew Cromer, Jamie Fravel, Kevin Hutson

The National Football League (NFL) schedules regular season games so that some matchups are based on the previous year's results. Since team composition changes from year to year, this scheduling policy creates variation in teams' strength of schedules and sometimes benefits teams unfairly, allowing some an easier path to the playoffs than others. We propose methods to produce an NFL schedule that combine some of its traditional elements with dynamically scheduled games aimed at optimizing different objectives, such as reducing the variability of teams' strengths of schedule or minimizing the number of pairwise comparisons needed to differentiate team quality.

4 - A Comparison of Official Sports Rating Systems at Predicting World Team Championship Matches

Raymond T. Stefani, Professor Emeritus, California State University, Long Beach, CA, 92630-2633, United States, Raymond.stefani@csulb.edu

The study includes all team sports with recognized federations that publish an official rating system and conduct a world championship. The 15 sport-rating system combinations were evaluated using 56 world championships and 2941 matches. Rating systems adjusted by the difference between an opponent-dependent prediction and the actual match result were 82% accurate at predicting match winners in netball, Rugby union, women's soccer, ODI cricket, T20 cricket and men's soccer. Rating systems that accumulated result points, generally not opponent-dependent, were only 74% accurate in water polo, Rugby 7s, field hockey, ice hockey, basketball, volleyball, handball, Rugby league and curling.

5 - Estimating the Impact of Mega-sporting Events on International Tourism, the Olympic Legacy

Steven E. Moss, Professor of Business Analytics, Georgia Southern University, Statesboro, GA, 30458, United States, smoss@georgiasouthern.edu, Jun Liu, Janet Moss

Tourism legacies are often used as a key justification for hosting the Olympics. Theoretical arguments have been made to support a positive tourism legacy. A time series methodology that controls for problems noted in prior studies, such as pre-existing trends, external events, seasonality, and the crowding out effect, is needed to isolate the legacy effect. Prior research has included simple pre-post aggregate differences, relative comparisons to similar cities, trend-line extension models and structural break tests. This research uses data from ten prior Olympics. Two methodologies are used in this research, structural change tests in regression models and outlier testing in SARIMA models.

6 - Selection & Shrinkage Method Comparison for Explaining NCAA FBS Athletic Contributions

Liz A. Wanless, Ohio University, Athens, OH, United States, wanless@ohio.edu

NCAA FBS athletic programs depend on contributions as a vital financial resource. A large mix of potential explanatory variables, limited population size, and wide-ranging revenues complicate the modeling process. The purpose of this project is to evaluate model selection and shrinkage method performance for explaining FBS athletic contributions. For one athletic fiscal year, 2016-2017, NCAA FBS market, university, athletic department, and athletic development department variables were collected along with athletic contributions as the response. Method performance with specific regard to statistical versus practical relevance will be discussed.

Digital Platforms

Sponsored: EBusiness

Sponsored Session

Chair: Tingting Nian, University of California, New York, NY, 10012, United States

1 - The Impact of Airbnb's Entry on Financial Delinquency

Jinan Lin, University of California, Irvine, Irvine, CA, United States, Tingting Nian, Vijay Gurbaxani

Policy debates continue on whether and how digital economy impacts local economic activities and organizations. As one of the most prominent peer-to-peer digital platforms for home sharing, Airbnb has raised much attention from local regulators. This paper investigates the impact of an entry of the home-sharing platform on zip-code level households' financial decisions. Our results suggest that the entry of Airbnb mostly affects households' short-term borrowing decisions.

2 - The Impact of Subscription Reciprocity on Charitable Content Generation and Sharing: Evidence from Twitter

Xue Tan, Indiana University, Kelley School of Business, Bloomington, IN, 47405, United States, Yingda Lu, Yong Tan

This paper investigates the impact of reciprocal and non-reciprocal followees (people who are being subscribed to) on followers' decisions to generate and share content. Leveraging a charitable movement on Twitter, we find that only reciprocal followees' participation prompts users to generate original content about this movement; participation of both reciprocal and nonreciprocal followees promotes content sharing, with nonreciprocal followees having a larger impact. Our study draws on social capital theory, and has great implications on diffusion theories concerning the strength of ties and contagion complexity.

3 - Adopting Seeker and Peer Feedback in Ideation Contests: An Anchoring Effect Perspective

Tat Koon Koh, Hong Kong University of Science and Technology, Kowloon, Hong Kong

Solution-seeking firms (seekers) can use online ideation contests to engage agents (solvers) in the crowd to generate ideas for addressing specific problems. An integral aspect of these contests is the solvers' use of feedback during ideation. In this study, we examine solvers' use of developmental feedback in their ideas by considering the anchoring heuristic that affects their decision-making. During contests, solvers can receive feedback from different sources (i.e., seekers or peers) and of different levels of practicality (i.e., the extent that the feedback is helpful and appropriate). In our theorizing, we formulate distinct expectations about how solvers anchor their ideas to seeker feedback and peer feedback, which we use to hypothesize the impact of feedback source and practicality on solvers' feedback use. In our first experiment, we show that solvers use feedback from seeker and peer differently. Specifically, solvers use low-practicality seeker feedback 1) about as much as they use high-practicality seeker feedback and 2) much more than they use low-practicality and high-practicality peer feedback. Such solver behaviors indicate a potential drawback of encouraging seeker feedback, which is prevalent on contest platforms. In our second experiment, we test a mechanism to address the downsides arising from the anchoring on feedback, particularly the overuse of low-practicality seeker feedback and underuse of high-practicality peer feedback. Our findings provide (i) insights into the scope of the anchoring effect and solvers' use of feedback and (ii) suggestions to better engage the crowd in ideation contests.

4 - The Influence of Self-Regulation of Sharing Economy: Evidence from Unstructured Information Disclosure

Zixuan Meng, University of Washington, Seattle, WA, 98105, United States, Zhijie Lin, Yingfei Wang, Yong Tan

This study analyzes the effectiveness of self-regulation disclosure in the sharing economy. Using the data from a large peer-to-peer meal-sharing platform in China, we integrate econometric analysis method with deep learning and computer vision techniques to conduct the analysis. We find that while the disclosure in general brings a sales increase to the inspected suppliers, disclosing image information only can create mis-interpretation, leading a non-monotonic sales increase in hygiene quality. We also find that competition and reputation are substitute to the self-regulation mechanism.

Joint Session BOM/Practice Curated: Behavioral Operations for Social and Environmental Responsibility

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Leon Valdes, University of Pittsburgh, Pittsburgh, PA, 15260, United States

1 - How Supply Chain Risks Influence Supplier Selection and Ordering Decisions: A Behavioral Investigation

Vincent Yu, Carlson School of Management, University of Minnesota, Minneapolis, MN, United States, yuxxx952@umn.edu, Karen L. Donohue

In this study, we combine modeling and experimental methods to investigate how sourcing managers make order allocation decisions between a high-cost supplier and a low-cost supplier with some potential risks. We consider two types of risk: (1) supply risk, which arises from reliability-related issues that disrupt the flow of supply, and (2) demand risk, which results from responsibility-related issues that influence the flow of customer demand. We examine how sourcing decisions are made in light of these risks, what implications this behavior has for firm profit, and whether this behavior encourages or detracts suppliers from investing in risk reduction efforts.

2 - How Transparency into Internal and External Responsibility Initiatives Influences Consumer Choice: Evidence from the Field and Lab

Ryan Buell, Harvard Business School, Morgan Hall 429, Boston, MA, 02163, United States, rbuell@hbs.edu, Basak Kalkanci

Across three experiments, conducted in the field and lab, we compare how transparency into internal and external social and environmental responsibility initiatives affects customer perceptions and sales. Our field evidence provides converging evidence that transparency into a company's internal responsibility practices can be at least as motivating of consumer sales as transparency into its external responsibility initiatives. We further investigate the perceptual effects of transparency into internal and external responsibility initiatives and find that the underlying psychological mechanisms linking both types of transparency to consumer purchase intentions are consistent.

3 - The Impact of Social Learning on Consumer Subsidies for Green Technology Adoption

Hang Ren, School of Business, George Mason University, Fairfax, VA, 22030, United States, hren5@gmu.edu, Tingliang Huang, Georgia Perakis

To incentivize consumer adoption of expensive green-tech products, governments typically o er consumers subsidies through rebates and tax credits. Apart from subsidies, consumers' adoption decisions are usually also influenced by the word-of-mouth information about product quality from earlier adopters. In this paper, we study a government's optimal dynamic subsidy decision in the presence of consumers' social learning.

4 - The Market Value of Sustainability Disclosure: A Cross-Cultural Field Study

Tim Kraft, Assistant Professor, North Carolina State University, Raleigh, NC, 02142, United States, timckraft@gmail.com, Markko Hamalainen, Douglas Thomas, Yanchong Zheng, Meng Zhang

Partnering with Goodio, a Finland-based craft chocolate producer, we explore how consumers react to values-based and evidence-based messaging regarding environmental and social initiatives. We test the effects of transparency in three markets (US, Finland, and Japan) with both online and field experiments.

5 - Trying and Failing: Donor Aversion to Rejection

Leon Valdes, Assistant Professor, University of Pittsburgh, Joseph M. Katz Graduate School of Business, Pittsburgh, PA, 15260, United States, lvaldes@katz.pitt.edu, Kaitlin Daniels

The outpouring of concern that follows a disaster often generates excess donations. Nonprofits routinely accept these donations, fearing that turning away donors will discourage them from donating again. We conduct an incentivized experiment to investigate whether this fear is warranted and explore the behavioral motives for not donating again. Our results show that learning about or experiencing a rejected donation decreases the estimated probability that a donation will be accepted in the future, which decreases the likelihood of donating again. Furthermore, we compare our results with a for-profit situation and show that self-serving bias plays a key role in explaining this behavior.

Sponsored Session

Chair: JaeHwuen Jung, Temple University

1 - The Impact of Sharing Economy on Tourism Industry

Jiyong Park, University of North Carolina at Greensboro, Greensboro, NC, 130-722, United States, jiyong.park@uncg.edu

The rapid growth of sharing economy presents opportunities to grow the tourism economy by allowing to rent one's residence to tourists and to provide transportation services in a personal vehicle. This study examines whether and how Airbnb and Uber influence tourism industry employment. Our findings demonstrate that the number of Airbnb reviews is associated with the increase in local employment of tourism industries, especially for food/beverage industries. Importantly, in low accessibility neighborhoods which are underserved by public transits, we find that Airbnb has a spillover effect on local employment in the food/beverage industries only when ride-sharing services are available.

2 - Enhancing Social Media Analysis with Visual Data Analytics: A Deep Learning Approach

Donghyuk Shin, Arizona State University, Tempe, AZ, 98109, United States

We propose a number of visual and textual content features including complexity, similarity, and consistency measures that can play important roles in the persuasiveness of social media content. We then employ state-of-the-art machine learning approaches such as deep learning and text mining to operationalize these new content features in a scalable and systematic manner. For the newly developed features, we validate them against human coders on Amazon Mechanical Turk. The proposed research framework illustrates how deep learning methods can enhance the analysis of unstructured visual and textual data for social media research.

3 - Enterprise Systems Deployment Disparity, Business Environments, and Firm Performance

Inmyung Choi, Texas Tech University, Lubbock, TX, United States, inmyung.choi@gmail.com

We examine the nuanced effect of the deployment of enterprise systems across business units on firm performance by developing the concept of enterprise systems deployment disparity (ESDD). ESDD captures the extent to which a firm allocates its enterprise systems across business units unevenly. Then, using a sample of 1,872 firm-year observations from the United States, we find that ESDD (i.e., unbalanced utilization of enterprise systems) is associated with superior financial performance. Further, we investigate the moderating role of business environments (i.e., industry dynamism, concentration, and velocity) on the relationship between ESDD and firm performance.

4 - Understanding Customer Flows in Shopping Centers Using WiFi Tracking

Changseung Yoo, Assistant Professor, McGill University, Montreal, QC, Canada, changseung.yoo@mcgill.ca

We develop a machine learning framework to help a marketing analytics company scale up its personalization for users of its WiFi services. In particular, we leverage the large amounts of data it holds to see how well our algorithms can predict individual's shopping/travel pattern. Furthermore, we uncover complementarities or substitutabilities between various location choices, which are then used to refine the personalization of landing pages upon logging onto the WiFi services.

Sponsored Session

Chair: Yixin Lu, George Washington University, Washington, DC, 20052, United States

1 - Measuring the Impact of Crowdsourcing Features on Mobile App User Engagement and Retention

Zhuojun Gu, UT Arlington, Arlington, TX, United States

The most commonly cited issues with mobile apps are low user engagement and retention levels. In this paper, we explore the efficacy of crowdsourcing features on enhancing user engagement and retention in the context of mobile gaming apps. To do so, we examine two specific crowdsourcing features, namely, the ability to contribute content and the ability to access crowdsourced content. Under a 2×2 factorial design, we assess the impact of these crowdsourcing features on usage outcomes via a randomized field experiment.

2 - The Role of Religion in Online Prosocial Lending

Amin Asabzehz@asu.edu, Arizona State University W.P. Carey School of Business, Phoenix, AZ, United States, asabzehz@asu.edu

We propose a measure of religious distance between any given pair of countries and incorporate it to explain lending volumes in online prosocial platforms. Results demonstrate the negative effect of religious differences on lending activity. We show that the effects of religious differences vary a great deal, being moderated by the social environment characterizing both lender and borrower countries in a given time period. That is, we find that increases in the degree of social hostilities within a lender country amplifies the negative effects of religious differences on lending activity and, at the same time, diversity of religion and greater physical distances attenuate such negative effects.

3 - Brokerage Model for Online Trading Platforms: One-side or Both-side?

Peng Wang, Xidian University, Xi'an, China, wangpeng7@stu.xidian.edu.cn, Rong Du, Hongpeng Wang

Motivated by the successful practice of both-side brokerage revenue model—charging both house owners and renters—in Airbnb.com, we investigate how an online trading platform should design its brokerage model. The main results indicate that it is preferable for an online platform to charge sellers and buyers when the mass of buyers who fully value trust is larger and the cost to build the seller-side platform-enabled trust is smaller. Furthermore, we identify a tradeoff between the buyer-side net benefit and the seller-side net loss of using the both-side brokerage model. We also reveal how transaction and culture differences influence the platform's choice between the two brokerage models.

4 - A Gamification-based Study on the Effect of Information Transparency and Social Value Orientation

Xu Han, Fordham University, New York City, NY, United States

We designed a game on social media platform and conducted randomized field experiments to study how information transparency and social value orientation (SVO) will affect user behaviors. Participants are invited to play a game under different information transparency levels and pre/post-game surveys are conducted to collect demographic information and their SVO. We found different effects of imformation transparency on high/low-performance players. We also found significant impact of SVO on players' engagement. Our research demonstrates possibilities to design a mechanism to achieve overall collaborative benefits in a competitive gamification setup.

Location Analysis I

Sponsored: Location Analysis

Sponsored Session

Chair: Dmitry Krass, University of Toronto, Toronto, ON, M5S 3E6, Canada

Co-Chair: Oded Berman, University of Toronto, Toronto, ON, M5S 3E6, Canada

1 - Coordination in Emergency Response: An Application to Hazardous Materials Transportation

Vedat Verter, McGill University, Faculty of Mgmt, 1001 Sherbrooke Street West, Montreal, QC, H3A 1G5, Canada, vedat.verter@mcgill.ca, Peng Hu, Jiahong Zhao

Coordination of multiple resources involved in emergency response is largely overlooked in the literature. This requires not only the response time of each resource, but also the amount of time the teams may have to wait for each other. We present a mathematical model for simultaneously siting ambulance and fire stations. We discuss a case study on Chengdu, China.

2 - Probabilistic Set Covering Problem

Robert Aboolian, California State University-San Marcos, San Diego, CA, 92130, United States, raboolia@csusm.edu, Oded Berman, Majid Karimi

We consider a network of congested service facilities which cover customers assuming a maximum average access time to service, which is the sum of average travel, average waiting for service and average service times. The objective is to minimize overall fixed and service capacity costs so that the average access time to service does not exceed a certain level. Demand is elastic and decreasing in access time to service. These problems are usually solved using bi-level programming techniques and since demand is a function of waiting time and vice versa, we need to solve a series of equilibrium conditions in the second level. Here we develop a MIP optimization model which solves the problem in single level.

3 - Optimal Pricing, Sizing and Location for Facilities Facing Stochastic Demand

Dmitry Krass, University of Toronto, Rotman School of Management, Toronto, ON, M5S 3E6, Canada, krass@rotman.utoronto.ca, Oded Berman

We analyse the problem of determining the number and locations of the facilities, service capacity of each facility, and the prices to charge for service. Utility-maximizing customers residing at the nodes of the network generate stochastic demand streams. Customer utility is influenced by the price, travel distance and waiting times. We obtain a number of structural and algorithmic results, including nodal optimality, conditions for separability of pricing, capacity and location decisions, and near- optimality of uniform prices when customer demand is log-additive. We show how single facility results can be applied to derive optimal or near-optimal solutions for multi-facility problems.

Latest Developments in Scheduling

Emerging Topic: Project Management & Scheduling

Emerging Topic Session

Chair: Zhi-Long Chen, University of Maryland, College Park, MD, 20742-1815, United States

1 - Coordinated Scheduling and Price Quotation with Due Dates

Zhixin Liu, University of Michigan-Dearborn, Dearborn, MI, United States, zhixin@umich.edu, Liang Lu, Xiangtong Qi

We study coordinated price quotation and scheduling for a manufacturer. Each quote for an order can be either accepted or rejected by a customer and has a due date related cost when processed. We develop an exact algorithm to calculate the expected profit under a given set of price quotations, and then design an algorithm to find near optimal price quotations. We also find an upper bound of the manufacturer's maximum expected profit. Computational study justifies the efficiency of our algorithm.

2 - Scheduling Problems with Assembly Operations in Alibaba's Hema Store

Weiya Zhong, Shanghai University, Shanghai, China, wyzhong@shu.edu.cn

Alibaba's Hema Store, provides a seamless blend of online and offline shopping experience for customers and is likely to reshape the landscape of China's retail industry. In this talk, we present a new scheduling problem in Hema Store. Each job(order) may be composed of several sub-jobs(sub-orders) . Inside the store, each sub-job is handled by a dedicated flowshop, then different sub-jobs of one job are assembled together. After the assembly operations, the jobs are delivered to their customers in different locations by multiple deliverymen. For different settings and objective values, we propose various scheduling models, analyze the time computational complexity and design heuristics.

3 - Artificial Intelligence and Machine Learning in Scheduling Research

Zhi-Long Chen, University of Maryland, Robert H. Smith School of Business, Dept of Decision, Operations & Info Tech, College Park, MD, 20742-1815, United States, zchen@rhsmith.umd.edu

This talk will take a look at existing research that applies AI or ML tools to scheduling problems.

Technology and Contests

Sponsored: New Product Development

Sponsored Session

Chair: Ersin Korpeoglu, University College London, London, E14 5AA, United Kingdom

1 - Green Technology Development and Adoption: Competition, Regulation, and Uncertainty – A Global Game Approach

Xin Wang, Hong Kong University of Science and Technology, Hong Kong University of Science and Technolog, IELM, Hong Kong, Hong Kong, xinwang@ust.hk, Soo-Haeng Cho, Alan Scheller-Wolf

When a government is considering tightening a standard on a pollutant, their decision often is influenced by the number of firms being able to meet the tightened standard, because a higher number indicates a more feasible standard. We study how such regulation may affect a firm's incentive to develop a new technology to reduce a pollutant. To analyze this problem, we use the global game framework recently developed in economics. We find that regulation that considers industry capability, compared with regulation that ignores it, can more effectively motivate development of a new green technology. Surprisingly, uncertainty in the payoff can also help promote development of a new green technology.

2 - How Procurement Contests Shape the Technological Landscape

Jochen Schlapp, Frankfurt School of Finance & Management gGmbH, Adickesallee 32-34, Frankfurt am Main, 60322, Germany, Jussi Keppo, Jurgen Mihm

Companies in technology-intense industries frequently engage in contest-like competition to provide customers with superior technologies. Oftentimes, the firm offering the best technology is able to reap large shares of the market. However, over time, competitors may introduce new technologies that outperform older ones and thus change the allocation of market shares. We study how the prevalence of such contest-like competition affects the competitors' technology choices over time, and whether competition leads to more desirable outcomes as compared to a monopoly market.

3 - Sourcing Innovation: Integrated System or Individual Components

Zhi Chen, INSEAD, Singapore, 138676, Singapore, zhi.chen@insead.edu, Jurgen Mihm, Jochen Schlapp

Many purchasing projects involve buying complex systems, which require the suppliers to perform some custom product or technology development regardless of whether they win the project or not. Viewing such a procurement setting through the lense of contest, we study under which circumstances a buying firm should source an integrated system or individual components.

4 - The Role of Participation in Innovation Contests

Konstantinos I. Stouras, UCD Smurfit, Dublin, Ireland, Jeremy Hutchison-Krupat, Raul Chao

We study how to design an innovation contest when solvers have a participation decision.

Sustainable Electricity Demand

Emerging Topic: Sustainable Growth

Emerging Topic Session

Chair: Zana Cranmer, Bentley University, Waltham, MA, 02452, United States

1 - Characterizing the Uncertainty on Future Residential Electricity Demand in China

Dalia Patino Echeverri, Associate Professor of Energy Systems and Policy, Duke University, Nicholas School of the Environment, Box 90227, Durham, NC, 27708, United States, dalia.patino@duke.edu

We project residential electricity demand in China under varying socioeconomic, technical and climate conditions. Adoption of electric appliances is estimated for forty-five scenarios that combine five levels of population growth, three levels of per-capita gross domestic product (GDP) and income growth, and three levels of change in household size. The population scenarios are generated with a province-specific cohort-component model that accounts the increase of life expectancy, the gradual balancing of the sex ratio at birth, and five plausible trends in fertility rate. Scenarios for time-of-use of appliances are based on a characterization of consumer types based on a household survey.

2 - Domain-constrained Statistical Inference from Sensor Data in Modern Buildings

Mario Berges, Professor, Carnegie Mellon University, Pittsburgh, PA, 15213, United States

Though our buildings are being covered with sensors and computing devices at an incredibly fast rate, and we have developed highly-flexible and efficient mathematical models to make sense of all the data that these devices are generating, our ability to make use of these two advances in the context of buildings is limited compared to other fields (e.g., computer vision). Broadly speaking, this is because of the lower data availability and because physics imposes more difficult constraints on the learning problem. Here I will discuss how to incorporate domain-expertise to improve our ability to perform (approximate) inference in two such settings: electricity disaggregation and HVAC control.

3 - A Portfolio Model for Energy Efficiency Projects

Zana Cranmer, Bentley University, Waltham, MA, 02452, United States, acranmer@bentley.edu

What are the best energy efficiency projects for commercial organizations to pursue? This work develops a portfolio model to help organizations determine the most valuable energy efficiency projects across their building stock. The model accounts for institutional constraints such as capital budgets, the interactions between projects, and uncertainty in project costs and performance. An organization's optimal strategy (set of energy efficiency projects) will depend on the building stock and how the buildings are used.

4 - Evaluating the Sustainability of Energy Pathways with a Multi Criteria Decision Analysis Approach: A Case Study on Mexico

Rodrigo Mercado Fernandez, University of Massachusetts Amherst, 65 McClellan Street, Amherst, MA, 01002, United States

This paper examines the use of multi criteria decision analysis (MCDA) to evaluate the sustainability of different expansionsin the Mexican Electrical Grid.In particular, we will include the transmission, and generation networks into the evaluation of sustainability for each pathway. We use a set of social, economic and environmental criteria to evaluate the sustainability of each expansion plan up to 2050. The goal will be to use the insight of the sustainability of each expansion plan to better inform decision maker in developing energy policy.

Empirical Research in Innovation and Entrepreneurship I

Sponsored: Technology, Innovation Management & Entrepreneurship

Sponsored Session

Chair: Panos Markou, Cambridge Judge Business School, Cambridge, CB2 1AG, United Kingdom

1 - Perils of Bargaining Power in R&D Licensing

Niyazi Taneri, National University of Singapore, NUS Business School, Singapore, 119245, Singapore, niyazi@nus.edu.sg, Arnoud De Meyer

License agreements present opportunities for innovators (licensors) and their partners (licensees) to leverage each other's complementary capabilities. It is natural for a firm to use a position of higher relative bargaining power for its potential gain but this can lead to a misalignment of incentives: An innovator with higher relative bargaining power may push for higher deal value but a partner facing higher payments at a continuation decision may prioritize other projects in its portfolio. We investigate how deal value is determined and how deal value — and its underlying drivers — influence downstream terminations.

2 - Invention Integrality and Gender Composition in Innovation Teams

Wenjie Tang, National University of Singapore-Business School, Singapore, 119245, Singapore, wenjie.tang@nus.edu.sg, Tian Chan, Haibo Liu, Steffen Keck

When do teams with female member(s) create more valuable innovations than do all-male teams? We theorize that this will be so when the invention is integral, i.e., hard to decompose into chunks amenable to independent efforts. Using utility patent data from 1985 to 2015, we show that, whereas innovation teams with at least one female member tend to generate patents of similar market value (compared to all-male teams) on the average, such teams outperform when the invention is integral. We undertake a laboratory experiment and confirm our prediction that the positive effect of female members on a team's output is explained by a higher level of psychological safety as compared to all-male teams.

3 - Sequential Decision Making: Biases and Heuristics

Evgeny Kagan, Johns Hopkins Carey Business School, Baltimore, MD, United States, Ozge Sahin, Stephen Leider

Many innovation and product development processes involve human decisions that are made sequentially, as new information is being revealed. In this paper we explore theoretically and experimentally decision biases in this setting, looking in particular at what decision policies humans adopt. We find support for a particular class of decision policies that deviate from the optimal policies in non-trivial, but predictable patterns.

4 - Exploring the Impact of Organizational Sponsorship on the Entrepreneurial Journey of Start-ups

Stylianos Kavadias, Margaret Thatcher Professor of Innovation & Growth, University of Cambridge, Judge Business School, Trumpington Street, Cambrige, CB2 1AG, United Kingdom, s.kavadias@jbs.cam.ac.uk, Keivan Aghasi

Start-up companies suffer from limited legitimacy and low social capital endowment, which make it difficult for them to gain access to vital information and other relevant resources, necessary for them to grow. Support programmes offer organisational sponsorship to them to help overcome these challenges. Our paper uses a unique sample of 1320 nascent ventures that have applied to Pitch@Palace - a well known support programme in the UK - to measure and validate the effect of such sponsorship on different dimensions of entrepreneurial performance. We show how the effect is contingent on the prior-to-entry status of the start-up.

Forestry V: Biodiversity Conservation Planning

Sponsored: Energy, Natural Res & the Environment/Forestry

Sponsored Session

Chair: Bistra Dilkina, University of Southern California, Los Angeles, CA, 90089, United States

Co-Chair: Robert G Haight, US Forest Service, Saint Paul, MN, 55108, United States

1 - The Cost of Institutional Hierarchies in Spatial Conservation Planning

Bistra Dilkina, University of Southern California,Los Angeles, CA, 90089, United States, bdilkina@gmail.com

We study how institutional constraints that limit how freely conservation funding can be moved around impact the biodiversity gains available from habitat protection programs. We present a hierarchical optimization framework, based on a mixed-integer bi-level model, that can account for differences between conservation actors regarding what aspects of biodiversity they most value. Through large-scale case studies, we evaluate the cost of ignoring institutional structure in spatial planning tools in terms of an over-estimation of possible conservation gains.

2 - A MIP Approach for Multi-action Planning for Threat Management

José Salgado, Phd Student, Forest Sciences Centre of Catalonia (CTFC), Solsona, Spain, jose.salgado@upc.edu, Jordi Garcia-Gonzalo, Virgilio Hermoso, Eduardo Álvarez-Miranda, Andrés P. Weintraub

This paper discusses multi-objective integer programming optimization models for designing conservation plans. The proposed models allow the dsicussion of trade-offs between ecological benefits, implementation cost and fragmentation of the area that is monitred or where actions are carried out.

3 - Optimizing Camera Trap Placement Designs for Species Density Estimation

Amrita Gupta, Georgia Institute of Technology, Atlanta, GA, United States, gupta.amrita20@gmail.com, Bistra Dilkina

Camera traps are becoming an increasingly widespread tool for wildlife ecologists that allows them to collect photo capture data that is then used as presence/absence information in species density estimation or habitat suitability estimation. Most studies use a simple grid design for the placement of the sensors. Prior research has shown that trap configuration and spacing influences parameter estimates in Spatial Capture-Recapture models. We investigate how one can optimize the design of the camera trap placement across the landscape to maximize the utility of the collected data and leverage any prior information about the species or the habitat.

Joint Session ENRE/Elec/Practice Curated: Addressing Computation and Market Integration Challenges in Power Systems

Sponsored: Energy, Natural Res & the Environment/Electricity

Sponsored Session

Chair: Murat Yildirim

Chair: Paritosh Ramanan, Georgia Institute of Technology, Atlanta, GA, 30324, United States

1 - Decentralized Multithreaded Maintenance for Large Scale Power System Planning Problems

Paritosh Ramanan, Georgia Institute of Technology, Atlanta, GA, 30324, United States, paritoshpr@gatech.edu

In this talk we present a decentralized solution framework for the maintenance and operations problem for large scale power networks based on streaming sensor data from assets based on a region based decomposition with the help of MPI. Within a region, we decouple the maintenance and operational problems by the week and exploit multithreading to make the combined long term problem tractable. A two phase algorithm is proposed that relies on the convex relaxation and privacy preserving valid inequalities in order to deliver algorithmic improvements. We show that our decentralized method delivers a superior computational performance as compared to the state of the art centralized method.

2 - Integrating Degradation Sensor Data to Electricity Markets

Farnaz Fallahi, Wayne State University, Detroit, MI, United States, gc5019@wayne.edu, Murat Yildirim, Jeremy Lin

Degradation sensor data enables new tools to monitor and control generation assets in power systems. These tools are typically used in engineering applications: i.e. detection of failure risks across the grid. In this talk, we develop a unified market framework for operations and maintenance (O&M) scheduling that adapts to real-time degradation sensor data. The proposed approach identifies optimal adaptive O&M bidding decisions of generation companies (GenCos) based on their sensor data and studies the impact of these adaptive decisions on the efficiency of the electricity markets. The proposed framework provides revenue opportunities to GenCos, and significantly improves grid reliability.

3 - Primal Heuristics for Unit Commitment with Transmission Switching

Emma S. Johnson, Georgia Institute of Technology, Atlanta, GA, 30309, United States, Shabbir Ahmed, Santanu Subhas Dey, Jean-Paul Watson

State-of-the-art unit commitment formulations are tight enough that, when we add transmission switching, the dual bound is in practice very good. The difficulty lies in finding quality primal solutions. We propose heuristics for finding primal switching solutions for both DC optimal transmission switching and for unit commitment with transmission switching. On the assumption that this is a problem which is solved often, we utilize solutions from already-solved related instances to generate solutions to a new instance. We compare to switching heuristics in the literature based on dual information from DC optimal power flow.

4 - Market-based Resource Adequacy Assessment under High Variable Renewable Resource Penetrations

Jonghwan Kwon, Argonne National Laboratory, 4808482924, Lemont, IL, 60439, United States, Kwonj@anl.gov, Zhi Zhou, Todd Levin, Audun Botterud

We will present a market-based resource adequacy assessment framework that captures the strategic capacity investment and retirement decision-making of profit-maximizing generation companies. The model is based on Stackelberg leader-follower games and is formulated as a bi-level optimization problem. Furthermore, we employ a Lagrangian decomposition algorithm and parallel computing to enhance computational performance. We will demonstrate the value and the potential application of the modeling framework with a case study.

Equilibrium Models in Energy I

Sponsored: Energy, Natural Res & the Environment/Electricity Sponsored Session

Chair: Simon Risanger, Norwegian University of Science and Technology (NTNU), 5542, Norway

Co-Chair: Steven Gabriel

1 - Inverse Equilibrium Analysis of Oligopolistic Electricity Markets

Simon Risanger, Norwegian University of Science and Technology, Stenderv. 65, Trondheim, 5542, Norway, simon.risanger@ntnu.no, Stein-Erik Fleten, Steven A. Gabriel

Equilibrium models are extensively used to investigate electricity market problems. Input parameters that represent market participants, such as costs or willingness-to-pay, are crucial to produce reasonable output for further analysis. However, these parameters are often unobservable and can be challenging to obtain. Equilibrium outcomes, such as market prices and volumes, on the other hand, are directly observable. We present inverse equilibrium models that use observations from market outcomes as input in order to estimate objective function parameters.

2 - Capacity and Energy Market Equilibria: Storage Load Carrying Capability and Unit Commitment Representation

Benjamin Field Hobbs, Schad Chaired Professor, Johns Hopkins University, Baltimore, MD, 21218, United States, bhobbs@jhu.edu, Shen Wang, Cynthia D. Bothwell

A capacity and energy market equilibrium model is used to identify the appropriate capacity credit (effective load carrying capability) to give to storage, demand response, and generation technologies, given unit commitment constraints and variable output of renewable generation. A capacity market simulation model shows the impact of giving inaccurate credit to different resource sin the market. The model considers multiple years of demand and variable renewable hourly realizations, but assumes perfect foresight in commitment and storage decisions.

3 - Market Equilibria and Interactions Between Strategic Generation, Wind, and Storage

Ramteen Sioshansi, The Ohio State University, Department of Integrated Systems Engineering, Columbus, OH, 43210-1271, United States, sioshansi.1@osu.edu, Antonio J. Conejo

Many electricity markets are seeing increasing penetrations of weather-dependent renewable generators and energy storage. This talk provides a modeling framework that can be used to examine how these types of assets interact with conventional generators in a market environment. Different asset-ownership and market structures will be compared in terms of market outcomes and efficiency.

4 - Equilibria in Electricity and Natural Gas Markets with Strategic Offers and Bids

Antonio J. Conejo, The Ohio State University, Department of Integrated Systems Engineering, Columbus, OH, 43210, United States, conejo.1@osu.edu, Sheng Chen, Ramteen Sioshansi

We study market equilibria achieved by strategic firms that participate in electricity and gas markets. These firms submit their offers and bids to both markets with the aim of maximizing profit or utility and consider firms that can include combination of electricity and gas supply and demand. The strategic actions of these firms are represented by upper-level problems that are optimized subject shared lower-level problems that represent the clearing of electricity and gas markets. We develop a solution methodology that allows us to find equilibria with different characteristics.

Equilibrium Models in Energy

Contributed Session

Chair: Felipe A. Feijoo, Pontificia Universidad Católica de Valparaíso, Av. Brasil 2241, Office 6-8, Valparaíso, Chile

1 - Combining Scenario Foresight and a Convex-quadratified MCP for Futures of Energy, Climate, and Policy

Dawud Ansari, DIW Berlin, Berlin, Germany, dansari@diw.de, Franziska Holz

This study presents four novel and multidisciplinary scenarios of energy, climate, and policy. They overcome previous barriers by combining qualitative and quantitative methods: First, we use structured analytic techniques to generate storylines, including a facilitated expert workshop. Then, we calibrate the energy and resource model Multimod to reflect the different storylines. In this, the study is the first major application of Baltensperger, Egging, and Tomasgard (2018): We cut computation time by 99.8% by reformulating Multimod, a mixed complementarity problem, into a convex-quadratic problem. Finally, we unite and refine storylines and model results into holistic narratives.

2 - Regulatory Competition: Discovering Strategic Energy Policy via EPECs

Jip Kim, New York University, Brooklyn, NY, United States, jipkim@nyu.edu, Yury Dvorkin

State regulatory bodies can exhibit strategic behavior to advance their energy policy goals at the expense of neighboring jurisdictions, which are connected via a transmission network. This talk describes the effects of this strategic behavior on the transmission-distribution interactions and state renewable portfolio standards using Equilibrium Problems with Equilibrium Constraints (EPEC). This EPEC accounts for operating and planning uncertainties, which are typical for power system expansion studies, using chance constraints. The case study is carried out for the 8-zone ISO-NE system.

3 - A Bilevel Approach to Optimize Electricity Price in Local Energy Transaction Market

Xiaochun Feng, Northwest A&F University, Yangling, China, Yang Chen

Along with the rising two-way communication smart grid technologies and distributed renewable energy, energy trading among neighborhood prosumers has been gained more and more attention, and local energy transaction market starts to be emerged. To better investigate the price-demand relationship for this local market operator (LMO) equipped with PV and energy storage, a bilevel optimization model is proposed where the goal is to optimize operation profit for LMO at upper level and bill payment for customers at lower level. Experimental results have shown that more cost savings and energy sharing level could be achieved.

4 - Trilevel Models and Reformulations for Preventing Tacit Collusion in Electricity Markets

Murat Elhuseyni, Sabanci University, Istanbul, Turkey, muratelhuseyni@sabanciuniv.edu, Guvenc Sahin, Emre Celebi

We consider a collusion model for competitive pool based electricity markets operated by an independent system operator (ISO), which aims to prevent tacit collusion among generators by changing market and network parameters. We have formed a game-theoretic model to represent the market clearing mechanism, where generators determine their bids in order to maximize their profit while ISO allocates power and determine locational marginal prices. The ISO's collusion prevention leads to a trilevel problem, which is already complex and difficult to solve. We provide equivalent reformulations and linearization methods to obtain results with reasonable computational time.

Advances in Large-Scale and Distributed Energy Generation

Sponsored: Energy, Natural Res & the Environment/Energy Sponsored Session

Chair: Alexandra M. Newman, Colorado School of Mines, Golden, CO, 80401, United States

1 - Optimal Policies for Dispatchable Solar Hybrid Energy

Phillip Buelow, Colorado School of Mines, Main Campus, Golden, CO, 80401, United States, pbuelow@mymail.mines.edu, Alexandra M. Newman

Concentrated solar power (CSP) towers are an emerging technology that utilize molten salt thermal energy storage to dispatch electricity during peak-market-priced hours. Hybridization of CSP, photo-voltaics (PV) and lithium-ion batteries offers a stable, price-competitive alternative to conventional grid-level energy production when informed by a mixed-integer linear program (MILP). The CSP-PV hybrid system's maximum effectiveness relies on an optimal operational and dispatch policy. We explore that MILP model's strategy and the impacts of subsystem design, environmental location, and component cost on the economics and policy regarding renewable energy market penetration.

2 - Optimizing Mirror-washing Assignments for Concentrating Solar Power Central Receiver Plants

Jesse Wales, Colorado School of Mines, Golden, CO, 80401, United States, jwales@mymail.mines.edu, Alexander Zolan, Alexandra M. Newman, Michael J. Wagner

Concentrating solar power central receiver plants use thousands of sun-tracking mirrors to reflect the heat from sunlight to a central receiver, which is collected and used to generate electricity. Over time, soiling reduces the reflectivity of the mirrors and, therefore, the efficiency of the system. We present a mixed-integer linear program that assigns wash crews to mirrors to minimize the sum of (i) the revenues lost due to soiling, (ii) the costs of hiring full-time and seasonal wash crews, and (iii) the costs of purchasing wash vehicles.

3 - Generation and Transmission Planning with Decentralized Distributed Resource Decision Making

Nan Zhang, PhD Student, The University of Texas at Austin, Austin, TX, United States, Juan Pablo Carvallo, Benjamin Leibowicz, Peter Larsen, Sean Murphy

Increasing deployment of distributed resources is challenging traditional power sector planning paradigms. In this paper, we formulate and implement an integrated generation and transmission planning model that separates distributed resource investment and dispatch decisions from centralized, utility-scale decisions. We focus on a single electric utility as a case study and experiment with different decision making structures, sequences of player decisions, and retail rate structures.

4 - Capacity Expansion Problem Considering Reserve Provision by Wind Power and Storage Units

Miguel Carrión, Universidad de Castilla-La Mancha, Toledo, Spain, Miguel.Carrion@uclm.es, Miguel Cañas-Carretón

The active participation of wind power units in the ancillary services has increased significantly during the last years. Considering this, we formulate a capacity expansion problem considering that wind power units and storage facilities are able to provide reserve. To this end, we assume that wind power units can follow a maximum power point track strategy or a deloaded one. The uncertainty associated with wind speed forecast is also considered. The proposed formulation is tested on a realistic case study that is based on an actual isolated power system in Spain.

5 - Optimal Sizing of a Hybrid Energy Storage System Operated on a Microgrid Using Climate Data Analytics

Fei Sun, Graduate Research Assistant, Texas state university, San Marcos, TX, United States, f_s38@txstate.edu, Tongdan Jin, Clara Novoa

The optimal sizing of a microgrid system that integrates Li-ion battery and supercapacitor is studied. The objective is to minimize the system investment and operating cost. The reliability criterion and time-of-use rate scheme are considered to achieve the carbon neutral goal. The hybrid system provides high energy density capacity to store renewable energy and smooths the quick fluctuations of load with high power density.

Sponsored Session

Chair: Kai Pan, Hong Kong Polytechnic University, Kowloon, Hong Kong

1 - EGRET: Electrical Grid Research and Engineering Tools

Bernard Knueven, Sandia National Laboratories, Albuquerque, NM, 87185-1326, United States, Michael Lee Bynum, Anya Castillo, Carl Laird, Jean-Paul Watson

EGRET is a Python-based package for electrical grid optimization based on the Pyomo optimization modeling language. EGRET is designed to be friendly for performing high-level analysis (e.g., as an engine for solving different optimization formulations), while also providing flexibility for researchers to rapidly explore new optimization formulations. This talk will focus on EGRET's unit commitment capabilities.

2 - The Future of Natural Gas Infrastructure in North America

Sauleh Ahmad Siddiqui, Johns Hopkins University, Baltimore, MD, 21218, United States, siddiqui@jhu.edu, Charalampos Avraam, Felipe A. Feijoo, Gokul Iyer

Low-cost supply from shale gas production along with the transition to a low-carbon economy has led to natural gas becoming the main fuel for electricity production in North America, and the leading source for electricity production in both the United States. In this presentation, we will examine inter-state natural gas pipeline infrastructure development in the US under different long-term socioeconomic scenarios by coupling the Global Change Assessment Model (GCAM-USA), an integrated assessment model, with NANGAM.

3 - On the State of the Art in Stochastic Unit Commitment: Software, Algorithms, and Challenges

Jean-Paul Watson, Sandia National Laboratories, Livermore, CA, 87113-2065, United States, jwatson@sandia.gov

Over the past decade, researchers have made significant progress toward modeling and solving industrial-scale stochastic unit commitment problems in operational run times. In this talk, we outline key advances over this period, and discuss recent research by the speaker and his collaborators.

4 - Tight-and-cheap Conic Relaxations for AC Optimal Power Flow and Optimal Reactive Power Dispatch

Miguel F. Anjos, University of Edinburgh, School of Mathematics, James Clerk Maxwell Building, Edinburgh, EH9 3FD, United Kingdom, anjos@stanfordalumni.org, Christian Bingane, Sébastien Le Digabel

The classical alternating current optimal power flow problem is nonconvex and generally hard to solve. We propose a new conic relaxation obtained by combining semidefinite optimization with RLT. The proposed relaxation is stronger than the second-order cone relaxation, nearly as tight as the standard semidefinite relaxation, and up to one order of magnitude faster than for the semidefinite chordal approach on benchmarks with up to 6515 nodes. We extend the approach to optimal reactive power dispatch with similar results and performance.

5 - Coordinating Electricity and Gas Markets

Kai Pan, Hong Kong Polytechnic University, M507a, 5/F, Li Ka Shing Tower, Kowloon, Hong Kong, kai.pan@polyu.edu.hk, Ming Zhao, Chung-Lun Li, Feng Qiu

We consider an independent power producer (IPP) that uses natural gas to generate electricity and participates in the wholesale electricity market. Optimal policy for the IPP to coordinate the electricity and gas markets are derived. Extensive case studies are conducted to show algorithmic efficiency and managerial insights.

Supply Chain Management V

Contributed Session

Chair: Abhishek Roy, Temple University, Fox School of Business, Philadelphia, PA, 19122, United States

1 - The Effect of Flexibility on the Benefits of Sales and Operations Planning

Juan Antonio Cedillo, Instituto Tecnológico y de Estudios Superiores de Monterrey, Monterrey, NL, Mexico, A00997352@itesm.mx, Neale R. Smith, González-Ramírez Rosa G.

Ongoing research in Sales and Operations Plannning focuses on the ability of companies to respond to demand uncertainty. This paper proposes a mathematical model to evaluate the quantitative relation between demand forecast error and flexible capacity of a production system by evaluating their impact on plan performance. In order to prove its usefulness, the model was applied to a make-to-order system. Preliminary results are presented.

2 - Production Time Variation Coordination in Prefabricated Construction

Yue Zhai, Beijing Jiaotong University, Beijing, China, zhaiyue@bjtu.edu.cn, Xiang Fang, Linjing LI

An on-site production time variation reduction (OPTVR) coordination is studied between a general contractor (GC) and a building contractor (BC). In order to entice the BC to adopt the OPTVR strategy, a buffer space hedging (BSH) method is offered by the GC. The BSH is to reserve more spare space at an intermediate warehouse serving for contingency usage. It can be an incentive to the BC, for site congestion always happens and causes serious project time and cost overrun. A Nash game and a BC leaded Stackelberg game are investigated. It is demonstrated that these two models successfully reduce the OPTVR amount while enable a win-win outcome.

3 - Social Media Trend Analysis for Fashion Supply Chain

Olena Rudna, Rutgers University, Newark, NJ, United States, omr20@rutgers.edu

An accurate demand planning is among the biggest challenges for fashion apparel companies. Fashion buyers have to forecast sales for their products on a near real-time basis (a very short lead time) and also with a very limited amount of data (due to the short selling season of the related to forecasting demand data). In order to reduce uncertainty in demand planning while minimizing product obsolescence, we propose to utilize fashion trend information derived from online social network such as Twitter and embed it to forecasting models to strengthen prediction accuracy.

4 - Equilibrium Production Decisions for Multi-firms Considering Consumers' Quality Preference

Xin Liu, Elon University, Elon, NC, United States, xliu3@elon.edu, Xiaoya Han

In this study, we consider multiple firms competing non-cooperatively in a market under the consideration of consumers' diversified preferences for product quality. We model the problem to investigate equilibrium production decisions of these firms and explore the effect of consumer quality preference on their decisions.

5 - Trust in Supply Chain with Double Marginalization

Xianghua (Jason) Wu, College of business, University of Texas-Arlington, Arlington, TX, United States, xianghua.wu@mavs.uta.edu, Kay Yut Chen

We examine the role of information sharing, as well as the roles of trust and trustworthiness in a setting that captures both of the double marginalization (DM) and capacity misaglinment (CM) problem. We first characterize information sharing's trade-off between these two problems. Secondly, we employ the trust-embedded model and find that, similar to information sharing, trust is not always beneficial to the supply chain. Similarly, we characterize the trade-off between too little, and too much trust. However, the most counter-intuitive result is that an untrustworthy retailer can manipulate a trusting supplier, which reduces the double marginalization problem, and benefits the supply chain.

6 - Seeking the Value in Leftovers: An Analysis of the Procurement and Pricing Decisions Involving Stock-lots

Abhishek Roy, Temple University, Fox School of Business, Philadelphia, PA, 19122, United States, abhishek.roy@temple.edu, Vishwakant Malladi, Changseung Yoo

Low and medium-sized merchants often seek to buy stock-lots, or merchandise from liquidation lots, which have the potential to provide a "great bargain", as well as an environment-friendly way to reduce wastage. The stock-lots sellers use this channel to liquidate excess finished goods inventory, lower quality products, returns, as well as work-in-progress inventory. Because of the non-traditional nature of the channel, the quality of supply, and the customers' demand, are both uncertain, and the cost of carrying inventory is very high. Departing from the usual newsvendor assumptions, we analyze the merchant's strategic procurement and pricing decisions under such both-sided uncertainties.

1 - Marketing the Cloud

Xianrong Zheng, Old Dominion University, Norfork, VA, United States, x1zheng@odu.edu

As cloud services become increasingly popular, cloud providers compete to offer the same or similar services over the Internet. Quality of Service (QoS), which describes how well a cloud service is performed, will be more important. QoS refers to nonfunctional properties of cloud services, and is an important differentiator among functionally equivalent cloud services. As a result, how to use QoS to differentiate and market cloud services becomes an important topic in both IT and business disciplines. We review the state of the art, report our latest work, and discuss future research directions and challenges on the topic.

2 - How It Business Spanning Capability Moderates the Effects of It Infrastructure Capabilities on Organizational Agility

Jinlong Zhang, Huazhong University of Science and Technology, Wuhan, China, Peiran Gao

3 - Two-sided Adverse Selection and Bilateral Reviews in the Sharing Economy

Murat M. Tunc, PhD Student, University of Texas-Dallas, Richardson, TX, United States, murat.tunc@utdallas.edu, Huseyin Cavusoglu, Srinivasan Raghunathan

Online peer-to-peer platforms elicit relevant information from and also disclose the information to the market participants by adopting bilateral review schemes. Although the bilateral review scheme has its own merits in reducing information asymmetry, its impact on the various stakeholders remains unexplored. We show that the bilateral review scheme intensifies price competition among service providers to attract low-cost consumers and reduces the platform's profit. Interestingly, service providers may be better off when the proportion of low-cost consumers is sufficiently high. More importantly, we find that social welfare is not always higher under the bilateral review scheme.

4 - Lemonads: Impression Quality in Programmatic Advertising

Francesco Balocco, Rotterdam School of Management-Erasmus University, Rotterdam, Netherlands, balocco@rsm.nl, Ting Li

Advertisers and publishers typically transact through Reservation contracts, Real Time Bidding (RTB), or a mixture of the two. The co-existence of multiple transaction methods is problematic since impression quality is difficult to assess. We use viewability as a proxy for impression quality. We show that publishers who engage in both Reservation Contracts and RTB offer higher quality impressions through Reservation Contracts while allocating the remaining lower quality impressions to RTB. By doing so, publishers can leverage on asymmetric information on impression quality to extract excess profit from advertisers.

Operations Management I

Contributed Session

Chair: Qiaohai Hu, University of Missouri

1 - Improving Personnel Management Decisions through IT Platforms and Data Analytics

Constantine Moros, Director - Advisory Services, E Y. (Ernst & Young) - Advisory Services, Athens, Greece, kmoros76@gmail.com

Managing workforce, one of the most critical resources for organizations operating within service industries, is undoubtedly becoming more challenging and complicated as technological advancements are accelerating and subsequently competition is growing. This practitioner article provides a conceptual framework and methodology for measuring, assessing and planning workforce capacity utilization in a more accurate and dynamic way,where operational research, data analytics and relevant IT transformation opportunities are exploited with the end-target of optimizing workforce productivity and efficiency levels.

2 - Price Information Asymmetry in Agricultural Contract Farming

Sreehari Karnam, Indian Institute of Management, Indore, India, f15sreeharik@iimidr.ac.in, Hasmukh Gajjar, Bhavin J. Shah

Despite very little success rate, contract farming still has been a growing practice in many countries as this practice protects both the food processing companies and the farmers from the uncertainties of supply and price. However, in the processed food sector, the processing companies who contract with farmers are exploiting the farmers by paying less to the farmers for the raw material (crop) and gaining more by selling the end product at a higher price. Due to this information asymmetry of end product prices, the farmers being unaware of the prices, unable to bargain, are exploited by not paying in the proportion of end product prices which needs further analysis to seek modeling solutions.

3 - Location Model for Cultural Facilities with the Consideration of Equity and Efficiency

Chaesung Lee, Kyungpook National University, Daegu, Korea, Republic of, cotjd3247@knu.ac.kr, Sukran Kim, Jaewoo Chung

This paper proposes a bi-criteria location model that uses spatial equity and efficiency as the criteria for public cultural facilities based on Getis-Ord Local G statistic and Gravity Model respectively. Clusters of cultural facilities such as museums and art galleries have synergies through a positive association for higher efficiency. Also, given the investment of huge public funds into public cultural facilities, the issue of social equity is important. The results of this study suggest that optimal location for cultural facilities serve as a catalyst for urban regeneration and achieving sociality.

4 - A Case Study of Demand Forecasting with Data Mining Methods for New Short-life-Cycle Products

Rie Gaku, Momoyama Gakuin University, Osaka, Japan, r-gaku@andrew.ac.jp, Soemon Takakuwa, K. Louis Luangkesorn

A major challenge for suppliers of small retail stores is how to improve a turnover rate of merchandise during a set period of time, and how to continue efforts to both ensure the availability of popular products as well as having a variety of product to satisfy multiple customer demand segments. Forecasts of product demand over its life cycle are needed for the production control system, end-of-life planning, and planning of product cycles during operational planning. This paper conducted a case-study of demand forecasting with Data Mining methods for new short-life-cycle products aiming to presenting how forecasting results can be incorporated into the operational planning process.

5 - Capacity Investment and Innovation with Renegotiation

Qiaohai Hu, University of Missouri-St. Louis, St. louis, MO, United States, huqiao@umsl.edu

This paper identifies initial contracts to induce the supplier to choose the first-best capacity investment and innovation decisions when it anticipates possible ex-post renegotiation with the buyer. Neither advance quantity commitment contracts nor price contracts yield the first-best decisions. The supplier will over-invest in cost reduction but under-build the specialized capacity under the quantity-only contract, whereas it will under-invest but over-build the specific capacity under the price-only contracts. There exist a quantity-and-price contract and a schedule of options contracts that align the supplier's interest with the channel's with or without ex-post renegotiation.

Sponsored Session

Chair: Maxim Dulebenets

1 - Understanding the Major Factors Affecting Emergency Evacuation Efficiency via Driving Simulation

Maxim A. Dulebenets, Florida A&M University-Florida State University, Tallahassee, FL, 32311, United States, mdlbnets@gmail.com, Olumide Abioye, Eren Erman Ozguven, Ren Moses, Walter Boot, Thobias Sando

Evacuation planning is an essential part of natural hazard preparedness, especially in hazard-prone areas. This study aims to fill the existing gap in the state-of-the-art by investigating the effects of a wide range of different factors on the travel time, lane deviation, crash occurrence, collision speed, average acceleration and brake pedal pressure of individuals under emergency evacuation. A set of statistical models is developed to identify the most significant factors that influence the aforementioned indicators. These models are tested using the driving simulator data.

2 - Assessing the Effects of Emergency Evacuation on Vulnerable Population Groups Using a Driving Simulator

Maxim A. Dulebenets, Florida A&M University-Florida State University, Tallahassee, FL, 32311, United States, mdlbnets@gmail.com, Olumide Abioye, Eren Erman Ozguven, Ren Moses, Walter Boot, Thobias Sando

A frequent occurrence of natural hazards underlines the importance of efficient hazard preparedness, especially in the areas with aging adults. The present study proposes a set of statistical models, developed based on driver characteristics, evacuation route characteristics, driving conditions, and traffic characteristics. The required data are collected using a driving simulator and a diverse group of participants with various socio-demographic characteristics. Mental demand, physical demand, frustration of evacuees, and other important indicators are captured by the proposed models.

3 - "Factory-in-a-Box": Towards Intelligent Manufacturing and Supply Chain Management

Maxim A. Dulebenets, Florida A&M University-Florida State University, Tallahassee, FL, 32311, United States, mdlbnets@gmail.com, Hui Wang, Zhengqian Jiang, Junayed Pasha

As the market demand becomes more diversified, the requirements for manufacturing systems feature a high degree of flexibility and short delivery times. One emerging way is "factory-in-a-box," by which manufacturing modules are transported by vehicles for on-site production. This study presents a model to jointly characterize the topology of supply chain network and subassembly planning. A mathematical model is formulated for the concurrent optimization of subassembly planning and supply chain network. Potential applications and advantages of the proposed methodology are discussed.

4 - Multi-Objective Heuristic Algorithms for Planning Emergency Evacuation in Areas with an Aging Population

Maxim A. Dulebenets, Florida A&M University-Florida State University, Tallahassee, FL, 32311, United States, mdlbnets@gmail.com, Olumide Abioye, Masoud Kavoosi, Junayed Pasha, Eren Erman Ozguven, Ren Moses, Walter Boot, Thobias Sando

Many U.S. coastal areas, which are characterized with a significant presence of vulnerable populations (e.g.., aging adults), often experience natural hazards. In order to facilitate emergency evacuation planning, this study proposes a set of multi-objective heuristic algorithms for assigning evacuees to the available evacuation routes and emergency shelters, considering socio-demographic characteristics of evacuees, which may further affect their driving ability. Numerical experiments are conducted to evaluate the proposed solution algorithms using real life emergency evacuation scenarios.

1 - AUC Maximization for Binary Classification Using Combinatorial Benders Cuts

Edhem Sakarya, Ozyegin University, Istanbul, Turkey, edhem.sakarya@ozu.edu.tr, Erhun Kundakcioglu

The purpose of this study is to maximize the area under Receiver Operating Characteristic curve for binary classification using a scoring-based mixed integer linear programming formulation. We investigate exact approaches using a reformulation, combinatorial Benders cuts, and heuristic bounding methods. Our study presents computational results on benchmark data sets and paves the way for future studies on scoring-based approaches.

2 - A Risk Based Approach for Minimum Variance Ensemble Learning Algorithms

Petros Xanthopoulos, Assistant Professor, Stetson University, DeLand, FL, 32723, United States, pxanthopoulos@stetson.edu, Ramazan Unlu

In unsupervised learning local optimality of algorithms cause significant performance variability for multiple runs on a given dataset. In this paper we demonstrate a method for controlling this variability by employing optimal portfolio theory. We also discuss the tradeoff between variance and performance.

3 - Uncertainty-aware Neural Networks for Medical Image Analysis

Seonho Park, University of Florida, Gainesville, FL, United States, seonhopark@ufl.edu, Panayote (Panos) M. Pardalos

Deep learning has attracted a lot of attention in various fields of engineering because of its accuracy surpassing human level. Most of the deep learning generates deterministic predictions which might be harmful especially in the critical systems such as physician diagnosis of disease, and autonomous vehicles system. To tackle this problem, we revisit the Bayesian or non-Bayesian approaches to obtain practical uncertainty estimates in deep learning. Especially, we present approaches to give uncertainty measures to applications in medical image analytics.

4 - Pattern-based Classification with Uncertainty

Ruilin Ouyang, Northeastern University, Boston, MA, United States, ouyang.ru@husky.neu.edu, Chun-An Chou

Logical analysis of data (LAD) is a data analysis methodology for classification based on combinatorial patterns of binary data. Pattern generation is a building block in LAD and highly impacts the classification performance. However, data are usually in a numerical format with uncertainty in most real-life classification problems, e.g., medical diagnosis and fault classification in manufacturing process. In this study, we propose a robust chance-constrained programming model for pattern generation and also develop an efficient solution approach based on model reformulation.

5 - Graph-based Clustering Analysis of Semantic Spaces

Vladimir Boginski, Associate Professor, University of Central Florida, Orlando, FL, United States, Vladimir.Boginski@ucf.edu

We present our recent results on graph-based exploration and clustering analysis of semantic spaces.

Chair: Gourab Mukherjee

1 - Large-scale Joint Modeling of Player Attributes in Freemium Mobile Games

Gourab Mukherjee, University of Southern California, Marshall School of Business, University of So, Los Angeles, CA, 90089-0809, United States

We develop a Constrained Extremely Zero Inflated Joint (CEZIJ) modeling framework for simultaneously analyzing player activity, engagement and drop-outs (churns) in app-based mobile freemium games. Our proposed framework addresses the complex interdependencies between a player's decision to use a freemium product, the extent of her direct and indirect engagement with the product and her decision to permanently drop its usage. CEZIJ extends the existing class of joint models for longitudinal and survival data in several ways.

2 - Changing the Power Equation: A Structural Analysis of the Impact of Used Cars on the Automobile Distribution Channel

Sivaramakrishnan Siddarth, University of Southern California, Marshall School of Business, Los Angeles, CA, 90089-1424, United States, siddarth@marshall.usc.edu, Dinakar Jayarajan, Jorge Mario Silva-Risso

Most new car dealers also sell used cars from the same physical location. We formulate a structural model of the demand and supply of new and used cars and estimate its parameters using transaction data from the mid-sized sedan segment to gain insights into the nature of competition between new and used markets. On the demand side, we find that new car prices have a higher impact on used car sales than vice versa. On the supply side we compare channel profits when dealers price new and used cars jointly to those realized when pricing decisions are independent. We find that the ability to sell used cars enables new car dealers to gain more power in the distribution channel relative to manufacturers.

3 - The Effect of Demonetization on Digital Payments in India: Causal Inference in the Absence of Controls

Bikram Karmakar, PhD, University of Florida, Gainesville, Gainesville, FL, United States, Bhuvanesh Pareek, Dylan S. Small, Pulak Ghosh

On 8 Nov, 2016, the Government of India declared that two high denominations of the Indian Rupee would cease to be legal tender after midnight; 86% of the money in circulation was deemed illegal tender, resulting in a currency squeeze. We aim to assess the impact of demonetization on digitization. Specifically, we ask whether demonetization had a causal effect that led to adoption of digital payment methods and a surge in digital transactions across the country. In a quasi-experiment, we look for the differential effect of demonetization on the more affected group over the less affected. We analyze a unique retail data of more than 30 mil transactions made in a supermarket chain across three cities of India.

4 - Lease for Less: A Price Discrimination Model of Why Auto Manufacturers Subsidize Leases

Srabana Dasgupta, Simon Fraser University, Vancouver, BC, V5A 1S6, Canada, Sivaramakrishnan Siddarth, Srabana Dasgupta

Firms often offer multiple price/quality combinations of their products with the objective of segmenting the marketing between high and low valuation consumers. In the automobile industry, manufacturers can create such low- and high-quality variants of the same physical vehicle through financial instruments such as leasing and financing. To test our theory, we develop and estimate, using vehicle transaction data, a demand model that uses the distribution of mileage in the population to derive the share of leases relative to purchases for an individual brand and then incorporate this into a profit maximizing model of firm behavior to explain the price differential between leases and purchases.

Recent Developments of Statistical and Machine Learning Models with Business Applications

Sponsored: Data Mining

Sponsored Session

Chair: Wenbo Wu

1 - Prediction with Spatially Correlated Functional Covariates

Yeonjoo Park, University of Texas at San Antonio, San Antonio, TX, United States, yeonjoo.park@utsa.edu

We present a novel spatial model that predicts scalar responses based on functional predictors observed at spatial locations. We incorporate spatial information in modeling via three steps: dimension reduction by introducing low-rank latent variables, conducting spatial model selection, and fitting a Spatially Varying Coefficient Model (SVCM) which allows for varying impact of variables on responses over locations. To preserve spatial continuity among functional covariates on dimension reduction, we place a spatial dependent structure on estimated functional PC scores. Then model estimation and selection will be simultaneously performed through a Bayesian approach with spatial prior.

2 - Robust Estimation of Customer Churn under Competing Risks

Arkajyoti Roy, University of Texas at San Antonio, San Antonio, TX, United States, arkajyoti.roy@utsa.edu, Pallav Routh, Jeff Meyer

Uncertainties in the process of customer churn, such as competing risks and random customer behavior, can degrade churn predictions and limit the efficacy of churn management programs. We propose a competing-risk random survival forest for modeling risk of churn, which improves accuracy by 28% compared to conventional models. Furthermore, we identify relationships between risk of churn and customer behavior without relying on specific functional forms or underlying distributions.

3 - Model Confidence Bounds for Model Selection

Yichen Qin, University of Cincinnati, Cincinnati, OH, United States

We introduce the concept of model confidence bounds (MCB) for model selection in the context of nested models. MCB identifies two nested models (upper and lower confidence bound models) containing the true model at a given level of confidence. MCB proposes a group of nested models as candidates and the MCB's width and composition enable the practitioner to assess the overall model selection uncertainty. A new graphical tool —- the model uncertainty curve —- is introduced to visualize the variability of model selection and to compare different model selection procedures. Our Monte Carlo simulations and real data examples confirm the validity and illustrate the advantages of the proposed method.

4 - Sufficient Variable Screening via an Independence Index

Qingcong Yuan, Miami University, Oxford, OH, United States, qingcong.yuan@miamioh.edu

Variable screening is very popular in modern data analysis and is particular useful for large p small n data. In this paper, we propose a novel two-stage sufficient variable screening procedure, especially when the response is categorical. This procedure is very general and model-free, thus is robust against model mis-specification. In addition, our procedure always improves existing screening approach in literature which only uses marginal relation. Numerical studies are provided to demonstrate the advantages of the method.

Obtaining Benefits and Avoiding Pitfalls When Implementing Data Mining in Your Firm.

Sponsored: Data Mining

Sponsored Session

Chair: Vladimir Kovtun

Co-Chair: Ian Mouzon

1 - Aggregating Demand Streams Efficiently While Minimizing Increase in Forecasting Error

Vladimir Kovtun, Yeshiva University Sy Syms School of Business, New York, NY, 11375, United States, kovtunv@gmail.com, Avi H. Giloni, Sridhar Seshadri

Often firms will aggregate demand across many possible demand streams and generate one (or several) demand forecast. This is usually done based on some unifying customer characteristic(s). We propose several algorithms for clustering demand streams based on the similarity of the ARMA models which govern them. In one such approach, streams are moved from one cluster to another if certain optimization criteria are met. Another algorithm determines an objective function and utilizes a constrained non-linear minimization technique to find the best clustering assignment. These algorithms lead to (or near) a global optimum with the best forecast accuracy among all possible clustering assignments.

2 - Interpretable Prediction with Text

Yuan Cheng, Cornell University, Ithaca, NY, 14850, United States, yc956@cornell.edu, Shawn Mankad

Analyzing text for business applications requires interpretable summaries in addition to prediction accuracy. We propose a new constrained matrix factorization model, which balances maximizing statistical and predictive power of regression models with capturing the underlying textual themes. We validate the effectiveness of our proposed model in terms of the combined goal with a comprehensive benchmarking study with online reviews.

3 - Counterfactual Explanations for Data-driven System Decisions

Carlos Fernandez, Stern School of Business, NYU, New York, NY, United States, cfernand@stern.nyu.edu, Foster Provost, Xintian Han

This paper proposes to explain system decisions by defining an explanation as a set of inputs that is causal (meaning that removing them changes the decision) and irreducible (meaning that removing any subset of the inputs in the explanation does not change the decision). Our explanations are designed to explain system decisions rather than model predictions and can incorporate inputs with arbitrary data structures. We also show how model-agnostic algorithms can be tweaked to find the most useful explanations depending on the context. Finally, we showcase our approach using real data to illustrate its advantages over other methods when the goal is to understand system decisions better.

4 - “Data Nuggets” Tools for Clustering Big Data

Javier Cabrera, Rutgers University, Newark, NJ, United States

Standard clustering algorithms require pairwise distance calculation which limit the number of observations to around 100K in a basic computer, which is too small when confronted with huge datasets found in modern business applications. Possible solutions to this are to use a random sample or (more recently) to generate a set of “support vectors”. These may not be adequate however since the structure of the dataset is not guaranteed to be captured very well. We present a new solution through the concept of “data nuggets”. These will reduce a very large dataset into a small collection of nuggets of data, each containing a center, weight, and a scale parameter. With these we may apply algorithms that compute standard unsupervised and supervised statistical methods, such as clustering.

Predictive Analytics in Healthcare

Sponsored: Data Mining

Sponsored Session

Chair: Afrin Kahkashan

1 - Heterogeneous Recurrence Quantification Analysis for Images – in Healthcare Application

Cheng-Bang Chen, The Pennsylvania State University, State College, PA, 16801, United States, czc184@psu.edu, Hui Yang, Soundar Kumara

The recurrence dynamics of image textures provide rich information of the corresponding objects. To characterize the recurrence features of the image data, we propose a novel approach utilizing the network presentation and fractal representation to quantify the heterogeneous recurrences of the image data. Experimental results illustrate that the proposed approach yields superior performance in the extraction of salient features to distinguish different characters of a system.

2 - Nested Gaussian Process Modeling and Imputation of High Dimensional Incomplete Data under Uncertainty

Farhad Imani, The Pennsylvania State University, State College, PA, 16802, United States, Changqing Cheng, Ruimin Chen, Hui Yang

Missing values exist pervasively for intensive care unit (ICU) variables pertinent to a patient’s health condition. This adversely affects time-critical decision making in patient care. This paper presents a novel nested Gaussian process (NGP) model that is tailored to represent multi-dimensional covariance structure of time, variable and patient for high-dimensional data imputation. We evaluate and validate the proposed NGP method on real tensor-form ICU data with high-level missing information. Experimental results show that the proposed methodology handles the data uncertainty in ICU settings, which helps further improve biomarker extraction, patient monitoring and decision making.

3 - Advanced Survival Analysis for Mortality Prediction of High Dimensional Multi-view Datasets

Kahkashan Afrin, Texas A&M University, College Station, TX, 77840, United States, afrin@tamu.edu, Satish Bukkapatnam

Critical applications such as life expectancy prediction rely on the accuracies of survival models. However, these accuracies are compromised by model and data limitations such as proportional hazard assumption and the curse of imbalance and dimensionality. To address these limitations, we propose a survival analysis model using a Bayesian framework with shrinking and diffusing prior for addressing high dimensionality and selective balancing techniques for addressing the extreme imbalance in the survival datasets. Investigations using genomic and mortality dataset suggest that the proposed model provides improved performance over the traditional proportional hazards model.

4 - Effects of Outliers and Robust Logistic Regression Tree

Doowon Choi, Texas A&M University, College station, TX, United States, Li Zeng

This study investigates effects of outliers in logistic regression tree (LRT) modeling of binary outcome data in healthcare applications and develops a robust logistic regression tree (RLRT) approach that can alleviate those effects. The effectiveness and advantages of the proposed method is demonstrated in a case study using dataset on cardiac surgeries.

5 - Estimate the Complexity of Multichannel EEG Signals Using Multivariate Multiscale Entropy

Shaodi Qian, Northeastern University, Boston, MA, United States, qian.shao@husky.neu.edu, Miaolin Fan

Understanding the complexity of physical and physiological time series are important for investigating into the signal generating mechanisms. The multivariate multiscale entropy (MMSE) provides a tool for estimating the long-term regularity of multichannel signals over various time scales. In this study, we aim to explore the capability of MMSE as a quantitative method to characterize the nonlinear dynamics of human scalp electroencephalography (EEG). Two datasets were used for testing our model via discriminating patients with neurological disorders from healthy controls using the MMSE features.

Panel: Combatting the Epidemic: Opioid Data Integration & Mining II

Sponsored: Data Mining

Sponsored Session

Chair: Matthew Hudnall

1 - Evaluating Interventions for Opioid Abuse in Rural underserved Populations

Lesley Clack, Assistant Professor, University of Georgia, Athens, GA, 30607, United States, lesley.clack@uga.edu

While many potential interventions for treating substance abuse exist, their efficacy can vary greatly across locations, populations, and types of addictions. Research on the efficacy of predicting intervention strategies in rural/underserved opioid populations is limited. The goal of this research study was to explore and rigorously define the spectrum of available intervention strategies for opioid abusers in rural/underserved communities in order to be able to evaluate the potential effectiveness of each intervention strategy using statistical tools and relevant empirical evidence.

2 - Medical Claims Data Mining in the Early Stages of Opioid Use

Katherine Bobroske, University of Cambridge, Trumpington Street, Cambridge, CB2 1AG, United Kingdom, kab80@jbs.cam.ac.uk

Medical and pharmaceutical claims provide a rich basis for studying how healthcare delivery design impacts a patient's opioid use. We integrated the claims sets of a US company (that hosts data for approximately 3.5 million patients) to infer the medical context of the patient's opioid use journey. Our research focuses on two key areas related to early-stage opioid use: (1) the impact of utilizing opioids as first-line therapy in preference-sensitive conditions and (2) whether continuity of care (typically promoted for managing chronic opioid patients) or a second opinion (by a clinician other than the original opioid prescriber) is more effective in curbing long-term dependence.

3 - Panelist

Ebrahim Mortaz, Pace University, New York, NY, 10038, United States, emortaz@pace.edu, Ali Dag

Drug overdose is the leading cause of accidental death in the United States, and opioid addiction drives this epidemic. In this talk, we propose a data analytics framework that aims to offer the best possible prediction for the opioid prescription for post-op orthopedics procedures. The proposed framework includes machine learning algorithms accompanied by feature selection efforts based on genetic algorithm and particle swarm optimization.

Recent Developments in Optimization for Machine Learning

Emerging Topic: Artificial Intelligence & Machine Learning

Emerging Topic Session

Chair: Raghu Bollapragada, Northwestern University, Evanston, IL, 60201, United States

1 - Recent Results in Sub-sampled Second Order Optimization Methods

Michael W. Mahoney, University of California-Berkeley, Berkeley, CA, United States

Sub-sampling has proven to provide a way to develop scalable optimization algorithms for many machine learning problems. Most work has focused on first order algorithms, e.g., stochastic gradient descent, but recent work has focused on sub-sampled Newton-type methods. We will describe the motivation, several recent theoretical results, and how the theory is used in several machine learning applications.

2 - Adagrad Stepsizes: Sharp Convergence over Nonconvex Landscapes

Xiaoxia (Shirley) Wu, University of Texas at Austin, Austin, TX, United States, xwu@math.utexas.edu

Adaptive gradient methods (AdaGrad) have gained widespread use in large-scale optimization for their ability to converge without the need to fine-tune parameters. Yet, the theoretical guarantees to date for AdaGrad are for convex optimization. We bridge this gap by providing strong theoretical guarantees for the convergence of AdaGrad over smooth, nonconvex landscapes. We show that the norm version of AdaGrad (AdaGrad-Norm) converges at the $O(\log(N)/\sqrt{N})$ rate in the stochastic setting and at the $O(1/N)$ rate in the batch setting. Both our theoretical and numerical results imply that AdaGrad-Norm is robust to the unknown Lipschitz constant and level of stochastic noise on the gradient.

3 - Quasi-newton Methods for Deep Learning: Forget the Past, Just Sample

Albert Solomon Berahas, Lehigh, Bethlehem, PA, 18018, United States, albertberahas@lehigh.edu, Majid Jahani, Martin Takac

In this talk, we present two sampled quasi-Newton methods for deep learning: sampled LBFGS and LSR1. Contrary to the classical variants of these methods that sequentially build Hessian approximations as the optimization progresses, our proposed methods sample points randomly around the current iterate at every iteration to produce these approximations. As a result, the approximations constructed make use of more reliable (recent and local) information. We provide convergence guarantees for the methods, discuss possible large-scale parallel/distributed implementations and illustrate their performance on several neural network training task.

4 - Towards understanding Embeddings and Optimization for Deep Neural Recommendation Systems

Hao-Jun M. Shi, Northwestern University, Evanston, IL, United States, hjmshi@u.northwestern.edu

Modern recommendation systems exploit categorical features by representing each feature by an embedding vector prior to passing this through a neural network architecture. Notably, these embeddings are simultaneously trained with the network parameters. The presence of these large embedding tables yields high-dimensional optimization problems (in the order of tens of billions), sparsity of the activations and gradients, and a mysterious phenomenon when training over multiple epochs. I will present my recent work on reducing the dimension of these models, understanding the multi-pass training phenomena, and devising specialized algorithms for training recommendation models.

Deep Learning and Neural Networks

Sponsored: Artificial Intelligence

Sponsored Session

Chair: Maria Calisto

Co-Chair: Susana Lai-Yuen, University of South Florida, Tampa, FL, 33620, United States

1 - Adapting an Ensemble of Fully Convolutional Networks with Multiobjective Evolutionary Optimization

Maria Baldeon Calisto, University of South Florida, Tampa, FL, 33647, United States, mariabaldeon@mail.usf.edu, Susana Lai-Yuen

Deep learning methods have become very successful at solving complex tasks. However, given the vast number of hyperparameters and massive search space, finding the proper configuration for a problem requires extensive experience and time. In this work, we propose an ensemble of Fully Convolutional Networks (FCNs) that adapts to a particular 3D image dataset through a multiobjective evolutionary-based algorithm, which minimizes both the model s error and size. The ensemble is comprised of a 2D FCN that extracts intra-slice information, and a 3D FCN that exploits inter-slice information. The model is evaluated on the complex problem of 3D medical image segmentation.

2 - Neural Networks for Prediction of HIV Incidence in Compartmental Modeling

Hanisha Tatapudi, University of South Florida, Tampa, FL, 33647, United States, tatapudi@mail.usf.edu, Seyedeh Nazanin Khatami, Chaitra Gopalappa

The annual number of new HIV infections is a key metric of decision-analytic models for evaluating HIV control strategies. Agent-based models (ABM) and compartmental models are commonly used simulation tools for such analysis, however, they're computationally inefficient and fail to capture non-linear dynamics of contact structures, respectively. We test the fidelity of training a neural network (NN) for prediction of new infections, using ABM samples, to replace the regression model in compartmental models. This hybrid model is key to analyzing 'how to reach zero new HIV infections in the US?'. We use dropout, a regularization method, to transform the deterministic NN to a stochastic model.

3 - Deep Learning Based Technique for Imaging Biomarker Identification Using 3D Kidney MRI

Yanzhe "Josh" Xu, Arizona State University, Tempe, AZ, United States, yanzhexu@asu.edu, Teresa Wu, Fei Gao, Jennifer Charlton, Kevin Bennett

Imaging biomarkers are being rapidly developed for early diagnosis and staging of disease. Detecting and segmenting objects from images are often the first steps in quantitative measurement of these biomarkers. The challenges of detecting objects in images, particularly small objects known as blobs, include low image resolution, image noise and overlap between the blobs. In this research, we propose a deep learning based technique, UH-DoG, to overcome these problems. Improved performance is obtained compared with other methods.

4 - Deep Reinforcement Learning Based Adversarial Evaluation of a Cyber Alert Management System

Ankit Shah, University of South Florida, Tampa, FL, United States

Timely analysis of cyber alerts is the primary goal of a cybersecurity operations center (CSOC). If the alerts remain unanalyzed for a long duration, malicious activities will persist in a network and cause serious damage. Recently, a reinforcement learning (RL) based defender system was proposed for near-optimal alert management at a CSOC in the wake of stochastic events. In this talk, we evaluate the defender's policy of actions by developing a deep RL based strategic adversary. The goal of the adversary is to learn the best policy of actions by interacting with the defender. Results show that by utilizing the concepts of experience replay and target network, adversary is able to outsmart the defender.

5 - Anomaly Detection in Deep Spatio-temporal Metamodeling for Cardiac Electrical Conduction Simulation

Xinyu Zhao, Arizona State University, Tempe, AZ, United States, xzhao119@asu.edu, Hao Yan, Zhiyong Hu, Dongping Du

Modeling and simulation have been widely used in both cardiac research and clinical study to investigate cardiac disease mechanism and develop new treatment design. However, the complexity of existing model makes the simulation time-consuming. This paper develops a new spatiotemporal model as a surrogate model of the time-consuming cardiac model. Specifically, we propose to investigate the auto-regressive convolutional neural network and convolutional long short-term memory to model the spatial and temporal structure for the metamodeling. The metamodel can accurately capture the properties of the individual cardiac cell, as well as the electrical wave morphology in cardiac fiber.

2019 SMA Best Student Paper Award

Sponsored: Social Media Analytics

Sponsored Session

Chair: Julie Zhang, University of Massachusetts-Lowell, Lowell, MA, 01854, United States

1 - SMA Best Student Paper Award

Theodore T. Allen, Ohio State University, Columbus, OH, 43210-1271, United States, allen.515@osu.edu

The Social Media Analytics Section of INFORMS announces the 2019 Best Student Paper Award to recognize excellence among its student members. Four finalists for the Best Student Paper Award will be selected to make presentations at the INFORMS Annual Meeting in Seattle, Washington. The winner will be announced at the Social Media Analytics business meeting later at the conference.

2 - Sympathy to the Seemingly Needy: Does Social Influence Alleviate Inequalities in Medical Crowdfunding?

Yun Young Hur, Georgia Institute of Technology, Atlanta, GA, 30312, United States, Fujie Jin

One major challenge in medical crowdfunding is the unequal chances of funding success. Cases with certain attributes that seem to be in greater need of help are usually more likely to receive donations. In this study, we first demonstrate the existence of donation inequalities. We present a potential explanation for such unequal chances based on the signaling theory and further propose that social influence potentially reduces donation inequality, by providing an additional signal of validity and funneling attention to cases that are likely overlooked otherwise. We conduct a large-scale randomized field experiment with a leading medical crowdfunding platform to examine whether leveraging social influence, through displaying friends' donation information, influences users' willingness to donate and how the impact differs for cases involving male and female patients. Our results show that social influence alleviates gender inequality in donations, particularly for cases lacking other strong signals such as involving patients of young age or with cancer-related conditions. On the other hand, presence of other strong case-level signals makes patient gender a redundant signal and therefore, social influence's impact on willingness to donate is likely similar across patient gender in these cases. Our findings on how social influence mitigates donation inequalities yield significant policy implications in promoting equality in medical crowdfunding.

3 - Does Social Media Speed Up Product Recalls? Evidence from Pharmaceutical Industry

Yang Gao, University of Rochester, Rochester, NY, United States, Huaxia Rui, Wenjing Duan

Social media becomes a vital platform to voice experiences or concerns related to products. Those voices not only provide signals of potential defects but also impose pressures on firms. Few systematic works have examined the influence of those voices from social media on product recalls. This study scrutinizes the relationship by focusing on the pharmaceutical industry since social media pharmacovigilance is becoming increasingly crucial for detecting drug safety signals. Using drug enforcement reports provided by FDA and social media data crawled from online forums and Twitter, we investigate whether social media can speed up drug recalls. The results derived from the discrete-time survival analysis suggest that more mentions on social media would lead to a higher hazard rate of being recalled and thus shorter time to recall. To better understand the underlying mechanism, we propose two effects: information and publicity effects and validate their impact with additional analyses. Collectively, this study proffers new insights for both managers and policymakers concerning the power of social media and its influence on product recalls.

4 - Detecting Customer Trends for Optimal Promotion Targeting

Tamar Cohen, Massachusetts Institute of Technology, Cambridge, MA, 02144, United States, Georgia Perakis

Trends can help retailers determine promotion plans. Social media data is essential for understanding these trends, but it is often unavailable. We introduce a demand model that captures these social interactions from transaction data. The resolting promotion targeting problem is NP-hard to solve, so we develop a greedy approach.

5 - The Effect of User Generated Content on Hotel Demand: The Role of Competitive Perception Spillovers

Sanghoon Cho, University of South Carolina, Columbia, SC, 29206, United States, Wang Jain, Pelin Pekgun, Ramkumar Janakiraman

We study the impact of user generated content (UGC) on hotel performance as measured by actual hotel bookings with a focus on the spillover effects from a focal hotel's competitors' UGC on its demand. Drawing on prospect theory, we cast the competitive perception spillovers of UGC as \gains" and \losses" in user reviews of the focal hotel, relative to its competitors. We propose a Bayesian learning model of consumers' dynamic updating of their perceptions of a hotel over time based on prior perceptions and new information in the form of UGC. To test our proposed model, we leverage a unique data set that has actual bookings of two hotel properties (of a major hotel chain) in two different markets in the United States. We supplement our unique data set with UGC garnered from a popular social media platform, TripAdvisor. We found that review sentiment, relative to competition, has a significant effect on a hotel's booking performance and that the relative negative sentiment (losses) has a higher influence on bookings than relative positive sentiment (gains). Specifically, we found that an increase in a hotel's positive (negative) sentiment score by one point, relative to competition, leads to 2.7% increase (4.5% decrease) in its bookings. To the best of our knowledge, our study is the first to quantify the effect of valence of UGC on hotel bookings. We propose and found evidence of the moderating effect of a hotel's own prices on competitive spillover effects. We also document sensitivities to price and UGC across different hotel customer segments. Our results provide hoteliers with new insights on how to leverage UGC for improved revenue management.

6 - A Twitter-Based Cyber Security Warning and Prioritization System

Enhao Liu, Ohio State University, Columbus, OH, 43210, United States, Theodore T. Allen

Cyber vulnerability management is difficult because there are more than 16,000 distinct vulnerabilities distributed across large numbers of hosts including PCs, laptops, printers, or even die casting or exercise machines. Fortunately, at any given time, only a tiny fraction of vulnerabilities are actually causing incidents. Further, by combining modeling, local data about vulnerabilities and incidents, and Twitter data, we demonstrate that warnings about specific vulnerabilities can likely provide enough specific intelligence to eliminate perhaps the majority of incidents. We use data from a Midwest university to demonstrate the system. The derived model predicting the probability an exploit exists for a Tweeted vulnerability, an indication of risk priority, has an AUC of 0.904 and the time series model to predict incident counts has all coefficients with p-values less than 0.05.

Reinforcement Learning and Data-Driven Control

Sponsored: Applied Probability

Sponsored Session

Chair: Daniel Russo, Columbia University, Northwestern University, New York, NY, 60208, United States

1 - Beating the Curse of Dimensionality in High-dimensional Options Pricing and Optimal Stopping

David Goldberg, Cornell University, Ithaca, NY, 14850, United States, dag369@cornell.edu, Yilun Chen

The fundamental problems of pricing high-dimensional options and optimal stopping are generally believed to be intractable, with modern ADP, duality, and simulation approaches either scaling poorly, requiring knowledge of basis functions, or having limited guarantees. We show that this general belief is incorrect, by developing the first algorithm which allows one to elegantly trade-off between accuracy and runtime through a parameter epsilon controlling the performance guarantee (analogous to a PTAS), with computational and sample complexity both polynomial in T (effectively independent of the dimension) for any fixed epsilon, in contrast to past methods which scale exponentially.

2 - The Optimality of Sparse Model Based Planning for Markov Decision Processes

Sham Kakade, University of Washington, Seattle, WA, United States

We study optimal planning in an MDP with samples using the most natural approach: we first find an optimal policy using a "plug-in" estimated model, where we use the maximum-likelihood model estimate from observed transitions, and then we consider the optimal policy in our estimated model. We show that that is approach is non asymptotically, statistically minimax optimal (matching the lower bounds); the bound holds in the sparse regime, where the learned model has a number of nonzero entries that is sub-linear in the model size. This resolves the question of wether a sparse model based planning approach can be statistically minimax optimal.

3 - Presenter

Stephen Tu, UC Berkeley, Berkeley, CA, United States

The effectiveness of model-based vs. model-free methods is a long-standing question in reinforcement learning (RL). Motivated by recent empirical success of RL on continuous control tasks, we study the sample complexity of popular model-based and model-free algorithms on the Linear Quadratic Regulator (LQR). We show that simple model-based plugin methods outperform classical model-free algorithms by at least a factor of state and input dimension. To the best of our knowledge, this is the first theoretical result which demonstrates a separation in the sample complexity between model-based and model-free methods on a continuous control task.

4 - Newton, Polyak and Nesterov: Quickest Stochastic Approximation and Reinforcement Learning

Adithya Devraj, University of Florida, Gainesville, FL, United States, Sean Meyn

It was shown in recent work by the authors that Q-learning is slow because its variance is infinite. Three new Q-learning algorithms are introduced to dramatically improve performance: (i) The Zap Q-learning algorithm that has provably optimal asymptotic variance, and resembles the Newton-Raphson method in a deterministic setting (ii) The PolSA algorithm that is based on Polyak's momentum technique, but with a specialized matrix momentum, and (iii) The NeSA algorithm based on Nesterov's acceleration technique. Coupling techniques are used to establish convergence rates for the new algorithms.

1 - Dynamic and Stochastic Knapsack Problems with Equal Rewards

Xinchang Xie, Duke University, Durham, NC, United States, xinchang.xie@duke.edu, Alessandro Arlotto

We study a dynamic and stochastic knapsack problem with n items with equal rewards and independent weights from a known continuous distribution. A decision maker seeks to maximize the expected total reward of items that she includes in a knapsack with finite capacity by making terminal decisions as soon as each item weight is revealed. We prove that the regret—the expected gap between the performance of the best sequential algorithm and that of a prophet—is logarithmic in n. We devise a re-optimized heuristic that achieves this regret bound. We also show that the total rewards collected by our heuristic, by the best sequential algorithm, and by the prophet share the same limiting distribution.

2 - A New Approach to High-dimensional Online Decision-making

Yilun Chen, Cornell ORIE, 292 Rhodes Hall, Ithaca, NY, 14853, United States, yc2436@cornell.edu, David Goldberg

High-dimensional stochastic dynamic programs(DP) arise in many practical settings, yet are believed to be computationally intractable in general. Building on recent algorithmic progress of Chen and Goldberg for optimal stopping, we devise a new algorithm that overcomes this fundamental computational barrier for a fairly general class of stochastic DP, subject to a ``limited policy change" condition. Beyond this, our results allow for arbitrarily complex dynamics of the underlying state, assuming only access to a black-box simulator. Time permitting, we also discuss several improvements to the original approach of Chen and Goldberg for optimal stopping.

3 - Dynamical Scheduling in Clearing Systems: Asymptotic Optimality of a Strict Priority Policy under Fluid Scaling

Lun Yu, Northwestern University, Evanston, IL, 60208, United States, Seyed Iravani, Ohad Perry

We consider a finite-horizon optimal scheduling problem for a clearing queueing system with two classes of impatient customers: The system starts with a significant backlog at time 0, which it needs to clear, while new demand, that matches the system's capacity, keeps arriving. The goal is to find an optimal scheduling policy that minimizes a linear holding-and-abandonment cost, up to the time when the queue is cleared. Based on a fluid approximation, we prove that a static priority policy is asymptotically optimal under different limiting regimes; analyze the impacts of preemption; and generalize the results to systems with multiple customer classes.

4 - Queues Networks Control with Primal Dual Reinforcement Learning

Yi Chen, Northwestern University, Evanston, IL, United States, yichen2016@u.northwestern.edu, Jing Dong, Zhaoran Wang

Queueing networks control is widely used in many fields, such as healthcare, ridesharing. There are numerous literatures on this problem. However, most of previous works are model-based and do not work well when the networks are complicated. In this work, we try to use reinforcement learning techniques, to solve this problem, which is model-free.

Counterfeit and Fake Purchase Problems

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Li Chen, Cornell University, Ithaca, NY, 14853, United States

1 - Luxury Pricing with Status-seeking Consumers and Strategic Counterfeiters

Zhen Lian, Cornell Tech, New York, NY, 10018-6280, United States, zl458@cornell.edu, Li Chen

We study the effects of non-deceptive counterfeits in the luxury market when consumers are status seeking. Without counterfeits, the status effect elevates consumers' demand and increases luxury brands' optimal prices and revenue. With counterfeits, we show that the status effect can be completely negated.

2 - Luxury Brands and Online Marketplace: Friend or Foe?

Yini Gao, Singapore Management University, 50 Stamford Road, #04-10, Lee Kong Chain School of Business #4031, Singapore, 178899, Singapore, yngao@smu.edu.sg, Wei Shi Lim, Ziqiu Ye

The expansion of the online marketplace has led to firms leveraging on it to increase access to consumers. However, the online marketplace is also a main propagator of the counterfeits. To study the dilemma faced by luxury brands, we adopt a game-theoretic framework to examine the interactions among a luxury brand seller, a counterfeit seller, and an online marketplace. We find that the online marketplace never deters the counterfeit seller. An authentic luxury brand seller may sell on the counterfeit prevalent marketplace when it has a low production cost but a high direct channel operating cost. The counterfeit the firm can discourage the authentic firm's entry with a high-quality counterfeit.

3 - Blockchain Adoption for Combating Deceptive Counterfeits

Hubert Pun, The University of Western Ontario, London, ON, N6A 3K7, Canada, hpun@ivey.ca, Jayashankar M. Swaminathan, Pengwen Hou

We consider a market with a manufacturer and a deceptive counterfeiter. The manufacturer can either use blockchain or signal through pricing to validate product authenticity. The government can incentivize blockchain adoption by providing subsidy to the manufacturer while optimizing social welfare. We find that without government subsidy, blockchain should be used only when the counterfeit quality is intermediate or when customers have intermediate distrust about products in the market. With subsidy, differential pricing strategy should never be used. Blockchain can be more effective than differential pricing strategy in eliminating post-purchase regret.

4 - Seeding the Herd: Pricing and Welfare Effects of Social Learning Manipulation

Yiangos Papanastasiou, University of California-Berkeley, Haas School of Business, Berkeley, CA, 94720, United States, yiangos@haas.berkeley.edu, Li Chen

This paper investigates the pricing and welfare effects of social learning manipulation within the classic model of binary observational learning.

1 - Serving Democracy: Evidence for Voting Resource Disparity in Florida

Dawson Kaaua, University of Pennsylvania, 3730 Walnut Street, Suite 500, Philadelphia, PA, 19104, United States, kaaua@wharton.upenn.edu, Gerard P. Cachon

We conduct the first panel data study examining whether minority and Democrat voters in Florida experience lower poll worker staffing, which could lengthen the time to vote. We do not find evidence of a disparity directly due to race, but we do observe a political party effect - a 1% increase in the percentage of Democrat registered voters in a county increases the number of registered voters per poll worker by 2.8%. This effect appears to be meaningful - using a voting queue simulation, a 5% increase in voters registered as Democrat in a county could increase the average wait time to vote from 40 minutes (the estimated average wait time to vote in Florida in 2012) to about 100 minutes.

2 - Agricultural Productivity and the Environment: Is Big Ag Evil?

Canberk Ucel, Doctoral Candidate, The Wharton School, Jon M. Huntsman Hall Room 527.5, Philadelphia, PA, 19104, United States, ucel@wharton.upenn.edu, Marshall L. Fisher, John Paul MacDuffie

U.S. agriculture has demonstrated outstanding productivity growth in the past half-century. These productivity gains came with sweeping technological and organizational changes. The public is increasingly concerned about the negative environmental and health effects of this unfamiliar mode of agriculture. Driven by extensive contextual information on the industry and with a unique focus on farm-level decisions, I first hypothesize about how organizational and production practices at the farms contribute to economic and environmental outcomes. Then, I use data from various public and private sources to quantitively investigate these hypotheses.

3 - Field Experiments with Rechargeable Lights in Rwanda

Bhavani Shanker Uppari, Singapore Management University, Singapore, 178899, Singapore, Serguei Netessine, Ioana Popescu, Rowan Clarke, Manuel Barron, Martine Visser

A significant proportion of world's population does not have access to electricity. Solar-based solutions are usually unaffordable due to consumers' poverty. There are alternative business models relying on rechargeable light bulbs that are sold at a subsidized price and require regular payments for recharges. We investigate the viability of these recharge-based models under poverty. In collaboration with a firm in Rwanda, we collected the bulb usage data from randomized experiments wherein the price and the bulb capacity were varied. We also build a structural model that incorporates the light consumption dynamics, and use it to evaluate theoretically-preferred changes to the existing model.

4 - Setting Retail Staffing Levels: A Methodology Validated with Implementation

Santiago Gallino, University of Pennsylvania, Jon M. Huntsman Hall, Philadelphia, PA, 19104, United States, Marshall L. Fisher, Serguei Netessine

Neither retail practice nor the academic literature provides a method for setting store associate staffing at the individual store level. We present and validate a systematic approach to do that.

MSOM Fellows Speech

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Gad Allon, University of Pennsylvania, Philadelphia, PA, 19104, United States

Co-Chair: Wedad Jasmine Elmaghraby, University of Maryland, RH Smith School of Business, College Park, MD, 20742-1815, United States

1 - "Theompirical" (Theoretical + Empirical) Research of Service Systems (Hospitals, Call Centers, Banks, Courts), in Support of Their Science, Engineering and Management

Avishai Mandelbaum, Technion - Israel Institute of Technology, Haifa, Israel

I shall describe my personal research journey through service systems (e.g. hospitals, telephone and chat centers, banks, courts,). I view these systems through MS/IE/OM lenses, often more specifically as a queueing scientist (e.g. "enjoying" congestion and flows), and sometimes using operational characteristics as surrogates for financial, psychological and clinical performance. The research goal is creation of principles and tools that support the above viewpoints; and the means for achieving this goal is the marriage of theory with data. To be more concrete, I am modeling complex service systems as relatively simple (robust) processing networks. My theoretical framework is (asymptotic) queueing theory, specifically parsimonious fluid models and their diffusion refinements: queueing theory is ideally suitable for capturing the operational tradeoff that is at the core of any service, namely quality vs. efficiency (possibly augmented with fairness or profitability); and asymptotic analysis accommodates complex service characteristics that are otherwise intractable, for example transience, scale and scope. My data/empirical framework builds on an extensive data repository of service event-logs, at the level of the individual customer-server transactions (e.g. patient-physician). Marrying theory with data, as I see it, will culminate in the creation of models directly from data - automatically and in real-time - and consequently the validation of the models' value against actual service systems. (This is in contrast to prevalent OR/MS/IE/OM practice, where models are too often remote from data, and approximations are validated for merely accuracy relative to their originating models.) Specifically, data-based models - simulation, empirical, statistical and mathematical - will be created via process-mining of their primitives, structure and protocols. Simulation models will then serve as a validation ground for the other models, and all will be universally accessible for applications by researchers, students and in the longer-run practitioners. The above research agenda has been advanced, over more than a decade, at the Technion SEE Laboratory (SEE = Service Enterprise Engineering); SEELab data will hence be used, throughout my lecture, to make it concrete.

Markets and Equilibria II

Sponsored: Manufacturing & Service Oper. Mgmt/Service Operations

Sponsored Session

Chair: Krishnamurthy Iyer, University of Minnesota, United States, kriyer@umn.edu

1 - Auction Design for Roi-constrained Buyers

Negin Golrezaei, Massachusetts Institute of Technology, Cambridge, MA, 02142, United States, golrezae@mit.edu, Ilan Lobel, Renato Paes Leme

We combine theory and empirics to (i) show that some buyers in online advertising markets are financially constrained and (ii) demonstrate how to design auctions that take into account such financial constraints. We use data from a field experiment where reserve prices were randomized on Google's advertising exchange. We find that, contrary to the predictions of classical auction theory, a significant set of buyers lowers their bids when reserve prices go up. We show that this behavior can be explained if we assume buyers have constraints on their minimum return on investment (ROI). We then design optimal auctions for ROI-constrained buyers.

2 - Regulating Markets for Personal Information

Rachel Cummings, Georgia Tech, Atlanta, GA, 30332-0205, United States

Verifiable personal information is becoming readily available to companies for risk-based discrimination—e.g., FitBit data and GPS trackers for pricing insurance. As “low risk” individuals are incentivized to share personal data for financial gain, the decision to not share is increasingly disclosive of “high risk” attributes. To prevent unraveling, policy makers could regulate the market for personal information. In this work, we quantify the social welfare loss from market unraveling, and consider disparate effects of privacy loss on protected groups. We also study optimal design of constrained signaling schemes, taking into account privacy, fairness, and accuracy in decision-making.

3 - Coordinating Distributed Experimentation in Dynamic Markets

Ankur Mani, University of Minnesota, Minneapolis, MN, 63108-2432, United States, amani@umn.edu

We consider the problem of experimentation and learning in sharing economy platforms. There are a few features of this environment that makes it different from the traditional experimentation problems faced by monopolies. First, all participants in the platform make the decisions independently. Second, there are positive externalities associated with experimentation; the spill over of the information helps other participants. Third, the environment is dynamic and the learning becomes obsolete over time. We introduce a coordination policy and show that if the arrival/departure rate is above a certain threshold, then the firm can maintain high quality information for the participants.

4 - Dynamic Credit-collections Optimization

Naveed Chehrazi, McCombs School of Business, Austin, TX, 78712, United States, Peter Glynn, Thomas A. Weber

Based on a dynamic model of the stochastic repayment behavior exhibited by delinquent credit-card accounts in the form of a self-exciting point process, a bank can control the arrival intensity of repayments using costly account-treatment actions. A semi-analytic solution to the corresponding stochastic optimal control problem is obtained. For a linear cost of treatment effort, the optimal policy in the two-dimensional (intensity, balance)-space is described by the frontier of a convex action region. The unique optimal policy significantly reduces a bank’s loss given default and concentrates the collection effort onto the best possible actions at the best possible times.

People Centric Operations

Sponsored: Manufacturing & Service Oper. Mgmt/Supply Chain

Sponsored Session

Chair: Santiago Gallino, University of Pennsylvania, Philadelphia, PA, 19104, United States

1 - Fulfillment by Platform and Upstream Market Power

Jiding Zhang, The Wharton School, Philadelphia, PA, 19104, United States, jiding@wharton.upenn.edu, Amandeep Singh, Senthil Veeraraghavan

Our research shows that Fulfillment by Platform leads to a more monopolistic upstream market.

2 - Surfacing the Submerged State: Operational Transparency Increases Trust in and Engagement with Government

Ryan Buell, Harvard Business School, Boston, MA, 02163, United States, rbuell@hbs.edu, Ethan Porter, Michael Norton

As trust in government reaches historic lows, frustration with government performance approaches record highs. We propose that peoples’ perceptions of government and their levels of engagement with it can be reshaped and enhanced by increasing government’s operational transparency - that is, by designing service interactions so that citizens can see the often-hidden work that government performs. Boston residents who used an app to report service requests to their government exhibited significant increases in engagement if they were shown a photo of the work being performed. Laboratory experiments unpack the psychological mechanisms linking transparency to increased engagement.

3 - Pay by the Hour or Pay by the Task?

Santiago Gallino, University of Pennsylvania, Philadelphia, PA, 19104, United States, Carolyn Deller

We empirically study the implications of the payment contract type on productivity and quality of outcomes. We designed a set of real tasks to learn the different productivity outcomes across contracts that way in which these outcomes can be affected through additional incentives.

4 - Democracy on the Line: Polling Place Closures and Their Estimated Impact on Wait Times in the 2016 Presidential Election in Georgia

Dawson Kaaua, University of Pennsylvania, 3730 Walnut Street, Suite 500, Philadelphia, PA, 19104, United States, kaaua@wharton.upenn.edu, Gerard P. Cachon

Between the 2012 and 2016 presidential elections, Georgia closed polling places while South Carolina’s polling place count remained flat. Based on wait times reported by voters in each state during the 2006, 2008, 2012, and 2016 elections, we perform a difference-in-differences analysis with Georgia as the treatment state and South Carolina as the control to examine the impact of the polling place closures on wait times in Georgia’s 2016 election. We estimate that polling place closures increased Georgia’s average wait time by 74% or approximately 7 minutes. In addition, the increase in wait time suggests that Georgia may not have redistributed all of its voting resources from polling place closures.

Retail Operations

Sponsored: Manufacturing & Service Oper. Mgmt/Supply Chain

Sponsored Session

Chair: Pnina Feldman, Boston University, Boston, MA, 02215, United States

1 - The Subscription Box Business Model: Learning, Shipments and Returns

Pnina Feldman, Boston University, Questrom School of Business, Boston, MA, 02215, United States, pninaf@bu.edu, Elnaz Karimi, Ella Segev

The subscription box business model has gained popularity across firms and consumers in recent years. This model promises a periodic delivery of a box of customized consumer goods to its customers in exchange for a subscription fee. In this study, we investigate customer preference learning in the context of a firm using the subscription box business model under various contract structures.

2 - Operational Execution and Pop Display Effectiveness: Evidence F\from Adoption of an IoT Technology

Ioannis Stamatopoulos, University of Texas at Austin, McCombs School of Business, Austin, TX, 78705, United States, yannis.stamos@mccombs.utexas.edu, Ashish Agarwal, Zijian Zeng

We use the adoption of an innovative IoT technology by a large retailer chain in the US to evaluate the operational execution of promotional inventory campaigns, as well as the effectiveness of these campaigns.

3 - The Effect of Multi-Channel and Omni-Channel Retailing on Physical Stores

Fei Gao, Indiana University Bloomington, Bloomington, IN, 47405, United States, fg1@iu.edu, Shiliang Cui, Vishal Agrawal

We study how a multi-channel or omni-channel retailer should decide the number and size of physical stores. We also study the effect of three common omni-channel strategies: physical showrooms, in-store return, and in-store pick-up.

4 - Information Sharing on Retail Platforms

Fuqiang Zhang, Washington University in St. Louis, Olin Business School, St. Louis, MO, 63130, United States, Zekun Liu, Dennis Zhang

This paper studies how a retail platform should share demand information with retailers selling substitutable products on the platform. We find that the optimal strategy is to either share all information with a subset retailer or partial information with all retailers. We also propose a simple pricing mechanism that can induce the optimal sharing outcome for the platform.

Joint Session INFORMed/Practice Curated: Applying Analytics/OR/MS to Improve Student Outcomes

Sponsored: Education

Sponsored Session

Chair: Kingsley Anthony Reeves, University of South Florida, Tampa, FL, 33620, United States

Co-Chair: Grisselle Centeno

1 - An Optimization-based Decision Support System for Student-to-teacher Assignment

Matthew D. Bailey, Professor of Analytics and Operations Management, Bucknell University, Freeman College of Management, Taylor Hall, Lewisburg, PA, 17837, United States, matt.bailey@bucknell.edu

School administrators spend their summers attempting to assign hundreds of students to teachers for the following school year. These assignments must satisfy federal guidelines, parent preferences, and principal preferences while pursuing classroom parity and equity in regards to academic performance, behavioral support, and demographics. We formulate the problem as a mixed integer program, present the implemented spreadsheet model interface, and illustrate on a set of student data. This system is currently in use for the assignment of 600 students to 24 classrooms saving dozens of staff and administration hours.

2 - Using System Dynamics to understand the Complexities Instructional Change in Higher Education

Juan M. Cruz, Rowan University, Glasboro, NJ, United States, juancruz@vt.edu

The purpose of this study is to create a conceptual System Dynamics Model (SDM) to understand how the dynamics of the academic system affect faculty motivation to enact and sustain instructional change. The model was constructed through an iterative process of three phases: 1) a theoretical Causal Loop Diagram (CLD), 2) an empirical CLD, and 3) a conceptual SDM. The resultant 34 CLDs are classified in five categories: change management, culture, institutional support, student experience and pedagogical knowledge. Their analysis explains potential unintended consequences of decisions and policies, possible sources of resistance, and suggests potential leverage points to instructional change.

3 - Identification of Critical Moments that Prevent Four-year Graduation

Xufei Liu, University of South Florida, Tampa, FL, 33612, United States, Kingsley Anthony Reeves, Changhyun Kwon

Based on recent student course registration and grade records, we develop a model for descriptive analytics to identify critical moments that prevent four-year graduation. Our model involves an optimization formulation built upon the current curriculum and course offerings.

4 - Opportunities to Improve Education through Engineering Research

Kingsley A. Reeves, University of South Florida, Tampa, FL, 33620, United States, reeves@usf.edu, Grisselle Centeno

This talk introduces the theme of this session and highlights opportunities for the use of traditional industrial engineering methods to solve specific problems affecting the complex network of organizations, information or management systems, financing mechanisms, logistics, and personnel engaged in delivering education. In doing so, the presenters advocate for the creation of education engineering (EDEN) as a new research discipline.

5 - A Data-driven Approach to Investigating Student Persistence

Morgan Chesnicka, University of South Florida, Tampa, FL, United States, mchesnicka@mail.usf.edu, Kingsley Anthony Reeves

Student persistence (SP) is a key performance measure of student success. In this work, we develop a multi-source data-integrated database with predictive analytics tools to improve understanding of the multi-factorial nature of SP by extracting information from heterogeneous data resources. The developed data-driven predictive model is capable of identifying relevant promoting factors and/or barriers that may affect SP with improved prediction accuracy. The proposed work will help advance evidence-based understanding of SP and further inform more proactive university-wide decision-making for increasing the student retention rate and improving student success.

CC- Room 309

Emerging topics on OM-Finance interface

Sponsored: Manufacturing & Service Oper. Mgmt/iFORM

Sponsored Session

Chair: Jie Ning, Case Western Reserve University, Cleveland, OH, 44106, United States

1 - The Demand-side Explanation for the Great Recession

Yi Zhang, Illinois Institute of Technology, Chicago, IL, United States, John R. Birge

Various theories have been given as triggering events for the Great Recession of 2008-2009. Most explanations, however, ignore the operational characteristics of the market for securities. This talk will describe an operational model of the supply chain from investment institutions (particularly pension funds) to mortgage originators. We will show evidence that the changes in this supply chain that triggered the Great Recession originated at the downstream end of the supply chain and therefore represent a demand-side explanation.

2 - Financing for Responsible Operations

Xavier Warnes, Stanford University Graduate School of Business, Stanford, CA, 94305, United States, xwarnes@stanford.edu, Dan Andrei Iancu, Erica Plambeck

We discuss a set of problems in developing economies where responsible operations are intrinsically tied to the provision of responsible access to capital.

3 - The Impact of Trade Credit Provision on Retail Inventory

Christopher J. Chen, London Business School, London Business School, Regent's Park, London, NW14SA, United Kingdom, cchen@london.edu, Nitish Jain, S. Alex Yang

This paper examines the potential negative implication of limiting trade credit on inventory decisions at the retailer level. Using an empirical strategy that leverages: (i) an exogenous shock imparted by the French government's intervention to impose a ceiling on trade credit repayment; (ii) a triple difference-in-differences identification strategy; and (iii) Synthetic Controls, we estimate the causal impact of trade credit on firms' inventory stocking decisions. We find that, in retail sectors affected by the French regulation, the decrease in trade credit led to both an economically and statistically significant decline in firms' inventory levels.

4 - Trade Credit, Risk Shifting, and Buyer Firm Competition

Jie Ning, Case Western Reserve University, Department of Operations, 328 Peter B. Lewis Building, Cleveland, OH, 44106, United States, jie.ning@case.edu

Trade credit is widely used in practice and many theories have been proposed to explain that. In this paper, we propose a novel theory that connects the use of trade credit with risk shifting and buyer firm competition.

CC- Room 310

Consumer Returns and Retail Operations

Sponsored: Manufacturing & Service Oper. Mgmt/Sustainable Operations

Sponsored Session

Chair: Guangzhi Shang, Florida State University, Tallahassee, FL, 32306, United States

Co-Chair: Hailong Cui, University of Southern California, Los Angeles, CA, 90089-0809, United States

1 - The Rise of Ship-to-store: Theoretical and Empirical Analyses of its Impact on Retail Sales

Necati Ertekin, University of Minnesota, Department of OM&IS, Leavey School of Business, Minneapolis, MN, 95053, United States, Mehmet Gumus, Mohammad Nikoofal

We consider an emerging fulfillment model called Ship-to-Store (STS) that enables customers to ship their online purchases directly to a nearby store. We theoretically and empirically explore the implementation of STS services with respect to the disclosure of in-store product availability information.

2 - Measuring and Mitigating the Impact of Free Shipping Threshold Policy

Jiaqi Xu, Carnegie Mellon University, Tepper School of Business, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, jiaqixu@andrew.cmu.edu, Gerard P. Cachon, Santiago Gallino

We develop a data-driven model to measure the financial impact of an online retailer's free shipping threshold policy. We consider the policy's effects on (i) customer activation, (ii) repeat purchase, and (iii) average profit per order. We apply the model to transaction data from an online retailer to offer recommendations.

3 - Consumer Return Policies in Omnichannel Operations

Leela Nageswara, University of Washington, Seattle, WA, 98195, United States, lnages@uw.edu, Soo-Haeng Cho, Alan Scheller-Wolf

We study the pricing and return policy decisions of an omnichannel retailer serving customers who differ in how they realize their valuation for a product — by inspecting in-store before purchase or by purchasing online and possibly returning misfit items. Our results show that generous refunds are driven by customer heterogeneity and the convenience of in-store returns. We find that omnichannel firms with good salvage partners as well as those with more store-based customers should offer full refunds. In contrast, firms with a significant store network and good in-store salvage opportunities should charge a fee for online returns in order to nudge customers to return in-store.

4 - Omnichannel Collaborations

Maryam M. Mahdikhani, Rutgers University, Newark, NJ, 07102, United States, m.mahdikhani@rutgers.edu, Tolga Aydinliyim, Monire Jalili

Motivated by partnerships between online and B&M retailers where the online retailer operates a micro store within the B&M store (e.g., Amazon within Kohl's), we study consumers' returns channel choice and induced B&M store customer traffic implications as well as when such partnerships are profitable for the involved parties.

■ MB23

CC- Room 3A

Inaugural Flash Session I (Decision Analysis)

Emerging Topic: Decision Analysis

Emerging Topic Session

Chair: Christian Wernz, Virginia Commonwealth University – VCU, Richmond, VA, 23298, United States

1 - Sourcing for Wind Power: Evidence from a Multifactor Analysis of the U.S. Electricity Industry

Ekundayo Shittu, George Washington University, Washington, DC, 20052, United States, eshittu@gwu.edu, Carmen B. Weigelt, Dor Hirsh Gai

We study how transaction costs with capability considerations such as the interaction between project development and ownership, power purchase agreements and state policy influence the make-or-buy decisions in the U.S. utilities industry. This is motivated by the surge in the adoption of wind energy in the upstream energy generation segment of the value chain where transaction hazards in contracting for wind power appear to be declining and capabilities related to the new segment accumulate affecting make-or-buy preferences. We show how resource proximity, timing of entry, and capability accumulation inform decisions over time under uncertainties in regulation for renewable energy.

2 - Evaluating the Trade-offs in Longitudinal Family Medicine Residency Schedules

Bjorn Berg, University of Minnesota, Minneapolis, MN, 55455, United States, bberg@umn.edu

Residency training in family medicine requires a comprehensive approach to care for a broad patient profile across a variety of settings. The current paradigm wherein residents progress through a series of month-long focused rotations is based on past precedent and draws from experienced understanding and perception of what works well. This research proposes to design and evaluate a new paradigm in family medicine residency training where a longitudinal schedule is used resulting in increased continuity and predictability in the clinic setting with their patients and care team and an elongated educational experience and exposure to specialty and hospital settings.

3 - Dynamic Modeling of Major Depressive Disorder and Marital Quality

Maede Maftouni, Virginia Tech, Blacksburg, VA, United States, Niyousha Hosseinichimeh, Andrea Wittenborn, Paula Fallas Valverde

Past studies showed reciprocal relations between marital quality and major depressive disorder. Depressive symptoms also increase financial hardship by reducing productivity and employment opportunities, at the same time, financial hardship increases depressive symptoms. Spouse support may alleviate some of the causes of distress but it may decline over time due to reduction in marital quality. We developed a simulation system dynamics model to examine reciprocal relations among these factors to understand their dynamic behaviors over time. Using the indirect inference method, we calibrated the model with the Fragile Families data and provided implications for practitioners.

4 - Behavior of FEMA Public Assistance Recipients with Repetitive Disaster Losses

Allison C. Reilly, University of Maryland, College Park, MD, 20017, United States, areilly2@umd.edu, Hamed Ghaedi

With nearly $100B in expenditures over the past two decades, FEMA'S Public Assistance Program is the largest disaster relief program for infrastructure in the US. In this work, we explore the behavior of infrastructure owners who file for disaster relief aid to quantify the role that repetitive losses have in filing decisions. We then make projections on how more frequent flooding events and behavioral adaptations to repetitive losses could escalate expenditures for FEMA.

5 - Decision Analysis: Past, Present, and Future

Ali E. Abbas, Professor, University of Southern California, Los Angeles, CA, 90089, United States, aliabbas@usc.edu

Decision Analysis is a normative approach to valuing and selecting decision alternatives. More than fifty years after the name was coined, there still exists some confusion about its application and especially to large systems and government enterprises. This talk will discuss recent developments in the field of decision analysis and will highlight some current opportunities and challenges of using Decision Analysis in large systems.

6 - Designing Sustainable Supply Chains

Jason R. W. Merrick, Virginia Commonwealth University, Richmond, VA, 23284, United States, jrmerric@vcu.edu

Government agencies contracting with private sector suppliers must balance economic performance with environmental sustainability. Suppliers try to interpret signals from prior bid decisions to form their most competitive bid. Working with a private company seeking to supply gasoline additives to the Brazilian federal government, we elicited the probability of winning the bid based on a deep knowledge of their potential competitors and the government's sustainability priorities. We then designed a distribution network to maximize expected revenue. These results provide insights to governments about how their priorities can incentivize greater improvements in sustainability.

7 - Forecasting the Cost of Offshore Wind: Expert Elicitation Versus Experience Curves

Erin Baker, Univ of Massachusetts-Amherst, Amherst, MA, 01003, United States, edbaker@ecs.umass.edu

We compare a formal expert elicitation with data-based experience curves, using offshore wind as a specific example. We find that experience curves predict lower costs than expert elicitations, and explore possible reasons why. We note that the experts' forecasts are consistent with the assumption that offshore wind is an offshoot of onshore wind, learning at a slower rate because it is farther on its experience curve.

MCDM and Medicine / Healthcare: A Mutually Beneficial Relationship- II

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Evangelos Triantaphyllou, Louisiana State University, Baton Rouge, LA, 70803, United States

Co-Chair: Juri Yanase, Complete Decisions, LLC, Baton Rouge, LA, 70810, United States

Co-Chair: Esra Buyuktahtakin Toy, New Jersey Institute of Technology, Newark, NJ, 07102, United States

1 - Multi-stage Stochastic Resource Allocation for the Optimal Control of Epidemic Diseases

Xuecheng Yin, New Jersey Institute of Technology, Newark, NJ, United States, xy276@njit.edu, Esra Buyuktahtakin-Toy

Existing compartmental models are limited in the optimization of resource allocation for controlling an epidemic outbreak. In this study, we address this core limitation and present a multi-stage stochastic programming epidemic compartmental model, which formulates spatio-temporally varying treatment rates based on an available budget. We apply this model to study the case of Ebola Virus Disease in West Africa to minimize an overall expected number of infected individuals, considering possible infection scenarios. Our model is practical, and can be adopted to study other infectious diseases in complex situations.

2 - Pandemic Influenza Vaccine Allocation with Equity

Osman Ozaltin, North Carolina State University, Industrial and Systems Engineering, Raleigh, NC, 27605, United States, oyozalti@ncsu.edu, Shakiba Enayati

We develop an age-structured influenza epidemic model with isolation. We then formulate a mathematical program to find an allocation policy that minimizes the vaccine stockpile needed to avoid a widespread infection. The proposed approach returns the optimal age-structured vaccine allocation rather than comparing the efficacy of just a few specific vaccination policies. Furthermore, we propose an equity constraint to help public health authorities integrate fairness in their vaccine allocation decisions

3 - Optimizing Multi-modal Cancer Treatment under 3D Spatio-temporal Tumor Growth

Eyyub Yunus Kibis, The College of Saint Rose, Albany, NY, 12203, United States, Esra Buyuktahtakin Toy

We introduce a new mixed-integer linear programming model that explicitly integrates the spread of cancer cells into a spatio-temporal model of cancer growth while taking into account treatment effects. The objective is to determine the optimal sequence of cancer treatment methods—surgery (S), chemotherapy (C), and radiotherapy (R)— as well as the optimal dosages for chemotherapy and radiation treatments while minimizing the newly generated tumor cells for early-stage breast cancer in a unique three-dimensional spatio-temporal system. The effectiveness of treatment combinations (i.e., SRC, SCR, CR, RC) are compared by tracking the number of cancer cells at the end of each treatment modality.

4 - Using MCDM to Determine the Best Treatment for Life-critical Diseases under Variable Health State Utility Scenarios

Juri Yanase, Complete Decisions, LLC, Baton Rouge, LA, 70810, United States, jurijuriy@aol.com, Evangelos Triantaphyllou

Some recent developments show that an MCDA approach that is based on maximizing QALYs (quality-adjusted life-years) and MAUT (multi-attribute utility theory) is the valid way to determine the best treatment when multiple treatments exist for life-critical diseases. A crucial role in such determinations is played by health state utilities (HSUs). Such quantities must satisfy certain consistency and independence assumptions. This talk describes a method based on quadratic optimization which offers a powerful way to decide what the best treatment is under various independence scenarios of HSU values. The proposed methodology is demonstrated with data related to non-metastatic prostate cancer.

CC- Room 401

Joint Session Not for Profit/PSOR: Application-Driven Research in Humanitarian, Health, and Non-Profit Operations

Emerging Topic: Humanitarian and NotforProfit Operations

Emerging Topic Session

Chair: Erica L. Gralla, George Washington University, Washington, DC, 20052, United States

1 - Implication of Abusive Leadership on Job Performance of Humanitarian Aid Workers

Mojtaba Salem, Kuhne Logistics University, Grosser Grasbrook 17, Hamburg, 20457, Germany, mojtaba.salem@the-klu.org, Maria Besiou, Niels Van Quaquebeke

Humanitarians may work under leaders who act aggressively towards them out of the belief that doing so will engender performance. While leadership research suggests this worsens performance, field reports show tough leaders can get the job done. This paper investigates factors that make humanitarian operations context resilient to destructive leadership.

2 - Ensuring Equity and Effectiveness Over Time in a Network for Good: a Multi-period Distribution Model for Food Banks with Stochastic Capacity

Irem Orgut, University of Alabama, Tuscaloosa, AL, United States, isorgut@cba.ua.edu, Julie Simmons Ivy, Reha Uzsoy

Based on our nine-year partnership with a local food bank, we address the equitable and effective distribution of food donations to charitable agencies with stochastic receiving capacities over a finite planning horizon. We develop a multi-period stochastic model that ensures equitable food distribution decisions by the food bank. We use the structural properties of this problem to obtain bounds on the optimal shipment amounts and develop heuristics. An extensive numerical study, based on data from our partner food bank, demonstrates the promising performance of the heuristics.

3 - A Network Design Problem Arising in the Restoration of the Water Supply System in Nepal

Marie-Eve Rancourt, HEC Montréal, Montréal, QC, Canada, marie-eve.rancourt@hec.ca, Gilbert Laporte, Jessica Rodriguez-Pereira, Selene Silvestri

We propose an optimization approach for the community water network rehabilitation problem targeting remote populations affected by the 2015 Nepal earthquake. To this end, we describe a new problem and a matheuristic developed to solve it. In this context, the primary objective of humanitarian organizations is to locate water taps such that people can access them accordingly to the national standards. The secondary objective consists of minimizing the cost to connect the water taps to the pipeline network. Since the water supply system is gravity-fed, the elevation has to be taken into account. Data provided by the Austrian Red Cross and satellite imagery are used to generate solutions.

4 - Kansas Healthcare Supply Chain Integrity: Mapping Vulnerabilities and Opportunities

Jessica L. Heier Stamm, Kansas State University, Manhattan, KS, 66503, United States, jlhs@k-state.edu, Camille Brown, Katherine Stachowiak, Michael McNulty

Continuity in care delivery during and after disasters is a key capability for healthcare organizations. Maintaining continuity depends on robust and resilient supply chains. We partnered with the Kansas Department of Health and Environment and the state's seven healthcare coalitions, through the federal Hospital Preparedness Program, to assess supply chain integrity for coalitions and their member organizations. This presentation describes the assessment process, including the online survey instrument used to gather supply chain information from healthcare coalition members statewide and next steps driven by the assessment.

5 - Approaches for Locating and Staffing FEMA's Disaster Recovery Centers

Erica L. Gralla, George Washington University, Washington, DC, 20052, United States, egralla@gwu.edu, Julia Nessa Moline, Jarrod D. Goentzel

FEMA has recently worked to make its operational decisions more data-driven. We worked with FEMA to develop two models for locating and staffing their temporary Disaster Recovery Centers. One model fits easily into FEMA's current decision-making process, while the other further improves service by challenging assumptions. Using data from three past disasters, we find cost savings of 75% on average while reducing travel time. We identify challenges and successes from the models' partial implementation, and draw insights on the potential for improving organizational decisions by developing models that either align with or challenge the decision-making culture.

Behavioral Issues in Service Operations Management

Sponsored: Service Science

Sponsored Session

Chair: Sina Golara, Massachusetts Institute of Technology, Cambridge, MA, 02142, United States

1 - Learning Best Practices: Can Machine Learning Substitute for Experience?

Park Sinchaisri, The Wharton School, Philadelphia, PA, 19104, United States, swich@wharton.upenn.edu, Hamsa Sridhar Bastani, Osbert Bastani

An increasing number of domains are providing us with detailed trace data on human decisions in complex, dynamic environments. These decisions are often made by experts with deep experience in the task at hand. For example, nearly every physician action is logged in electronic medical record data; every movement of a driver is recorded on a ride-sharing platform; even store managers' decisions on daily pricing and inventory management are recorded. How can we leverage these large-scale logs of sequences of decisions and outcomes to identify better decision policies? We propose that machine learning algorithms are well suited to help supplement human decision-making in these applications.

2 - Multi-channel Delivery in Healthcare: The Impact of Telemedicine Centers in Southern India

Kraig Delana, London Business School, PhD Program Office, London, NW1 4SA, United Kingdom, kdelana@london.edu, Sarang Deo, Kamalini Ramdas

Telemedicine is increasingly used in rural communities across the developing world. However, the impact of telemedicine in these settings is not well understood. We analyze data from the Aravind Eye Care System in Southern India to examine the impact of opening telemedicine centers on access, treatments, and costs, at both the telemedicine center channel and the pre-existing hospital channel. We find evidence telemedicine centers improve access, particularly for patients with simple conditions, which contributes to an increase in the rates of glasses prescriptions. They also enable patients to substitute telemedicine center visits for hospital visits leading to savings in patient costs.

3 - Matching Dynamics in Highly Heterogenous Marketplaces

Ashish Kabra, University of Maryland-College Park, Robert H. Smith School of Busin, 7621 Mowatt Lane, College Park, MD, 20742, United States, akabra@rhsmith.umd.edu, Qingchen Wang

Several two-sided matching platforms exhibit a much larger heterogeneity in their demand and supply users (eg: Airbnb, TaskRabbit) compared to some of the other mainstream platforms (eg: Uber, Ofo). In collaboration with a large scale freelancer matching platform, we study the drivers of the match selection behavior using econometrics and machine learning methods.

Pricing and Contracting under Uncertain Customer Perceptions

Sponsored: Service Science

Sponsored Session

Chair: Yimin Wang, Arizona State University, Tempe, AZ, 85287, United States

Co-Chair: Mei Li, PhD, Michigan State University, East Lansing, MI, United States

1 - Optimal Pricing under Customer Return Risk

Xiangjing Chen, PhD Candidate, Arizona State University, Tempe, AZ, United States, xchen328@asu.edu, Yimin Wang

We analyze a manufacturer's pricing strategy when customers' evaluation of product features is uncertain at the time of purchase. Customers' propensity to return the product depends on the realized fit of product features and the price paid. We characterize the optimal price and offer insights on how the risk of product returns influence the optimal pricing strategy.

2 - Management of Digital Innovative Services: Update Dynamics under Demand Uncertainty

Seongkyoon Jeong, Arizona State University, Business Administration, Tempe, AZ, 85281, United States, sjeong19@asu.edu, Adegoke Oke

Today, digital innovative services show distinct features from conventional products. Such services witness a rapid demand surge due to their innovativeness and a rapid decline and dissipation of demand as the service loses its appeal and innovativeness. The rapid decline of demand motivates service providers to replenish the demand by introducing major updates frequently due to supporting IT infrastructure. Using novel online game service data, this study shows that this practice leads to "saw-tooth" pattern of demand, which is synonymous with an inventory management profile, and that demand uncertainty plays a significant role in determining the demand replenishment point.

3 - Saving Outsourced Customer Service: Evolving Quality Uncertainty and Dynamic Monitoring Efforts

Yimin Wang, Arizona State University, W.P. Carey School of Business, Tempe, AZ, 85287, United States, Mei Li

Customer services play an important role for firms to retain customers and spur revenue growth. Many firms outsource customer services to third-party suppliers. We develop a normative model to investigate performance outcomes of outsourced customer services over a finite time horizon.

4 - Advance Selling in Video Games

Lifei Sheng, University of Houston Clear Lake, Houston, TX, United States, sheng@uhcl.edu, Xuying Zhao, Christopher Ryan

We study the pricing strategies of premium contents in video games. Players can purchase the premium contents in advance before the game starts or purchase in spot when they need them in the game. We find when the ratio of skilled players over non-skilled players among consumers is sufficiently large, the firm should adopt the pure advance selling strategy, which motivates all consumers buy early. Otherwise, the firm should adopt a hybrid advance selling strategy, where skilled players buy at spot while non-skilled players buy in advance. Moreover, we show that the firm benefits more from a game of chance, compared to a game of skill, because players are more homogeneous in the market in a game of chance.

Matching Theory

Sponsored: Auction and Market Design

Sponsored Session

Chair: Thayer Morrill, North Carolina State University, Raleigh, NC, 27695, United States

1 - Stability in Matching Markets with Complex Constraints

Thanh Nguyen, Purdue University, West Lafayette, IN, United States

We consider a new model of many-to-one matching markets in which agents with multi-unit demand aim to maximize a cardinal linear objective subject to multidimensional knapsack constraints. The choice functions of agents with multi-unit demand are therefore not substitutable. As a result, pairwise stable matchings may not exist and, even when they do, may be highly inefficient. We provide an algorithm that finds a group-stable matching that approximately satisfies all the multidimensional knapsack constraints.

2 - A Theory of Simplicity in Games and Mechanism Design

Peter Troyan, University of Virginia, Charlottesville, VA, United States, petetroyan@gmail.com, Marek Pycia

We introduce a general class of simplicity concepts for games that vary the foresight abilities required of agents. Agents are presumed to be able to plan only for those histories that are viewed as simple from their current perspective (rather than all histories), and may update their strategic plan as the game progresses. For an action to be simply dominant, it must lead to unambiguously better outcomes, no matter what occurs at non-simple histories. We use our approach to characterize simple mechanisms in general social choice environments both with and without transfers, which includes canonical mechanisms such as ascending auctions, posted prices, and Random Priority.

3 - Pre-college Human Capital Investment and Affirmative Action, a Structural Policy Analysis of U.S. College Admissions

Aaron Bodoh-Creed, University of California-Berkeley, Berkeley, CA, United States, acreed@berkeley.edu, Brent R. Hickman

We estimate a model of college admissions wherein students endogenously accrue pre-college human capital (HC) as part of a contest for enrollment at high quality colleges. We identify the roles of school quality, HC, and students' privately known learning costs on post-college household income. Conditional on graduating, college quality is the most important factor in determining income, while unobserved student characteristics play a nontrivial secondary role. Pre-college HC drives college placement and graduation probability, but not post-college income. We also compare the status quo to a color-blind admissions rule and a proportional quota for minority students.

4 - Matching with Non-poaching

Umut Dur, NCSU, Raleigh, NC, 27695, United States, Mustafa Oguz Afacan

Non-poaching contracts prevent firms from hiring each other's employees. Not every worker-firm pair can match with each other even if they would rather do so. A constrained stability term is proposed. Stability is a special case of our constrained stability notion. We show that some properties of the stable matchings do not carry over to the constrained stable matchings. DA fails to be worker-optimal, yet it is the unique constrained stable and strategy-proof one. We propose 2 mechanisms. The first one is worker-optimal constrained stable and improves the workers' welfare upon that under DA. The second one is worker-optimal and assigns as many workers as possible subject to constrained stability.

5 - Partitionable Choice Functions

Thayer Morrill, North Carolina State University, Raleigh, NC, 27695, United States, Umut Dur, William Phan

We provide properties of choice functions that are necessary and sufficient for the existence of a stable assignment. Our results show that the substitutable domain is not the only one where stable assignments exist. Furthermore, these new types of choice functions have natural interpretations for real-life applications e.g. schools with multiple grades, hospitals and departments with different types of positions.

1 - From Hotelling to Nakamoto: The Economic Meaning of Bitcoin Mining

Steven Kou, Boston University, Questrom School of Business, Boston, MA, 02215, United States, Min Dai, Wei Jiang, Cong Qin

We proposed a model for Bitcoin mining from the miners' perspective, by extending the classical Hotelling model for exhaustible natural resources, via the addition of inventory and profits from Bitcoin transaction fees. The model is calibrated to the empirical data and dynamics of the average transaction fees.

2 - Forest Behind the Trees

Markus Pelger, Stanford University, Stanford, CA, 94305, United States, mpelger@stanford.edu, Svetlana Bryzgalova, Jason Zhu

Sorting-based strategy of building portfolios is the default empirical approach in asset pricing for creating both test assets and factor-mimicking returns. A natural limitation of this technique is its inability to adequately reflect the information contained in more than 2 characteristics and their interaction. We analyze the effect of a large number of characteristics on expected stock returns with decision trees. As a learning method for classification, the new approach is well-suited for building composite cross-sections of portfolios reflecting the rich conditional information contained in many characteristics and is a generalization of the conventional sorting-based strategies.

3 - Optimal Nonnegative Production

Abel Cadenillas, Professor, University of Alberta, Department of Mathematical Sciences, Edmonton, AB, T6G 2G1, Canada, abel@ualberta.ca

We consider an infinite horizon stochastic production planning problem with the constraint that the production rate must be nonnegative. We obtain an analytical solution for the optimal production policy.

4 - Digital Currencies: The Tradeoff Between Efficiency and Trust

Christoph Frei, University of Alberta, Mathematical and Statistical Sciences, CAB 621, Edmonton, AB, T6G 2G1, Canada, cfrei@ualberta.ca

Minimizing volatility in their exchange rates, new forms of digital currencies become viable alternatives to traditional currencies for payments. We develop a model to capture incentives and preferences behind the use of different payment methods in over-the-counter market transactions. Our model features the tradeoff between (i) welfare gains from lower transaction costs and (ii) costs of setting up the digital technology and trust concerns when using digital currencies. While participants in the digital currency benefit from welfare gains, people lacking trust in the digital currency suffer from fewer trading opportunities and decreased welfare when digital currencies become widely used.

Tutorial: Health System Innovation: Analytics in Action

Emerging Topic: Tutorials

1 - Health System Innovation: Analytics in Action

Retsef Levi, Massachusetts Institute of Technology, Sloan School of Management, Cambridge, MA, 02142, United States, Martin S. Copenhaver, Michael Hu, Kyan Safavi, Ana Cecilia Zenteno Langle

This tutorial focuses on the implementation of data- and analytics-driven innovation in health systems. In particular, we focus on innovation around operations, system design, and optimization of large delivery systems. Additionally, the tutorial discusses a formal project management framework, general principles, and key success drivers that enable field implementations of high impact, analytics-driven projects. These discussions are specifically centered around facilitating collaboration between academics with analytics expertise, clinicians and administrative leaders in healthcare systems, as well as policy makers. To illustrate the usage of these ideas in practice, we describe three projects done in collaboration between Massachusetts General Hospital (MGH) and the Massachusetts Institute of Technology (MIT) Sloan School of Management.

1 - Quantifying the Effectiveness of Border Security Investment

Jun Zhuang, Professor, University at Buffalo, SUNY, 317 Bell Hall, Buffalo, NY, 14260, United States, jzhuang@buffalo.edu, Ridwan Al Aziz

This research presents a comprehensive data-driven approach involving regression modeling, Principle Component Analysis, and Structural Equation Modeling to analyze the relationship among three groups of variables: (a) border security outcome metrics, input border security countermeasure metrics, and (c) external/environmental metrics. This project provides some novel insights on quantifying the effectiveness of border security counter-measures, and thereby facilitate more informed resource allocation in preventing drug/weapon smuggling, illegal migration, and terrorism.

2 - Risk Assessment and Security Measure Allocation for Optimal Aviation Security

Eva Lee, Georgia Tech, Industrial & Systems Engineering, Ctr for Operations Research in Medicine, Atlanta, GA, 30332-0205, United States, evalee-gatech@pm.me

This project establishes a quantitative construct for enterprise risk assessment and optimal portfolio investment to achieve the best aviation security. We first analyze and model the various aviation transportation risks and establish their interdependencies. Using the security measures and their capabilities, we formulate the multi-objective portfolio investment model via a mixed integer programming framework. The portfolio risk model determines the best capabilities of current budget. It can pinpoint potential capabilities when changes in budget occurs. This work is joint with TSA.

3 - Bayesian Predictive Threat Modeling Enhances Border Threat Detection

Dejan Neskovic, DHS S&T, Washington, DC, United States, Geoffrey Berlin

As the threat of illegal smuggling and entry along the Southern border continues to evolve, accurate and timely suspect threat classification is paramount. Using Bayesian analytics to make sense of our data-rich world in support of the law enforcement and homeland security is advantageous because it avoids making initial presumptions about relationships among data elements. Applying various machine learning algorithms and network scoring creates the best, most accurate and uncomplicated model. The DHS Science and Technology Directorate are developing a Bayesian Threat Model for the Air and Marine Operations Center (AMOC) as a decision support system bridging operations and strategic needs.

4 - Using Game Theory for Optimizing System Deterrence Strategies

Nick Betzsold, Pacific Northwest National Laboratory, Richland, WA, United States, nicholas.betzsold@pnnl.gov

In this presentation, we will discuss the use of signaling games as a modeling construct for optimizing deterrence-specific system strategies. Signaling games allow varying player beliefs and uncertainties to be modeled with an overarching goal to model deterrence as an outcome of a game where optimal adversary actions at equilibria conditions favor the defender. We begin with an overview of signaling games, including mathematical elements of such games. Next, selected perfect Bayesian equilibria solution strategies for these games will be presented. Finally, results from a numerical case study applied to a generic security venue with practical implementation takeaways will be discussed.

5 - Managing Information Security Investments under Uncertainty

Yueran Zhuo, Harvard Medical School, Boston, MA, United States, yzhuo1@mgh.harvard.edu
Yueran Zhuo, University of Massachusetts-Amherst, Amherst, MA, United States, YZHUO1@mgh.harvard.edu, Senay Solak

Information systems security has become an integral part of today's business operations. Firms are concerned with whether their investment portfolio is aimed towards maximizing returns, while also gradually come to acknowledge the importance of information sharing in information system security. In this presentation, we introduce our work on three practical problems related to information system security investment management which derive managerial insights for technology investment and information sharing decisions. The findings of our study help firms to improve the efficiency of information system security practice and better defend against attacks on their information properties.

Emerging Topic: Daniel H. Wagner Competition

Emerging Topic Session

1 - London Heathrow Airport Uses Real-Time Analytics for Improving Operations

Xiaojia Guo, University College-London, London, United Kingdom, Yael Grushka-Cockayne, Bert De Reyck

Improving collaborative decision-making is at the heart of airport operations centers (APOCs), recently established in major European airports. Our project's goal was to examine the opportunities offered by the co-location and real-time data sharing in the APOC at London's Heathrow airport. In the paper, we describe the process of how we chose the subject of a pilot, namely the improvement of transfer passenger flows through the airport, and how we helped Heathrow move from their legacy system for predicting passenger flows to an advanced machine learning based approach using real-time inputs. The framework we present can support the development and implementation of other data-driven systems.

2 - Ride-hailing Order Dispatching on DiDi via Reinforcement Learning

Zhiwei Qin, DiDi Research America, 450 National Ave, Mountain View, CA, 94043, United States, Xiaocheng Tang, Yan Jiao, Fan Zhang, Zhe Xu, Hongtu Zhu, Jieping Ye

Order dispatching (or order matching) is instrumental to the marketplace engine of a large-scale ride-hailing platform like DiDi. Due to the dynamic nature of supply and demand, the ride-hailing order dispatching problem is very challenging to solve over a long horizon. Added to the complexity are considerations of system performance and multi-objectives. In this paper, we describe the evolution of our approach to this optimization problem from a myopic combinatorial optimization approach to one that encompasses a semi-MDP model and deep reinforcement learning for long-term optimization.

Decomposition Methods

Sponsored: Optimization/Computational Optimization and Software

Sponsored Session

Chair: Matthew Galati, SAS Institute, Inc., Glen Mills, PA, 19342, United States

1 - Distributed Dantzig Wolfe Decomposition

Mohamed El Tonbari, Georgia Institute of Technology, Atlanta, GA, United States, Shabbir Ahmed

Dantzig-Wolfe decomposition (DWD) is a classical algorithm for solving large-scale linear programs which decomposes the problem into a master problem and a set of independent subproblems. Typically, the master problem is solved centrally, which can be undesirable or infeasible, such as in the case of decentralized storage of data or privacy issues. In this work, we propose a fully distributed DWD algorithm that relies on solving the master problem using a distributed consensus based ADMM algorithm. We derive error bounds on the optimality and feasibility gaps, and illustrate the validity of our algorithm using a Message Passing Interface (MPI) implementation.

2 - Decomposition Branching for Mixed Integer Programming

Baris Yildiz, Assistant Professor, Koc University, Istanbul, Turkey, Natashia Boland, Martin W. P. Savelsbergh

We introduce a novel and powerful approach for solving certain classes of mixed integer programs (MIPs): decomposition branching. Two seminal and widely used techniques for solving MIPs, branch-and-bound and decomposition, form its foundation. Computational experiments with instances of a weighted set covering problem and a regionalized p-median facility location problem with assignment range constraints demonstrate its efficacy: it explores far fewer nodes and can be orders of magnitude faster than a commercial solver.

3 - Learning Generalized Strong Branching for Set Covering / Packing and 0-1 Knapsack Problems

Yu Yang, Georgia Institute of Technology, Atlanta, GA, United States, yangyu@gatech.edu, Natashia Boland, Martin Savelsbergh, Bistra Dilkina

Set branching, a natural generalization of standard branching, branches on a set of variables, which potentially gives tighter local bounds and consequently yields smaller search trees. However, to decide a good set to branch on can be prohibitively time-consuming. Generalized Strong Branching on sets up to size k (GSB-k) considers sets of size no larger than k and chooses the set in a strong branching fashion. We apply machine learning techniques to learn GSB-2 and demonstrate that the learned branching method significantly outperforms CPLEX default branching on set covering/packing as well as 0-1 knapsack problems.

4 - Item Aggregation and Column Generation for Online-retail Inventory Placement

Annie I-An Chen, USC Marshall, Los Angeles, CA, 90064, United States, annieich@usc.edu, Stephen C. Graves

We study an online retailer's problem of selecting fulfillment centers for placing items so as to minimize costs. There can be millions of items, and fulfillment centers have fixed costs, so the resulting optimization problem has a large number of binary variables. We propose a large-scale optimization framework that aggregates items into clusters, solves the cluster-level problem with column generation, and disaggregates the solution into item-level placement plans. We develop an a priori optimality gap bound, and apply the framework to a numerical example with 1,000,000 items to show that it produces near-optimal solutions in a computationally efficient manner.

5 - Recent Progress in CPLEX Benders Decomposition

Andrea Tramontani, IBM Italy, Via Martin Luther King, 38/2, Bologna, 40132, Italy

In this talk we present the Benders decomposition branch-and-cut that is implemented in CPLEX for Mixed Integer Linear Programming (MILP). We illustrate the main algorithmic components behind our implementation and discuss the latest improvements that are currently work in progress. Finally, we present an extensive computational analysis on some classes of decomposable MILP problems, to assess the performance of Benders branch-and-cut in comparison with the default branch-and-cut of CPLEX. The results show that some models that are out of reach for a "standard" branch-and-cut can instead be solved by Benders decomposition.

Chair: Cemil Dibek

Co-Chair: Bachir EL Khadir, Princeton, NJ, 08540, United States

1 - Sudoku via Optimization

Robert J. Vanderbei, Professor, Princeton University, Operations Research & Financial Engineering, Princeton, NJ, 08544, United States, rvdb@princeton.edu

Optimization tools can be used to create and solve Sudoku problems. The simplest formulation of a solver is as an integer programming problem. But, if the problem is known to have a unique solution, as is the case in real Sudoku problems, then the solution can be found by solving a linear optimization problem. We will discuss these formulations and, if time permits, also discuss how to generate Sudoku problems that have a unique solution.

2 - Implicit Regularization for Solving Random Quadratic Systems of Equations

Yuxin Chen, Princeton University, Princeton, NJ, 08540, United States, Cong Ma, Kaizheng Wang, Yuejie Chi

Recent years have seen a flurry of activities in designing efficient nonconvex procedures for solving quadratic systems of equations. The state-of-the-art procedures often require proper regularization to ensure fast convergence. However, prior theory either recommends highly conservative learning rates to avoid overshooting, or completely lacks performance guarantees. This work uncovers a striking phenomenon: even in the absence of explicit regularization, GD enforces proper regularization implicitly. This “implicit regularization” feature allows GD to proceed far more aggressively without overshooting, which results in substantial computational savings.

3 - Learning Dynamical Systems with Side Information

Bachir EL Khadir, Princeton University, Princeton, NJ, 08540, United States, bkhadir@princeton.edu, Amir Ali Ahmadi

We study the problem of learning dynamical systems from very limited data but in presence of “side information”, such as physical laws or contextual knowledge. This is motivated by safety-critical applications where an unknown dynamical system needs to be controlled after a very short learning phase where a few of its trajectories are observed. (Imagine, e.g., the task of autonomously landing a passenger airplane that has gone through sudden wing damage.) We show that sum of squares optimization is particularly suited for exploiting side information in order to assist the task of learning when data is limited.

4 - An Algebraic Perspective on Perfect Graphs

Cemil Dibek, Princeton University, Princeton, NJ, 08540, United States, Amir Ali Ahmadi

For a graph G=(V,E) with clique number (G), if we define the quartic form bG(x) in the variables x=(x1, ..., x|V(G)|)T by bG(x) = -2 (G) ∑ xi2xj2 + ((G) - 1) (∑ xi2)2, then the Motzkin-Straus theorem implies that bG(x) is nonnegative. In this work, we introduce the notion of sos-perfectness. A graph G is perfect if for every induced subgraph H, the chromatic number of H equals the clique number of H. A graph G is sos-perfect if bH(x) is a sum of squares (sos) for every induced subgraph H of G. We show that a graph is perfect if and only if it is sos-perfect. This equivalence together with the strong perfect graph theorem allows us to explicitly provide an infinite family of nonnegative polynomials that are not sos.

Sponsored Session

Chair: Akshay Gupte, Clemson University, Clemson, SC, 29634-0975, United States

1 - Partial Symmetries and Grid-free Algorithms for Cut-generating Functions

Matthias Koeppe, University of California-Davis, Dept of Mathematics, Davis, CA, 95616, United States, mkoeppe@math.ucdavis.edu, Robert Hildebrand, Yuan Zhou

The infinite group problem is an infinite-dimensional model that provides the coefficients of general-purpose cutting planes to integer programs via cut-generating functions (CGFs). For any CGF, we define a space of perturbation functions, improving directions that strengthen (lift) the CGF. If the space is trivial, the CGF is extreme. We express partial symmetries of perturbations using inverse semigroup actions. We provide a complete characterization of the space of perturbations and the foundation for grid-free algorithms for cut-generating functions. We benchmark our implementation of these methods against earlier, grid-based algorithms related to Gomory’s finite group problem.

2 - Algorithms for Discrepancy Minimization

Thomas Rothvoss, University of Washington, Seattle, WA, 98103, United States, rothvoss@uw.edu

A classical theorem of Spencer shows that any set system with n sets and n elements admits a coloring of discrepancy O(n^1/2). Recent work of Bansal, Lovett and Meka shows that such colorings can be found in polynomial time. We continue this exciting line of research and present two new algorithms: (1) We present a deterministic polynomial time algorithm for finding colorings in the Lovett-Meka setting. The algorithm is based on the Multiplicative Weight Update Method. (2) We also prove that a surprisingly simple randomized algorithm can find a partial coloring in a symmetric convex set with large enough Gaussian measure in polynomial time. This is joint work with Avi Levy and Harish Ramadas.

3 - Approximability of Constrained Submodular and Subadditive Maximization

Akshay Gupte, Clemson University, Dept. of Mathematical Sciences, Clemson, SC, 29634-0975, United States, agupte@clemson.edu

We prove that maximizing a submodular function subject to arbitrary number of $\le$ and $\ge$ easy knapsack constraints is NP-hard to approximate within factor 0.6622 \sqrt{n}/(2(log n)^(0.75 + eps)) for arbitrary eps > 0. “Easy” refers to knapsacks for which the cover relaxation is integral. If the number of easy constraints is bounded by a constant, then the complexity is O(poly(n) K) where K is the complexity of submodular maximization over the remaining set of constraints. We also give a simple rounding algorithm that for any constant k >= 1 gives a factor n/k approximation for maximizing a subadditive function over multiple matroid constraints.

4 - Fair Dimensionality Reduction and Iterative Rounding for SDPs

Uthaipon (Tao) Tantipongpipat, PhD candidate, Georgia Institute of Technology, Atlanta, GA, United States, Samira Samadi, Mohit Singh, Jamie Morgenstern, Santosh Vempala

We model “fair” dimensionality reduction as an optimization problem. A central example is the fair PCA problem: an input data is divided into k groups, and the goal is to find a single d-dimensional representation for all groups for which the maximum variance (or minimum reconstruction error) is optimized for all groups in a fair (or balanced) manner. We give an exact polynomial-time algorithm for k=2 groups. The result relies on extending results of Pataki (1998) regarding rank of extreme point solutions to semi-definite programs. This approach generalizes to any monotone concave function of the individual group objectives and general d,k with O(sqrt(k)) violation in the number of target dimension d.

Data-Driven Optimization Under Uncertainty

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Dimitris Bertsimas, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States

1 - Dynamic Optimization with Side Information

Bradley Sturt, Massachusetts Institute of Technology, Cambridge, MA, 02144, United States, bsturt@mit.edu, Dimitris Bertsimas

We present a scalable approach for leveraging machine learning in dynamic optimization under uncertainty. Our approach finds policies by solving a robust optimization problem with multiple uncertainty sets, which are constructed using historical data and machine learning (such as random forests and kNN). Through a novel concentration inequality, we show that the policies have near-optimal average performance in big data settings (w.p.1) and can be tractably approximated using overlapping linear decision rules. Across examples from inventory management and finance with over ten stages, our method finds policies in under one minute which outperform alternatives by 15%.

2 - Distributionally Robust Risk Measures with Structured Wasserstein Ambiguity Sets

Viet Anh Nguyen, Ecole Polytechnique Federale de Lausanne (EPFL), OD Y. 1.19, Station 5, Lausanne, 1015, Switzerland, Soroosh Shafieezadeh-Abadeh, Damir Filipovic, Daniel Kuhn

By injecting structural information about the unknown true distribution of the uncertain problem parameters into the outer approximation of the Wasserstein ambiguity set, we obtain several new optimization problems where the decision maker is minimizing risk measures such as the Value-at-Risk, the Conditional Valueat-Risk or the entropic risk measure.

3 - Data Analytics with B(R)agging Prediction Models

Bart Paul Gerard Van Parys, MIT Sloan School of Management, Cambridge, MA, 02139, United States

Boostrap aggregation or bagging is a well known statistical tool which increase the power of statistical predictions. In this presentation we generalize bagging methods to data-driven decision-making as well. In particular, we discuss how bootstrap robust aggregation (bragging) methods can make robust decisions based directly on supervised data. In addition, we reveal how bragging formulations are intimately related to distributionally robust optimization. Crucially, our bragging methods are computationally tractable and are interpretable.

4 - Optimization over Continuous and Multi-dimensional Decisions with Observational Data

Christopher G. McCord, Massachusetts Institute of Technology, Cambridge, MA, 19711, United States, mccord@mit.edu

We consider the optimization of an uncertain objective over continuous and multi-dimensional decision spaces in problems in which we are only provided with observational data. We propose a novel algorithmic framework that is tractable, asymptotically consistent, and superior to comparable methods on example problems. Our approach leverages predictive machine learning methods and incorporates information on the uncertainty of the predicted outcomes for the purpose of prescribing decisions. We demonstrate the efficacy of our method on examples involving both synthetic and real data sets.

1 - Computationally Efficient Approximations for Distributionally Robust Optimization

Jianqiang Cheng, University of Arizona, Tucson, AZ, 85721, United States, jqcheng@email.arizona.edu, Meysam Cheramin, Ruiwei Jiang

Many distributionally robust optimization (DRO) instances can be formulated as semidefinite programming (SDP) problems. However, SDP problems in practice are computationally challenging. In this talk, we present computationally efficient (inner and outer) approximations for DRO problems based on the idea of the principal component analysis (PCA). We also derive theoretical bounds on the gaps between the original problem and its PCA approximations. Furthermore, an extensive numerical study shows the strength of the proposed approximations in terms of solution quality and runtime.

2 - Multistage Distributionally Robust Mixed-integer Programming with Decision-dependent Ambiguity Sets

Siqian Shen, Associate Professor, University of Michigan, Industrial & Operations Engineering, Ann Arbor, MI, 48109, United States, siqian@umich.edu, Xian Yu

We study multistage distributionally robust optimization models with integer variables and endogenous uncertainty. We consider ambiguity sets defined by 1) decision-dependent bounds on the moments, 2) exact decision-dependent mean and covariance, and 3) ambiguous mean and covariance that lie in an ellipsoid and a positive semidefinite cone, respectively. We apply McCormick envelopes and inner approximation of positive semidefinite cones to recast the subproblem in each stage as a mixed-integer linear program and then apply Stochastic Dual Dynamic integer Programming (SDDiP). We test instances of the decision-dependent multistage facility location problem to demonstrate the results.

3 - Tractable Reformulations of Distributionally Robust Two-stage Stochastic Programs with ∞-Wasserstein Distance

Weijun Xie, Virginia Tech, Department of Industrial and Systems Engineering, Blacksburg, VA, 24061, United States, wxie@vt.edu

This paper studies distributionally robust two-stage stochastic programs (DRTSP) with ∞-Wasserstein distance by providing sufficient conditions under which the worst-case expected recourse function in DRTSP can be efficiently computed via a tractable convex program. The developed reformulation techniques are extended to DRTSP with binary random parameters. The main tractable reformulations in this paper are projected into the original decision space and thus can be interpreted as conventional two-stage stochastic programs under discrete support with extra penalty terms enforcing the robustness. These tractable results are further demonstrated to be sharp through complexity analysis.

4 - Nurse Staffing under Uncertain Demand and Absenteeism

Minseok Ryu, University of Michigan, Ann Arbor, MI, 48105, United States, msryu@umich.edu, Ruiwei Jiang

This paper describes a data-driven approach for nurse staffing decision under uncertain demand and absenteeism. We propose a distributionally robust nurse staffing (DRNS) model with both exogenous (stemming from demand uncertainty) and endogenous uncertainty (stemming from nurse absenteeism). We provide a separation approach to solve the DRNS model with general nurse pool structures. Also, we identify several classes of nurse pool structures that often arise in practice and show how the DRNS model in each of these structures can be reformulated as a monolithic mixed-integer linear program that facilitates off-the-shelf commercial software. Also, we propose an optimal nurse pool design model.

Stochastic Programming on Power Systems with Uncertainty

Sponsored: Optimization/Optimization Under Uncertainty

Sponsored Session

Chair: Yiling Zhang, University of Michigan, Ann Arbor, MI, 48105, United States

1 - Distributionally Robust Chance Constrained Optimal Power Flow Assuming Unimodal Distributions with Misspecified Modes

Bowen Li, Argonne National Laboratory, Lemont, IL, 48105, United States, bowen.li@anl.gov, Ruiwei Jiang, Johanna Mathieu

Recent OPF works have explored distributionally robust chance constraints, in which the constraints are satisfied over a set of distributions called the ambiguity set. Commonly, ambiguity sets contain only moment-based information; however, specifying additional characteristics such as the unimodality information can reduce conservatism and cost. In practice, it is difficult to estimate the mode location from the data and so we allow it to be potentially misspecified. We formulate the problem and derive a separation-based algorithm to efficiently solve it. With simulations, we find that a misspecified mode significantly affects the reliability of the solution.

2 - Benders Decomposition with Projection Cuts – A Case Study on Two-stage Stochastic Unit Commitment Problem

Haoming Shen, University of Michigan, Ann Arbor, MI, United States, Ruiwei Jiang

We study a class of two-stage stochastic linear programs and their solution via Benders decomposition. In particular, we propose a family of cutting planes, termed the projection cuts (PCs), for accelerating the Benders decomposition. Through incorporating the structural information of the second-stage formulation, PCs could help reduce the number of feasibility cuts involved in Benders. In a case study, we apply PCs to the stochastic unit commitment test instances and report promising results.

3 - Temporal and Spatial Decomposition of Power System Planning Problems

Antonio J. Conejo, The Ohio State University, Department of Integrated Systems Engineering, Columbus, OH, 43210, United States, conejonavarro.1@osu.edu, Ramteen Sioshansi

Power system planning problems are becoming increasingly challenging. High renewable penetration levels complicate the problem in two ways. First, accurate uncertainty modelling requires require short- and long-term uncertainties to be captured. Second, economic renewable integration requires greater use of spatially diverse resources, thereby increasing the physical footprint of planning problems. In this talk, we explore the use of decomposition techniques (e.g., efficient variants of Lagrangian relaxation and Benders's decomposition) to tackle this important problem by exploiting its temporal and spatial structures.

4 - Distributionally Robust Building Load Control to Compensate Fluctuations in Solar Power Generation

Yiling Zhang, University of Michigan, Ann Arbor, MI, 48105, United States, zyiling@umich.edu, Jin Dong, Teja Kuruganti, Siqian Shen, Yaosuo Xue

This paper investigates the use of a collection of dispatchable heating, ventilation, and air conditioning (HVAC) systems to absorb low-frequency fluctuations in renewable energy sources, especially in solar photovoltaic (PV) generation. Given the uncertain and time-varying nature of solar PV generation, its probability distribution is difficult to be estimated perfectly. We formulate a distributionally robust chance-constrained model to ensure that PV generation is consumed with a desired probability for an ambiguity set based on moment information. We show that the DRCC model achieves constantly good performance even in the case with the presence of probability distribution ambiguity.

Round Table – Positive Train Control

Sponsored: Railway Applications

Sponsored Session

Chair: Jeremiah Dirnberger, GE Transportation, Jacksonville, FL, 32217, United States

Moderator

Jeremiah Dirnberger, Product Manager, Wabtec Corporation, Jacksonville, FL, 32217, United States, jeremiah.dirnberger@wabtec.com

Positive Train Control (PTC) is one of the largest infrastructure projects ever undertaken by a single industry. Mandated by the U.S. government, PTC aims to further reduce the risk of accidents on the nation's rail network. The amount of data collected for the operation of this system is unprecedented and the industry is looking to leverage it to create the backbone of a digital railroad. In these panels, experts from several leading will discuss the potentials within this new data, how it is already being used, the opportunity for data scientists and operations researchers, and its role in the path toward automation in the rail industry.

Panelists

- Larry Chalmers, Wabtec Corporation
- Marty Schlenker, BNSF Railway, Fort Worth, TX, United States
- Patricia Randall, Princeton Consultants, Greenville, SC, 29605, United States
- Steven Harrod, Technical University of Denmark, Lyngby, 2800, Denmark

Optimization Perspectives on Reinforcement Learning

Sponsored: Optimization/Nonlinear Programming

Sponsored Session

Chair: Alec Koppel, U.S. Army Research Laboratory, Silver Spring, MD, 20910, United States

1 - Provably Efficient Reinforcement Learning with Linear Function Approximation

Zhuoran Yang, Princeton University, Princeton, NJ, 08544, United States

The introduction of function approximation in RL raises a fundamental set of challenges involving computational and statistical efficiency, especially given the need to manage the exploration/exploitation tradeoff. As a result, a core RL question remains open: how can we design provably efficient RL algorithms that incorporate function approximation? In this talk, we present the first provable RL algorithm with both polynomial runtime and polynomial sample complexity in the setting with linear dynamics and linear rewards, where linear value functions are adopted. Without requiring a "simulator" or additional assumptions, we prove that an optimistic modification of Least-Squares Value Iteration (LSVI) achieves O(\sqrt{d^3H^3T}) regret, where d is the ambient dimension of feature space, H is the length of each episode, and T is the total number of steps. Importantly, such regret is independent of the number of states and actions. This is based on a joint work with Chi Jin, Zhaoran Wang, and Michael Jordan.

2 - Global Convergence of Policy Gradient Methods: A Nonconvex Optimization Perspective

Alec Koppel, Research Scientist, U.S. Army Research Laboratory, 8710 Cameron street apt 1509, Adelphi, MD, 20910, United States

Reinforcement Learning (RL) has gained popularity recently with the success of AlphaGo besting the world champion in Go during summer 2016. However, recent successes of RL have been called into question due to high variance across training runs. Motivated by this gap, we spotlight efforts to solidify theoretical understanding of the rate analysis and limiting properties of policy gradient (PG) methods in continuous Markov Decision Problems from a non-convex optimization perspective. Moreover, we design modified step-size rules that yield convergence to local extrema under additional hypotheses on the reward. These results yield a framework for the future design of stable and reliable RL tools.

3 - Plan Online Learn Offline: Efficient Learning and Exploration via Model-based Reinforcement Learning

Aravind Rajeswaran, PhD Student, University of Washington, Seattle, WA, United States, aravraj@cs.washington.edu

We propose a plan online and learn offline (POLO) framework for the setting where an agent, with an internal model, needs to continually act and learn in the world. Our work builds on the synergistic relationship between local model-based control, global value function learning, and exploration. We study how trajectory optimization copes with approximation errors in the value function and stabilizes training. Conversely, we also study how value functions can help reduce planning horizon. Finally, we also demonstrate how and why planning is a critical component for efficient exploration.

4 - Target-based Temporal-difference and Q-learning

Donghwan Lee, Postdoctoral Associate, University of Illinois, Urbana-Champaign, Urbana, IL, United States, donghwan@illinois.edu, Niao He

In this work, we introduce a new family of target-based temporal difference (TD) learning algorithms and provide theoretical analysis on their convergence. In contrast to the standard TD-learning, target-based TD algorithms maintain two separate learning parameters{the target variable and online variable. Particularly, we introduce three members in the family, called the averaging TD, double TD, and periodic TD, where the target variable is updated through an averaging, symmetric, or periodic fashion, mirroring those techniques used in deep Q-learning practice. We establish asymptotic convergence analyses for both averaging TD and double TD and a finite sample analysis for periodic TD. Finally, we briefly discuss the Q-learning extension of the target-based TD learning.

CC- Room 610

Conic Optimization III

Sponsored: Optimization/Linear and Conic Optimization

Sponsored Session

Chair: Palma London, Caltech, 1200 E. California Blvd., Pasadena, CA, 91125, United States

1 - Computational Experience with a Modified Potential Reduction Algorithm for Conic Optimization

KuoLing Huang, Principal Scientist, Anthem, Inc., Chicago, IL, United States, jupiters1117@gmail.com

We present a homogeneous algorithm equipped with a modified potential function for solving conic optimization problems. The potential function described here ensures a global linear polynomial-time convergence while providing the flexibility to integrate heuristics for generating the search directions and step length computations. A practical algorithm based on this potential function is implemented in a free software package named Colin. Computational results on standard test problems against other mature software packages will be discussed.

2 - Lower Bounds for Parallel and Randomized Convex Optimization

Cristobal Guzman, PUC-Chile, Santiago, Chile, Jelena Diakonikolas

We study the question of whether parallelization in the exploration of the feasible set can be usedto speed up convex optimization, in the local oracle model of computation. We show that the answer is negative for both deterministic and randomized algorithms applied to essentially any of the interesting geometries and nonsmooth, weakly-smooth, or smooth objective functions. In particular, we show thatit is not possible to obtain a polylogarithmic (in the sequential complexity of the problem) number of parallel rounds with a polynomial (in the dimension) number of queries per round.

3 - The Outcome Range Problem: Exact and Approximation Methods

Mohsen Mohammadi, University of Louisville, Louisville, KY, United States, m0moha15@louisville.edu, Monica Gentili, Milan Hladík

We consider the linear programming problem in which all or some of input data can vary within given real intervals. Determining the set of all optimal solutions arising from all perturbations of uncertain data has been a problem of interest in this topic. We introduce, in this context, the outcome range problem which consists of determining the best and the worst values of a given (additional) linear function over the set of all optimal solutions of a linear program with interval data. We formally define the problem and address its complexity. We then investigate lower and upper bound approximation for the problem. We also propose a branch and bound based algorithm to solve the problem to optimality.

4 - An Acceleration Framework for Packing Linear Programs

Palma London, Caltech, Pasadena, CA, United States, plondon@caltech.edu, Shai Vardi, Adam Wierman, Hanling Yi

This paper presents an acceleration framework for packing linear programming problems where the amount of data available is limited, i.e., where the number of constraints m is small compared to the variable dimension n. The framework can be used as a black box to speed up linear programming solvers dramatically, by two orders of magnitude in our experiments. We present worst-case guarantees on the quality of the solution and the speedup provided. The framework can be used to accelerate exact solvers, approximate solvers, and parallel/distributed solvers. Further, it can be used for both linear programs and integer linear programs.

Cliques, Relaxations, and Interdiction

Sponsored: Optimization/Network Optimization

Sponsored Session

Chair: Balabhaskar Balasundaram, Stillwater, OK, 74078, United States

Co-Chair: Juan Sebastian Borrero, Oklahoma State University

1 - Fault-tolerant S-clubs

Yajun Lu, Bucknell University, Industrial Engineering & Manag, Lewisburg, PA, 74078, United States, Hosseinali Salemi, Baski Balasundaram, Austin Buchanan

Cliques and their graph-theoretic generalizations are frequently used to model tightly knit clusters in graphs. One such model is the s-club, a vertex set that induces a subgraph of diameter at most s. As low diameter requires the presence of short paths in the induced subgraph, this property is not hereditary on vertex-induced subgraphs. The pursuit of a "robust" extension of the s-club model spawned the r-robust s-club model variant that we discuss in this talk. We address the complexity of the feasibility testing and optimization problems associated with these variants, propose cut-like formulations, and explore algorithmic ideas to solve benchmark instances with several thousand vertices.

2 - Clique and 2-club Signatures

Hao Pan, Oklahoma State University, Stillwater, OK, 74074, United States, hao.pan@okstate.edu, Baski Balasundaram, Juan Sebastian Borrero

We introduce the notion of graph signature in a finite sequence of graphs that can accommodate multiple graph-theoretic structures simultaneously in order to describe a persistent pattern in a sequence of graphs. This modeling framework is motivated by the need to detect a subset of vertices that model for instance, a cohesive social subgroup in a series of "snapshots" of a social network that is evolving over time. In this setting we assume that the subgraphs of interest may not all look alike in the snapshot graphs. We formulate the general problem and propose an algorithmic framework that we investigate computationally for clique and 2-club signatures.

3 - Blocking Cliques via Edge Removals

Foad Mahdavi Pajouh, University of Massachusetts Boston, Boston, MA, United States, Foad.Mahdavi@umb.edu

The minimum cost edge blocker clique problem (EBCP) is introduced as the problem of removing a minimum cost subset of edges in a graph so that each clique's weight is bounded above by some threshold. Large-weight cliques effectively model clusters of important actors with quick communications in real-world settings such as social, communication, and biological systems. This talk presents complexity results, polyhedral results, and two exact algorithms for this problem. Computational results of solving EBCP on a collection of random graphs and power-law real-world networks by using our proposed exact algorithms are also provided.

4 - Perfect Neighbor Sets in Graphs

Umur Hastürk, Middle East Technical University, Ankara, Turkey, hasturk@metu.edu.tr, Mustafa Kemal Tural

In this study, we examine perfect neighborhood sets in undirected graphs. We propose two integer programming formulations for the problem and these formulations are made stronger with additional valid inequalities. Then, we conduct computational experiments to see the effect of these valid inequalities for different graph classes and for both weighted and unweighted objective functions.

5 - Minimum-cardinality Balanced Edge Addition in Polarized Networks: Formulation and Solution Approaches

Celso C. Ribeiro, Universidade Federal Fluminense, Rio de Janeiro, Brazil, Ruben Interian, Jorge R. Moreno

The node set V of a polarized network is divided into two or more strongly connected groups, with few inter-group edges. The minimal intervention principle assumes that a small number of changes should be made in the network to reduce polarization. The Minimum-Cardinality Balanced Edge Addition Problem seeks to minimize the number of edges to be added to a polarized network in order that any vertex of a vertex subset A can reach a vertex of V-A by a path with a limited number of edges in the resulting network. Integer programming and heuristic approaches and numerical results are presented.

Joint Session ICS/Opt. Integer & Discrete: Integration of Discrete Optimization and Machine Learning

Sponsored: Computing

Sponsored Session

Chair: Elias B Khalil, Atlanta, GA, 30309, United States

1 - Decision-focused Learning for Combinatorial Optimization

Bistra Dilkina, University of Southern California, 941 Bloom Walk, Los Angeles, CA, 90089, United States, Bryan Wilder, Aaron Ferber, Milind Tambe

In many real-world setting, we use ML models to estimate values that play a role in a downstream combinatorial optimization task. We propose a Decision-Focused Learning framework which melds the data-decisions pipeline by integrating prediction and combinatorial optimization into a single end-to-end system. The predictive model is trained using the quality of the decisions which it induces via the optimization algorithm. We show how the framework applies to predicting objective coefficient values for combinatorial problems that can be represented as linear programs (LPs) or as mixed integer linear programs (MILPs).

2 - Optimal Sparse Decision Trees

Cynthia Rudin, Duke, LSRC / Box 90129, Durham, NC, 27708, United States

The problem of computing optimal sparse decision trees is one of the oldest problems in artificial intelligence. Its solution has implications for interpretable machine learning. It is also extremely hard in practice. I will present an algorithm that achieves superior performance on the problem of sparse, binary-split decision trees for categorical variables. This algorithm is several orders of magnitude faster than prior approaches. Joint work with Xiyang Hu and Margo Seltzer.

3 - Embedding Constraint Reasoning in Machine Learning via Decision Diagrams

Yexiang Xue, Purdue University, Institute for Computational Sustainability, 344 Gates Hall, West Lafayette, IN, 14853-7501, United States, yexiang@purdue.edu, Willem-Jan Van Hoeve

The emergence of large-scale constraint reasoning and machine learning have led to a number of successful applications. Yet, a few applicational domains still remain out of reach of constraint reasoning or machine learning, when applied in isolation. To leverage the capabilities of both technologies, we propose an integrated method that Embeds Constraint Reasoning in Machine Learning (ECOR-ML). The core idea is to augment machine learning algorithms with a constraint reasoning module that represents operational constraints. By enforcing the constraints, the output of generative models can now provide assurances of safety, correctness, and/or fairness.

4 - The Voice of Optimization

Bartolomeo Stellato, Massachusetts Institute of Technology, MIT, Cambridge, MA, United States, stellato@mit.edu, Dimitris Bertsimas

We present a machine learning approach to predict the strategy behind the optimal solution of mixed-integer convex optimization problems. Using interpretable algorithms such as optimal classification trees (OCTs) we gain insights on the relationship between the problem parameters and the optimal solution. In this way, optimization is no longer a black-box and we can understand it. Moreover, using machine learning classifiers such as OCTs or neural networks (NNs), our method is able to compute optimal solutions at very high speed. We benchmark our approach on several examples obtaining accuracy above 90% and computation times multiple orders of magnitude faster than state-of-the-art solvers.

Decomposition Approaches in Integer Programming

Sponsored: Computing

Sponsored Session

Chair: Mucahit Cevik, Ryerson University, Toronto, ON, Canada

1 - Subtree Decomposition Method for Multistage Stochastic Programs

Rahman Khorramfar, NC state University, Raleigh, NC, 27606, United States, Osman Ozaltin

Considering the general multi-stage stochastic problem, this research develops a bounding framework based on the decomposition of the scenario tree. The framework is essentially a grouping methodology which systematically divides the scenario tree into sub-trees where each of them is amenable for commercial solvers. The independence of sub-trees allows computational parallelism. Therefore, the proposed framework can accommodate large-sized instances of Multi-stage Capacity Acquisition Problem (MCAP) with millions of scenarios and obtains tight bounds.

2 - A Decomposition Approach to Solve the Selective Graph Coloring Problem in Perfect Graphs

Oylum Seker, University of Toronto, Toronto, ON, Canada, oylum.seker@utoronto.ca, Tınaz Ekim, Z. Caner Taskin

The Selective Graph Coloring Problem is a generalization of the standard graph coloring problem; given a graph with a partition of its vertex set into clusters, the objective is to choose exactly one vertex per cluster so that, among all possible selections, the number of colors needed to color the vertices in the selection is minimum. The problem is known to be NP-hard, and remains so in many special classes of graphs. We focus on a decomposition based exact solution framework for selective coloring in perfect graphs. Our experiments indicate that our approach significantly improves solution performance compared to an integer programming formulation and a state-of-the-art method from the literature.

3 - Simultaneous Optimization of Isocenter Locations and Sector Duration in Radiosurgery

Mucahit Cevik, Ryerson University, Toronto, ON, 53726, Canada, Dionne Aleman, Young Lee, Mark Ruschin

Stereotactic radiosurgery (SRS) is an effective technique to treat brain metastasis for which inverse planning methods are considered to be appropriate. We propose an integer programming model for the simultaneous sector duration and isocenter optimization (SDIO) problem in SRS to tractably incorporate treatment time to the planning process. We devise a Benders decomposition scheme to solve the SDIO problem to optimality. The performances of our approaches are assessed using anonymized data from previously treated cases, and obtained treatment plans are compared against each other and against the clinical plans.

4 - Combinatorial Benders Decompositions for Optimal Discretization Orders in Distance Geometry Problems

Merve Bodur, University of Toronto, 5 King's College Road, Toronto, ON, M5S 3G8, Canada, bodur@mie.utoronto.ca, Moira MacNeil

The Discretizable Distance Geometry Problem (DDGP) is a feasibility problem, based on determining total orders in graphs. Recently, measures of the quality of these orders have been proposed, transforming the DDGP from a feasibility problem to an optimality problem. We present two novel integer programming formulations for this optimality-based DDGP problem and develop Combinatorial Benders Decomposition algorithms for their solutions. Our computational experiments show these decompositions outperform existing integer programming formulations in the literature.

Fast and Provable Nonconvex Optimization Algorithms in Machine Learning

Sponsored: Optimization/Nonlinear Programming

Sponsored Session

Chair: Lam M Nguyen, IBM Research, Thomas J. Watson Research Center, Yorktown Heights, NY, 10562, United States

Co-Chair: Quoc Tran-Dinh, University of North Carolina at Chapel Hill, NC, United States

1 - Optimized SARAH for Finite-sum Smooth Non-convex Optimization

Lam M. Nguyen, IBM Research, Thomas J. Watson Research Center, Yorktown Heights, NY, 10562, United States, lamnguyen.mltd@ibm.com, Marten van Dijk, Dzung Phan, Phuong Ha Nguyen, Tsui-Wei Weng, Jayant Kalagnanam

We introduce NC-SARAH for non-convex optimization as a practical slightly modified version of the original SARAH algorithm that was developed for convex optimization. NC-SARAH is the first to achieve two crucial performance properties at the same time - allowing flexible minibatch sizes and large step sizes to achieve fast convergence in practice as verified by experiments. NC-SARAH has a close to optimal asymptotic convergence rate equal to existing prior variants of SARAH called SPIDER and SpiderBoost that either use an order of magnitude smaller step size or a fixed minibatch size.

2 - A Unified Variance-reduced Accelerated Gradient Method for Convex Optimization

Yi Zhou, IBM Almaden Research Center, 650 Harry Road, San Jose, CA, 95120, United States, yi.zhou@ibm.com, Guanghui Lan, Zhize Li

In this talk, we propose a novel randomized incremental gradient algorithm, namely, the variance-reduced accelerated gradient (Varag) algorithm, for solving finite-sum optimization problems whose objective function consists of the average of m smooth components. We demonstrate that Varag exhibits the unified optimal rates of convergence for solving both convex and strongly convex problems. In addition, we show that Varag exhibits an optimal linear rate of convergence for solving a wide class of weakly strongly convex problems, which only satisfy a certain error bound condition rather than strong convexity.

3 - Proxsarah an Efficient Algorithmic Framework for Stochastic Composite Nonconvex Optimization

Nhan Pham, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, nhanph@live.unc.edu, Lam M. Nguyen, Dzung Phan, Quoc Tran-Dinh

We propose a new stochastic first-order algorithmic framework to solve stochastic composite nonconvex optimization problems that covers both finite-sum and expectation settings. Our algorithms rely on the SARAH estimator and consist of two steps: a proximal gradient and an averaging step making them different from existing nonconvex proximal-type algorithms. The algorithms only require an average smoothness assumption of the nonconvex objective term and additional bounded variance assumption if applied to expectation problems. In all cases, we prove that our algorithms can achieve the best-known complexity bounds.

4 - On the Complexity of Approximating Wasserstein Barycenters

Cesar A. Uribe, MIT, Cambridge, MA, 02138, United States, cauribe@mit.edu, Alexey Kroshnin, Darina Dvinskikh, Pavel Dvurechensky, Alexander Gasnikov, Nazarii Tupitsa

We study the complexity of approximating the Wassertein barycenter of m discrete measures of size n using entropic regularization. The first approach is based on the Iterative Bregman Projections (IBP) algorithm for which our novel analysis gives a complexity bound proportional to mn2/ 2. Using an alternative accelerated-gradient-descent-based approach, we obtain a complexity proportional to mn2/ . We show that the regularization parameter in both approaches has to be proportional to , which causes instability when the desired accuracy is high. We propose a novel proximal-IBP algorithm, which can be seen as a proximal gradient method, which uses IBP on each iteration to make a proximal step.

1 - Anticipatory Network Path Assignment for Shared-ride Automated Vehicles Considering Proximity to Future Demands

Michael Hyland, University of California, Irvine, Irvine, CA, United States, hylandm@uci.edu

Shared-ride mobility services such as demand-responsive transit and UberPool/Lyft Line face operational challenges associated with dynamically planning vehicle routes under stochastic demands. To improve operational efficiency, this study proposes a bi-criteria network path assignment strategy for shared-ride vehicles that considers travel time and proximity of network paths to expected future demands. Compared with shortest path assignments, the bi-criteria approach should increase sharing opportunities and decrease operational costs. The study assumes fully-automated vehicles (AVs) that comply with non-shortest path directions.

2 - Critical Market Share of Fleet-optimal Vehicles for Reducing Traffic Congestion

Matthew Battifarano, Carnegie Mellon University, Pittsburgh, PA, United States, mbattifa@andrew.cmu.edu

Connected and autonomous technologies have radically altered mobility systems by enabling ad hoc vehicle fleets which may be easily coordinated by a central service. Previous studies have investigated how route choices of connected vehicles may be coordinated to regulate traffic flow. However, service providers may route their vehicles in a fleet optimal manner to benefit the fleet, neither optimized for the system nor for individuals. We investigate how ad hoc fleet routing impacts the network. We identify the minimum market penetration rate of these service fleets at which fleet optimal routing benefits the system and the minimum penetration rate at which traffic flow is system optimal.

3 - Finding Optimal Park-and-Ride Facility Locations in an Urban Network

Pramesh Kumar, University of Minnesota, Minneapolis, MN, 55414, United States, Alireza Khani

This study proposes a mixed integer nonlinear programming (MINLP) problem to find the optimal location of park-and-ride facilities in an urban network. The objective is to minimize the total system travel time while satisfying stochastic user equilibrium.

4 - A Bi-Level Approach for Control of Large-Scale Urban Network using Macroscopic Fundamental Diagram

Seiran Heshammi, University of Calgary, Calgary, AB, Canada, Nadia Moshahedi, Lina Kattan

In this work, a large-scale urban network control problem under user equilibrium is investigated. The modeling approach adopted is Macroscopic Fundamental Diagram, dividing urban network into roughly homogeneous regions with a unimodal low-scatter relationship between network accumulation and outflow. To be able to globally control the large-scale urban network and reduce computational burden, both control and traffic assignment are done at regional level. The problem is modeled in the form of bi-level programming and solved using iterative optimization approach.

Joint session TSL AIR/ AAS/Practice Curated: Machine Learning Models for Airline Scheduling and ATM

Sponsored: Transportation Science & Logistics/Air

Sponsored Session

Chair: Lavanya Marla

Co-Chair: Ankur Mani, University of Minnesota, Minneapolis, MN, 63108-2432, United States

1 - Collaborative Routing and Sensing in the National Airspace

Jing Gao, University of Minnesota, Minneapolis, MN, 55114, United States, gao00030@umn.edu

The lack of availability of real-time information about changing weather makes the reconfiguration of airspace's and airline's network become difficult. To overcome this shortcoming, our project developed an integrated model-based and data-driven approach to design the detours deviating from normally optimal routes by utilizing in-use aircrafts as sensors to collect data. It can be shown our approach can enable true dynamic routing of aircrafts, minimize future delays and disruptions.

2 - Flight Plans Vs. Flight Policies: A Pilot'S Perspective

Ashish Kapoor, Microsoft, Redmond, WA, United States, akapoor@microsoft.com

Aerial Autonomy promise to increase efficiency, reduce cost and most importantly take on tasks that are too difficult for humans. The current flight missions, often with a human pilot in the loop, are plans based - where the sequence of actions or the path is (mostly) known a priori. Many recent advances in autonomy are resulting in systems that are policy based, where the set of actions are stochastic, non-deterministic and often difficult to predict. I'll discuss various advantages and disadvantages of along the continuum between flight plans and flight policies. I'll also put forward a pilot's perspective on various case studies which will range from small UAVs to real-world commercial aircraft.

3 - Integrated Aircraft and Crew Recovery Using Machine Learning and Optimization

Ahmet Esat Hizir, Massachusetts Institute of Technology, Cambridge, MA, United States, aehizir@mit.edu, Cynthia Barnhart, Vikrant Vaze

Due to the irregular nature of flight operations, airlines need to take a range of actions to recover their aircraft/crew schedules and passenger itineraries. In practice, this process has a sequential structure in which aircraft recovery is followed by crew and passenger recovery. While recovery problems are smaller in scope than their planning counterparts, limited time frames prevent airlines from using a full-scale optimization approach. This study proposes a set of new and practical ideas that combine machine learning and optimization tools to find near-optimal solutions for the integrated aircraft and crew recovery problem within limited time frames.

Innovative Last-Mile Delivery Concepts

Sponsored: Transportation Science & Logistics/Freight Transportation & Logistics

Sponsored Session

Chair: Tino Henke, Otto-von-Guericke University Magdeburg, Magdeburg, 39106, Germany

1 - When Microseconds Add Up: on the Real-Time Performance of Dynamic Time Slot Management

Niels Agatz, Rotterdam School of Management, Erasmus University, Rotterdam School of Management, Burg. Oudlaan 50, Rotterdam, Netherlands, nagatz@rsm.nl, Thomas Visser, Remy Spliet

To facilitate attended home delivery, e-grocers typically offer customers a menu of narrow delivery time slots to choose from. When the fulfillment capacity is scarce, the e-grocer should determine which time slots to offer to specific customers given the already accepted customer orders. Dynamically constructing the set of delivery time slots for a specific customer is often referred to as dynamic time slot management. In this contribution, we present several synchronization issues that occur due to the simultaneous interaction of different customers with the system and introduce procedures to deal with these issues.

2 - Package Deliveries with Autonomous Robots

Iurii Bakach, University of Iowa, Iowa City, IA, 52240, United States, iurii-bakach@uiowa.edu, Ann Melissa Campbell, Jan Fabian Ehmke

Autonomous robots can help making last-mile deliveries more efficient and customer friendly. We examine the use of robots to deliver individual packages in urban last-mile delivery. We look at the number of robots and robot hubs required along with time of completion as compared with traditional truck delivery models. We examine different assumptions on the speed of travel, geography, working hours and customer time window preferences to understand where autonomous robots are particularly valuable.

3 - An Urban Freight Share-a-Trip Delivery Problem

Dingtong Yang, University of California, Irvine, CA, United States, dingtony@uci.edu, Michael Hyland, R. .Jayakrishnan, Chenying Qin

Large numbers of drivers commute daily with empty space in their personal vehicles, which can be leveraged for freight delivery. This paper presents an urban freight delivery system where packages share space in light-duty personal vehicles as well as commercial trucks. The problem is formulated as a quadratic mixed integer program based on the m-VRP. The formulation minimizes total delivery cost and considers time window and capacity constraints. Preliminary results show a 55% reduction in VMT and a 60% decrease in total delivery costs compared to truck-only commercial delivery services.

4 - Mobile Collection Points in Crowdshipping

Alp Arslan, Singapore Management University, Pannekoekstraat 58C, Singapore, 3011LJ, Singapore, amuzaffera@smu.edu.sg, Shih-Fen Cheng

In this study, we introduce mobile collection points in last-mile delivery systems that rely on crowdsourced delivery capacity. We study the benefits of these points, i.e large size trucks, in a setting, in which they bring batches of parcels to the vicinity of crowd drivers' preferred delivery areas. We develop an optimization algorithm to solve a large scale the home delivery problem by integrating these collection points. In the numerical experiments, we show that one can increase the number of customers served by using mobile points.

5 - A Matheuristic for Planning Last-Mile Deliveries with Mobile Pick-up Stations

Tino Henke, Otto-von-Guericke University, Universitaetsplatz 2, Magdeburg, 39106, Germany, Jan Fabian Ehmke

Mobile pick-up stations have recently been proposed as an innovative concept for efficient last-mile deliveries. Such stations can be moved flexibly to temporary locations from which customers can then conveniently collect their parcels. We regard one particular problem in this context, which combines vehicle routing and location planning. For solving this problem, a matheuristic approach has been developed and tested by means of numerical experiments. The main findings as well as managerial insights on using mobile pick-up stations will be presented.

1 - An Integrated Learning & Progessive Hedging Matheuristic for Stochastic Network Design

Teodor Gabriel Crainic, Universite du Quebec a Montreal, School of Management, Department of Management & Technology, Montreal, QC, H3C 3P8, Canada, TeodorGabriel.Crainic@cirrelt.net, Walter Rei, Fatemeh Sarayloo

The matheuristic decomposes the stochastic network design problem into multi-scenario subproblems according to progressive-hedging principles. A learning-based procedure, combining heuristic-search techniques with mathematical programming, is used to address the subproblems and to acquire knowledge on promising design structures. This knowledge is then used to update the reference point and guide the overall search. Extensive computational experiments illustrate the efficiency of the proposed matheuristic in obtaining high-quality solutions with limited computational effort, particularly when addressing instances with many scenarios.

2 - Tripod: An Online Choice-Based Recommender System

Mazen Danaf, PhD Candidate, Massachusetts Institute of Technology, Cambridge, MA, United States, mdanaf@mit.edu, Yifei Xie, Carlos Lima de Azevedo, Bilge Atasoy, Moshe Emanuel Ben-Akiva

This paper presents the choice-based recommender system for Tripod, an app-based trip planner offering a personalized menu with real-time predicted information and optimized incentives. Users receive incentives in the form of tokens that can then be redeemed in a market place for goods and services offered by third party providers. Personalized recommendations are generated for each trip once a Tripod menu is requested. The online estimation framework proposed by Danaf et al. (2019) is used to update individual preferences after each choice. A large number of users is simulated to demonstrate scalability and show how the average hit-rate increases over time as we learn individual preferences.

3 - Bayesian Optimization for Stochastic Traffic Network Planning Problems

Zhen Tan, Nottingham University Business School (China), Ningbo, China

We propose a Bayesian learning method for solving stochastic traffic network optimization problems. By incorporating structured beliefs on the performance of each candidate solution, this method allows relatively cheap implementation and prevents evaluation of a large number of solutions. As an illustration, we apply the method to a public bicycle planning problem in which we have to decide the location and the size of each of the bicycle stations with the goal of minimizing the expected travel cost and construction cost under uncertain demand.

4 - Sequential Line Planning Problem with Integrated Learning for Emerging Mobility Routes

Gyugeun Yoon, New York University, Brooklyn, NY, 11201, United States, ggyoon@nyu.edu, Joseph Y.J. Chow

With limited information about travel patterns, operating a flexible transit system is difficult to achieve. This study proposes a novel sequential line planning algorithm incorporating the learning of prevailing mobility service demand to overcome the uncertainty of demand. From a generated feasible route set, the algorithm sequentially deploys individual routes and expands the system to obtain the optimal route set. Decisions made to determine which route to introduce is based on the ridership information learned by experimental vehicle operations. It will be able to assist the decision making to set the order in which route should be launched and keeping a limited resource budget.

Recent Trends in Facility Logistics

Sponsored: Transportation Science & Logistics/Facility Logistics

Sponsored Session

Chair: Sadan Kulturel-Konak, Penn State Berks, Reading, PA, 19610, United States

1 - The Forward-reserve Design Problem in Order Picking Warehouses with High Volume of Small Parts

Alice E. Smith, Auburn University, Dept of Industrial/Sys Engineering, Auburn, AL, 36849, United States, smithae@auburn.edu, Eliana Pena Tibaduiza, Mario Velez Gallego

Some order picking warehouses have improved their operations by designating a forward area. This area is a small zone that concentrates selected Stock Keeping Units (SKUs), thereby reducing travel times for order pickers. These SKUs must be replenished from the reserve area, incurring a replenishment labor cost. The forward-reserve design problem includes the definition of the size of the forward area, the SKUs to be stored in it, and the space allocate to each SKU. The aim of this research is to relax the common assumption that the distance traveled by pickers within the forward area is negligible.

2 - Advances in QAP and M-facility Placement

Rakesh Nagi, University of Illinois at Urbana, Urbana, IL, 61801, United States, nagi@illinois.edu

Finite-size facility location is an interesting confluence of facility layout and location analysis. We will cover the M-Finite size facility location problem where the continuous placement on a plane is transformed to a set of discrete candidate points. We will also cover recent advances in solving the Quadratic Assignment Problem, using RTL2 formulation and GPU computing.

3 - Game Theoretic Genetic Algorithm to Solve the Facility Location Problem

Sadan Kulturel-Konak, Penn State Berks, Reading, PA, 19610, United States, sadan@psu.edu, Abdullah Konak, Lawrence V. Snyder

We demonstrate an application of Game-Theoretic Genetic Algorithm (GTGA) to the Competitive Maximal Covering Location Problem, which is typically modeled as a two-player Stackelberg game such that first one player and then the other locate a fixed number of facilities to capture a maximum amount of revenue in a region. In contrast, the present work considers multiple players as well as both sequential and simultaneous games. Computational experiments show that the GTGA can converge to Stackelberg and Nash equilibria as well as outperform some existing approaches.

1 - Online Gradient-descent Methods for Computing Capacity Allocation and Bid Prices with Stochastic Demand

Shashi Mittal, Director, Research Science, Amazon, Seattle, WA, United States

Accurately controlling the package and passenger flow in an airline network is central to the financial health of an airline carrier. We illustrate that using Online Gradient Descent algorithm, which is inspired from similar algorithms used for solving optimization problems arising in Machine Learning literature, performs better than traditional methods. Our computational experiments show a reduction in the overall run-time for computing the optimal bid prices by 43% compared to traditional sub-gradient algorithms. Joint work with Pornpawee Bumpensanti, Shashi Mittal, Tim Jacobs and Tyler White.

Computational Methods in RM

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Gustavo J. Vulcano, Universidad Torcuato di Tella, Buenos Aires, 1428, Argentina

1 - Revenue-utility Trade off in Assortment Optimization under the Multinomial Logit Model with Totally Unimodular Constraints

Mika Sumida, Cornell Tech, New York, NY, 10128, United States, ms3268@cornell.edu, James Mario Davis, Guillermo Gallego, Paat Rusmevichientong, Huseyin Topaloglu

We consider an assortment optimization problem under a multinomial logit choice model with a social welfare objective that is the weighted sum of the revenue from the assortment and the expected maximum utility obtained by each customer. Our formulation allows for arbitrary totally unimodular constraints on the offered sets and generalizes existing formulations in the literature. We characterize the structural property of an optimal solution and prove that revenue-maximizing assortments, for appropriately adjusted revenues, are also socially optimal. We develop an efficient algorithm that computes the optimal solution based on parametric linear programming.

2 - Heteroscedasticity in Discrete Choice: An Empirical Test of Exponomial and Logit Models on Transportation Data

Rajesh Paleti, Pennsylvania State University, University Park, PA, United States, Aydin Alptekinoglu

An attractive feature of the heteroscedastic exponomial choice (HEC) model is its closed-form probability expression. In this study, the empirical applicability of HEC model is demonstrated in two choice contexts within the transportation domain - new vehicle purchase decisions and airline itinerary choices. The model fit as well as behavioral implications of the HEC model are compared against the heteroscedastic variant of the MNL model, called the heteroscedastic extreme value (HEV) model, which does not have a closed-form choice probability expression.

3 - Customer Loyalty in Ride-Hailing: Empirical Evidence

Dmitry Mitrofanov, New York University, New York, NY, 10012, United States, Maxime Cohen, Srikanth Jagabathula

Are customers loyal to a specific ride-hailing platform or they see this service as a commodity? Using a large panel dataset on ride-hailing transactions, we investigate to what extent customers are loyal. Our dataset offers a unique opportunity to study this question as we observe the choices for both Uber and Lyft. We first propose a way to overcome the issue of missing data on waiting times and competitor prices. We then estimate several reduced-form and choice models to examine customer loyalty and switching patterns. We find that even after controlling for prices and waiting times, customers are loyal to the most frequently used platform.

4 - Assortment Optimization Over Dense Universe is Easy

Goutam Kumar, Columbia University, New York, NY, United States, kg2621@columbia.edu, Vineet Goyal, Henry Lam

We investigate an alternate, continuous-space approximation to assortment optimization under mixed MNL model. We consider the case where product space is large. When features are densely populated (in stochastic or deterministic sense), we show that, among any possible assortment schemes represented by open sets containing assorted features, there exists a nested-by-revenue policy that is optimal. This characterization holds regardless of mixture distribution (it can be discrete or continuous) and dimension of feature space. We utilize tools from empirical process literature and derive an error bound between expected revenue evaluated by nested-by-revenue policy and global best policy.

Interface between Operations and Marketing

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Simone Marinesi, Wharton, Philadelphia, PA, 19103, United States

Co-Chair: Ruslan Momot, HEC Paris, HEC Paris, Jouy-en-Josas, 78350, France

1 - Managing Outside Funds in a Crowdfunding Campaign

Behrooz Pourghannad, University of Minnesota, Minneapolis, MN, 55901, United States, behrooz@umn.edu, Guangwen Kong, Laurens G. Debo

We study how an entrepreneur's use of social network infuses the crowdfunding campaign. We investigate how the investment from family and friends may impact the amount of investment that the entrepreneur could seek and how reciprocities can change the information flow.

2 - Incentive Design for Operations-marketing Multitasking

Christopher Ryan, University of British Columbia, 5807 S. Woodlawn Ave, Vancouver, BC, 60637, Canada, Tinglong Dai, Rongzhu Ke

A firm hires a store manager to make operational and marketing efforts. The outputs — demand and capacity — face demand censoring. We show the optimal compensation plan is a base salary with bonus paid when (i) a minimum level of inventory is sold out, or (ii) sales meets an inventory-dependent target.

3 - Should I Pay with Money or Redeem Points for this Purchase? How Exchange Rate Stability Influence Loyalty Point Redemption

So Yeon Chun, INSEAD, McDonough School of Business, 37th and O. Streets NW, Fontainebleau, 20057, France, soyeon.chun@insead.edu, Rebecca Hamilton

In many loyalty programs, customers earn points for their purchases, which they can later exchange for additional products and services. In this work, we examine how the program design characteristics of the exchange rate between money and points affect consumers' redemption choices. We first propose a conceptual model of the consumer's choice to redeem points then we analyze both secondary data from an airline loyalty program and primary data from experimental studies. We propose an underlying mechanism that can explain systematic behavior biases and discuss managerial implications.

4 - Created Unequal: Bundling with Crowdsourced Products

Lu Wang, Shanghai University of Finance and Economics, #100 Wudong Road, Shanghai, China, wang.lu@mail.shufe.edu.cn, Ming Hu

As consumer buying habits are trending toward more simple and hassle-free experiences, more and more companies are jumping into the innovative business model of subscription services. Subscription providers such as Spotify, Netflix and OneGo (an all-you-can-fly subscription service provider) crowdsource products/services from many vendors and bundle them for the price of one. The collected subscription fees for the bundle then are allocated according to the realized contributions by each crowdsourced product. However, this allocation scheme may create incentive incompatibility for vendors. We examine the incentive compatibility of different parties under various bundling strategies.

Networks, Mechanism Design, and New Markets – I

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Ozan Candogan, University of Chicago, Chicago, IL, 27708, United States

1 - Optimal Subscription Planning of Digital Goods

Ali Makhdoumi, Duke University, W315, 100 Fuqua Drive, Durham, NC, 27705, United States, Azarakhsh Malekian, Saeed Alaei

We consider the problem of a service provider selling digital goods such as movies to customers. The service provider (platform) chooses a subscription planning which specifies the set of movies to include in the subscription set, the subscription fee, and the price of individual movies. We find the optimal characterization of these choices.

2 - Incentives to Crowdsource Information in Informal Supply Chains

Joann de Zegher, MIT Sloan, Cambridge, MA, 02142, United States, jfz@mit.edu, Irene Yuan Lo

Over 60% of global employment operates in informal work environments, where decisions often rely on limited information from informal networks. In informal supply chains, network members also compete, which further disincentivizes sharing valuable information. We design incentive-compatible information-sharing mechanisms for such informal supply chains. To incentivize sharing, we select information disclosure policies that depend on information shared by members. We characterize optimal policies and show that sharing emerges as a SPNE that improves welfare of all members. Our model is informed by an information-sharing platform in informal palm oil supply chains in rural Indonesia.

3 - A Tale of Timescales: Surge Pricing and Dynamic Matching in Ride-hailing Networks

Zhe Liu, Columbia University, New York, NY, United States, ZLiu18@gsb.columbia.edu, Philipp Afeche, Costis Maglaras

We study a ride-hailing platform that matches price and delay sensitive riders with strategic drivers. Our model jointly considers surge pricing and dynamic spatial matching when the platform responds to an uncertain demand shock at a hotspot. Our results show the interplay between important timescales, e.g., rider patience, shock duration, and drivers' travel delay to the hotspot, and their impact on system performance.

4 - Fake Content Propagation in Social Networks and Factchecking Policies

Gizem Yilmaz, The University of Chicago, Chicago, IL, 60615, United States, Ozan Candogan, Varun Gupta

Social media platforms have introduced fact-checking programs to combat misinformation in online social networks. However, the limited capacity of the fact-checking resource does not allow to review all content in a timely manner. In this paper, we develop policies that prioritize different pieces of content for fact-checking to reduce the spread of erroneous content in the underlying social network. Our approach allows us to develop online matching algorithms with provable performance guarantees in settings where rewards decay over time, provided that they exhibit a 'decreasing differences' property.

Revenue Management and Marketplace Analytics I

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Kalyan Talluri, Imperial College Business School, London, SW7 2AZ, United Kingdom

1 - On the Power of Bounded Memory Peak End Demand Models

Tamar Cohen, MIT, Somerville, MA, 02144, United States, tcohen@mit.edu, Georgia Perakis, Kiran Panchamgam

We consider the problem of promotion planning for a single product, with bounded memory peak end demand. We show that when using this demand model, the optimal promotion policy will require at most two price levels. We then show that with a finite planning time horizon and a limit on the number of deviations from full price, we can find the structure of the optimal pricing policy. We characterize when the optimal policy is cyclic, as well as when a cyclic policy is not optimal. Finally, we show that even in the cases that we misclassify the demand model, and the true demand model does not fit the bounded memory peak end model, the estimation error is small. We provide an analytical bound on this estimation error.

2 - Dynamic Pricing in Ride-Hailing Marketplaces

Hamid Nazerzadeh, USC Marshall / Uber Technologies, Los Angeles, CA, United States, nazerzad@usc.edu

Ride-hailing marketplaces match millions of riders and drivers every day. One of the key features of Uber's marketplace is dynamic pricing, so called surge, that balances the demand for trips and the supply of available cars. The surge pricing also motivates drivers to relocate to parts of the city with higher demand. In this talk, I'll discuss the design and implementation of Uber's new driver surge mechanism.

3 - Threshold Utility Model with Applications to Retailing and Discrete Choice Models

Guillermo Gallego, Hong Kong University of Science and Technology, Hong Kong, 852, Hong Kong, ggallego@ust.hk, Ruxian Wang

We consider a threshold utility model (TUM) where consumers buy all products whose net utility exceeds a product-specific threshold. The consumer selects the thresholds to maximize the expected surplus subject to a bound on the expected number of selected products. We analyze properties of the TUM and consider both pricing and assortment optimization problems. We obtain optimal pricing policies and show that the assortment problem is NP-hard. An efficient approximation is developed with tight bounds. The TUM can also be used as a consideration set model. We establish tight bounds on the expected surplus of this consideration set model relative to that obtained by observing all products.

4 - Overbooking with Endogenous Demand

Rowena J. Gan, Wharton School of Business, University of Pennsylvania, Philadelphia, PA, 19103, United States, ganj@wharton.upenn.edu, Noah Gans, Gerry Tsoukalas

Using airlines as a backdrop, we study optimal overbooking policies with endogenous customer demand, when customers internalize their expected cost of being bumped. We first consider the traditional setting in which compensation for bumped passengers is fixed. We then extend our analysis to the case of auction-based compensation schemes and demonstrate that these generally outperform fixed compensation schemes. Numerical experiments that gauge magnitudes suggest that fixed-compensation policies that account for demand endogeneity can significantly outperform those that do not and that auction-based policies bring smaller but still significant additional gains.

Urban Applications of Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Claudius Steinhardt

Co-Chair: Arne Strauss

Co-Chair: Catherine Cleophas, Cau Kiel, Kiel, 24114, Germany

1 - Dynamic Pricing of Nested Time Windows in Attended Home Delivery

Sebastian Spindler, Bundeswehr University Munich, Munich, Germany, sebastian.spindler@unibw.de, Claudius Steinhardt

A common practice in attended home delivery is that customers can choose from differently priced time windows in which delivery will take place. The offered time windows are often nested in the sense that customers can either choose to be delivered in one of several narrow time windows, or in a wider window comprising several adjacent narrow windows, which then is usually cheaper. In this research, we address this setting and present an approach of dynamically determining prices, taking the suppliers additional operational flexibility arising from nested time windows into account.

2 - Dynamically Managing Delivery Time Slots and Vehicle Routing Across Multiple Days

Arne K. Strauss, University of Warwick, Coventry, United Kingdom, Arne.Strauss@wbs.ac.uk, Nalan Gulpinar, Yijun Zheng

Current research on demand management for attended home delivery typically considers deliveries for a single day only due to the difficulties in dynamically optimizing slot availabilities for many slot options across multiple days. However, in practice customers do typically choose a slot across multiple delivery days and hence we investigate how the modeling assumption that a customer is only interested in a single day affects overall profits. We empirically show that using more accurate choice models can increase total profitability when delivery capacity is tight. However, somewhat counterintuitively, this improvement is small and if capacity is ample, simple MNL models may in fact be better.

3 - Price List Optimization for Free-Floating Car Sharing Systems

Matthias Soppert, Universität der Bundeswehr München, Werner-Heisenberg-Weg 39, Building 36, Neubiberg, 85577, Germany, matthias.soppert@unibw.de, Claudius Steinhardt

Free-floating car sharing providers experience a strong growth of users but often struggle in generating a profitable fleet utilization. We study a car sharing provider's tactical problem of finding a profit-maximizing price list that differentiates minute prices locally and temporally. The car sharing system is represented as a network flow model in which the area of operation is discretized into zones and car rentals between different zones are modeled by flows within the network. In particular, we focus on the special characteristics of a free-floating system and its appropriate modeling and discuss solution approaches as well as numerical results for practice-relevant problem sizes.

4 - Surge Pricing in Shared Mobility Systems

Dennis H. Proksch, Bundeswehr University Munich, Neubiberg, Germany, Claudius Steinhardt

Research about shared mobility systems (SMS) has been mainly focused on either improving the service quality - often assuming public subsidies - or introducing vehicle relocation. This research focuses on increasing profit margins sustainably by dynamically adjusting the rent per minute. To compute efficient rents we present a mixed integer program which defines the system model according to approximate dynamic programming. As a direct lookahead only yields minor improvements, we set on to exploit the model structure and derive simple pricing policies, whose parameters we estimate via stochastic search. Our results suggest that SMS might increase their net revenue by up to ten percent.

5 - Anticipative Dynamic Slotting for Attended Home Deliveries

Catherine Cleophas, CAU Kiel, Kiel, 24118, Germany, cleophas@bwl.uni-kiel.de, Magdalena K. Lang, Jan Fabian Ehmke

To enable short time slots and punctual arrivals, efficient planning has become crucial factor in ensuring the profitability of attended deliveries. Planners need to anticipate the effect of promising to deliver orders in specific time slots on the further capacity for deliveries. To find reasonable solutions with limited computational effort, we present dynamic slotting approaches that consider anticipative routing information and approximate the opportunity cost of accepting orders based on a value function model. The results inform the dynamic time slot allocation per arriving order request. We present computational results on synthetic and empirical demand scenarios.

6 - Flexibility-based Time Window Pricing for Attended Home Deliveries

Jan Fabian Ehmke, Otto-von-Guericke University, Magdeburg, 39106, Germany, jan.ehmke@ovgu.de, Charlotte Köhler, Ann Melissa Campbell, Catherine Cleophas

In the challenging environment of attended home deliveries, pricing of time windows can play a crucial role to ensure the profitability and service quality of online retailers. Our goal is to nudge customers to choose time windows that do not overly restrict the flexibility of route plans. To this end, we present dynamic pricing policies that vary delivery fees according to the flexibility of the evolving route plans. We examine in which situations our policies can induce more revenue for the retailer and/or improve customer service. We compare these policies to simpler static pricing policies that reflect common business practice.

Data Driven Disaster Resilience

Sponsored: Public Sector OR

Sponsored Session

Chair: Benjamin Rachunok, Purdue University, West Lafayette, IN, 47906, United States

1 - Twitter and Disasters, Learning Resilience from Social Media

Benjamin Rachunok, Purdue University, West Lafayette, IN, 47906, United States, brachuno@purdue.edu, Jackson Benentt, Roshanak Nateghi

Understanding the resilience of a community facing a crisis event is critical to improving its adaptive capacity. Community resilience has been conceptualized as a function of the resilience of components of a community such as ecological, infrastructure, economic, and social systems etc. In this talk I introduce the concept of a resilience fingerprint and propose a multi-dimensional method for analyzing components of community resilience by leveraging existing definitions of community resilience with data from the social network Twitter. Results are presented showing how natural disasters and crisis events have distinguishing signatures which are apparent in Twitter data.

2 - Measuring and Modeling Information Flow Online

James Bagrow, University of Vermont, Burlington, VT, United States, James.Bagrow@uvm.edu

Society now depends on the flow of information over online social networks, especially during disasters and extreme events, and popular social platforms now generate significant volumes of behavioral and communication data. In this talk, I will review some of our prior studies using social media to understand disaster situations. This work has led us to study information flow by applying tools from information theory to estimate the information content of posts from Twitter users and to what extent information flows between users. Temporal and social effects are visible in the information flow, and these estimates provide a fundamental bound on the predictive accuracy achievable with these data.

3 - Sensemaking Around Visual Hurricane Risk Messaging

Melissa Bica, PhD Candidate, University of Colorado Boulder, Boulder, CO, United States, melissa.bica@colorado.edu

My research investigates the difficulty in conveying risk and uncertainty for hurricanes. Hurricane risks are commonly communicated through visualizations, some of which are issued as formal products by organizations like NOAA. However, little is known about the effectiveness of such risk products in supporting people's risk assessment and decision-making. To address this, I use a mixed-methods approach to investigate aspects of individual and collective human interaction with hurricane risk imagery during real hurricane events, using Twitter as the platform for capturing this activity. This work offers contributions regarding design, methodology, and policy.

4 - Analytics-driven Inspection Strategies for Post-storm Infrastructure Damage Assessment

Andrew Lee, Massachusetts Institute of Technology, Cambridge, MA, United States, aclee@mit.edu, Mathieu Dahan, Jeremy Justice, Cynthia Barnhart, Saurabh Amin

Delayed identification of storm-induced damages across coastal infrastructures often contributes to high economic and societal costs. To reduce the impact of damage, we address a critical knowledge gap by developing an analytics-driven approach for inspection of large-scale infrastructure networks in the aftermath of storm events. Our approach integrates flexible diagnostic information from fixed and aerial sensors to design inspection crew routing strategies for rapid post-storm damage identification. Using drainage network inspection data following 2017's Hurricane Harvey, we show that prioritizing inspection based on damage indicators leads to significant cost and time-savings.

5 - Towards the Discovery of Emergent Behaviors for Transportation Planning

Cathy Wu, MIT, Cambridge, MA, United States

How will self-driving cars change urban mobility? This talk focuses on the systems and optimization methods neccessary to gain insight into this question by enabling the discovery of their emergent behaviors in the complex transportation dynamical system. The optimization methods, empirical findings, and the systems that power them demonstrate how small changes in vehicles, sensors, and infrastructure can be harnessed for insights that inform transportation planning, potentially affecting everyday use, disaster planning, as well as the design of future mixed autonomy systems.

Joint Session Policy and Government/PSOR: Cybersecurity & Homeland Security Policy

Emerging Topic: Policy & Government

Emerging Topic Session

Chair: Laura Albert, University of Wisconsin, Madison, WI, United States

1 - A Network Interdiction Model for Delaying Adversarial Attacks and Protecting Cyber-infrastructure

Laura Albert, University of Wisconsin-Madison, Industrial & Systems Engineering, Madison, WI, 53706, United States, laura@engr.wisc.edu, Kaiyue Zheng

We present Stackelberg game models that formulate the interaction between a defender and multiple attackers with application to cyber-infrastructure protection. Network interdiction models are formulated that prioritize cost-effective security mitigations to maximally delay adversarial attacks. Attacks originate from multiple adversaries, each of whom aims to find a "critical path" through the attack surface to complete the attack as soon as possible. Decision makers can deploy mitigations to delay attack exploits, however, mitigation effectiveness is uncertain.

2 - Optimal Off-Line Experimentation for Designing Cyber Security CTF Red/Blue Team Games

Theodore T. Allen, PhD, Ohio State University, Columbus, OH, 43210-1271, United States, allen.515@osu.edu

We study a new class of experimental planning problems in which one has uncertain game parameters and the ability experiment off-line, i.e., with no cost in actual (on-line) games but with testing costs. The off-line experimentation could use a simulation model of a system with inputs from two or more players. It could also be a pre-experiment before the commission of significant resources. Through novel analysis, we obtain results about optimal efficient off-line experimentation and the sufficiency of experimentation for characterizing the Nash equilibria. Finally, we illustrate the application of the methods to a cyber security Capture The Flag (CTF) red team/blue team game problem.

3 - Estimating Wireless Mesh Network Vulnerability: A Search for the "Best" Interference Model

Tanveer Bhuiyan, PhD Student, University of Tennessee, Knoxville, TN, United States, tbhuiyan@vols.utk.edu, Hugh Medal

This paper studies the problem of placing a set of jammers in 3-D space to minimize the throughput of a wireless communication network. The main goal of this paper is to study the effects of jamming under the following models of interference: physical, capture, protocol, and interference range. This paper presents a mixed-integer programming model and branch-and-cut procedure for the jammer location problem under several models of interference. We implement multiple valid inequalities including clique and odd-cycle inequalities to speed-up the branch-and-cut algorithm. Numerical experiments demonstrate the effect of different interference models on runtime and solution tractability.

4 - Multifirm Models of Cybersecurity Investment Competition vs. Cooperation and Network Vulnerability

Shivani G. Shukla, University of San Francisco, San Francisco, CA, 94117, United States, shivani.shukla@usfca.edu, Anna Nagurney

We develop and compare three models for cybersecurity investment in competitive and cooperative situations to safeguard against cyber threats. A Nash equilibrium model of noncooperation in terms of cybersecurity levels of the firms involved is introduced. The equilibrium of this model then acts as the disagreement point over which bargaining takes place in the second model, which yields a cooperative solution that guarantees their expected utilities are no lower than those achieved under noncooperation. Nash bargaining theory is utilized to argue for information sharing and to quantify its monetary and security benefits in terms of reduction in network vulnerability to cyberattacks.

11:00-11:45 JMP, a Division of SAS
11:45-12:30 AIMMS

Vendor Tutorial

1 - For the Love of Crocs: Text Mining Product Reviews with JMP Pro

Ruth Hummel, JMP, a Division of SAS, Cary, NC, 27513, United States

JMP Pro from SAS provides leading edge descriptive and predictive analytics capabilities including text mining which will be demonstrated in this session. Are you wondering what you can do with your unstructured text data? Or are you just very interested in figuring out why people love Crocs shoes so passionately? In this talk we will explore the world of text-mining, using product reviews of Crocs shoes. We will look at summary info and word clouds, we will build features like keyword indicators and clusters (both for the terms that tend to co-occur and for the people who seem to say similar things). We will then use these document term analytics in modern variable selection methods to incorporate information from the unstructured text back into structured data analytics problems.

2 - Accelerating Optimization Model Development with AIMMS

Mohan Chiriki, AIMMS, Bellevue, WA, United States

Looking to accelerate optimization model creation? Whether you are in academia or business, AIMMS allows you to easily combine the power of Operations Research and Data Analytics in a single platform. Along with an integrated user interface, AIMMS makes model creation, visual representations and scenario analysis a breeze. In this tutorial, we will demo some of the platform's features, including: • An intuitive modeling interface o See how simple it is to model variables and constraints from your mathematical formulation o See how our built-in diagnostic tool allows you to analyze a model and helps improve efficiency • Discover ready to use extensions like Collaborative Data Management (CDM) and how they help you bring an app to life • Easy data import/export • See our Excel and database data exchange in action • Leverage the power of R • Number crunching with R libraries through IMMS R-link to add statistical and other Data Science capabilities to your model • Fun AIMMS integrations • Extract Photos Using the Flickr API • Retrieve Geographic Data with the Google Maps API Like what you see? You can continue exploring with our free academic licenses and 30-day trial license for industry users.

Finance I

Contributed Session

Chair: Thunyarat Bam Amornpetchkul, NIDA Business School, 10240, Thailand

1 - How Can SMEs Obtain Supply Chain Financing? An Empirical Research of Information Transmission

Mengyin Li, Renmin University of China, Beijing, China, limengyin@ruc.edu.cn, Song Hua

Unlike traditional bank lending, supply chain financing relies on specific information generated by the supply chain networks and operation process. We consider supply chain financing decision making based on the specific information, including upstream and downstream enterprises, operation efficiency, and other information.

2 - Optimal Dynamic Pricing of Products with Decreasing Quality under Stochastic Preferences

Arik Sadeh, HIT Holon Institute of Technology, Holon, Israel, sadeh@hit.ac.il, Idan Babay, Cristina Feniser

Consider a single product with varying levels of quality. The total amount of products by their quality has to be sold in predetermined units of time steps. The expression of an agent's choice is made by using a stochastic preference utility. Agents strive to maximize their preference utility from the product and its quality. They have a defined sensitivity random parameter for the quality of the product as well as its cost. This stochastic dynamic pricing problem is solved in a dynamic programming framework. Having solved the dynamic pricing scheme, decision makers can handle: pricing policy insights, product lifecycle management, and capacity management to confront strategic type questions.

3 - Determinants of Corporate Bankruptcy: Identification and Uncertainty

Tianhai Zu, University of Cincinnati, Cincinnati, OH, United States, zuti@mail.uc.edu, Yichen Qin, Yan Yu

Corporate bankruptcy is socially influential and economically detrimental. This paper explores various variable selection tools to identify important determinants of bankruptcy and constructing model confidence bounds to measure the reliability of the selected determinants. We further propose a graphical representation of the model selection distribution and define deviation and skewness measures to facilitate the understanding of the uncertainty of determinants. We find that among eight predictive variables in Campbell et al. (2008), price is identified with high confidence, while excess return is included within the model confidence bound, yet market to book ratio is outside the bound.

4 - Systemic Credit Freezes in Financial Lending Networks

James Siderius, Massachusetts Institute of Technology, Cambridge, MA, United States, jpsiderius@gmail.com

We consider a network model of financial intermediation where banks lend to and borrow from each other and supply funds to clients. A key decision for a bank is whether to extend credit to other banks, which may then default on those loans. In contrast to much of the previous literature on financial networks, the focus is on how "fear of future default" can lead to "credit freezes" before the realization of these uncertainties. Notably, credit freezes can happen in parts of the network that are not directly affected by increased uncertainty, both because the potential consequences of uncertainty travel throughout the network and also because such changes affect profitability of different loans.

5 - Reputational Impact on Startup Accelerator's Information Disclosure and Performance

Thunyarat Bam Amornpetchkul, NIDA Business School, Bangkok, Thailand, thunyarat.a@nida.ac.th

This study examines the implication of reputational concerns on a startup accelerator's decisions towards the effort exertion in a venture's quality certification process and the strategic information revelation policy. Our findings show that the accelerator's incentive to exert a high effort level in the startup accelerating program and disclose credible quality information is characterized by the reputational loss from misreporting the venture's quality and the size of the equity share that the accelerator receives from the venture's payoff.

1 - Scale-free Resilience of Real Traffic Jams

Daqing Li, Professor, Beihang University, Beijing, China, daqingl@buaa.edu.cn

The resilience represents the ability of a system to adapt and recover from various disturbances in natural and engineering systems. We define city traffic resilience based on the spatiotemporal clusters of jam in real traffic and find that the resilience follows a scale-free distribution in 2D city road networks and 1D highways with different exponents but similar exponents on different days and in different cities, and there is a scaling relation between the cluster size of the spatiotemporal jam and its recovery duration independent of microscopic details. Our findings can provide an indication for better understanding and design of system resilience under disturbances.

2 - Efficient Monitoring of Autocorrelated Poisson Counts

Jian Li, Xi'an Jiaotong University, , Xi'an, 710049, China, jianli@xjtu.edu.cn, Qiang Zhou, Dong Ding

Traditional monitoring of autocorrelated Poisson counts usually focuses on separately either the marginal mean or the autocorrelation coefficient. Inspired by multivariate SPC, we transform autocorrelated Poisson counts into a bivariate representation and propose an efficient chart. By borrowing the power from likelihood ratio test, albeit surprisingly, this chart demonstrates almost uniformly stronger power than the existing alternatives in simultaneously detecting shifts in both the marginal mean and the autocorrelation coefficient. Besides, we also show the proposed chart is fairly robust to overdispersion and has superiority in monitoring autocorrelated overdispersed counts.

3 - Reliability Inference for Degradation Process with Practical Effects Included

Qingpei Hu, Chinese Academy of Sciences, Academy of Math & Syst Science, 307 St East Zhonguan Cah, Beijing, 100190, China, qingpeihu@amss.ac.cn, Dan Yu

In order to conduct credible reliability assessment for the highly reliable products, practical testing factors should not be neglected, such as the inconsistency of product initial status, the recoverability with stress relaxation, and random lifetime delay due to complex failure mechanisms. In this talk, studies addressing the three practical issues in degradation process for reliability assessment would be presented, with more precise assessment approaches proposed. Corresponding planning issues are also explored.

4 - An Indirect Deep Learning Approach for Multisensor Degradation Modeling and Prognostics

Di Wang, Peking University, Beijing, China, dwang375@wisc.edu, UW-Madison, Madison, WI, United States, Kaibo Liu, Xi Zhang

With the development of sensor technology, multiple sensors have been widely used to monitor the degradation status of a unit simultaneously. As each sensor signal often contains partial and dependent information on the degradation status of a unit, effective fusion of such diverse sensor signals is important to better understand the degradation process of the unit. To address this issue, this paper proposes an indirect deep learning approach that constructs a health index by combining multiple sensor signals to better characterize the degradation process and provide accurate prognostic performance.

Empirical Studies of Healthcare Process Quality and Patient Outcomes

Sponsored: Health Applications

Sponsored Session

Chair: Lesley Meng, The Wharton School, University of Pennsylvania, Philadelphia, PA, 19104, United States

Co-Chair: Benjamin Grant, Kellogg School of Management, Evanston, IL, 60201, United States

1 - Physician-hospital Integration and Financial Incentives

Jong Myeong Lim, The Wharton School of the University of Pennsylvania, Philadelphia, PA, United States, jongmlim@wharton.upenn.edu

Physicians and hospitals are traditionally separate entities where a patient who needs inpatient care is admitted to the hospital in which the responsible physician has an admitting privilege. As patients are critical inputs in the production of health care, hospitals have sought to build various forms of relationships with physicians. This paper examines the effect of physician-hospital integration in the form of employment contracts on hospital quality measured by patient experience. The results show that integration alone does not affect hospital quality but does improve quality in response to changes in financial incentives.

2 - Structural Estimation of Kidney Transplant Candidates' Quality of Life Score

A. Cem Randa, University of Chicago, Chicago, IL, United States, randa@chicagobooth.edu, Baris Ata, John Friedewald

This paper develops a framework for assessing the impact of changes to the deceased-donor kidney allocation policy on the transplant candidates' organ acceptance behavior. To be specific, it advances a dynamic structural model of the transplant candidates' accept/reject decisions for organ offers. Our formulation allows various important features of the transplant system as well as the heterogeneity in transplant candidates' quality of life scores. Using United Network of Organ Sharing (UNOS) data on transplant candidates, donors and organ offers, we first estimate the transplant candidates' quality of life scores. We then perform various simulation based counterfactual studie.

3 - The Physician Learning Curve for Quality and Cost Outcomes for Congestive Heart Failure Patients

Benjamin Grant, Kellogg School of Management, Evanston, IL, 60201, United States, Jillian Berry Jaeker, Hannah A. Jackson, R. Kannan Mutharasan, Nicholas Soulakis, Clyde Yancy, Jan A. Van Mieghem

Congestive Heart failure (CHF) has some of the highest readmission rates, mortality rates and cost of treatment. While the relationship between physician experience and improvement in health outcomes is documented for procedures, such as surgeries, it is not clear if this relationship is present for chronic illness care. We find evidence that recent accumulated physician experience, or learning, is associated with a reduction in readmissions, mortality, and costs for CHF patients.

4 - How Do Worker Schedule Characteristics Impact on Absenteeism, Turnover and Client Satisfaction? An Empirical Study of a Home Care Organization

Poonam Jassi, IE Business School, Madrid, Spain, Fabrizio Salvador

We investigate how absenteeism, turnover and client satisfaction are affected by the characteristics of workers' schedules using data from a home care organization covering 1,356,113 home visits done by 1,827 caregivers to 21,472 patients over 5 years. Preliminary findings indicate that different measures of schedule desirableness impact these outcomes and highlight possible heuristics to improve scheduling of caregivers.

5 - Improving Productivity: An Emergency Service System in which Cross-Trained Fire-Medics Respond to Medical Calls and Fire Incidents

Cheng Hua, Yale School of Management, East Haven, CT, 06512, United States, Arthur Swersey, Fernando Chiyoshi, Ana Paula Iannoni, Reinaldo Morabito

We focus on modeling and evaluating a novel emergency service system in which cross- trained fire-medics respond to both fire calls and medical emergencies. Fire demand in the U.S. has decreased dramatically in the last three decades, while emergency medical calls have surged. With this changing landscape, cities are under pressure to reduce their budgets by closing fire stations. We show that a better alternative would be to implement a fire-medic system in terms of cost savings and response time performance. Our model is original and contributes to the literature on stochastic models for service systems. A cross-trained fire-medic may be in one of three states: available, busy at an emergency medical incident, or busy at a fire call. We develop an exact spatial queuing model and an approximation method that solves two 2-state systems rather than a single 3-state system. We provide the convergence condition and demonstrate numerically that our algorithm will always converge in a few iterations. In several constructed examples, performance errors are very small compared to the exact model. We apply our model to the fire-medic system in St. Paul, Minn. and find close agreement between predicted and actual average response times. We compare St. Paul's system to a traditional system having separate engine and medical units with the same number of personnel, and show the very large response time reductions achievable under the fire-medic system. We also present conditions under which a fire-medic system in any city would outperform a traditional system. The fire-medic approach and our modeling have widespread applicability to cities in the U.S. and other countries.

Joint Session HAS/Practice Curated: Data-Driven Models for Healthcare Applications

Sponsored: Health Applications

Sponsored Session

Chair: Emisa Nategh, University of Washington, Seattle, WA, 98105, United States

Co-Chair: Michael R. Wagner, Associate Professor, University of Washington, Seattle, WA, United States

1 - The Role of Machine Learning Models in End of Life Care

Margret Bjarnadottir, Assistant Professor of Man. Science and Statistics, University of Maryland, College Park, MD, United States, margret@rhsmith.umd.edu, David Anderson, Kim Rhoads

Predictions, driven by machine learning models of varying complexity, have become common place in the health care system. In this talk we will discuss the role of risk prediction in difficult decision making scenarios such as cancer and end of life care. We will present a case study of cancer survival predictions and their use.

2 - Optimization Methods for Fair Decisions

Matt Olfat, University of California Berkeley, Berkeley, CA, United States, molfat@berkeley.edu, Anil Aswani

Fair data-driven decision-making plays a pivotal role in the application of machine learning and computational techniques to healthcare, as it allows us to actively bar uninformative or undesirable correlations inherent in data from impact highly sensitive decisions. To that extent, we provide a series of fairness constraints that can be flexibly applied to the optimization underlying a number of training methods, for any number and type of protected attributes. We explore the strength of these constraints on a case study involving morphine dosage, as well as a number of other datasets.

3 - Did England's Policies on Sepsis and Antibiotic Resistance Have Their Intended Effects?

Spyros Zoumpoulis, INSEAD, Boulevard de Constance, Decision Sciences Area, Fontainebleau, 77305, France, spyros.zoumpoulis@insead.edu, Stephen E. Chick, Stephen Harris, Christos Oikonomou, Edward Palmer, Mervyn Singer

Sepsis is a life-threatening condition. The treatment guidelines of sepsis mandate the immediate use of antibiotics in suspected cases. However, the increase of antibiotic resistance has raised concerns regarding the appropriate usage of antibiotics. These concerns led to the design of policies in 2016 that target the potential excess usage of antibiotics in all levels of care. Using patient level data from intensive care units of several hospitals in England, we study the impact of such policies on the usage of antibiotics and health outcomes.

4 - Online Advance Scheduling with Overtime: A Primal-dual Approach

Esmaeil Keyvanshokooh, University of Michigan, Ann Arbor, Ann Arbor, MI, 48108-1020, United States, keyvan@umich.edu, Mark P. Van Oyen, Cong Shi

We study an online advance scheduling problem with reward and service time heterogeneity as well as budgeted overtime in which patients arrive one by one. Upon each arriving patient, the scheduler chooses both a resource and a day over a planning horizon without any information on the subsequent patients. By solving an online linear program, we design online optimization algorithms for this purpose and prove a worst-case performance guarantee. A case study of outpatient clinic scheduling is conducted.

5 - Predicting Treatment Related Toxicity and Efficacy in Multiple Myeloma from Clinical Entities Extracted from Amazon Comprehend Medical

Emisa Nategh, PhD, University of Washington, Seattle, WA, 98195, United States, emisan@uw.edu, David Coffey, Michael R. Wagner, Yong-Pin Zhou

Multiple myeloma is an incurable cancer and the second most common hematologic malignancy in the USA. While 19 drugs have been approved to treat the disease, these treatments are not effective for everyone. Hence, the goal of the treating oncologist is to choose a therapy that maximizes efficacy while reducing toxicity.The aim of our research is to develop a machine learning model to match patients to the most effective therapy while minimizing related toxicities. We are using Amazon Comprehend Medical to extract clinical entities from patient's medical records in order to train a model that identifies which clinical features are most informative for predicting toxicity and efficacy.

Disease Screening, Diagnosis, and Management

Sponsored: Health Applications

Sponsored Session

Chair: Sze-chuan Suen, University of Southern California, Los Angeles, CA, 90089-0193, United States

1 - Optimizing Diabetes Screening Frequency for At-risk Groups

Sze-chuan Suen, University of Southern California, Los Angeles, CA, 90089-0193, United States, Chou-Chun Wu

BMI is a key risk factor for type 2 diabetes, but current guidelines do not provide BMI-category-specific screening frequency recommendations by age and prior testing history. We aim to determine the optimal policy with the above factors using a POMDP. We assume the physician has an estimate of the patient's health state (non-diabetic, prediabetic, or diabetic) at each period, and updates his beliefs about the patient's health given progression trends and observed test results. We show that our model has a threshold policy structure and find that the current recommended screening policy is suboptimal. High-risk individuals should be screened earlier and more frequently.

2 - The Impact of Transmission Patterns in Infectious Disease Simulations for Disease Control

Anthony Nguyen, University of Southern California, Los Angeles, CA, United States, nguyenac@usc.edu, Sze-Chuan Suen

Disease transmission patterns are often unknown but can have significant effects on disease prevalence and incidence over time. Modelers often use approximations for mixing patterns in infectious disease control simulations, but these may lead to suboptimal recommendations if the approximation is poor. We use individual-level sexual contact data among MSM from an HIV research center in Los Angeles to parameterize mixing pattern for a microsimulation model of HIV. We examine prevalence trends under homogeneous, race-specific, age-specific, and race-age mixing patterns. We additionally characterize PrEP and HIV screening interventions with projected prevalence under each scenario.

3 - Robust Partially Observable Markov Decision Process with Uncertain Parameters

Shan Liu, Assistant Professor, University of Washington, Seattle, WA, 98195-2650, United States, liushan@uw.edu, Jue Gong

Partially observable Markov decision process (POMDP) is an e ective tool in modeling decision making in uncertain and dynamic environment. We introduce two types of robust POMDP with uncertainties in the reward function and transition probabilities. The first model assumes parameters are bounded with linear constraints, and the second model assumes the transition probabilities follow Dirichlet distributions. We develop modified value iterations for each type of the POMDP to find optimal solutions. We illustrate the e ectiveness of our approach using a case study in designing personalized treatment plan for chronic depression in a heterogeneous population.

4 - A Data-driven Policy to Improve Newborn Screening for Cystic Fibrosis

Seyedehsaloumeh Sadeghzadeh, Assistant Professor, Binghamton University, Binghamton, NY, 24060, United States, Ebru Korular Bish, Douglas R. Bish

Cystic fibrosis (CF) is one of the most common genetic diseases in the United States, with an approximate prevalence rate of 1 in 3,700 newborns. Early diagnosis of CF, through newborn screening, substantially improves health outcomes, while a delayed diagnosis may lead to complications or even fatality. Therefore, newborn screening for CF is conducted throughout the United States. We propose optimal data-driven approaches, based on a five-year data set from the North Carolina State Laboratory of Public Health, and show that our proposed screening policies, which are easily implementable, substantially improve the screening outcomes.

5 - Identifying Optimal Screening Schedules for Breast Cancer in Low- and Middle- Income Countries: Application to Peru

Xinmeng Zhao, University of Massachusetts-Amherst, Amherst, MA, United States, xinmengzhao@umass.edu, Shifali Bansal, Vijeta Deshpande, Jeremy A. Lauer, Filip Meheus, André Ilbawi, Chaitra Gopalappa

Due to late-stage diagnosis, a large proportion of cancer deaths, about 70%, occurred in low-and-middle-income countries (LMICs). Early diagnosis of breast cancer through mammography screening can significantly reduce premature mortalities, as evidenced in high-income countries (HICs). Current guidelines for mammography screening are infeasible to implement in most LMICs due to infrastructure unavailability. Current guidelines are extrapolations of modeling studies conducted in HICs since data challenges limit the development of models specific to LMICs. We discuss model development and Markov decision process analysis to identify optimal mammography screening schedules for Peru.

Joint Session HAS/Practice Curated: Evaluating Interventions for Diabetes Care

Sponsored: Health Applications

Sponsored Session

Chair: Maria Esther Mayorga, North Carolina State University, Raleigh, NC, 27695, United States

1 - Evaluating Engagement Patterns of Using a Mobile App for Diabetes Self-Management among Older Adults and Effects on Outcomes

Shinyi Wu, University of Southern California, Los Angeles, CA, 90015, United States, shinyiwu@usc.edu, Haomiao Jin

Mobile diabetes applications (app) can be a useful tool. Few studies assessed older adults' app use and effects. This study investigated 334 community-dwelling older adults with type 2 diabetes taught to use an app. Trajectory clustering analyses identified three distinct longitudinal engagement classes of individuals. The relationships between the app engagement class memberships and 4- and 8-month diabetes outcomes were assessed using an econometric regression analysis approach. The results showed the degree of app engagement was positively correlated with diabetes self-care scale scores. Only the engagement on the blood sugar function significantly associated with HbA1c improvement.

2 - Evaluating Screening and Care of Diabetic Retinopathy in Veterans Using Mixed-integer Programming and Simulation

Adam VanDeusen, Doctoral Candidate, University of Michigan, Ann Arbor, MI, United States, ajvandeu@umich.edu, April Maa, Amy Cohn

Veterans report greater delays in seeking care than non-veterans. Veterans also experience higher prevalence of diabetes, which is a significant risk factor for eye disease, including diabetic retinopathy. These factors contribute to a need for more accessible eye care in Veterans Administration (VA) healthcare facilities. We evaluate VA eye care facility location options, including implementing trained technicians to perform visual disease screenings typically conducted by ophthalmologists. We review how these screening models can be expanded to consider follow-up care using simulation. Our work may guide decision-makers in locating and staffing clinics to improve patient access.

3 - A Multi-scale Co-designed Simulation Model for Gestational & Type 2 Diabetes

Nathaniel D. Osgood, PhD, University of Saskatchewan, Saskatoon, SK, Canada, nathaniel.osgood@usask.ca, Yang Qin, Louise Freebairn, Jo-An Atkinson, Roland F. Dyck

We describe a multi-scale model capable of addressing interventions that can be involving any combination of targeted individual focus, innovations in health service delivery, and population level programs within the ACT. We particular highlight the way in which such flexibility is enabled via integration of physiological, individual-level, granular characterization of clinical pathways and public health levels of analysis realized via combinations of 3 types of dynamic modeling. We further describe the broadly consultative and closely interdisciplinary team effort that made model development possible, and the grounding of the model in diverse sources of empirical understanding.

4 - An Analytics-driven Approach for Optimal Individualized Diabetes Screening

Hossein Kamalzadeh, Southern Methodist University, Dallas, TX, United States, hkamalzadeh@smu.edu, Michael Hahsler, Vishal Ahuja, Michael Bowen

About 10% of the US adult population has diabetes, and almost 40% are at risk of developing diabetes. Guidelines suggest population-based screening, however, in resource-restricted settings (e.g., for safety-net providers), prioritizing whom to screen and when is essential. We combine analytics methods (hidden Markov models and predictive analytics) with partially observable Markov decision process models to derive the optimal screening policy customized to the characteristics of the provider's subpopulation. We will present results for electronic health record data from the Parkland Health & Hospital System.

5 - Identification and Prioritization of Barriers to Care for Patients with Diabetes

Breanna Swan, North Carolina State University, Raleigh, NC, 27703, United States, bpswan@ncsu.edu, Maria Esther Mayorga, Julie Simmons Ivy

This work identifies and prioritizes barriers to coordinated care between patient and provider, focusing on screening and treatment for microvascular complications. Patients progress through disease states according to a Markov model and interact with the care system through a discrete event simulation model. Interventions to improve adherence and to overcome impactable barriers to care already identified in literature will be tested through the simulation model and prioritized to improve effectiveness, efficiency, and quality of care from diagnosis to treatment.

Emerging Topics in Personalized Medicine I

Emerging Topic: Personalized Health

Emerging Topic Session

Chair: Marina A. Epelman, University of Michigan, Ann Arbor, MI, 48109-2117, United States

1 - Brachytherapy Plan Generation Using Pareto Surface Generation, Visualization, and Navigation

Marina A. Epelman, University of Michigan, Ann Arbor, MI, 48109-2117, United States, mepelman@umich.edu, Victor Wu, Christopher Deufel, Mustafa Y. Sir, Kalyan Pasupathy

In designing radiation therapy treatment plans, multiple instances of the planning optimization problem need to be solved to identify the trade-off between treatment objectives best for each patient. In high-dose brachytherapy, efficient exploration of these trade-offs is especially important, since the patient experiences discomfort or is under anesthesia while awaiting the generation of the treatment plan. We propose a methodology for fast generation, visualization, and navigation of approximate Pareto surfaces of dose-volume metrics, which are approximated via convex "truncated CVaR" functions to account for long upper tails common in dose distributions in brachytherapy treatments.

2 - Learning from Clinical Time-series

Jenna Wiens, University of Michigan, Ann Arbor, MI, United States

Recurrent neural networks (RNNs) are commonly applied to clinical time-series data with the goal of learning risk stratification models. Their effectiveness is due, in part, to their use of parameter sharing. We hypothesize, however, that this trait contributes to the increased difficulty such models have with learning relationships that change over time. We illustrate the advantages and disadvantages of complete parameter sharing on three clinically-relevant prediction tasks: acute respiratory failure, shock, and in-hospital mortality. To improve upon the dichotomy between complete parameter sharing vs. no parameter sharing, we propose a novel RNN formulation based on a mixture model in which we relax parameter sharing over time. The proposed method outperforms standard LSTMs and other state-of-the-art baselines across all tasks.

3 - Logic-based Benders Approach for the Kidney Paired Donation Problem

Carolina Riascos, University of Toronto, Toronto, ON, Canada, Dionne Aleman, Merve Bodur

Kidney paired donation consists of patients exchanging their donors with others so that they can obtain a suitable kidney. Those exchanges are in the form of cycles and chains and have an associated priority. The kidney exchange problem is to find a collection of vertex-disjoint chains and cycles of a given size in a directed graph. The problem is NP-hard and challenging for real-sized instances. The literature has addressed it mainly by designing Branch and Price approaches. We develop the first Logic-based Benders Decomposition in the literature for this problem. Our computational results show the advantage of our model for large instances and a sensitivity analysis for various matching priorities.

4 - A Simulation Framework to Leverage Patient-specific Data in Improving Cardiac Intensive Care Unit Utilization

Amanda D. Moreno-Hernandez, University of Michigan, Ann Arbor, MI, 48103, United States, admh@umich.edu, Amy Cohn

We present a simulation framework to model the operations of a cardiac ICU at the Michigan Medicine Cardiovascular Center (CVC). Patients receiving care in the CVC for critical cardiac conditions arrive through many different channels (e.g. the emergency department, inpatient wards, and transfer from other institutions when advanced care is warranted). These patients also vary in their medical diagnosis, condition, and their genetic, socio-economic, and other characteristics that impact their care needs. Our aim is to provide flexibility in analyzing operational policies and procedures, enabling patient information of any level of detail to be used to improve the granularity of the model.

Empirical Studies in Healthcare Operations

Sponsored: Manufacturing & Service Oper. Mgmt/Healthcare Operations

Sponsored Session

Chair: Maria Ibanez

1 - Who is an Efficient and Effective Physician? Evidence from Emergence Medicine

Raha Imanirad, Harvard Business School, Boston, MA, 02472, United States, rimanirad@hbs.edu, Soroush Saghafian, Stephen Traub

Improving the performance of the healthcare sector requires a deep understanding of the efficiency and effectiveness of care delivered by physicians. Despite recent advances, scientific methods of measuring efficiency and effectiveness of physicians have proven elusive. We utilize a large data set along with Data Envelopment Analysis (DEA) to shed light on scientific metrics that can gauge physician performance in terms of efficiency and effectiveness. We use machine learning tools to validate our DEA scores. In addition, we carry out a Tobit analysis to identify factors related to physician, patient and peer characteristics that are associated with higher levels of physician performance.

2 - Is Good Research Worth it? How Compliance with Best Scientific Standards Affects Academic Scientists and Firms

Maryaline Catillon, Harvard Business School, Wyss Doctoral Office, Boston, MA, 02163, United States, mcatillon@hbs.edu

The reproducibility crisis has sharpened focus on research quality. Previous research has modelled academic scientists and firms' incentives to produce high quality science. This paper builds on a new database to ask, empirically, how compliance with best scientific standards affects scientific impact and evidence driving sales. I find that better methods are associated with higher scientific impact. However, better methods reduce the probability of reaching positive results, and are not associated with measures affecting drug sales. Altogether, these results suggest that it may be in more of a academic scientist's interest than a pharmaceutical company's interest to use adequate methods.

3 - Incident and Near Miss Reporting in Radiation Oncology

Olivia S. Jung, Doctoral Student, Harvard Business School, Harvard Business School, Boston, MA, United States, ojung@hbs.edu, Palak Kundu, Amy C. Edmondson

Near misses—harm averted due to chance or intervention—present a low-cost learning opportunity. To study whether near misses are reported and perceived as success or failure, we surveyed radiation oncology staff and linked responses to submissions. Respondents were more likely to indicate willingness to report (WTR) scenarios deemed as failure than success. Those expressing higher psychological safety were more likely to indicate WTR for scenarios due to a human error that led to a proximate negative outcome. We observe differences in submission of incidents by role, suggesting impact of hierarchy on likelihood of reporting.

4 - Decomposing Volume's Impact on Judgment and Skill: Lessons from Kidney Transplantation

Philip Saynisch, National Committee for Quality Assurance, Washington, DC, 02128, United States, Robert Huckman, Nikolaos Trichakis

In markets for credence goods, suppliers act both providers and expert advisors. This dual role complicates learning-by-doing explanations of the volume-outcome relationship: improvements may result from better judgment or better skill. This paper explores kidney transplantation, where clinical decision-making and surgical performance are separately observable. We find that greater volume is associated with improved post-transplant outcomes, but worse decision-making. This tension between improved skill and reduced quality of judgment implies that practice may not make perfect in complex medical decision-making.

Urban Air Transport II

Emerging Topic: Sharing Economy & Crowdsourcing

Emerging Topic Session

Chair: Laurie A Garrow, Georgia Institute of Technology, Atlanta, GA, 30332-0355, United States

Co-Chair: Alexandre Jacquillat, Carnegie Mellon University, Pittsburgh, PA, 15213, United States

1 - Commuting in the Age of the Jetsons: Mode Choice between Autonomous Ground Vehicles and Air Taxis in Five Large U.S. Cities

Laurie A. Garrow, Georgia Institute of Technology, School of Civil & Environmental Engineering, Atlanta, GA, 30332-0355, United States, laurie.garrow@ce.gatech.edu

Imagine a world where instead of sitting in traffic on the downtown connector, you could simply drive to a vertiport near your home, enter into a small electric propulsion aircraft, fly over traffic, land on a rooftop near your work, and either walk or have an rideshare vehicle take you to your office. In this presentation, we provide an overview of ongoing research in air taxi flights for cities and present results from two surveys we conducted of commuters in five cities in the U.S. to estimate commuting demand and willingness to pay for these air taxi flights and competition with self-driving cars.

2 - On-demand Urban Aerial Mobility: Strategic Vertiport Network Design

Kai Wang, The Hong Kong Polytechnic University, Kowloon, Hong Kong, kai.k.wang@connect.polyu.hk, Alexandre Jacquillat, Vikrant Vaze

Urban Aerial Mobility (UAM) will rely on a network of vertiports—where electric vertical-takeoff-and-landing (eVTOL) aircraft will be operated. This paper optimizes the number, location, and capacity of vertiports while capturing the interdependencies between strategic vertiport deployment, tactical eVTOL operations, and customer adoption. This is cast as a nonlinear mixed-integer model, embedding a queuing network model of UAM operations and a robust optimization model of customer adoption. We propose an iterative discretization algorithm to reformulate it as a second-order conic program and obtain a high-quality solution. Results provide insights on future UAM systems in urban areas.

3 - By Schedule or on Demand? – A Hybrid Operational Concept for Urban Air Mobility

Syed Arbab Mohd Shihab, Iowa State University, Ames, IA, United States, Peng Wei, Rodrigo Mesa Arango, Christina L. Bloebaum

Taking into account the unique set of operational constraints associated with Urban Air Mobility services, this paper proposes mathematical models for commercial transport service providers to decide which type of scheduling to offer, how many vehicles to deploy and how to dispatch resources based on simulated market demand such that profit is maximized. Three different settings of services - on-demand service, scheduled service, and a mix of both services (hybrid operations) - are considered.

4 - A Risk Assessment Framework for Communications in Autonomous Air Traffic Operations

Karthik Gopalakrishnan, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, karthikg@mit.edu, Hamsa Balakrishnan, Vanessa Kuroda

Robust, reliable, and effective communications are essential for the safe integration of autonomous aircraft into the air traffic control system. Emerging applications such as Urban Air Mobility (UAM) and Unmanned Aircraft Systems (UAS) in turn rely on such autonomous air traffic operations. We develop a framework to assess vulnerabilities and threats in air traffic communications. We present an analysis of the likelihood and impact of a set of 'atomic attacks' on elements of the communications network, assess the risk levels of individual elements, and identify mitigation strategies. Finally, we use the proposed methodology to evaluate the robustness of candidate UAM architectures.

Chair: Kent J Kostuk, Federated Co-Operatives Limited, Saskatoon, SK, S7J 2T2, Canada

1 - Assessing NFL Team Performance using Points Added

Martin L. Puterman, University of British Columbia, Sauder School of Business, Vancouver, BC, V6T 1Z2, Canada, martin.puterman@sauder.ubc.ca, Tim Chan, Craig Fernandes

In this talk we provide a rigorous foundation for estimating and interpreting value functions in NFL (American professional) football based on the Poisson equation for Markov reward processes and martingale theory. We then use the value function to construct a "points added per play" metric and show how this metric can provide insights into why the New England Patriots won the 2019 Super Bowl.

2 - Do You Ever Not Want to Bat Last?

Kent J. Kostuk, Industrial Engineering Manager, Federated Co-Operatives Limited, Saskatoon, SK, S7J 2T2, Canada, kent.kostuk@usask.ca, Keith A. Willoughby

During the round robin portion of a softball tournament most events use runs for and against as a team ranking criteria in addition to wins and losses. Traditional thinking suggests that you maximize your success by having last at bat. Some teams elect to be the visiting team to guarantee they maximize their offensive opportunities. We will investigate which approach will provide the best outcome and under what circumstances.

3 - Automatic Event Detection in Basketball Using Hidden Markov Model with Energy Based Defensive Assignment

Min-hwan Oh, Columbia University, New York, NY, 10027, United States, m.oh@columbia.edu, Suraj Keshri, Sheng Zhang, Garud N. Iyengar

We propose an unsupervised learning framework for automatically labeling events in a basketball game. We first learn the time series of defensive assignments using a novel player and location dependent attraction based model which uses hidden Markov models (HMMs), Gaussian processes, and a "bond breaking" model for changes in defensive assignments. Next, we use the learned defensive assignments as an input to a set of HMMs that automatically detect play actions. We show that our models provide significant improvements over existing benchmarks both on defensive assignments and event detection.

4 - Does Sports Analytics Work Part Three

Walt DeGrange, CANA Advisors, Chapel Hill, NC, 27517, United States, wdegrange@canallc.com

With the recent success of sports teams heavily using analytics (Red Soxes, Patriots, Capitals, Warriors, Manchester City F.C.), does this mean that analytics has gained a foothold in the sports world? And if so, is there a career path that a high school student can use to become a sports analytics professional? This presentation builds on two prior years of analysis and adds another year of professional team results and additional factors.

5 - Pay Per View Pricing in a Subscription Model

Mike Gordon, University of Pittsburgh, Pittsburgh, PA, 15224, United States, m.gordon@pitt.edu

We analyze pay-per-view pricing on a subscription platform. This model accounts for consumer technological abilities along with illegal streaming.

1 - How to Share Prosocial Behavior Without Being Perceived a Braggart?

Xue Tan, Indiana University, Kelley School of Business, Bloomington, IN, 47405, United States, janetan@iu.edu, Lu Yan, Alfonso J. Pedraza-Martinez

People are reluctant to share their prosocial behavior on social media because by announcing their good deeds, they run the risk of being perceived as braggers. However, by keeping silent, they run the risk of receiving no credits for their effort. This is the braggart's dilemma. In this study, we use both empirical evidence and lab experiments to show that by acknowledging a third party in the announcement of prosocial behavior, one will be perceived highly due to less suspicion of bragging. Specifically, we find that when an individual shows gratitude to the corporate sponsor of his prosocial activity in the social media post, he will obtain more positive social reactions.

2 - The Impact of Crime on the Sharing Economy: A Spatial Analysis

Chenhui Guo, Michigan State University, Lansing, MI, United States, guochen8@msu.edu, Inkyu Kim, Anjana Susarla

We analyze the impact of crime on demand for the sharing economy in urban areas. In particular, we are interested in how features of the sharing economy associated with deterrence could internalize some of the negative externalities caused by crime. By conducting aggregate demand estimation at the neighborhood level, we find evidence that the sharing economy provides a positive social benefit to individual establishments through deterrence features. We also consider alternate explanations that results could be driven by gentrification in neighborhoods. Our results suggest that the sharing economy might provide some social insurance to neighborhoods.

3 - Does Illusionary Progress Make You Exercise More?

Guneet Kaur, University of Connecticut-Storrs, Mansfield, CT, United States, guneet.kaur@uconn.edu, Xinxin Li, Jing Peng

We study the impact of illusionary progress, i.e., endowing progress while increasing the goal by the same amount, on both short-term participation in gym exercises and habit formation reflected in long-term participation. We run a randomized field experiment in collaboration with a gym. To moderate the effect of illusionary progress on enhancing overconfidence about future self-control, we introduce social comparison as a second intervention by showing members the top scores of their peers a month after the experiment starts. By also studying moderating factors such as app usage, the study has important implications about how to use fitness apps to motivate people to exercise and stay healthy.

Channel Relationships and Planning Decisions

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Eirini Spiliotopoulou, Tilburg University, Tilburg, Netherlands

1 - A Behavioral Investigation of the Demand Allocation Game

Yinghao Zhang, University of Cincinnati, Cincinnati, OH, 45221, United States, yinghao.zhang@uc.edu, Tianjun Feng, Lin Tian, Lin Tian

We consider a situation with two competing retailers who make inventory decisions. The total market demand is divided proportional to their stocking levels. Experimental results suggest that human subjects' decisions systematically deviate from the Nash Equilibrium. We use theory of reciprocity to explain this off-equilibrium behavior.

2 - Inventory Rationing Across Channels

Eirini Spiliotopoulou, Tilburg University, Netherlands, e.spiliotopoulou@uvt.nl, Nienke Hofstra

When demand exceeds available inventory, suppliers ration their inventory among sales channels. How does inventory risk and payment schemes affect allocation decisions in such cases? We conduct lab experiments to study the role of risk aversion, loss aversion and mental accounting in inventory allocation decisions between two channels. On average, subjects allocate significantly less inventory than the expected profit maximizing quantity to the risky, yet more profitable, channel. Subjects with stronger risk appetite allocate larger quantities to the risky channel, but also exhibit higher loss aversion. Risk attitude moderates the effect of the timing of payments on allocation decisions.

3 - Long-term or Short-term Suppliers under Dual Sourcing? Behavioral Evidence from an Order Allocation Game

Wanshan Zhu, Tsinghua University, Beijing, China, Chao Xue, Diana (Yan) Wu, Xiaobo Zhao

We consider a supply chain setting where a manufacturer needs dual sourcing to meet demand. To benefit from quantity discounts, the buyer has to unevenly allocate his demand between two suppliers, generating dependence asymmetry under the triadic channel.To investigate the sourcing strategy as to whether long-term or short-term suppliers should be employed, we manipulate the matching protocol within a triad to be either fixed or random in the experiments. We observe behavioral differences between the two suppliers under both matching conditions, and dynamics in the manufacturer's decisions. Behavioral models are developed to provide further managerial insights for dual sourcing.

4 - Judgmental Adjustments in Forecasting: Implications and a Strategy for Improvement

Rob Basten, Eindhoven University of Technology, Eindhoven, Netherlands, R.J.I.Basten@tue.nl, Bregje van der Staak, Philippe Van de Calseyde

We analyze how planners adjust statistical sales forecasts. In an initial data set with more than 55,000 sales forecasts and outcomes, we consistently find that planners perform worse than the statistical forecasting algorithm when making upward adjustments, but are highly accurate in predicting whether the statistical forecast should go up or down. These findings are used in a follow-up study, using more than 12,000 new forecasts to test what happens when planners decide on the direction of the adjustment, while the algorithm decides on the magnitude of the adjustment. We thus significantly reduce the forecasting error by on average 17%.

Online Ratings & Reviews

Sponsored: Information Systems

Sponsored Session

Chair: Arslan Aziz

1 - The Effects of Online Review Platforms

Limin Fang, The University of British Columbia, Vancouver, BC, Canada, limin.fang@sauder.ubc.ca

This paper quantifies the effect of online review platforms on restaurants and consumer welfare. Using a novel dataset containing restaurant revenues and information from major online review platforms, I show that these platforms help consumers learn faster about restaurant quality. In particular, they increase the revenue and survival rates of high-quality independent restaurants and decrease those of low-quality restaurants, but have little effect on chains or old independent restaurants. Based on the evidence, I develop a structural demand model with social learning. Counterfactual analyses show online review platforms improve the welfare for restaurant goers by $2.5 per person per meal.

2 - Reputation Inflation

Apostolos Filippas, Assistant Professor, KMC, New York, NY, 10012, United States, apostolosfilippas@gmail.com, John Joseph Horton, Joseph Golden

A solution to marketplace information asymmetries is to have trading partners publicly rate each other post-transaction. Many have shown these ratings are effective; we show that their effectiveness deteriorates over time. The problem is that ratings are prone to inflation, with raters feeling pressure to leave "above average" ratings, which in turn pushes the average higher. This pressure stems from raters' desire to not harm the rated seller. As the potential to harm is what makes ratings effective, reputation systems, as currently designed, sow the seeds of their own irrelevance.

3 - The Platform Value of a Review

Andrey Fradkin, Boston University, Cambridge, MA, 02139, United States

Online reviews are public goods and are consequently underprovided in equilibrium. In order to correct for this, digital platforms may incentivize reviews through payments or coupon offers. In this paper, we use a large scale field experiment in incentivized reviews to study the value of these reviews to the platform. We evaluate the effects of reviews induced by this policy on the reviewed sellers, the buyers who subsequently transact with these sellers, and the reviewers themselves. We show how the value of a review varies with market conditions on the platform.

4 - How Rating Inflation Affects Consumer Purchase

Arslan Aziz, Assistant Professor, The University of British Columbia, Vancouver, BC, V6S 0K4, Canada, Hui Li, Rahul Telang

Even as online ratings become an increasingly important source of product quality information, they are plagued by a number of systematic biases that cause them to be inflated. In this paper, we conduct a novel quasi-field experiment that exogeneously induced rating inflation on a food delivery platform. We investigate the consequences of this induced rating inflation on consumer purchasing behavior. We find that rating inflation reduces a consumer's degree of trial as well as their average spend per transaction. Inflated ratings are perceived as less informative by consumers which makes trial riskier.

5 - Speech Is Silver, Silence Is Golden: Evidence from a Field Experiment on Motivational Framing Backfiring

Aishwarya Deep Shukla, Assistant Professor, Simon Fraser University, Vancouver, BC, Canada, adshukla@sfu.ca, Tianshu Sun, Guodong (Gordon) Gao, Ritu Agarwal

Online Word of Mouth (WOM) is economically significant, but there is a lack of empirical evidence on strategies to stimulate WOM. We ran a field experiment on a digital healthcare platform to test the effectiveness of message framing. Contrary to prior research, our results show that motivational email framing backfires. It reduces WOM quantity and has no significant effect on WOM quality. Findings suggest that explicit messaging to induce motivation, i.e., specifying reasons why a user should contribute, reduces the volitional drive to contribute. This is plausibly because such framing converts the implicit motivation into an obligation, suppressing the desire to contribute.

Transformative Impact of IT

Sponsored: Information Systems

Sponsored Session

Chair: Jingyang Zheng

1 - Would Users Post More? A Hidden Markov Model of Review Learning Dynamics in User-generated Content Platform

Zheng Fang, Purdue University, West Lafayette, IN, United States, fang227@purdue.edu, Jinyang Zheng, Karthik Kannan, Guopeng Yin

Review-in-review (RIR) is a function that information technology companies apply to collect users' valuation of the generated content. Users could click "helpful", "unhelpful" or write "review" to the content they read. RIR would reshape the content generating process since users' behavior would be influenced by RIR. To evaluate the effectiveness of our idea, we root our research in the context of a movie review platform and we implement the Hidden Markov Model (HMM) to capture the learning dynamics of users based on their unobserved learning patterns. We estimate the learning state of users on a daily basis and it shows significant evidence that RIR would influence users' content generating process.

2 - Estimate the Value of Destination Disclosure: A Dynamic Structural Model of Transportation Network

Weilong Wang, Purdue University, 403 W. State St, West Lafayette, IN, 47907, United States, wang4167@purdue.edu, Jinyang Zheng, Karthik Kannan, Fei Ren

The efficiency of taxi services in big cities influences not only the convenience of peoples' travel but also urban traffic and profits for taxi drivers. With the help of information sharing, many efforts have been made to improve transportation system, i.e. ridesharing platform. Our results show that our method improves profits and efficiency for taxi drivers and increases matching probability between passengers and taxi drivers. Based on our setting, several different policies are evaluated to test the impact of information on both passengers and drivers.

3 - Alexa Shopping: The Effect of Voice Assistants on Consumer Purchase and Search Behavior

Chenshuo Sun, New York University, New York, NY, 10011, United States, Xiao Liu, Anindya Ghose

A voice assistant, such as Amazon's Alexa, is a wireless device with artificial intelligence that can be activated by voice command. Increasingly, consumers are using voice assistants for shopping. However, little is know about the effect of voice assistants on consumer purchase and search behaviors. We collaborate with one of the largest online retailers in the world and run a field experiment to answer the following three research questions: 1) How does a voice assistant (VA) affect search and purchase behavior? 2) Does a VA lead to a category expansion effect or a store switching effect? and 3) Does a VA affect search breadth or search depth? We combine a machine learning method and a causal inference method to deal with the two-sided non-compliance issue in the experiment and estimate heterogeneous treatment effects. We find that a voice assistant can increase consumer purchase and search on the associated e-commerce site. The increase in purchase comes from both the category expansion effect in the smart home category and the store switching effect in the repeatedly-purchased FMCG category. A voice assistant leads to a larger increase in search breadth than in search depth. These insights can help online retailers with category planning decisions and help brands with voice search engine optimization strategies.

4 - What Can Physician-Generated Content Tell Us? Evidence from Healthcare Recommender System

Jianing Ding, Purdue University, West Lafayette, IN, United States, ding246@purdue.edu, Susan F. Lu, Karthik Kannan

The unified medical information system becomes much more crucial in the entire healthcare industry. Motivated by the desire of providing more appropriate medical care to each patient with taking the advantages of information techniques, we focus on physician-generated content posted in the healthcare recommender system (unlike prior studies which focus on patient-generated content) and attempt to explore the value hidden in those self-expression content. To achieve this goal, we then provide a predictive test of the measure by applying it to a sample of more than 5,630 physicians of 280 hospitals in state Florida to explore the direct impacts of physicians' personality traits on their job performance, discharging habits, and treatment efficiency. Our analyses show that the patient treated by the physician with higher score in openness is more likely to achieve better efficacy, reduce expenditure, and save time in treatment. In contrast, the conscientious physician tends to charge more and spend more time on lab test with no enhance in performance. Furthermore, the underlying mechanism reveals causal effect of personality traits on physician's performance, discharging habits, and treatment efficiency. The methods we introduce can be used to analyze the impact of personality in other fields, and suggest that consumers need to take into account the personality effects of service providers when making decisions.

5 - When Donation Meets Reward: An Empirical Examination of Contribution Dynamics in Crowdfunding

Yipu Deng, Purdue University, West Lafayette, IN, 47906, United States, deng127@purdue.edu, Jinyang Zheng, Guoxin LI, Karthik Kannan

With the growing popularity of crowdfunding, it is necessary to understand the behavior of backers. In this study, we empirically examine peer influence and signaling theory in a reward-based crowdfunding market. Further, we investigate how the content of projects' description influence subsequent crowdfunding behavior (i.e., donating and contributing). We find evidence in support of a crowding-out effect, where the increase in the volume of prior period contribution/donation is associated with a decrease in subsequent contribution/donation. Besides, fundraisers' own support behaviors could encourage more backers. Finally, more subjective project titles will repel potential backers.

Gender Gap

Sponsored: Women in OR/MS (WORMS)

Sponsored Session

Chair: Margarit Khachatryan, MagAnalytics, St. Louis, MO, 63044, United States

1 - Using Simulation Modeling to Examine Policy Effects on the Workforce Outcomes of Women in Academic Science

Julie A. Maurer, Ohio State University, Columbus, OH, 43210, United States

Despite gains made over the past 20 years toward gender pay equity for female scientists working in academic research, a persistent gap suggests that existing policies have not gone far enough. Insights into how the workforce structure, institutional policies and employer preferences interact to impact the career development of female scientists using ABM and SD modeling will be shared.

2 - Do Less Discretionary Tenure-clock Extension Policies Improve Career Outcomes among New-parent Faculty?

Maryam Andalib, Data Scientist, Ford Motor Company, Dearborn, MI, United States, maryam.andalib@gmail.com, Joshua Hawley, Navid Ghaffarzadegan

Tenure-track faculty often experience high stress levels affecting their career, mental health, and work-life balance. Childbearing and childrearing, which coincide with the tenure probationary periods of 45% of the faculty, exacerbates the situation. To support faculty members in special life circumstances universities use policies to extend the tenure clock (TCE). Based on data from top 250 U.S. universities, we answer the following question: "How does automatically extending the tenure probationary period of new parents affect their career outcomes?" We discuss the findings and implications.

3 - Gender Gap and Microaggressions at a Workplace

Liana Babayan, Augusta University, Augusta, GA, United States

Although much has been studied on damaging consequences of everyday prejudice, gender bias, harassment and discrimination upon marginalized groups in a typical workplace, it still remains difficult to define and examine the discrimination that occurs via implicit bias. Subtle sexism and microaggressions continue to have significant negative impact on women, resulting in anger and frustration, lack of productivity; and often keeping them from potential promotions and professional advancement. In the era of #metoo movement, where sexual harassment is getting more and more coverage, the microagressions taking place in professional settings need to be taken just as seriously, since they not only have the potential to perpetuate the gender bias, hence the gender gap but also are symptoms of potential sexual harassment or coercion. To successfully and systematically fight against this common type of discrimination and to thrive for a more financially and emotionally equitable workplace, it is imperative to understand how those microagressions attack underrepresented groups; and study their detrimental economic consequences on women at a workplace. This study looks into different types of microagressions against professional women and offers a discussion on how to engage in a productive fight for a fair workplace.

Scheduling III

Emerging Topic: Project Management & Scheduling

Emerging Topic Session

Chair: Yumei Huo, City University of New York, College of Staten Island, Staten Island, NY, 10314, United States

1 - Multitasking Scheduling with Controllable Processing Times

Yan Wang, Northwestern Polytechnical University, Xi'an, China, pacpos.ywang@gmail.com, Junqiang Wang

We investigate a single-machine multitasking scheduling problem subject to unlimited or limited resource availability. The job processing times are controllable as a linear or convex function of the amount of a common continuously divisible resource allocated to the jobs. We study several problems in terms of different objective functions and processing time functions. We provide structural properties of the optimal schedules and polynomial-time algorithms for the considered problems.

2 - Bi-criteria Ant Colony Optimization Algorithm for Minimizing Makespan and Energy Consumption on Parallel Batch Machines

Zhaohong Jia, Anhui University, Hefei, China, zhjia@mail.ustc.edu.cn

We investigate the problem of minimizing makespan and electric charge simultaneously on batch-processing machines with different-size jobs. A Pareto-based ant colony optimization algorithm is proposed. Depending on delaying the batch or not, two candidate lists are constructed to select jobs. Moreover, heuristic information is designed for each candidate list to guide the search. In addition, objective-oriented local optimization is applied to improve solution quality. Results of comparative experiments indicate that the proposed algorithm outperforms several other state-of-the-art algorithms, especially on large-scale problems.

3 - Approximation Algorithms for Parallel-batch Scheduling with Processing Set Restrictions

Wenhua Li, Zhengzhou University, Zhengzhou, China, liwenhua@zzu.edu.cn, Xing Chai, C.T. Ng, T.C E. Cheng

We consider job scheduling on m parallel-batch machines to minimize the makespan. Each job has a given set of machines to be assigned. Each machine can process several jobs simultaneously as a batch. We study two models: (i) scheduling on parallel-batch machines with the nested processing set restrictions and (ii) scheduling on uniform parallel-batch machines with the tree-hierarchical processing set restrictions. For the first model, we design a strongly polynomial-time solution algorithm. For the second model, we design two fast algorithms for the case with non-identical batch capacity and the case with identical batch capacity, respectively.

4 -Revisit Heuristics for Flowhsop Scheduling with Availability Constraint

Yumei Huo, City University of New York, College of Staten Island, Staten Island, NY, 10314, United States

This paper studies two stage flowshop scheduling with availability constraints. There are two machines, an upstream machine M1 and a downstream machine M2. Each machine may have one or more unavailable intervals. There are n jobs, denoted as Ji, $1 \leq i \leq n$. Each job Ji, $1 \leq i \leq n$, has two operations ai and bi which have to be processed on machine M1 and on M2, respectively. The operation bi cannot start on machine M2 before ai finishes on M1. We want to find a schedule of the jobs so that the total completion time is minimized. The problem is NP-hard in the strong sense even if both machines are always available, so we assume there is only one unavailable interval, either on M1, or M2. We focus on optimal solutions for special cases and good heuristics for general case. We first study some special cases and give some theoretical results. Then through numerical study, we investigate the performance of various existing heuristics when the machine availability constraint is present.

Incentives and Teamwork in R&D

Emerging Topic: New Product Development

Emerging Topic Session

Chair: Anant Mishra, Carlson School of Management, University of Minnesota, Minneapolis, MN, 55455, United States

1 - Team Collaboration in Innovation Contests

Sidika Tunc, University College London, London, United Kingdom, C. Gizem Korpeoglu, Christopher S. Tang

An innovation-contest organizer posts a problem to agents who can submit their solutions as individuals or teams. We show that agents may benefit from collaborating as teams if they are less likely to conform each other and if the organizer's problem requires indivisible tasks. Also, the organizer may benefit from this collaboration if he runs a contest on a platform to obtain high-novelty solutions or low-novelty solutions that require highly divisible tasks. If the organizer runs a contest internally to obtain low-novelty solutions that require divisible tasks, he may also benefit from it.

2 - Backers or Socializers? Alternative Mechanisms for Learning by Co-creation

Berke Emre Guzelsu, Boston University, 595 Commonwealth Avenue, Boston, MA, 02215, United States, bguzelsu@bu.edu, Nitin R. Joglekar

Learning based on knowledge and financial input from customers is an emergent co-creation phenomena. A Transactive Memory System (TMS) is a mechanism through which groups collectively encode, store, and retrieve knowledge. We extend TMS by conducting an intermediate theory building exercise using data from the tabletop gaming industry. Our data accounts for Kickstarter backers, that represent the crowdfunding channel, and Discord threads that represent a social media channel for socializers. We contrast alternative TMS learning mechanisms for backers and socializers. Results yield new constructs and novel linkages of these constructs to characterize learning via co-creation.

3 - Set Asides for Small Businesses in Public Sector Procurement: Evidence from US Federal Government R&D Contracts

Dwaipayan Roy, Carlson School of Management, University of Minnesota, Minneapolis, MN, United States, royxx298@umn.edu, Anant Mishra, Kingshuk K. Sinha

This paper investigates the performance outcomes of R&D contracts that have been awarded preferentially to small businesses by the US Federal Government. Specifically, we examine how the contract pricing type and contractor experience influences the relationship between the Set-Asides status of a contract and its performance outcome.

4 - Incentive Design and Equity Contracting in Startup Teams

Evgeny Kagan, Johns Hopkins University, Baltimore/Washington DC, MD, United States, ekagan@jhu.edu, Stephen Leider, William S. Lovejoy

This paper examines the effects of equity contracts on effort and value generation in startup teams.

Joint Session Agriculture/Practice Curated: Prediction and Decision Models for Agricultural Seed Development

Emerging Topic: Agriculture

Emerging Topic Session

Chair: Dieter Armbruster, Arizona State University, Tempe, AZ, 85287-1804, United States

Co-Chair: Esma S Gel, Arizona State University, Tempe, AZ, 85287-8809, United States

1 - Optimize Training Data for Genomic Prediction

Christopher J. Basten, Science Fellow, Syngenta, Durham, NC, United States, christopher.basten@syngenta.com, Zhigang Guo

Genomic prediction utilizes joint marker and phenotypic data to form a training dataset and construct predictive models for inbred lines and hybrids. Predictions are on the genotypes of individuals that are genotyped but not phenotyped. Specifically, we will focus on a method known as GBLUP (genomic best linear unbiased predictor). Current datasets are testing the limits of GBLUP with respect to computational feasibility, time and expense. One major area of interest is how to trim training data sets to a reasonable size and still maintain predictive accuracy and power.

2 - Multi-task Learning for Asset Allocation

Wenjun Zhou, University of Tennessee Knoxville, 916 Volunteer Boulevard, SMC 247, UT BAS, Knoxville, TN, 37996, United States

Sellers of crop seeds need to plan for the variety and quantity of seeds to stock at least a year in advance. There are a large number of seed varieties of one crop, each can perform best under different growing conditions. Given the unpredictability of weather, farmers need to make decisions that balance high yield and low risk. In this study, we propose a data-driven approach for selecting a portfolio of seed varieties that integrates the predictive and the prescriptive steps.

3 - Quantitative Modeling and Analysis of Trial Data for Variety Advancement Decisions

Esma S. Gel, Arizona State University, School of Computing, Informatics and, Decision Systems Engineering, Tempe, AZ, 85287-8809, United States, esma.gel@asu.edu, Dieter Armbruster, Greg Doonan

Global food security depends strongly on sustaining the unprecedented growth in crop yields that has been observed over the past 70 years. A major enabler of increased crop yields (e.g., bushels per acre) has been due to the biological innovation (hybrid crops, biotechnology) that has been involved in the identification and development of new varieties for a number of major crops. The agricultural seed development process is performed through testing the varieties over multiple years, in multiple locations and climates. We consider prediction, visualization and optimization approaches to improve the performance of seed advancement decisions in partnership with a major seed manufacturer.

4 - Planning and Coordination Tools for the Insertion of Small Farmers into Rapid-response Fresh Food Supply Chains

J. Rene Villalobos, Arizona State University, Tempe, AZ, 85287, United States, Rodrigo Ulloa, Hector Flores

In this presentation, we introduce a supply chain integrated planning and coordination environment that includes information acquisition and coordination supply-demand tools to close the logistics and information gap between small growers of fresh fruits and vegetables and existing and emerging markets, especially those created by direct sales to consumers through ecommerce. In particular, we discuss some of the analytical tools being used to achieve a better coordination between the demand and the supply of highly perishable crops.

Joint Session TIME/Practice Curated: Empirical Research in Innovation and Entrepreneurship II

Sponsored: Technology, Innovation Management & Entrepreneurship

Sponsored Session

Chair: Tian Chan, Emory University's Goizueta Business School, Atlanta, GA, 30322, United States

1 - Process Innovation in Pharmaceutical Industry

Ivan Lugovoi, HEC Paris, 1 Square Theodore Judlin, Jouy-en-Josas, 75015, France, ivan.lugovoi@hec.edu, Dimitrios Andritsos, Claire Senot

Through a collaboration with expert patent attorneys we construct a unique dataset that: i) evaluates process innovation through a detailed observation of pharmaceutical manufacturers' portfolios of process patents and ii) measures key qualitative dimensions of process innovation, such as novelty, scope of protection and locus of application. We find a positive association between overall process innovation and firm performance. When differentiating between dimensions of process innovation, results further suggest that high novelty is beneficial, and complemented by a broad scope, but only for patents applying to the later phase of the manufacturing process.

2 - Best in Class: The Effect of Relative Perceived Quality on Demand in the U.S. Automobile Industry

Hallie Cho, INSEAD, PhD Office, Singapore, 138676 features, Singapore

Based on co-occurring product mentions in online customer reviews, we find which products are perceived similarly in the context of the U.S. automobile industry. We use aggregate customer review measures as a proxy for product quality to investigate how relative perceived quality amongst similar products influences market shares in a competitive market. We also develop a uniqueness index of product to examine what drives the difference in perceptions. Our findings help to understand the optimal distinctiveness from the consumer's perspective and have important implications for an automobile manufacturer's product differentiation strategy.

3 - Patent Grant Delays and Future Innovative Activities

Param Pal Singh Chhabra, Grad Student, Georgia Tech, Atlanta, GA, 30308, United States, param.chhabra@scheller.gatech.edu, Manpreet Singh Hora, Karthik Ramachandran

Patent grant delays have the potential of negatively affecting future patenting activities of inventors. Utilizing patents application data, spanning more than three decades, published by the USPTO, we verify this negative relationship. Additionally, we find that the delays not only affect the quantity but also the quality of the patents. Inventors also diversify their patents portfolio in pursuit of the fast track domains.

4 - Project Selection and Competitive Signals: Insights from Drug Development

Panos Markou, UVA Darden Business School, Charlottesville, VA, CB2 1AG, United States, markoup@darden.virginia.edu, Stylianos Kavadias, Nektarios Oraiopoulos

Selecting the right R&D projects is challenging because of the uncertainty and complexity inherent in making such decisions. We leverage a unique database comprising the development pipelines of the Top 15 pharma firms to examine how signals from competitive projects drive the selection decision. Early-stage competitive projects decrease the likelihood of the firm selecting to compete in the same domain, whereas late-stage projects signal high technological feasibility and increase this likelihood. These effects are moderated by the relatedness of the underlying technologies and market potential. Finally, we provide evidence on how such selection meaningfully contributes to productivity.

Supply Chain Optimization Models for Petrochemicals

Sponsored: Energy, Natural Res & the Environment/Natural Resources Petrochemicals

Sponsored Session

Chair: Said Rahal, University of Alberta, AB, Canada

1 - Challenges in Multilevel Supply Chain Optimization

Braulio Brunaud, Data Science Lead, Johnson & Johnson, Bridgewater, NJ, United States, BBrunau1@its.jnj.com, Satyajith Amaran, John M. Wassick, Ignacio E. Grossmann

Supply chain decisions are hierarchically organized in strategic, tactical, and operational decisions. In practice, these planning processes are conducted independently with minimal feedback, leading to suboptimal solutions. There is a large hidden benefit in integrating these decision-making processes. This challenge is usually approached by standardizing the data systems first with the hope to optimize in the future. In this seminar, we discuss an alternative modular approach that does not require data standardization, in which each decision-making process is encapsulated identifying the transfers of information. We apply this framework to the integration of planning and scheduling.

2 - Proactive and Reactive Scheduling for the Steelmaking and Continuous Casting Process under Uncertainty via Adaptive Robust Optimization

Said Rahal, PhD Candidate, University of Alberta, Edmonton, AB, Canada, rahal1@ualberta.ca, Zukui Li

The schedule of a steel-making and continuous-casting process defines the unit assignments of molten steel, their sequence and their start and finish processing time in each unit. These decisions have to meet strict production requirements in spite of the uncertain processing time. In this work, we discuss robust-proactive and deterministic-reactive scheduling methods. We show the significance of computing ``here and now” decisions which are immune to small disruptions. For larger magnitudes, a robust proactive hybrid method is devised that combines the fortes of the previous two methods.

3 - A Static Transshipment Model for Crude Oil Logistics Planning at a Petroleum Company

Badri Toppur, Rajalakshmi School of Business, Chennai, India, badri.toppur@rsb.edu.in

As an aspect of implementing their operations strategy and planning, a petroleum company faces the complex problem of procuring crude oil from suppliers in Persian Gulf, West Africa, North Africa, West Asia, Bombay High, India, and USA. The crude oil is shipped to two ports in Gujarat by tankers and other vessels. From these two ports the crude oil is moved to three refineries, pumped via pipelines or transported by the railroad lines. Instead of demand, the refineries have known capacity, that are different for two types of crude oil. We have modelled the problem as a static transshipment network, and used an LP solver to obtain an optimal solution. Sensitivity analysis shows that the solution is stable.

Sustainable and Responsible Supply Chain Management

Sponsored: Energy, Natural Res & the Environment/Environment & Sustainability

Sponsored Session

Chair: Jose Cruz, University of Connecticut, Hartford, CT, 06103, United States

1 - Sustainable Supply Chain Management with Environmental Tax Policies

Min Yu, University of Portland, Pamplin School of Business, Portland, OR, 97203, United States, Jose Cruz, Dong Li, Amir H. Masoumi

We develop a multiperiod model to study the firm’s long-term investment strategy on sustainable energy-efficient technologies to take advantage of tax incentives while maximizing the net present value of the investment. We also investigate the impacts of different environmental tax policies on equilibrium product demands, prices, total emissions, and investment strategies on sustainable technologies.

2 - Sustainable Supply Chain Network Model Through Reduction in Pollution Stock

Sara Saberi, Worcester Polytechnic Institute (WPI), Foisie School of Business, Worcester, MA, 01609, United States, ssaberi@wpi.edu

This study presents a multiperiod, multitier, sustainable supply chain with freight carriers network model to address such concerns. The model comprises manufacturers, retailers, and carriers engaged in a dynamic, noncooperative game. It considers the longitudinal accumulation of pollution stock, pollution absorbtion by nature, and mitigation actions. The study examines numerical examples with an analysis of the effect of different tax rates on production, transportation, sales, and levels of pollution stock and mitigation efforts. The outcome presents important strategic reactions of decision makers to tax policies.

3 - The Interaction of Forward and Reverse Logistics

Qiang Qiang, Penn State, Management Division, Malvern, PA, 19355, United States, qzq10@psu.edu, Rong Fu

In this paper, we analyze the interaction of two supply chain networks. The product of the forward supply chain is recycled and treated as the input of the reverse supply chain. Theoretical and computational results are discussed, which are illustrated by numerical results.

4 - Corporate Social and Environmental Sustainability: A Multiperiod Supply Chain Integration and Economic Framework

Jose Cruz, University of Connecticut, 100 Constitution Plaza, Hartford, CT, 06103, United States, jose.m.cruz@uconn.edu

We analyze the effects of social and environmental sustainability activities on multiperiod supply chain network economic sustainability. Suppliers, manufacturers, and retailers decide about their production and transaction quantities as well as the level of investment on social and environmental sustainability they want to pursue to maximize net return and minimize their externality risk/cost over the multiperiod planning horizon. The results show that high levels of sustainability can lead to the lower overall cost and therefore, lower prices and higher product transaction.

Handling Uncertainty in Power System Operations

Sponsored: Energy, Natural Res & the Environment/Electricity

Sponsored Session

Chair: Evangelia Spyrou, Johns Hopkins University, Baltimore, MD, 21218, United States

1 - The Parametric Cost Function Approximation for Practical Stochastic Optimization in Energy

Warren B. Powell, Princeton University, Dept of Operations Research and Financial Eng, Princeton, NJ, 08544, United States, powell@princeton.edu, Saeed Ghadimi, Hugo P. Simao

There has been a widespread misconception that the way to handle uncertainty in planning problems in energy is through dynamic programming or stochastic programming. For problems that require planning into the future, these methods overlook a powerful strategy, widely used in industry which we call the parametric cost function approximation (CFA) approach. This involves solving a parametrically modified approximation (such as a deterministic lookahead), where tunable parameters have to be optimized to produce robust solutions. We formalize this approach, and describe the challenges of forming and tuning parametric CFAs, which closely parallel similar problems in online machine learning.

2 - Dealing with Wind Uncertainty in Two-settlement Electricity Markets: A PJM Case Study

Ali Daraeepour, Postdoctoral Research Associate, Andlinger Center for Energy and Environment, Princeton, NJ, United States, a.daraeepour@princeton.edu, Dalia Patino-Echeverri, Antonio J. Conejo

The economic efficiency of power systems where wind energy represents a large share of generation, improves by considering an explicit characterization of wind uncertainty into the electricity market clearing process. This study estimates the economic and environmental efficiency gains achieved by using stochastic commitment and dispatch programming approaches for dealing with wind uncertainty. It also proposes second best deterministic methods that achieve up to 60% of the efficiency enhancement gained by the stochastic ones. A simulation of a system representative of PJM's resource mix is used to quantify the differences between the stochastic and proposed deterministic methods.

3 - Dynamic Dimensioning Approach for Operating Reserves: Proof of Concept in Belgium

Anthony Papavasiliou, CORE, UCLouvain, Voie du Roman Pays 34, L1.03.01, Louvain la Neuve, 1348, Belgium, anthony.papavasiliou@uclouvain.be, Kristof De Vos, Nicolas Stevens, Olivier Devolder, James Matthys-Donnadieu

We present a new method for the sizing of operating reserves. The talk revisits the current static sizing method applied in Belgium, which determines the required capacity once a year. The presented dynamic sizing method determines the required capacity on a daily basis, using the estimated probability of facing a system imbalance during the next day. This risk is estimated based on historical observations of system conditions by means of machine learning algorithms. A proof of concept is presented for the Belgian system. The implementation of the method is underway by ELIA, the Belgian TSO.

4 - The Value of Probabilistic Forecasts for Sizing Flexible Ramping Products: A CAISO Case Study

Evangelia Spyrou, National Renewable Energy Laboratory, Geography and Environmental Engineer, Golden, CO, 21218, United States, elina.spirou@gmail.com, Venkat Krishnan, Benjamin Field Hobbs, Qingyu Xu, Jie Zhang, Binghui Li, Rui Zhang

Flexible ramping products help Independent System Operators (ISOs) manage uncertainty and variability. Currently, US ISOs estimate net load uncertainty through statistical analysis of historical forecast errors. Existing approaches fail to see the impact of real-time weather information on the magnitude of the uncertainty. Here, we present how advanced probabilistic forecasts of solar radiance can inform ISO's estimates of uncertainty. We compare the suggested approach to current ISO practice and analyze the economic and reliability benefits for a 118-bus system mimicking CAISO.

Battery Energy Storage in Long-Term Energy-Economy Planning Models

Sponsored: Energy, Natural Res & the Environment/Energy Sponsored Session

Chair: Cara Marcy, U.S. Environmental Protection Agency, United States Energy Information Administration, Washington, DC, 20585, United States

1 - Firm Capacity from Battery Storage in Long-term Planning Models

Wesley Cole, National Renewable Energy Laboratory, Golden, CO, United States, wesley.cole@nrel.gov

Long-term models of the electricity sector aim to ensure resource adequacy for the buildouts considered in the models. This presentation will consider how battery storage, which is energy limited according to its duration, can contribute toward the firm capacity requirement in long-term planning models, with a specific look at the ReEDS model.

2 - Evaluating the Emissions Impact of Utility-scale Battery Storage: Investment Versus Dispatch

Ryan Sims, U.S. Environmental Protection Agency, Washington, DC, United States, Sims.Ryan@epa.gov

Spurred by improving costs and growing regulatory support, the pace and scale of new battery storage installations to support power system operations have accelerated in recent years. This presentation utilizes the U.S. Environmental Protection Agency's Integrated Planning Model to evaluate the emissions impact of new, four-hour battery storage on the grid, with an emphasis on understanding how various levels of storage penetration alter the economic landscape for new investment.

3 - Capturing the Value of Storage in Generation Capacity Expansion Models

David Young, Electric Power Research Institute, Palo Alto, CA, United States, dyoung@epri.com, John Erik Bistline

We add a representation of battery storage to an 8760 hour static equilibrium electric sector model with endogenous capacity rental and dispatch across interconnected regions. We apply this framework to study how the energy arbitrage and capacity values of storage vary across a range of sensitivity scenarios and draw some inferences as to how the results might change with lower temporal resolution - a common assumption among long-term capacity expansion models. We find that magnitudes of energy and capacity revenues vary by region and scenario, that both are required for properly valuing storage, and argue that lower temporal resolution can mis-represent the relative value streams.

4 - Modeling Battery Storage in EIA's National Energy Modelling System (NEMS)

Chris Namovicz, Team Lead for Renewable Electricity Analysis, U.S. Energy Information Administration, Washington, DC, United States, chris.namovicz@eia.gov, Manussawee Sukunta, Vikram Linga

Over the past several years, EIA has incorporated energy storage into it National Energy Modeling System (NEMS), addressing challenges including representing serial charge/discharge; the diurnal value of variable renewables; and value toward meeting reserve margins. This paper will address public presentation and interpretation of the energy storage model results, in particular assessment of the competitiveness of storage compared to conventional resources using levelized cost and levelized value metrics derived from model results to develop a proposed levelized cost of storage metric.

The Role of Demand Response in Managing Future Electricity Loads

Sponsored: Energy, Natural Res & the Environment/Energy Sponsored Session

Chair: Nils Johnson, PhD, Electric Power Research Institute, Palo Alto, CA, United States

1 - Potential Roles for Demand Response in More-electrified Futures

Elaine Thompson Hale, National Renewable Energy Laboratory, National Renewable Energy Laboratory, Golden, CO, 80401, United States, elaine.hale@nrel.gov

Power systems, both supply- and demand-side, are rapidly evolving due to technological change and various policy goals. This talk will describe potential roles for demand response in future power systems serving more electrified loads (including transport) and with higher shares of variable renewable generation. Starting from a broad definition of demand response as any change imposed on demand-side end-use operations meant to support power grid functionalities, we draw on a number of past and ongoing research topics to provide insight into the value of different kinds of demand response in different kinds of power systems.

2 - The Implications of Coordinated Electric Vehicle Charging for Power Supply

Nils Johnson, Senior Technical Leader, Electric Power Research Institute, Palo Alto, CA, 94025, United States

Depending on when electric vehicles (EVs) are charged, large-scale adoption of EVs will likely increase electricity demand and may have significant impacts on future load shapes. This analysis uses an integrated electricity demand and supply model, US-REGEN, to explore the load implications of large-scale EV deployment and to examine the potential impacts of vehicle charging on the US electricity supply system through 2050. A scenario approach is used to explore the implications of uncoordinated versus coordinated vehicle charging for capacity requirements, plant utilization, and electricity prices.

3 - California Optimal Grid Operation for a High Renewable Electricity Supply System: Future Role of Electric Vehicles

Behdad Kiani, PhD, University of California-Davis, Davis, CA, United States

A mathematical optimization model is introduced to optimize the grid interaction of electric vehicles in long term electricity planning towards high renewable supply system. Optimal vehicle-to-grid (V2G) and grid-to-vehicle (G2V) energy flows are calculated based on various factors, such as battery capacity, charging and discharging rates, required energy for driving demand, hourly electricity price, and ramp-up constraints. We assume a ramp-up of VRE to 60% of all electricity generation by 2030 and 100% by 2050, with a similar increase in the EV share of new LDV sales, creating a significant stock (about 7 million) by 2030 and nearly complete transition (to over 20 million vehicles) by 2050.

4 - Quantifying the Benefits of Imperfect Demand Response

Patricia J. Levi, PhD Candidate, Stanford University, Palo Alto, CA, United States

Demand Response (DR) could help integrate renewables into the electricity grid by making electricity demand more flexible. However, it has unique restrictions on its usage. This study identifies the impact of several types of usage and advance-notification constraints on the system-wide value of DR. A unit commitment model based on ERCOT's wholesale market is used. DR representation is based off of current incorporations of DR into existing wholesale markets across the US. Results suggest which characteristics of DR may lead to greater system value and explore how DR should be represented in wholesale markets to respect customer preferences.

Chair: Daniel Nielubowicz, Clemson University, Central, SC, 29630, United States

1 - Proposal of Coordinated Trading System for Eliminating Double Marginalization

Sidi WU, Waseda University, Tokyo, Japan, sidiwu@gmail.com, Jiahua WENG, Seung-Jin Ryu

Double marginalization occurs while an upstream company and a downstream company negotiating their transaction price and quantity only in consideration of their own profit. As a result, total profit of the supply chain is usually lower than the exclusive profit of one company. In this study, we focus on the negotiation between a manufacturer and a mass retailer. A coordinated trading system with information estimation and negotiation guide function is proposed to make the manufacturer and the retailer realize win-win relationship. Mitigation effects on the whole supply chain profit are shown in the experiment results. The profit allocation is also to be discussed in this study.

2 - Understanding the Impact of Partner Trust Level on Supply Chain Surplus

Seong-Hyun Nam, Professor, University of North Dakota, Grand Forks, ND, United States, snam@business.und.edu

Trust-based collaboration is viewed as one of the most critical factors in achieving effective and efficient forecasting performance in a supply chain. Research indicates that the willingness to cooperate and share forecast information with a certain level of partner trust can create mutual competitive advantage throughout the supply chain networks. The efforts to shift the business relationship to a certain level of trust, however, may incur operational costs including additional investments in developing trust. This paper examines how partner trust can improve demand forecast accuracy and develops a decision-making model for trust-level optimization that can promote supply chain surplus.

3 - An Investigation of SaaS Adoption W/in the Supply Chain

John F. Kros, Vincent K. McMahon Distinguished Professor, East Carolina University, Greenville, NC, United States, krosj@ecu.edu

This research investigates the adoption or non-adoption of Software as a Service (SaaS) within the supply chain. Survey data will be used to discuss why/how/when/what supply chain professionals are adopting when it comes to transportation management systems (TMS), warehouse management systems (WMS), yard management systems (YMS), etc.

4 - Measuring Supply-chain Performance for Strategic Management and Managerial Control

Anthony Gerard Vatterott, University of Missouri-Saint Louis, Saint Louis, MO, United States, anthonygvatterott@gmail.com, Wesley Boyce, Laurence Douglas Smith

Supply-chain engineering and management require an understanding of interrelationships among supply-chain metrics, strategic business principles and the foci of supply-chain managers as they pursue superior supply-chain performance. With data from an extensive review of supply chain metrics proposed in the literature, we use text analytics to demonstrate these interrelationships. Then we discuss how strategies for containing risk while maximizing supply-chain performance may be embedded in optimizing models for supply-chain management.

5 - The Impact of Blockchain Technology within SCOM: An Event Study

Daniel Nielubowicz, Clemson University, Central, SC, United States, dnielub@g.clemson.edu, Aleda Roth

Blockchains are perceived as key to solving industry issues around accountability, traceability and transparency. We utilize company announcements to illustrate the key drivers of blockchain adoption and its effects on the supply chain.

6 - Dynamic Consolidation of Picked Orders in an Online Orders Fulfillment Warehouse

Wen Zhu, New Jersey Institute of Technology, Newark, NJ, United States, wz83@njit.edu, Sanchoy Das

Order fulfillment warehouses (F-Warehouses) are a critical component of the physical internet behind online retail supply chains. Items are stocked in multiple random locations dispersed throughout the F-warehouse. Orders are then picked and collected in totes which are assigned to one of many packaging stations. The F-Warehouse is continuously generating totes. Each multi-item order is therefore located in several totes and must be consolidated. This research formulates and solves the order consolidation problem. We formulate the problem a MIP and present a fast heuristic solution.

Information Systems III

Contributed Session

Chair: Rafat Elsharef, UW-Milwaukee, Milwaukee, WI, 53211, United States

1 - Data Compression with Attribute Homomorphism in Information Systems

Yanbin Hao, Northwestern Polytechnical University, Xi'an, China, nwpuhyb@163.com

Data compression is an important topic in data processing and homomorphism is considered as an effective tool for data compression. This paper defined the attribute isomorphism and attribute homomorphism for information system based on the functional dependency relation over attributes. It then investigated major properties of the attribute homomorphism. By using the attribute equivalence to acquire the deal homomorphism, it achieved lossless compression for information system. Finally, this paper provided a method to measure the ideal level of any attribute homomorphism by comparing distance between the original system and the image information system.

2 - Security-sensitive vs. Security-general: A Study of Information Security Decision under Security Externality

Yong Wu, Glorious Sun School of Business & Management, Donghua University, Shanghai, China, wuyong1202@sina.com

Information security incidents leading to firms suffer the loss of information assets have been occurring on a regular basis. The goal of security investment for security-sensitive firms is to improve the survival probability as high as possible, while that for security-general firms is to reduce the security loss as far as possible. This paper examines how security-sensitive firms differ in timing of security investment from security-general firms, characterizing how asset uncertainty, security externality, and environment riskiness influence both security quality and investment timing.

3 - Examining Technostress on Employees' Security-related Behaviors

Forough Nasirpouri Shadbad, Oklahoma State University, Stillwater, OK, United States, David Biros, Madhav Sharma

The behavioral information security literature depicts employees as a major information security threat in organizations. To explore how employees' interaction with IT increases security vulnerabilities, we utilize the technostress literature. Although, technostress studies have examined the effect of stressors on employees' performance, its effect on security-related behaviors is unclear. To this end, we examine the effect of IT stressors on individuals' information security behaviors through their responses to the stressors (strain). Using SEM to test the proposed model, we expect individuals with high of perceptions of stressors are more likely to engage in security violations.

4 - Cyber Security for Industrial Control Systems: Evaluation and Recommendations

Rafat Elsharef, PhD Student and lecturer, UW-Milwaukee, Milwaukee, WI, United States, elsharef@uwm.edu, Wilkistar Otieno

There is a great demand to connect ICS and SCADA systems to the internet for monitoring, control, and data gathering, by doing so, we exposing these critical devices to the internet which will increase the probability of security threat and risk against these critical devices. This presentation will cover best practices and security recommendations as we are connecting these devices to the internet. Current popular protocols will be discussed. Real hacked cases with lessons, recommendations and security measures to prevent such hacks will be addressed. Wireshark analysis of captured data will be analyzed to show vulnerabilities of such devices.

Monday Poster Competition

Competition Poster Session

1 - Approximation Algorithms of Maximum Entropy Sampling Problem

Yongchun Li, Virginia Tech, Blacksburg, VA, United States, liyc@vt.edu, Weijun Xie

This paper studies the maximum entropy sampling problem (MESP), which selects the most informative principal submatrix of a given size from a positive semidefinite matrix. We first derive a new convex integer programming formulation for MESP. Using the convex relaxation solution, we propose a sampling algorithm and its deterministic implementation, which improves the best known approximation bound. We also analyze the widely used local search algorithm for MESP and prove its first known approximation bound. Finally, we extend our analysis to A-optimality.

2 - Efficient Algorithms for Discrete Distributionally Robust 2-stage Stochastic Program

Zhe Zhang, Georgia Tech, Atlanta, GA, United States, zzhang724@gatech.edu, Shabbir Ahmed, Guanghui Lan

Recently, there has been a growing interest in distributionally robust optimization because of data-driven optimization. However, very few efficient algorithms have been developed, and most of them cannot handle the non-smoothness of the second stage cost effectively and tend to scale poorly with the usually large number of scenarios K. In this paper, we fill the gap by developing two accelerated algorithms whose iteration complexity only mildly depend on K for solving distributionally robust two-stage stochastic optimization problems with different ambiguity set. Moreover, the major computations involved in each iteration of these algorithms can be conducted in parallel if necessary.

3 - Development of an Interactive Visualization for Best Transport Scenario to Optimize Outcomes for Stroke Patients Using a Statistical Probability Model

Noreen Kamal, Assistant Professor, Dalhousie University, Halifax, NS, Canada, Noreen.Kamal@dal.ca, Kimberly K. Chan, Michael J. Francis, Jessalyn Holodinsky

Endovascular treatment (EVT) for ischemic stroke is a new treatment that is only available at urban tertiary hospitals; it is given with a medical treatment that is widely available. There is uncertainty on the best transportation scenario. Is it better to transport to the closest hospital and receive medical treatment early and then transfer for EVT or bypass this hospital to receive both treatments at the tertiary hospital? A mathematical model was developed incorporating variables that effect patient outcomes using data from clinical trials. The model was the basis for the development of a cloud software showing the best transport scenario through interactive maps to assist with decision making.

4 - A Novel Positive Transfer Learning (posTL) Approach for Telemonitoring of Parkinson's Disease

Hyunsoo Yoon, Postdoctoral Scholar, Arizona State University, Tempe, AZ, United States, hyoon15@asu.edu, Jing Li

Telemonitoring of voice signals of Parkinson's Disease (PD) patients using an At-Home Testing Device is a cost-effective logistically-convenient way to monitor disease progression and optimize treatment. Key challenges in telemonitoring are patient heterogeneity and limited data for each patient. We propose a transfer learning approach, PTL, which can leverage other patients' information when building a predictive model for a target patient. The unique features of PTL include intelligent selection of patients to transfer to avoid negative transfer and maintain patient privacy preservation.

5 - An in Depth Look on the Effect of Abortion Policy in Alabama with System Dynamic Modeling

Yi Ling Chang, Claremont Graduate University, Newport Beach, CA, United States, yi-ling.chang@cgu.edu, Yuan-Yuan Lee

A debate has recently ensued when Alabama signed a state-level legislation restricting access towards abortion. This research adopts system dynamic modeling to demonstrate the complex government expenditure budget and further illustrates the effects abortion restriction has on welfare budget coping the contemporary issues with teenage pregnancy and prenatal detection of transmittable diseases.

6 - Home Bias in Non-profit Online Lending: A Perspective of Social Identity Theory

Yingli Gong, Tongji University, Shanghai, China, 1630977@tongji.edu.cn, Hongwei Wang

As a crucial factor affecting individual preference and even economic decision-making in experimental economics, social identity is a persuasive perspective to reveal the home bias in online lending. Using the data from a non-profitable online lending platform and employing logistic regression model, we find that regional identify can promote lender's lending behavior: borrowers and lenders from the same country or closer are more willing to trade. The closer the geographical distance is, the higher the financing rate is, and the higher the average financing amount is. Our study identifies that regional identity exists and introduces social identity into online lending.

7 - Dynamic Pricing Solves the Urban Transportation Disparity - Evidence from NYC On-demand Ride-sharing Drivers

Qing Wei, Clemson Univeristy, Fargo, ND, United States, qwei@clemson.edu

We investigate the effect of dynamic pricing on ride-sharing drivers' supply. Instead of the hour and wage relation explored by previous literature, we look at the instantaneous response of drivers to price surges. Using data from NYC, we estimate the structural model through a constrained non-parametric approach. We find that dynamic pricing effectively solves the geographical disparity problem of the taxi, it increases the overall accessibility and quantity of pickup service. Without dynamic pricing, in our counterfactual case, platform drivers will be clumped in Manhattan and airports as taxi drivers. And 27 % of the total supply will be lost, with a tremendous 59% drop in the non-Manhattan area.

8 - Does Shopping Behavior Impact Food Waste

Alwin Dsouza, Arizona State University, Mesa, AZ, United States, adsouza3@asu.edu

Significant food waste by households particularly in developed countries has gathered attention recently. Food waste happens when households are not able to match their purchases and consumption. In our study, we intend to measure the magnitude of food waste across online, mixed and offline shoppers. There are two opposing factors playing here. Online shoppers are more inclined to follow the shopping list which may reduce food waste, but online shoppers need to pay for delivery costs and follow a minimum basket size, which may increase the food waste. The net impact is inconclusive. We will be using scanner data to test the hypothesis. We focus on shoppers learning behavior to measure food waste.

9 - Biofuel Supply Chain Optimization Considering Economic and Environmental Aspects Using a Genetic Algorithm

Juan V. Fernandez, The University of Texas at El Paso, El Paso, TX, United States, Heidi A. Taboada, Jose F. Espiritu

Biofuel production has been identified as an alternative source to mitigate greenhouse gas emissions, reduce dependence on fossil fuels, and to alleviate increase in energy demand. The growing demand of biofuel production has prompt the need for efficient and sustainable biofuel supply chain networks. The following paper presents a multiple objective genetic algorithm considering the simultaneous optimization of economic and environmental objectives. Furthermore, the model determines harvested and purchased biomass units, as well as the openings of intermediate warehouses and the transportation flows.

10 - Efficient Trust Region Methods for Inverse Mixed Integer Optimization

Ian Yihang Zhu, University of Toronto, Toronto, ON, Canada, i.zhu@mail.utoronto.ca

We study inverse mixed integer linear optimization (inverse MILP) problems, which seek to infer the unobserved objective function of an optimization problem (a forward MILP problem) using a solution of this problem. The standard solution method is a cutting-plane algorithm which requires solving the forward problem numerous times in order to add cuts. We propose a trust region method in which we can generate cuts within a restricted feasible space of the forward problem. We show using MIPLIB instances that our approach significantly reduces both the computational complexity of obtaining each cut as well as the number of cuts required until the optimal solution to the inverse problem is obtained.

11 - Fast Security-constrained Optimal Power Flow for Application in Flow Based Market Coupling

Richard Weinhold, Technische Universität Berlin, Berlin, Germany, Robert Mieth

Power flows and thus electricity market outcomes are constrained by physical transmission system constraints and its security requirements such as the N-1 criterion. Internalization of this criterion in optimal power flow (OPF) analyses often leads to prohibitive computational complexity even for linearized (DC) power flow equations. We present a methodology to obtain a minimal set of linear constraints that yields an exact N-1 secure DC-OPF solution that can be leveraged in multi-period economic analyses. The reduction process depends only on time invariant parameters and needs to be performed only once. The effectiveness of the method is shown on a large-scale real world power system.

12 - Assessing Models for Reducing Rate of Pavement Deterioration in Crack Sealing Treatments

Bortiorkor Nii Tsui Alabi, Purdue University, West Lafayette, IN, United States, Julius Keller, Samuel Labi

Cracks in highway/airfield pavements pose safety challenges as they lead to surface defects that impair utility and hence the need to apply treatments that reduce rate of deterioration by cracking. This study presents a model for determining effectiveness of crack sealing in terms of reduction in the rate of pavement deterioration. The model utilizes a functional form to account for pre-sealing level of deterioration and effort (maintenance dollars) expended on crack sealing treatments, thus facilitating an intuitive interpretation of the model formulation. Study result show sealing effectiveness does not exceed certain limit/cap. This cap is a function of the pre-sealing pavement condition.

13 - Adaptive Scheduler for Job-shop Problems: Reinforcement Learning on Disjunctive Graphs

Junyoung Park, KAIST, Daejeon, Korea, Republic of, junyoungpark@kaist.ac.kr, Jaehyeong Chun, Jinkyoo Park, Sanghoon Kim, Youngkook Kim

Job shop scheduling problem (JSSP) is an NP-hard problem with various applications in manufacturing domains. Due to the time-varying structure of a problem and the size of real manufacturing facilities, optimization methods are not applicable in practice. The majority of manufacturing facilities utilize rule-based dispatching methods to schedule production. Designing dispatching rules are dependent on experts' insight, which considers only partial information. We suggest a JSSP solver which is (1) adaptive so that it can schedule based on the real-time status of facilities with the understanding of the system (2) transferable so as to schedule any JSSP without additional training.

14 - Idle Vehicle Rebalancing in Manufacturing System Using Graph Neural Network and Multi Agent Reinforcement Learning

Kyuree Ahn, KAIST, Daejeon, Korea, Republic of, Jinkyoo Park

In this study, we propose a cooperative rebalancing strategy of idle vehicles to increase the productivity of the semiconductor system. We discretize the fab into zones and derive decentralized rebalancing strategies by applying a graph neural network (GNN) based multi-agent reinforcement learning (MARL). We first represent the fab into a directed graph to construct embedding values for each zone. After applying GNN to input graph, the node embedding values are then used to determine the cooperative rebalancing action from each zone in a decentralized manner. Simulation studies show that the proposed algorithm increases system-level performance compared to other strategies.

15 - Deep Learning-based Optimization of Battery Systems

Yifan Lu, UBC, Vancouver, BC, Canada, yifanlu823@gmail.com

The need for frequency regulation increases as wind power introduces frequencies never seen before. Battery systems are used in frequency regulation due to their flexibility and low price. In order to reduce the time in solving the optimization problem in each time step, the artificial neural network is employed to make this process faster without sacrificing its accuracy.

16 - Forecasting Wind Turbine Generation with Machine Learning Regression Model

Fei Sun, Texas State University, San Marcos, TX, United States, f_s38@txstate.edu, Tongdan Jin

Wind power is a main alternative energy resource, which has been applied broadly worldwide as moving towards an increasingly diverse energy mix to attain the emissions target in 2050. However, the challenge of utilizing wind energy is that the output of the wind turbine (WT) is intermittent and uncertain. Therefore, a hybrid wind speed forecasting method for estimating the short-term and long-term wind speed using advanced computer algorithms. Feedforward Artificial Neural Network (FANN) model and Recurrent Artificial Neural Network (RNN) models are applied. The primary result shows the machine learning models outperform the ARIMA model especially when the forecasting steps extend.

17 - A Hybrid AI Solution for Enterprise Client Advocacy Enhancement

Lei Huang, Research Staff Member, IBM Almaden Research, San Jose, CA, United States, Rodrigo Goulart Silva, Belen Gutierrez Gomez, Marie Hamburg, Elizabeth Regina Carreiro, Kim Christopher Cabugos, Jay Arvin Lego, Guangjie Ren, Vinicius Souza

How to improve client advocacy has been a great challenge for enterprise and large organizations given their large business size, versatile business services/products, and large number of touchpoints along the client journey. In this work, we propose a hybrid AI solution based on dictionary and machine learning methods for client surveys classification and insights extraction, thereby enhancing client advocacy. The solution has been implemented and applied to IBM client surveys that are collected through Medallia platform. We not only share results and improvements, but also discuss the future directions.

18 - Design and Maintenance for the Data Storage System Considering System Rebuilding

Jun Wang, University of Chinese Academy of Sciences, Beijing, China, wangjun172@mails.ucas.ac.cn
Jun Wang, Rutgers University, Piscataway, NJ, United States, wangjun172@mails.ucas.ac.cn, Xiaoyan Zhu, Tao Yuan

Considering the working and failure modes and maintenance process of a data storage system, we propose and study a reliability and maintenance model of a k-out-of-n:F system, in which the system experiences a rebuilding process with downgraded performance that follows preventive maintenance (PM) with replacement of failed components, and the system is subject to failure with different failure criteria during such rebuilding process. the external shocks would occur and possibly result in the failure of all the components. These characteristics bring in a new reliability and maintenance model and a new optimization problem that synthetically determine system reliability design and PM schedule.

19 - Sustainable Operations of Vertical Farm with Onsite Renewables Integration

Jose Luis Ruiz Duarte, University of Arizona, Tucson, AZ, United States, jlruizduarte@email.arizona.edu, Neng Fan

Controlled environment agriculture improves food systems efficiency by simulating ideal environment for crops growing, with the drawback of highly energy intensive operations. We present a mathematical programming model for optimal lighting system scheduling of vertical greenhouses with onsite energy storage systems and renewable energy sources operating under demand-side management policies.

■ Poster Session

CC- Exhibit Hall, Level 4

Monday Poster Session

Poster Session

1 - Strategic Inference under Private Sampling

Erik Miehling, University of Illinois at Urbana-Champaign, Champaign, IL, United States, Roy Dong, Cedric Langbort, Tamer Basar

We present a simple model to analyze the strategic signaling effects present when an agent’s learning process is partially observed by another agent. By computing the perfect Bayesian equilibria of the game, we characterize when a rational agent should collect private information and how the information influences future play.

2 - Application of a Flexible Gradient Descent to Machine Learning

Mostafa Rezapour, Washington State University, Pullman, WA, United States, mostafa.rezapour@wsu.edu, Nairanjana Dasgupta

One of the most widely optimization methods in machine learning is Gradient Descent. It is an iterative method that estimates model parameters by minimizing the error function. It reduces the error by stepping a specific length (learning rate) toward the steepest descent direction (negative gradient). The learning rate is a hyper parameter, which means it is fixed. However, in this poster we show that by converting the learning rate from a hyper parameter (fixed value) to an adjustable parameter, we can guarantee that the algorithm obtains the model accuracy faster and independent of the initial choice of the learning rate.

3 - Behavioral Business Intelligence Approach for Occupational Health & Safety

Abdulaziz Ahmad, Assistant Professor, University of Minnesota-Crookston, Crookston, MN, United States, aaahmed@crk.umn.edu, Salih Tutun, Sedat Irgil, Ilker Yesilkaya, Tulay Korkusuz

This research aims to develop a Behavioral Business Intelligence (BBI) approach for investigating problems to improve Occupational Health and Safety (OHS). We collected the dataset with 270 workers and 630 features. We utilized and proposed the Heterogonous Similarity Function to capture relations of workers by looking at behaviors and the Company’s structure. Afterward, based on relations, a network model is developed to analyze workers’ personality, and it explains the relationship between psychological status of the workers. Finally, we defined around 30 outliers (workers) that have problems for OHS, and we defined alpha/alphas leaders of the group for managing the OHS system.

4 - Effect of EHR Use and Information Security Controls on Time-sensitive Emergency Care Process Quality at U.S. Hospitals

Eric Johnson, Dean and Professor of Strategy, Vanderbilt University, Nashville, TN, United States, Ajit Appari

In this study, we examined the impact of EHR use on the emergency care performance; and how the cybersecurity controls adopted by hospitals affect this relationship between EHR use and emergency care performance. We analyzed 2,746 non-federal US hospitals based on data from multiple sources for year 2015 using generalized linear model for three process outcomes: median time to ECG for chest pain/heart attack, median time in ED for hospitalized patients, proportion of cases that had CT/MRI results available within 45minutes of arrival. We find mixed evidence on the ‘impact’ of EHR use and cybersecurity controls on emergency care performance.

5 - Association of Information Technology Use and Provider Characteristics with Opioid Prescribing Rates in the United States

Ajit Appari, Vanderbilt University, Nashville, MA, United States, aappari.work@gmail.com

The rising growth of electronic health record (EHR) systems among providers may help to stem the Opioid crisis as they could make informed decisions. In this cross-sectional study, I examined the association of provider-level Opioid prescribing rates with their EHR use, select provider characteristics and market competition by estimating mixed-effects generalized linear model regression, adjusting for patient population characteristics. Analysis of 892,664 providers (data obtained from 2016 Medicare Part-D prescription program file) suggests that EHR users and providers at larger practices and facing high competition are less likely to prescribe Opioids.

6 - ExpenDrogram – Comprehensive Visualization of Segmentation Over Time

Anna Khalemsky, Bar-Ilan University, Ramat Gan, Israel, anna.khalemsky@gmail.com, Roy Gelbard

In a big and dynamic data environments, the visualization of a segmentation process over time often doesn’t allow the user to monitor different aspects simultaneously, thus the main goal of ExpenDrogram visualization technique is to improve the comprehensiveness of a visualization analysis in order to support the decision-making process.

7 - What Information Support Does a Regional Innovation System (RIS) Need? Comparing Government-driven RISs with Grassroots-driven RISs

Benjamin Matheson, University of New Mexico, Albuquerque, NM, United States, Urusha Thapa, Fred Phillips

A regional innovation system (RIS) supports the diffusion of knowledge across economic, social, political and institutional relationships. With the support of information infrastructures, a successful RIS promotes the translation of knowledge into new technologies and products. This research focuses on current information infrastructures found in various RISs. The research team compared a government-driven RIS (Daejeon, Korea) with grassroots-driven RIS (Austin, Texas and Oregon, USA). The empirical bases are taken from in-depth interviews with regional initiative leaders, statistical data, historical documents, and research literature.

8 - Classification Methods with Neural Networks and Hybrid SVM

Enrique Martinez, Student, Heritage University, Yakima, WA, United States, John Tsiligaridis

Support Vector Machine (SVM) is an accurate classification method but computationally infeasible on large datasets due to time and space complexities. To reduce training complexity of SVM a hybrid SVM (DT_SVM), based on a probabilistic Decision Tree and Tabu Search algorithms, is developed. Superiority of SVM over Neural Network and simulation results with different complexity data sets are provided.

9 - Machine Learning for Objective Pain Measurement

Fatemeh Pouromran, Graduate Research Assistant, Northeastern University, Boston, MA, United States, pouromran.f@northeastern.edu, Sagar Kamarthi

Objective pain measurement has long been clinician’s Holy Grail for effective pain management. In practice, they typically rely on the patient’s self-report which doesn’t work when patients are not alert and cooperative. In this study, we developed the objective pain measurement model based on physiological signals and machine learning techniques.

10 - Impacts of Multimodal Information in E-commerce: An Analysis of Verbal, Visual and Affective Information in Videos on Sales

Gaurav Jetley, University of South Florida, Tampa, FL, United States, gauravjetley@mail.usf.edu, Shivendu Shivendu

Unlike textual reviews, videos convey information on multiple dimensions, yet, there is little research on their impacts on sales. Previous literature also have contrasting findings on persuasiveness of rich presentation and visual cues. We investigate the impacts of verbal, visual and affectual information in customer, professional and manufacturer videos on product sales. Among other results, we find video aspects such as word speed, length & scenes have inverse U-shaped relationship with sales, clarifying contrasting results from previous studies. We discuss implications to practice and theory.

11 - Amplifying the Imitation Effect for Reinforcement Learning of UCAV’s Mission Execution

GyeongTaek Lee, Yonsei University, Seoul, Korea, Republic of, SangJin Kim, ChangOuk Kim

This paper proposes a new reinforcement learning algorithm that enhances exploration by amplifying the imitation effect (AIE). This algorithm consists of self-imitation learning and random network distillation. We argue that these two algorithms complement each other and that combining these two algorithms can amplify the imitation effect for exploration. In addition, by adding an intrinsic penalty reward to the state that the RL agent frequently visits, the AIE leads to deep exploration. We applied the AIE to a simulated environment of unmanned combat aerial vehicle (UCAV) mission execution, and the empirical results show that AIE is very effective for finding the UCAV’s shortest flight path.

12 - Adaptive Neural Architecture Optimization for Medical Image Analysis

Haifeng Wang, Assistant Professor, Mississippi State University, Mississippi State, MS, United States, wang@ise.msstate.edu

Optical Coherence Tomography (OCT) is an interferometric imaging modality that can visualize biological microstructure via cross-sectional images. Machine learning algorithms have been widely applied and investigated for automatic medical image analysis. However, neural architecture is a crucial aspect that influences the performance of convolutional neural networks (CNNs). Identifying an effective CNN architecture requires a great amount of time and efforts due to the complexity of CNN connections. To overcome the challenge, an adaptive neural architecture optimization (ANAO) model is proposed, which can adaptively design and optimize the CNN structure based on a given dataset. Neural blocks are designed as basic elements in the optimization process. Experiment results are conducted on retinal disease diagnosis and show that the proposed models can obtain higher accuracy for both 2D and 3D OCT image classification tasks.

13 - The Role of Social Network Sites on the Relationship Between User and Developer in Games: An Evolutionary Game Analysis for Virtual Goods

Haitao Chen, Jilin University, Changchun City, China, htchen@126.com, Chen Hao, Dong Zhaohui

Recently, the emergence of social network sites (SNS) has gradually solved the dilemma of online games that neither of game developer and user takes little consideration on virtual goods. This paper adopts the evolutionary game method to model the repeating multi-stakeholders progress and finds that it is the social influence of SNS drives both sides to take positive strategies on virtual goods market through the impact of other players in games.

14 - Real-time Significant Wave Height Classification from Raw Ocean Images Based on Convolutional Neural Network

Heejeong Choi, Korea University, Seoul, Korea, Republic of, heejeong_choi@korea.ac.kr, Pilsung Kang

Among various ocean conditions, a wave height is one of the most significant considering factors for economic routing which aims at reducing fuel expenses. The previous approaches have estimated the ocean-wave conditions by either solving equations or training machine learning models. The former cannot estimate the wave heights in real time and the latter did not fully utilize the wave images. In this paper, we propose a real-time convolutional neural network (CNN)-based significant wave height level classification model based solely on raw ocean images. To achieve higher classification accuracy efficiently, four CNN structures are and two image preprocessing techniques are investigated.

15 - A Deep Reinforcement Learning Approach for the Stochastic Inventory Problem

Henri Dehaybe, UC Louvain, Gembloux, Belgium, henri.dehaybe@uclouvain.be

We consider the classic Single-Level Stochastic Inventory Problem (SL-SIP) and we propose a heuristic to identify close to optimum policies based on Deep Reinforcement Learning. The neural network at the core of the heuristic can be extended to a continuous demand space and proves able to approximate the optimal (S,s) policy after an appropriate training on random instances of the problem. The proposed approach to solution of the problem is novel in the literature of the SL-SIP and constitutes a further example of the benefit that a cooperation between optimization and machine learning can bring both to the respective research areas and to practical problem solving.

16 - Big Data Research in Information Systems: A Meta-analysis

Hua Dai, Associate Professor, California State University-Channel Islands, Camarillo, CA, United States, hua.dai@csuci.edu, Tao Hu, Xi Zhao

Based on an extensive literature review and meta-analysis of 176 articles published in the “Senior Scholars” list of the eight information systems (IS) focused academic journals over the period of 2000-2019, this study reports the preliminary findings of topics and methodologies of Big Data research in the IS field. The meta-analysis compares research methodologies applied and topic areas investigated, and identifies the emerging research trends. Then, a research framework of Big Data is proposed to synthesize and aid in theoretical perspectives and empirical studies of the Big Data research in the IS field.

17 - Health Monitoring and Anomaly Detection of a Power Plant Boiler Using Unsupervised Autoencoder

HyoJung Kim, Undergraduate Student, Chosun University, Gwangju, Korea, Republic of, Seongjoon Kim, Seongjoon Kim

Please check the mobile app for this abstract.

18 - A Conditional System Health Index Based Prognostics and Health Management Method for Uncertainty Management

Jaeyeon Jang, Yonsei University, Seoul, Korea, Republic of, jjy009@yonsei.ac.kr, Daeyeol Yang, Chang Ouk Kim

This study proposes using a deep conditional health index extraction network (DCHIEN) for prognostics and health management (PHM) to effectively manage uncertainty. DCHIEN is a model that combines a stacked denoising autoencoder with a neural network that extracts a health index (HI) based on user-defined monitoring conditions. This approach supports system health monitoring using the conditional HI, as well as prognostics. We conducted experiments using NASA's turbofan engine degradation data. The results showed that the proposed method showed a superior remaining useful life prediction performance compared to existing methods and that uncertainties can be effectively managed.

19 - Handling Nonignorable Missing Values in Information Systems Research: Toward Imputation with Machine Learning

Jiaxu Peng, National University of Singapore, Singapore, Singapore, j.peng@u.nus.edu, Jungpil Hahn

We review top IS journals and show the ubiquitous existence of missing values in quantitative empirical research. To handle missing values, modern approaches often assume missing at random (MAR) although in many cases we often strongly suspect missing not at random (NMAR). We propose a missing value imputation method which considers the missingness mechanism and increases the robustness to the NMAR mechanism. Moreover, our method can be extended to imputation using machine learning algorithms which enable potentially more accurate imputation. This study has important implication for both quantitative empirical researchers, not only for IS researchers, as well as practical data analytics.

20 - Time Series Models in the Presence of Ouliers or Extreme Values

Mian Arif Adnan, Graduate Student, Indiana University Bloomington, Bowling Green State University, Bowling Green, OH, United States, maadnan@iu.edu

Estimates of the Time Series Models suffer from the exaggeration of the contribution of the outlier(s) or extreme observations. Time Series Models based on least deviation method have been developed to minimize the total sum of errors. It also suggests some new measures of fit.

21 - Explainable Machine Learning Model for Crop Yield Prediction

Javad Ansarifar, Iowa State University, Ames, IA, United States, ansarifar.javad@gmail.com, Lizhi Wang

Crop yield prediction is important because accurate predictions help farmers to make right decisions, allow seed industries to evaluate new varieties, and support famine-prevention efforts. The existing methods are either accurate models like machine learning models or explainable models like crop models. We designed a new explanatory predictive framework, which integrates domain knowledge of crop science into the explainable predictive framework. Optimization tool was used to determine the best combinations of explanatory variables leading to high crop yield. Comparison of the new model with existing models reveals that using the proposed model improves crop yield prediction.

22 - Optimization of Retrieval Rate Based on Minimal Information

Babu K. Baniya, Assistant Professor, Grambling State University, Ruston, LA, United States, baniyab@gram.edu

We proposed the minimal information approach that calculates the different statistics to preserve the distinctive information from extracted features. The bunch of audio features was extracted and calculated low- (mean and variance) and high order statistics (skewness and kurtosis) from them. In the next stage, linear discriminant analysis (LDA) algorithm was implemented to acquire the distinctive knowledge from the feature pool and the outcome presented in the 2-dimensional space. The distinctive features divided into ten-fold and fed into the kernel support vector machine (SVM) to determine the corresponding class label. The overall accuracy is 84.75%.

23 - A Dynamic Transit Model for Vulnerable Road Users

Justice Darko, Student, North Carolina A&T State University, Greensboro, NC, United States, jdarko@aggies.ncat.edu

Vulnerable road users (VRUs) are most sensitive to risk and uncertainties in transit networks. In many scenarios, these travelers prefer decisions that is one-shot, avoiding high-risk actions. We model the behavior of the constant risk-sensitivity of these travelers by assuming the exponential function. Integrating the exponential function into Markov Decision Process ensured that the actions taken by the traveler is now conditioned on the level of uncertainty and risk in the stage of decision making. In general, integrating the exponential utility presented a personalized transit model for VRUs enabling them to take actions that lead to less regret.

24 - Marketing Analytics in Banking

Mou Dutta, Genpact, New York, NY, United States, drimjhim36@gmail.com

Customer churn is one of the most notable business challenge for any marketer.

25 - Developing Ensemble Predictive Model for Supplier Assessment

Ramkumar Harikrishnakumar, Supply chain research analyst, Wichita state university, Wichita, KS, United States, hramkumar21@gmail.com, Vatsal Maru, Alok Dand, Krishna Krishnan, Saideep Nannapaneni

Supplier assessment is a multi-criteria decision making approach that requires several criteria for the proper assessment of the suppliers. For a comprehensive and robust assessment process, we propose machine-learning algorithms to classify various suppliers into four categories: excellent, good, satisfactory, and unsatisfactory. In this paper, machine learning algorithms (especially classification algorithms) are applied for a supplier assessment problem. Machine learning techniques that include bagging and boosting methods are used to create various ensemble classifiers from training data, and their performance is measured using test data.

26 - Machine Traders Beat Man Traders? Why?

Bo Han, Texas A&M University-Commerce, Commerce, TX, United States

Algorithmic trading (AT) has gained tremendous popularity. This paper compares the decision making features between AT based trading and human controlled trading, and propose useful framework to fund managers.

27 - Effectiveness of Decision Making Strategies in Uncertain and Time-Sensitive Environments

Mark Calafut, George Washington University, Washington, DC, United States, mcalafut@gwu.edu, Shahram Sarkani, Thomas Mazzuchi

Decision making strategies are often applied in challenging environments, characterized by uncertainty and time-sensitivity. This situation was modeled as a stochastic knapsack optimization that considered multiple criteria for arriving opportunities. Online and periodic strategies were implemented in simulation and their performance was characterized at levels of opportunity variety, uncertainty, and time-sensitivity. At low and moderate uncertainty, online strategies created more value and at high uncertainty, periodic strategies created more value. In cases where uncertainty and time-sensitivity are not well known, online methods are preferred due to greater robustness.

28 - A Data-based Competitive Market Strategy Model for Higher Education Organizations

Scott J. Warren, Professor, University of North Texas, Denton, TX, United States, scott.warren@Unt.edu

Like their for-profit brethren, universities seek to determine whether there is demand for their academic products before going to the expense of marketing them to prospective students. However, until recently public universities were supported by substantial state funds, meaning this was not a concern. Many higher education organizations have small marketing departments primarily focused on protecting branding, rather than on using the marketing concept to analyze potential markets to determine demand for their academic products as part of a broader recruitment strategy. This piece explores how some U.S. universities can exploit market-based analytic approaches to better compete.

29 - Integrated Deep Multi-task Learning and Stochastic Optimization Approach for Chronic Disease Operations Management

Mohammad Hessam Olya, Wayne State University, Detroit, MI, United States

Efficient managing of chronic disease operations leads to a reduced healthcare operation cost. In this study we propose an integrated approach for chronic disease operations management. We developed a deep multi-task learning approach for patient workload prediction. Then, we suggested a stochastic optimization model for capacity planning in the healthcare system. This approach leads to chronic disease operations cost reduction by using data analytics and operations research techniques in order to plan for required resources and allocate them to the patients based on their various demand while balancing workload of the resources.

30 - Decision Making Using Multi-task Learning

Mohammad Hessam Olya, Altair Product Design, Troy, MI, United States

Using single-task learning approaches as prediction methods to assist decision makers became common, lately. Depending of the problem type, different single-task learning approaches are sufficient for getting fair and reasonable outcomes. But for certain problems, we need to use multi-task learning approaches in order to increase the efficiency of algorithm. In this research we explain some applications of multi-task learning as well as its advantages for decision makers.

31 - A Decision Support Tool for Defense Planning

Sandra Huber, Defense Planning, München, Germany, hubersandra100@gmail.com

One of the key challenges for defense planning is to define capabilities to meet the mission requirements. In addition, promising projects have to be selected to fulfill the expected outcome. The selection of projects includes several factors, such as multinational commitments, political-military strategy of the German Federal Ministry of Defense as well as the capability guidelines of the German Armed Forces. We developed a multi-stage genetic algorithm solution approach for the resource-constrained project scheduling problem and investigated different versions of the algorithm on several instances.

32 - Comparative Analysis of User Innovation Mechanisms: A Mechanism Design Approach

Sangjic Lee, Doctoral program student, The University of Tokyo, Tokyo, Japan, sangjiclee@css.t.u-tokyo.ac.jp, Kohei Nishiyama, Nariaki Nishino

This study aims to compare the various pathways of user innovation commercialization with the mechanism design framework. By conducting a case study of the Lego company and examining it along with the existing literature, a set of shared game model elements is constructed. Then five mechanisms - user entrepreneurship, user community, personalization, crowdsourcing, and in-house innovation as a benchmark case - that contain different message sets and outcome functions are formulated with the elements. With other features being controlled, the pure-strategy equilibria are searched and the implementability of the social choice function is compared under several preference settings.

33 - Evaluating Stakeholder-driven Criteria for Airfield Pavement Investment

Bortiorkor Nii Tsui Alabi, Purdue University, West Lafayette, IN, United States, Tariq U. Saeed, Julius Keller, Samuel Labi

A comprehensive and explicit definition of performance goals and associated decision criteria is critical for ex ante or ex poste evaluation of investments. In application of airport runway pavements, this can help airport authorities to assess consequences of alternative investment actions as costs and benefits accruing to the airport authority, users, and society. This study synthesizes concepts of stakeholder-related criteria for evaluating airport runway pavement investments and provide airport authorities with guidelines (including criteria dimensions and desired attributes) to identify appropriate decision criteria for investments.

34 - Feature Based Procurement Contract for Intermediary Agri-service Providers with Co-production

Omkar D. Palsule-Desai, Indian Institute of Management-Indore, Indore, India, omkardpd@iimidr.ac.in, Yini Gao, Teo Chung Piaw

A challenge for an intermediary agri-service provider is achieving an appropriate balance between yield improving efforts and assured prices to be offered to the farmers. We develop a noncooperative game theoretic model that captures farming yield of traditional and high-value farm-produce, the trader's commission rates in the open-market, and the supply chain players' farming and effort-cost functions. We describe the economics associated with co-production, gather farmer level data from a firm, and validate observed behavior of players in the real-world setting.

35 - A Case Study in Line Balancing and Simulation

Chelsea Spence, Clemson University, Clemson, SC, United States, cspenc2@g.clemson.edu, Alexis Fiore, Adarsh Jeyes, Edwin Chase Wentzky, Ibrahim Ozan Yilmazlar, Nicole Zero, Mary Beth Kurz, Joshua D. Summers, Kevin M. Taaffe

Assembly line balancing allocates individual tasks to work stations while respecting physical, safety, and quality constraints. Because this is an NP hard problem, it is often difficult to find an optimal solution. We balance a two-sided transfer line using integer programming, metaheurisitics, and simulation and compare the methods. The methods are evaluated based on data from a currently operating assembly line for a local OEM.

36 - Tele-medicine Value for Patients, Payers, Providers, and Society

David D. Cho, Woodbury University, Burbank, CA, United States, Jon M. Stauffer

Medicare and many insurance providers do not reimburse providers for constant patient tele-monitoring. However, with today's pay-for-performance reimbursement plans, there can be benefits for discharged patients, such as shorter skilled nursing facility stays and reduced readmissions with follow-up monitoring immediately after discharge. We model the costs and benefits of tele-monitoring in a multi-period setting to study the cost-effectiveness and design of reimbursement plans for different players involved.

37 - Pricing Strategies of Dual—Channel Closed—Loop Supply Chain under Government Reward—Penalty Mechanism

Haitao Chen, Jilin University, Changchun City, China, htchen@126.com, Dong Zhaohui, Chen Hao

Government plays an important role in the products recycling in order to encourage sustainability. This research develops two dual channel closed-loop supply chain models with the government reward-penalty mechanism under different collecting scenarios. And we explore which collecting model is more efficient. Our equilibrium results show that the direct collecting model is prior to the third-party collecting model. In addition, the sensitive analysis indicates that the government financial intervention can moderate the channel conflict and competition. We further provide the government with the method to find the optimal to maximize the total social welfare with the approximate budget.

38 - Retail Competition at the E-commerce Era

Qiang Li, Rutgers University, Newark, NJ, United States, Xiaowei Xu

We study retail markets, in which brick-and-mortar retailer competes against an e-retailer. Many department stores announced to close more stores. On the other side of the competition, e-retailers have been growing their business at a double-digit annual rate. The brick-and-mortar retailer needs scale constraint. We build a mathematical model and try to answer some questions such that: will online retailers win the final trophy and eliminate more local stores in the next decade? What's the suitable population density that a local store should cover?

39 - Inventory and Pricing Decision for a Non-instantaneous Deteriorating Item under Environmental Investment

Sepideh Zohoori, Doctorate of Engineering, Lamar University, Beaumont, TX, United States, szohoori@lamar.edu, Reza Maihami, Iman Ghalehkhondabi

Fresh fruit, vegetable, and frozen fast food are known as "non-instantaneous deteriorating items". These items keep their original quality for a span of time, then the normal deterioration process begins. In this paper, a new inventory control model for a non-instantaneous deteriorating item is presented. The demand depends on selling price and level of environmental improvement. This paper aims to indicate the optimal price, inventory control variables, and level of environmental improvement simultaneously such that the vendor's total profit is maximized. the proposed model is designed according to a non-linear optimization model and the analytical closed-form of the solution is computed.

40 - Cooperative Advertising in a Dual-supply Chain under Asymmetric Market Information

Yan Zong, Renmin University of China, Beijing, China, zongyanrbs@ruc.edu.cn, Jianghua Wu

This paper focuses on the incentive for vertical information sharing in the context of cooperative advertising within a dual-channel supply chain. Our results show that information sharing leads to an increase in supplier's profit and, under certain conditions, in the whole supply chain's. The retailer can also be better off when supplier "reverse" the retailer's purchase to support advertising.

41 - Multi-image Monitoring with MPCA for Statistical Process Control

Shengfeng Chen, Western Michigan University, Kalamazoo, MI, United States

A Two-image monitoring framework is introduced and proved to be more sensitive to a wide range of shifts than a single-image framework. Specifically, two images being monitored are fused together with Multilinear Principal Component Analysis (MPCA) and then monitored through a Multivariate Exponential Weighted Moving Average (MEWMA) control chart. The proposed image-fusion MEWMA outperforms either 2-MEWMA combinations or individual MEWMA in detecting wide range of shifts. The spatial cross-correlation between images is investigated and indicating images with weaker cross-correlation can increase control chart's sensitivity to process shifts.

42 - Underpricing in SME Initial Public Offerings

Hariprasad Bellamkonda, IIM Indore, Indore, India, hariprasad@iimidr.ac.in

The signalling role of underwriters and auditors in underpricing of SME initial public offerings in the aftermath of demonetisation was examined in this study in Indian context. This study reveals that the underwriter's presence has reduced the information asymmetry thereby signalling the issue quality to investors. The interaction effect between the underwriter and the auditor examined in this context reveals that underwriter reputation plays a significant role in decision making.

43 - Toward Green Fashion Design: A Systems Engineer's Perspective

Ana G. Duque, Rensselaer Polytechnic Institute, Troy, NY, United States, duquea@rpi.edu, Jennifer A. Pazour, Sérgio Pequito

The objective of this research is to determine if industrial hemp fiber can be produced as a competitive alternative to cotton. Through the elaboration of a holistic supply chain, the fiber production process of both textiles is juxtaposed, highlighting key economic and environmental considerations. All stages of fiber production are measured under three main pillars: time, cost and yield. Preliminary results show industrial hemp as a high yield crop with at least 8 times more tonnes of fiber per hectare cultivated and lower ecological footprint than cotton. The continuing research aims to demonstrate that industrial hemp fiber has the potential to become a staple within the fashion industry.

44 - Differentiating Interhospital Transfer Types: Varied Impacts and Diverging Destination Choice Strategies

Raymond Lei Fan, University of Houston, Houston, TX, United States, raymondfan@bauer.uh.edu, Ming Zhao, David Xiaosong Peng

This study first develops a method to empirically separate clinical interhospital transfers (IHTs) from non-clinical IHTs. Next, we evaluate their impacts on care outcomes and find: (1) clinical IHTs are associated with better outcomes than non-clinical IHTs; (2) for non-clinical IHTs, transfers within the same healthcare system are associated with better outcomes than those out of the system, whereas for clinical IHTs, destinations out of the system are better than those in the system. We use Heckman selection model and propensity score matching to address potential sample selection bias. The results provide managerial insights on IHT destination choice strategies.

45 - Equilibrium Analysis in Dual-channel Supply Chain with Dominant E-tailers

Jin Zhang, RWTH Aachen University, Aachen, Germany, zjchitu@gmail.com

This paper models the strategic interaction between e-tailers and a monopolistic manufacturer and allows that e-tailers have price-setting power vis-à-vis the manufacturer. It investigates the performance of the manufacturer and the e-tailers in a model that incorporates a vertical variable and a horizontal variable and allows for a dominant e- tailer structure and a dominant manufacturer structure. It considers a two-stage game theoretical model that captures the two key factors and solves for an equilibrium. It compares the firms' performances under the two different power structures and investigates the magnitude of the e-tailers benefit that is related to a change in their bargaining power.

46 - Determine Slack in the Enterprise Operations Support

Pawan Chowdhary, IBM Research, San Jose, CA, United States, chowdhar@us.ibm.com, Sunhwan Lee, Guangjie Ren

Enterprise operations and Support (EO&S) provides back office service to the frontline sales force for IBM. It has thousands of staff that support several million service requests each year. We plan to present our analysis on capacity and utilization to identify the slack in the system for optimal performance

47 - Dynamic Pricing by Combining Xgboost and Dual Annealing

Abhinav Khare, University at Buffalo, Buffallo, NY, United States, abhinavk@buffalo.edu, Suirong Dong, Diala Gammoh, Sivalenka Amruth

Dynamic Pricing to maximise revenue requires an accurate estimation of the demand curve that varies with season, day of the week and other business-related factors. We developed a two-stage model to find the optimal price points for an online digital product where prices vary on daily basis. We used a machine learning model to capture the relationship between demand & all other factors in the first stage while we applied a simulated annealing algorithm to find the optimal price point in the second stage. We found out that xgboost algorithm outperforms other machine learning algorithms in predicting the demand on a large scale. The proposed methodology is estimated to increase the revenue by 20%.

48 - If You Want to Finish Your Next Project on Time, Work in Sprints! How Agile Project Management Improves Output Performance

Tobias Lieberum, Technical University of Munich, Munich, Germany, tobias.lieberum@tum.de, Sebastian Schiffels, Rainer Kolisch

At the heart of the agile project management approach Scrum is project execution through sprints. Sprints are short-term project phases characterized by timeboxed progression to the next sprint and self-contained output goals for every sprint. We experimentally show for a given duration that in the absence of timeboxed progression and phase-specific output goals participants spend too much time on early at the expense of late project phases. Timeboxed progression alone mitigates this effect, but does not improve the exerted effort. Phase-specific output goals alone lead to an amplification of the progression delay. The combination of both components results in a significant performance uplift.

49 - Personality Type and Systems Thinking Skills of Practitioners

Morteza Nagahi, Graduate Research Assistant, Mississippi State University, Starkville, MS, United States, mn852@msstate.edu

As organizations operate in more and more turbulent and complex environments, it has become increasingly important to assess practitioners' Systems skills Preferences (SSP) and Personality Types (PT). The current literature lacks studies related to the impact of practitioners' PT on their SSP, and this study aims to address this gap. A total of 99 engineering managers and 104 systems engineers provided the data to test four hypotheses posed in this study. The results show that the PT of practitioners have a positive impact on their level of SSP and that the education level, the current occupation type, and the managerial experience of the practitioners moderate the main relationship in the study.

50 - Navigating the Aisles: Nutritive Optimization for Single-parent Households

Jessica Knobloch, Saint Joseph's University, Philadelphia, PA, United States

The Nutritive Optimization Model (NOM) was designed to enable financially restricted households to leverage data-sharing technology for increased efficiency in planning grocery shopping trips. Twenty-one price points of commonly consumed perishable foods were collected from the ten largest grocery retailers in the United States to observe pricing variation across the country. Prices are displayed based on companies' national geographic presence. Pricing surveys were conducted to begin expanding NOM into a multi-objective linear program for nutritive optimization.

51 - Hostile Takeovers or Friendly Mergers?: A Real Options Analysis

Katsumasa Nishide, PhD, Hitotsubashi University, Kunitachi, Japan, Takeshi Ebina, Yuya Kumakura

This paper analyses a real options model of mergers and takeovers between two firms experiencing different, but correlated uncertainty in profits. It is assumed that firms can choose two alternatives; hostile takeover or friendly merger. In a hostile takeover, a bidder firm takes all the extra value but should incur merger costs, while in a friendly merger both firms do not bear merger costs and share the extra value through Nash bargaining. We shall show with numerical analysis the condition for which firm to be a bidder and for which form of amalgamation to happen.

52 - An Application of Hotspot Analysis for Optimal Location Analysis

Lakshika Nishadhi Kuruppuarachchi, The University of Toledo, Toledo, OH, United States, lakshika.nsh@gmail.com, Zonghua Xu, Matthew Franchetti

Food waste is the largest component of waste by weight in U.S.A. Food waste sent to landfill releases Green House Gas (methane) which is at least 28 times more potent than carbon dioxide. Residential food waste collection in the U.S.A has grown significantly in the past few years. The feasibility of introducing a commercial food waste collection program is studied. Currently, the study area does not have any food waste collection program and the food waste collection points needed to be identified. The study proposes the optimal places to be selected as the collection points using the hotspot analysis and then assign each demand point to the selected collection points.

53 - Causal Models to Identify the Most Responsive Customers to Email Promotions

Michael Bostwick, Squarespace, New York, NY, United States, mbostwick@squarespace.com

Modeling heterogeneous treatment effects can be used to identify customers most responsive to marketing efforts. We demonstrate the effectiveness of this approach at Squarespace to develop an optimal email promotion policy. We also show what the most responsive customers look like in terms of product and email engagement features.

54 - A Clothes Inventory Balancing Scheduling Problem in Fast Fashion Industry

Xiaodong Wang, Tongji University, Shanghai, China, xiaodongwang2017@tongji.edu.cn, Shijin Wang, Ruochen Wu, Li Yu

Fast fashion industry is a highly competitive business. Quick response capabilities are required to capture the fashionable trends and satisfy customers demands. Inspired by a real-world fast-fashion operation system, this study investigates a clothes inventory balancing problem, where a distributer schedules demanded clothes among a warehouse and several branch stores. A mixed integer programming is formulated with some practical constraints to maximize the distributor's total profits. A real-world illustrative case study is conducted to validate the effectiveness of the proposed model. Efficient heuristic and decomposition algorithms have been developing for further study.

55 - Environmental and Economic Modelling for Recycling Collection System in Lucas County

Zonghua Xu, University of Toledo, Toledo, OH, United States, Zonghua.Xu@rockets.utoledo.edu, lakshika Kuruppuarachchi, Matthew Franchetti

This study is to optimize the drop-off collection system for recyclables in Lucas County, to reduce the environmental and Economic cost, including reduction in total vehicle traveling miles and GHG gas emissions. There are two recycling streams: Fiber and commingled containers in Lucas County. The periodic vehicle routing Optimization models are built, which can fully applied to minimize the Environmental and Economic cost for the recycling streams in Lucas County. This study applied GAMS/CPLEX which based on branch and bound algorithm to solve the models. The analysis shows the validity of the models and algorithm. This work can be used in related theory of PVRP and reverse logistics.

56 - Determining Optimal Gasoline Fuel Delivery Strategies under Uncertainty

Dominiqueca Edwards, North Carolina A&T, Greensboro, NC, United States, dredward@aggies.ncat.edu, Lauren Berrings Davis, Pitu B. Mirchandani, Sierra Marshall

The uncertainty of how a hurricane can affect society is inevitable. In preparation for a hurricane, potential individuals affected by the hurricane often are required to evacuate. Evacuations can cause high increases in the demand for gasoline fuel needed for transportation. The fuel is imported by vessels which often have to divert from the intended destination port due to the path of a hurricane. The purpose of this research is to determine a real time port diversion strategy for incoming fuel vessels given the forecast of an approaching hurricane. We develop a heuristic scheduling algorithm that finds the optimal diversion strategy that minimizes the unmet demand of gasoline fuel in each county.

57 - Using Buffered Probability of Exceedance in Risk Management

Giorgi Pertaia, University of Florida, Gainesville, FL, United States, gpertaia@ufl.edu, Stan Uryasev, Artem Prokhorov

Credit ratings are fundamental in assessing the credit risk of a security or debtor. The failure of the CDO ratings during the financial crisis of 2007-2008 and the massive undervaluation of corporate risk leading up to the crisis have caused a review of the ways ratings are constructed. Yet the fundamental risk metric that guides the construction of credit ratings has not changed. We present a new methodology based on a buffered Probability of Exceedance (bPOE). The new approach offers a conservative risk assessment, with substantial conceptual and computational benefits, which we illustrate using synthetic and real-world financial data.

58 - A Multi-objective Optimization Model for Designing Industrial Symbiosis Network

Lufei Huang, Shanghai University, Shanghai, China, huanglufei@shu.edu.cn

Waste material produced by industrial manufacturing processes is one of the main sources of environmental pollution. The industrial symbiosis initiative, which aims to address the economy, the environment and society synchronously, is regarded as an effective sustainable solution. Waste material exchange, similar to water exchange and energy exchange, is one of the key links that to be put into practice at the beginning of industrial symbiosis. However, very few studies develop a tri-objective optimization model for material exchanges decisions in the industrial symbiosis networks. This study presented a multi-objective model regarding the material exchange decisions, which simultaneously accounts for the three pillars of sustainability. By-product flow, material reprocessing node and reprocessing technology level selections are formulated in a Mixed-Integer Programming model. An Epsilon-constraint approach is provided to tackle with the presented multi-objective model efficiently. Affected by the trade-off among three objectives, nine scenarios derived from objective priority are employed to review the performance of the proposed symbiosis network. Computational results verify that our approach is effective for obtaining solutions. Some managerial insights highlighted from numerical analysis are presented for industries' practice.

59 - Joint Pricing and Ordering Decisions to Manage Deteriorating Inventory

Omid Jadidi, Assistant Professor, St Edward's University, Austin, TX, United States, ojadidi@stedwards.edu

A perishable product of different ages are usually displayed side-by-side on shelves. Ageing items, in most situations, become less appealing to customers. This study considers a joint pricing and inventory management problem in which a retailer sells a perishable product of two different ages. The demand for the product is assumed to be price- and time-dependent. We formulate the problem by using a mathematical programming approach and develop an algorithm to solve it numerically. The numerical analysis shows that an appropriate pricing decision can reduce the waste considerably. Further results are discussed to bring some managerial insights.

60 - Approximation Ratio of LPT* Algorithm for Multi-Processor Scheduling

Peruvemba Sundaram Ravi, Associate Professor, Wilfrid Laurier University, Waterloo, ON, Canada, pravi@wlu.ca, Jackie W. Baek, Levent Tuncel

In 1993, Eck and Pinedo proposed a heuristic algorithm, the LPT* algorithm, to minimize makespan over flowtime-optimal schedules for a set of jobs on a set of parallel identical machines. Their algorithm was an extension of a very well-known list scheduling algorithm, Longest Processing Time (LPT) list scheduling, to this bicriteria scheduling problem.They proved that, for the two-machine case, their algorithm had a worst-case performance ratio of 28/27. Huang and Tuncel (2004) proposed worst-case performance ratios for the case when the number of machines exceeds two. We outline an approach that may lead to a proof of the ratios proposed by Huang and Tuncel.

61 - Using Twitter to Analyze Tesla Stock Price

Richard Gruetzemacher, Auburn University, Auburn, AL, 36830, United States, Sam LaPlatney, Brett Roeber

This study uses Twitter data to analyze sentiment of Tweets concerning Tesla and Tesla's stock price. We compare relevant hashtag sentiment and the sentiment from cashtags. There are significant differences between hashtag sentiment and cashtag sentiment, with hashtag sentiment sometimes being a better indicator of Tesla's stock price. This suggests that previous automated trading systems developed based on sentiment analysis of Twitter cashtags may be enhanced by also including sentiment information from hashtags.

62 - Evaluating Alternative Network Designs for Closed Loop Supply Chain Using SNA Metrics

Sara Akbar ghanadian, Ohio university, Athens, OH, United States, sa129715@ohio.edu

Social Network Analysis (SNA) has been developed to identify and analyze the patterns in social networks. Although SNAis a powerful method to study networks in many areas, it has not been comprehensively applied to supply chain networks. Likewise, there is no application and interpretation of SNA metrics in closed loop supply chains (CLSCs). In this study, SNA metrics are introduced and interpreted for components in CLSC networks and forward and reverse logistic activities. Correspondingly, a decision making tool is developed based on selected SNA metrics for comparing alternative network designs in terms of network reliability and balance of the flows.

63 - Overlap Packing Optimization for Spacecraft Layout Design

Richard Alaimo, University of North Carolina-Charlotte, Charlotte, NC, United States, ralaimo@uncc.edu, Claudia Ramirez-Wade, Churlzu Lim, Simon Hsiang, Maijinn Chen, John Arellano, Jerry Myers

This study considers the layout design of a spacecraft where adjacency and volume are optimized using a biobjective mixed-integer linear program. The model can generate design alternatives accommodating physical design requirements and the designer's preference. Noting the NP-hardness of the problem, enhancements are proposed and tested to improve computational efficacy.

64 - Optimization of Production and Packaging Schedules in a Mixed Discrete Continuous Manufacturing Environment

Faraz Dadgostari, Univ of Virginia, Charlottesville, VA, United States, fd4cd@virginia.edu, Jarett Cestaro, Peter A. Beling

Please check the mobile app for this abstract.

65 - Sonoco Uses a Stochastic Lot sizing and Scheduling Model to Optimize the Production of Coreboard

Niels De Smet, Ghent University, Ghent, Belgium, nedsmet.desmet@ugent.be, Solventure, Ghent, Belgium, Stefan Minner, El-Houssaine Aghezzaf, Bram Desmet

Since several years we have been working together with the European supply chain team of Sonoco, one of the largest global players active in the packaging industry, to solve a variety of supply chain challenges encountered in their industrial products & services division. In this work, we present the result from a pilot project related to production planning for which we developed a novel stochastic lotsizing and scheduling model and a solution approach tailored to their specific business environment.

66 - A Data-driven Analysis of Competitive Free Shipping Policies by Online Retailers

Gihan S. Edirisinghe, Washington State University, Pullman, WA, United States, gihan.edirisinghe@wsu.edu, Charles L. Munson, Narmada Balasooriya

Amazon Prime has revolutionized home delivery cost perceptions. We develop a model using non-linear MIP to analyze several common shipping programs used by online retailers to determine the best policies under different circumstances and make recommendations. We build a Python-based web crawler to obtain data from Amazon for this analysis. We find at current industry parameter levels that shipping policies with a membership free shipping component are more profitable. Our results indicate that the cost savings felt by customers significantly vary across different policies based on many factors. We also make recommendations on setting optimal membership fees and free shipping thresholds.

67 - Optimize the London Bike Sharing System through Advanced Analytics

Filippo Focacci, DecisionBrain, Paris, France, contact@decisionbrain.com

Based on machine learning and mathematical optimization models, DecisionBrain's applications are used every day to optimize the workforce of market leaders in the Services industry such as ISS, JLL and Serco. In this session, we will discuss how we optimize operations for the London Cycle Hire (LCHS), one of the largest bikes sharing systems in the world and their mobile workforce.

68 - Preferred Boarding Passes Optimization by Markov Chains

Jose G. Flores-Muniz, Tecnologico de Monterrey, Monterrey, Nuevo Leon, Mexico, Viacheslav V. Kalashnikov, Nataliya I. Kalashnykova, Vladik Kreinovich

We examine a bilevel optimization problem where the upper level decisions are made by the airline's management governing the proportion of preferred boarding passes and the price of the latter. The economy class passengers seek the Nash equilibrium at the lower level of the model venturing to maximize their payoff functions thus generating a Markov chain's transition matrix. The steady-state probabilities of the chain are used at the upper level to define the groups into which the economy class passengers are partitioned. The existence of solutions to the problem is established, and simple numerical experiments are made. Important conclusions and bypass practical recommendations can be developed.

69 - Analysis of Complete Information Disclosure Behavior of Pollutant Enterprises and Government's Supervision Based on Evolution Game Theory

Dan Luo, Student, Tongji University, Shanghai,China, China, 1550724@tongji.edu.cn

The evolution game model is established to analyze the influence of complete information disclosure subsidy rate, failure compensation rate, penalty rate, central subsidy to local government and public attention on this system.MATLAB is used to directly show the results.The research shows that a certain level of reward and subsidy helps to form a trust relationship between enterprises and government.The central reward to local is helpful to the rapid stability of the system.The increase of the penalty rate to eliminate enterprises with incomplete disclosure will accelerate the system. The increase of social attention is conducive to the prudent decision-making of enterprises and governments.

70 - A New Scenario Resource for Integrated 1.5°C Research in the Context of Climate Change and Sustainable Development

Daniel Huppmann, International Institute for Applied Systems Analysis (IIASA), Vienna, Austria, huppmann@iiasa.ac.at

This poster presents the scenario ensemble of quantitative pathways compiled to support the assessment for the IPCC Special Report on Global Warming of 1.5°C (SR15). It also provides an overview of the suite of open tools to facilitate exploration and analysis of this resource and highlights how the tools were implemented following the FAIR principles for open, collaborative research.

71 - Data Intensive Industrial Asset Management for Distributed Energy Resources

Farhad Balali, PhD. Candidate, University of Wisconsin-Milwaukee, Milwaukee, WI, United States, mbalali@uwm.edu, Hamid Seifoddini, Adel Nasiri

The main purpose of this study is to develop an analytical methodology to assess the reliability based on the data-driven degradation model. Auto-Regressive degradation models are considered in a state-space environment. Ther proposed predictive models of Asset Management is able to predict the failure in order to schedule the optimized maintenance orders and replacement schedules. Failure events are usually defined as a point of the time when the degradation profile hits the critical limit. Therefore, this study seeks to present an exact formulation of the data-driven models of Asset Management based on the time-series degradation estimates.

72 - High Accuracy in Ultrasonographics Patterns Detection over 30.000 Images in Lateral Elbow Tendinopathy with Artificial Intelligence

Guillermo Droppelmann, Research Director, MEDS Clinic, Santiago, Chile, guillermo.droppelmann@meds.cl, Manuel Tello, Cristóbal Greene, Julio Rosales, David Prieto, Felipe Feijoo

Ultrasound diagnostic techniques have shown moderate accuracy in objectively diagnosing tendinopathies. We develop a machine and deep learning model and show that they have higher discriminatory accuracy than standard diagnostic methods based on ultrasound exams. The models are built and tested using 30.977 ultrasounds images with lateral elbow tendinopathy.

73 - Avoidable Acute Hospitalizations During the Early Phase of Post-Acute Care? Opportunities to Drive Preventive Strategies and Reorient Care

Jakka Sairamesh, CapsicoHealth, Inc, San Francisco, CA, United States

Over 1 in 9 patients are hospitalized from home health settings within a 60-day episode of care. With Value based care being promoted by CMS (e.g. BPCI, BPCI-A and CJR) and Commercial payors, there is a growing trend to discharge patients to home-health care with the right support. CMS has launched initiatives over the past few years to reduce unplanned 30-day readmissions to hospitals to tackle the 17 Billion in 30-day readmissions costs per year. Our data for analyses includes Medicare claims over a 2-year period from 2016-Q1 to 2018-Q1. We conclude that identification of hospitalization risk will help target and orient the appropriate care to the patients at home.

74 - Evaluating the Structural and Temporal Aspects of Responses to a Short Daily Wellness Questionnaire

Michael Tolston, Ball Aerospace and Technologies, Fairborn, OH, United States, mtolston@ball.com, Maegan O'Connor, Nickolas Mackowski, Samantha Leyh, Adam Strang

Short daily wellness questionnaires given as part of a controlled physical training program are rarely evaluated for simple factor structure or to see how that structure might change over time. Further, different analyses may be required to capture how individuals are related compared to how training sessions are related. In this work, we show that partial triadic analysis—a generalization of principal components analysis designed for repeated measures data—of responses to a daily-administered wellness questionnaire addresses this and reveals different structures for individuals and training sessions.

75 - Exploiting Vulnerabilities of Load Forecasting

Yize Chen, University of Washington, Seattle, WA, United States, yizechen@uw.edu

Load forecasting plays a critical role in the operation and planning of power systems. By using input features such as historical loads and weather forecasts, system operators build forecast models to guide decision making in commitment and dispatch. We study the vulnerability of a class of load forecasting algorithms, and propose data injection attack that require minimal assumptions on the ability of the adversary. The attacker does not need to have knowledge about the load forecasting model or the underlying power system. Surprisingly, standard load forecasts are quite vulnerable to the designed black-box attacks, and attacker could cause significant and targeted damages to system operations.

76 - The Application of Semi-supervised Learning for Breast Cancer Subtyping

Asala Erekat, Graduate Research Associate, State University of New York at Binghamton, Binghamton, NY, United States, aerekat1@binghamton.edu

In healthcare getting a fully labelled dataset is cumbersome and expensive. Most of the current studies in genomics have focused on supervised or unsupervised learning. Using supervised learning on a high-dimensional small labelled dataset is prone to overfitting, while using unsupervised learning on a large unlabeled dataset might lead to complications in interpreting the clusters specifically when the models yield low accuracy. Hence, this research tackles the mentioned problems by utilizing semi-supervised learning on a mix of labelled and unlabeled multivariate genomics data to help identify different breast cancer subtypes with high accuracy.

77 - Optimal Scheduling of Community-based Social Workers to Mitigate Opioid-related Overdose

Carolina Vivas-Valencia, Purdue University, West Lafayette, IN, United States, Nan Kong, Yunan Liu, Paul Griffin

We are currently in a public health crisis for opioid use disorder (OUD). OUD has become a challenging mental health issue, where people will benefit the most from an integrated system of care. However, in many cases, psychosocial services cannot be ensured due to scheduling inconvenience and resources availability. In this study, we formulate an optimal scheduling model for social workers from a community network that provides behavioral nudging to mitigate opioid-related overdose and relapse. We conduct a case study using data from the Indiana Family and Social Services Administration to validate the need for the optimal scheduling to engage OUD users in community-based support.

78 - Current Challenges in Development of a Survival Analysis Data Mining Study

Hamidreza Ahady Dolatsara, Clark University, Worcester, MA, United States, hamid@auburn.edu, Fadel Mounir Megahed, Ying-Ju Tessa Chen

This study highlights the issues and challenges that are associated with the development of a data mining (DM) study in the transplantation field. The UNOS dataset was investigated for the development of a data mining study to predict survival of patients within one year after heart transplantation surgery. CRISP-DM (CRoss Industry Standard Process for Data Mining) was adopted as the outline of the DM based survival analysis.

79 - Modeling an Energy System Model for the Road Transportation Sector to Analyze Greenhouse Gas Reduction Policies in South Korea

Hansung Kim, Pohang University of Science and Technology (POSTECH), Pohang, Gyeongbuk, Korea, Republic of, Daiki Min, Dong Gu Choi

South Korea needs to reduce greenhouse gas (GHG) emissions by 37% compared to the BAU scenario by 2030. The road transportation sector is one of the major sectors that consume a large amount of energy. The Korean government is planning various policies to reduce GHG emissions in the sector such as the dissemination of eco-friendly vehicles. In this study, we model a bottom-up energy system for the road sector and analyze the effects of various policies. The model comprises the demand projection module, modal shift module, vehicle stock module, and scrappage module. Based on the model, we analyze the amounts of GHG reduction by 2050 from four major policies.

80 - Optimal Capacity Planning of Generation System Integrating Uncertain Solar and Wind Energy with Seasonal Uncertainty

Heejung Park, Assistant Professor, Kyungpook National University, Daegu, Korea, Republic of, h.park@utexas.edu, Ross Baldick

We present a generation capacity planning model for integration of utility-scale wind farms and grid-connected solar photovoltaic (PV) generation systems via multi-stage stochastic programming. A multi-stage scenario tree for available wind power, electric load, and solar irradiance is constructed with nine stages for a year. Random samples for wind, load, and solar irradiance are generated using Gaussian copula which represents correlation between random samples. Environmental energy policies to control carbon dioxide emissions and increase energy generation from renewable sources are implemented, and the resulting generation capacity mix is investigated.

81 - Complication of Patients undergoing Living Donor Nephrectomy Using Clavien-dindo Grades: An Analysis of HCUP-NIS Data (2008-2015)

Maryam Soltanpour Gharibdousti, PhD Candidate, Binghamton University, Binghamton, NY, United States, msoltan1@binghamton.edu, Mohammad Khasawneh, Amy L. Friedman

The predictors of early clinical outcomes following living donor nephrectomy are determined. A comprehensive analysis, using 2008-2015 discharge data from the Healthcare Cost and Utilization Project Nationwide Inpatient Sample, was performed. Cases were identified by ICD-9 codes. Clinical outcomes were analyzed with regard to patient and provider characteristics using machine learning tools. Using the ICD-9 codes provided for each patient, we used the Clavien-Dindo Grades to classify patients based on their level of complications after surgery. Having Grade III or higher is considered as major complications and gradient boosting algorithms is used to predict the complication level.

82 - Scenario Selection for Iterative Stochastic Transmission Expansion Planning

Faezeh Akhavizadegan, Iowa State University, Ames, IA, United States, Faezeh.akhavizadegan@gmail.com, Lizhi Wang

Reliable transmission expansion planning is a critical part of a power system development due to existing numerous sources of uncertainty. We develop a new approach to selecting a small number of high-quality scenarios as representative of all scenarios. A bilevel optimization model was used to generate reasonable scenarios and regression model was used to estimate social welfare of scenarios to select high-quality scenarios. The US Eastern and Western Interconnections power system was used as the case study to select ten high-quality out of one million scenarios for two transmission plans.

83 - An Evolutionary Game Theory Approach to Comparing the Effect of Alternative Policy Instruments on Electric Vehicles

Camila Apablaza, PhD Student, Georgia Tech, Atlanta, GA, United States, capablaza@gatech.edu, Valerie Thomas

The widespread adoption of electric vehicles (EVs) is an important aspect of the efforts for curbing carbon emissions. However, is it not clear what type of policy instruments are more effective and efficient in achieving a high adoption of electric technologies among vehicles owners. This study uses an evolutionary game theory approach to compare the effect of adopting policies aimed at increasing EVs adoption through market-oriented instruments such as subsidies and research and development investments in technology improvements. We simulate random interactions in the network of private and public stakeholders that are relevant to the consumers' decision-making process.

84 - Biorefining and Machine Learning: Towards a Universal Model of Wood Deconstruction

Riley H. Ballachay, Undergraduate Research Assistant, The University of British Columbia, Vancouver, BC, Canada

Hemicellulose has diverse applications in the industry. Industrial use of hemicellulose often requires that the polymer be hydrolyzed into constituent oligomers and monomers. Models exist to predict sugar yield during hydrolysis, but none can be applied to varied feedstock and operating conditions. Machine learning is used to develop a universal model to predict xylose yield. Two models (ordinary least squares regression and artificial neural networks) are assessed and compared to a simplified kinetic model. In total, 2048 data points were mined from the literature and used to create the models. The machine learning models are shown to perform better than the kinetic model.

85 - Multiple Objective Land-use Change Optimization for Biofuel Feedstock Production

Ana C. Cram, Research Assistant, University of Texas at El Paso, El Paso, TX, United States, accram@miners.utep.edu, Heidi Taboada, Jose Espiritu

This research proposes a coupled modeling framework to optimize land use allocation for biofuel feedstock production. This framework uses the Soil and Water Assessment Tool to estimate the potential effects of Land-Use Change on soil and water quality, and the Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation model to quantifies the emissions produced from cultivating biofuel feedstock to its conversion to bioethanol. Land use allocation is optimized using a Multi-Objective Genetic Algorithm, maximizing biomass yields while minimizing environmental impacts.

86 - A Personalized Recommender System for Education

Chul Kim, Baruch College, New york, NY, United States, William Rand, Pallassana K. Kannan

We develop a machine-learning-based personalized recommender system for such a context. The proposed recommender system extracts three vital educational factors of efficiency, importance, and diversity in lieu of the ratings by utilizing the learning outcomes and hierarchical relationships among learning objects. Both supervised and unsupervised machine learning methods are applied. We implement the proposed recommender system in an online adaptive learning platform for K-12 mathematics education. Analyzing one year of data generated from a natural experiment, we find empirical evidence of the efficacy of the proposed system in improving learners' proficiency.

87 - Analysis of Higher Education Financing Trends and Options

Cindy Stuch, University of Michigan-College of Engineering, Canton, MI, United States, cstuch@umich.edu

The landscape of higher education has changed greatly in the last 35 years. Enrollment trends have gone down after peaking seven years ago and student debt has risen to an all-time high at over 1.5 trillion dollars. Higher education institutions, mainly private for-profit colleges, are increasingly going out of business. We use logistic regression to map the landscape of higher education and predict the likelihood of a school failing. We also present a system dynamics model to evaluate the impact of policies on different types of higher education institutions.

88 - Blockchain Business Model: Value Creation and Appropriation

H. Michael Chung, Professor and Director, California State University-Long Beach, Long Beach, CA, United States, hm.chung@csulb.edu

This study focuses on how blockchain and its applications create and appropriate value, impact institutional governance, and eventually provide opportunities to develop new business models. The paper analyzes disintermediation in organizational business processes and value creation from economic and organizational perspectives. The research analyzes how value would be captured and appropriated, as well as how institutional governance would further evolve in the future. We address why and how of disintermediation or its variations, and its occurrence in centralized governance. Then we develop a theoretical framework encompassing the above discussion.

89 - Agent-based Modeling of Client Preferences at Food Pantries

Benjamin F. Morrow, North Carolina A&T State University, Greensboro, NC, United States, bfmorrow1@aggies.ncat.edu

Last year, the Feeding America network distributed more than 3.6 billion meals through food pantries and meal programs. Traditional food pantries have several disadvantages including overstocking of certain foods, increased food waste, and negative psychological effects on the clients. This study will use agent-based modeling to model client preferences, food donations, and food distribution. One of the key goals of this research is to use agent-based modeling to compare the client choice food distribution model to the traditional food pantry distribution model to determine which food distribution model is more efficient.

90 - Simulating Diverse Eastern Gamagrass Ecotypes in Texas

Angela Avila, University of Texas at Arlington, Arlington, TX, United States, angela.avila2@mavs.uta.edu, Sumin Kim, Jianzhong Su, Amber Williams, Jim Kiniry

Eastern gamagrass is a valuable, productive native grass that ranged from eastern and southern U.S. It is highly palatable, high quality forage and produces high yields on marginal land due to excess moisture. This study summarizes measurements of 5 ecotypes collected from various locations in Texas and Oklahoma and growing in Temple, TX. Measurements are made for plant parameters for the ALMANAC model. The model is applied to a diversity of soils and environments, looking at productivity of the 5 ecotypes and examined for determining which ecotype is optimum for these different environments.

91 - A Discrete Event Simulation Based Approach to Maximize the Piston Throughput for a Manufacturer of Diesel Engines

Samaneh Davarzani, Mississippi State University, Starkville, MS, United States, Morteza Nagahi, Mehrnaz Noroozi Esfahani

The auto manufacturing system is a complex system which exhibits conditions of uncertainty, ambiguity, and emergence. Using a data-driven discrete event simulation approach, this paper portrays to identify and to optimize key process input variables to the production output for a manufacturer of diesel engines in Mississippi, USA. The outcome of the analysis of current system exhibits that deploying a few numbers of carts and also unbalanced process times results in bottlenecks which decreases the systems' throughput substantially. An analysis of optimal solutions, the best balance between input variables, is demonstrated, and followed by recommendation and avenues for future research.

92 - A Library of Wiedemann 99 Car-following Model Parameters

Amir Ghiasi, Leidos, Inc., McLean, VA, United States, amir.ghiasi@leidos.com, David Hale, Zhitong Huang

Recent studies suggest that ignoring the correlations between different car-following model parameters results in inaccurate representation of driving behaviors. This study calibrates the Wiedemann 99 car-following model parameters to individual drivers using a subset of Next Generation Simulation (NGSIM) trajectory dataset. The results show that some model parameters are significantly correlated. This methodology enables us to develop a library of Wiedemann 99 car-following model parameters that could address the heterogeneity nature of driving. With this library, people's driving styles are further studied and categorized into three levels: aggressive, moderate, and conservative.

93 - Future Aviation Crew Planning

Burak Cankaya, Embry Riddle Aeronautical University, Daytona Beach, FL, United States, Aaron Glassman, Bulent Erenay

This research poster will contribute to the crew resource planning for multi fleet aviation companies. The crew training plannings will be optimized to serve the current fleet needs and future crew need of the aviation companies.

94 - Electric and Autonomous Vehicles Technology in Private and Shared Mobility Systems with Multiclass Users

Harprinderjot Singh, Michigan State University, East Lansing, MI, United States, singhh24@msu.edu, Mehrnaz Ghamami

Autonomous Vehicles (AV) are known to increase vehicle miles traveled and congestion, which affects energy consumption and emission production. Electric Vehicles (EV) with zero running emissions can compensate for a part of these losses. However, the limited range of current EVs and low density of charging stations can hinder the adoption of these vehicles. A modeling framework is developed to estimate optimum fleet configuration resulting in minimum system cost, considering different tradeoffs in adoption EVs and AVs, in a private and shared mobility system with multiclass users.

95 - A Many-to-Many with Split Load Routing Problem

Sudheer Ballare, University of Illinois-Chicago, Chicago, IL, United States, Jane Lin

The rise of e-commerce and same-day delivery service may lead to negative externalities. One of the emerging urban last mile delivery paradigms is the so-called microhubs with crowdshipping (M+C). In particularly, the truck routing among microhubs is a Many-to-Many with Split Load routing problem (MMSLRP). This study presents and evaluate a solution method of MMSLRP by comparing with exact solution methods and existing heuristics. Furthermore, performance of M+C is compared with the traditional hub-and-spoke delivery service paradigm in terms of number of trucks and crowdshippers dispatched, fuel usage, vehicle miles traveled, and operating costs.

96 - Dynamic Platooning for Mixed Traffic Flow of Human-driven and Autonomous Vehicles

Jia Li, Texas Tech University, Lubbock, TX, United States, jia.li@ttu.edu, Lidong Wu

This research proposes a dynamic strategy to enhance platooning formation in mixed traffic flow of human-driven vehicles and automated vehicles. When no control is imposed, platooning between automated vehicles (AVs) relies on spontaneous peer-to-peer matching in traffic flow, which is random, myopic, and not efficient. We develop a dynamic platooning mechanism to address the problem, which is centered on customized information dissemination and incentive design for different subgroups of AVs. We provide analytical insights into the proposed strategy along with simulation experiments.

97 - Do Transportation Network Companies Reduce Public Transit Use in the U.S.

Narendra Malalgoda, Graduate Research Assistant, North Dakota State Universiy, Fargo, ND, United States, narendra.malalgoda@ndsu.edu, Siew Hoon Lim

The rise of transportation network companies (TNCs) has revolutionized urban transportation across the globe. Using top 50 U.S. agency-level data from 2007 through 2017, this study examines the effect of TNCs and transit effectiveness on public transit ridership in the U.S. We find that (1) transit effectiveness of both bus and rail transits declined over the study period (2) TNC availability significantly increased rail transit ridership in 2014 and 2015, but the positive effect subsided in 2016 and 2017 (3) transit effectiveness was highly significant for rail transit, and when examining its effect year-by-year, rail transit effectiveness trumped TNCs availability.

98 - Deep Adaptive Learning for Safe and Efficient Navigation of Pedestrian Dynamics – Airport Evacuation

Nigel Pugh, PhD Student, North Carolina A&T State Univeirsity, Greensboro, NC, United States, John Park, Srish Namilae, Dahai Liu, Pierrot Derjany

An efficient and safe evacuations of passengers is important during emergencies. A congested route would delay the evacuation performance; hence decision-making is needed to optimally distribute passengers. Previous evacuation planning studies focused on either simulation of realistic human behaviors or simple route planning, the best route decisions with several intermediate decision-points, has not been considered. We develop an optimal navigation model for evacuation path planning to minimize the total evacuation time composed of arrivals at intermediate decision points while considering the influence on other passengers based on the social-force model.

99 - An Epidemiological Modeling Approach to Fuel Shortages During Hurricane Evacuations

Sirish Namilae, Associate Professor, Embry-Riddle Aeronautical University, Daytona Beach, FL, United States, namilaes@erau.edu, Sabique Islam, Scott Parr, Dahai Liu, Richard Prazenica

High-volume mass evacuations have led to fuel shortages lasting several days during several recent hurricanes. While news reports mention fuel shortages in many past hurricanes, the crowd-sourced platform Gasbuddy has quantified the shortages in the recent hurricanes. Analysis of this data suggests the characteristics of an epidemic. We present an epidemiological model for hurricane fuel shortage and devise an optimal control strategy to mitigate the epidemic. Results show a direct correlation between evacuation traffic volume and fuel shortages. The control strategy is effective in estimating the level and duration of intervention required to mitigate the fuel shortage epidemic.

100 - Estimating Multiclass Dynamic O-D Demand Through a Forward and Backward Algorithm on Computational Graphs

Wei Ma, Carnegie Mellon University, Pittsburgh, PA, United States, weima@cmu.edu, Zhen Qian

Transportation networks are unprecedentedly complex with heterogeneous vehicular flow. Conventionally, vehicle classes are considered by vehicle classifications (such as standard passenger cars and trucks). Provided with some observations of vehicular flow, how to estimate the multi-class spatio-temporal vehicular flow, in terms of time-varying Origin-Destination (OD) demand, remains a big challenge. This paper solves this problem by proposing a computational graph with tensor representations of spatio-temporal flow and all intermediate features involved in the MCDODE formulation. The proposed framework is examined on a small network as well as a real-world large-scale network.

101 - Air Traffic Noise Pollution Management with ADS-B and GIS: State of Art Review and Initial Results in UAE

Young-Ji Byon, Khalifa University of Science and Technology, Abu Dhabi, United Arab Emirates, youngji.byon@ku.ac.ae, Tadahiro Kishida, Maryam Abdulqader Alkhalifi

Advancements in 3-D GIS computing complemented by newly available ADS-B signals from commercial airplanes can provide a platform for monitoring air traffic noise near airports, by utilizing embedded information including 3-D location, aircraft type, speed etc. Due to aggressive developments in airport expansions in UAE, associated issues with the air traffic noise are also expected to arise. This research develops an air traffic noise management framework utilizing ADS-B and GIS for airports in UAE along with a state of art review on a topic of airport noise monitoring.

102 - Machine-learning-based Vehicle Delay Prediction at Signalized Intersections

Behnoush Garshasebi, Former Graduate student at University of Illinois at Urbana Champaign, Urbana, IL, United States

Measuring performance at signalized intersections is crucial in planning for efficient traffic operations by optimizing the traffic signal timing plans. Delay is among the critical performance measures for signalized intersections. Delay calculation from field data is time-consuming and predominantly relies on tedious manual counting of vehicles and post-analysis, making quick decision-making difficult for practitioners. Thus, a more efficient way of delay calculation is needed. As a contribution to this field, we propose a Random Forest (RF) predictive model for fast and straightforward vehicle delay prediction at signalized intersections.

103 - Does Being Socially Responsible Correlate with Traffic Congestion in Metropolitan Areas in the United States?

Bukola Bakare, North Dakota State University, Fargo, ND, United States, bukola.bakare@ndsu.edu, Joseph Szmerekovsky

Traffic congestion is a critical environmental event with a direct adverse impact on people's health and productivity. This study investigates the level of socially responsible Fortune 500 corporations in major cities in the United States. Through interviews conducted by the authors, qualitative analysis is used to study one of the top metropolitan areas to capture and explore how traffic congestion trends and corporate social responsibility ratings apply on a local level. This study presents the results of the qualitative analysis.

104 - Column Generation Approach for Train Scheduling and Rolling Stock Circulation Plan Considering Skip-stop Patterns in Urban Railway Network

Bum Hwan Park, Korea National University of Transportation, Uiwang, Korea, Republic of, bumhwan.park@gmail.com

In recent years, in order to reduce the congestion and travel time of passengers, there is a great interest in the construction of a train schedule in which trains that stop at all stations and trains that stop only at major stations are mixed. This study is a study on the optimization model for constructing train schedule and circulation plan simultaneously in consideration of various stop patterns in urban railway. To this end, this study presents an optimization model based on the path flow variable defined in the time-space network, proposes a column generation based heuristic to solve it, and presents the application results for Seoul Line 9.

105 - Analysis of the Road Freight Structure Characteristics in Sichuan Province Based on the Data from O2O Freight Platform

Xinyuan Li, Southwest Jiaotong University, Chengdu, China, 505336717@qq.com, Mi Gan, Qiujun Qian, Dandan Li

Based on O2O freight platform data, this paper studies the freight structure of Sichuan Province. The research focuses on the road freight structure of Sichuan Province. First of all, to understand the current situation of Sichuan road freight, through data mining and data visualization of freight volume demand structure, cargo type structure analysis. Then the relationship between logistics industry and regional industrial structure is studied by grey correlation method, and the degree of correlation between logistics industry and regional industrial development in Sichuan Province is obtained.

106 - Identification of Empty Driving Behavior Using Truck Trajectory Data

Dandan Li, Southwest Jiaotong University, Chengdu, China, 2016210837@my.swjtu.edu.cn, Mi Gan, Wenchang Zhang

This paper aiming to using the data from the online freight exchange (OFEX) platform to identify the empty driving condition of trucks. OFEX platform collects data through the truck drivers' mobile phone APP, which contains not only positioning information, but also the online behavior of drivers. The main method in this paper is to use the trajectory data and online data of 2000 drives, combined with POI information to construct a clustering algorithm to extract the Origin-Destination (OD) of the truck, so that the trips can be obtained, and then using the driver online behavior data and other information to identify the empty driving condition of the truck in a trip.

107 - Freight Mode Mining Based on GPS Data of Trucks

Qiujun Qian, Southwest Jiaotong University, Chengdu, China, Yuling Deng, Mi Gan, Dandan Li

This paper takes the GPS data obtained by the road freight platform as the data source, establishes the model through relevant algorithms, analyzes and studies the freight modes and basic characteristics, and proposes the trajectory-based freight mode selection method. the Hausdorff distance is used to measure the trajectory similarity from both time and space. The DBSCAN algorithm is used for trajectory clustering, and found that the current vehicle trajectory can be divided into three modes: reciprocating, ring and hub-and-spoke.

108 - Optimal Deployment of Autonomous Buses in Bus Service Operation

David Z.W. Wang, Associate Professor, Nanyang Technological University, Singapore, Singapore

This paper proposes a multi-stage model for optimizing the deployment strategy in which the conventional buses are sequentially replaced by the autonomous vehicle buses (AvB). Specifically, we study which lines should be deployed with AvB at each planning stage. In this work, passengers' adoption attitudes towards autonomous buses are explicitly considered and the transit assignment problem is formulated as a multi-class UE model. To forecast the evolution of the adoption rate, we apply a diffusion model. We propose a multi-stage model for the optimal replacement strategy that minimizes the total travel cost during the planning periods. A hybrid solution method is used to solve the model.

109 - Shuttle Bus Solution to Keep the City Moving

EunSu Lee, Associate Professor, New Jersey City University, Jersey City, NJ, United States, elee3@njcu.edu, Eve Anderson, Bui A. Thy

The Hudson-Bergen Light Rail (HBLR) shuts down the West Side Avenue branch temporarily for planned sewage pipeline work. New Jersey Transit discussed how it would provide alternate means of transportation using shuttle buses, but this shutdown will have a major impact on the community. This study evaluates scenarios of cost effective and commuter efficient resource assignment and scheduling of the shuttle buses with local light rail systems. For discussing scenarios, the study developed integer linear programming (ILP).

110 - Scattered Storage for E-commerce Warehouses

Harol Mauricio Gamez Alban, University of Antwerpen, Antwerp, Belgium, mauricio.gamezalban@uantwerpen.be

Please check the mobile app for this abstract.

111 - Option of Urban Function Patterns of Railway Integrated Passenger Transport Hub Based 0n TOPSIS

Siyu Tao, School of Transportation and Logistics, Southwest Jiaotong University, Chengdu, China, 15221309@qq.com
Siyu Tao, National United Engineering Laboratory of Integrated and Intelligent Transportation, Chengdu, China, 15221309@qq.com, Tao Feng, Xinmei Chen, Anjun Li, Qiyuan Peng, Xin Xie

The commercial development pattern of the railway integrated passenger transport hub is faced with the problems of how to opt the type of real estate & determine the size of the business volume. According to the option of combination pattern of the urban functions, the entropy weight method-extended TOPSIS evaluation model is proposed. The advantage of this model is that an evaluation index system can be established according to the economic development, population scale & traffic status of the city. The integrated urban function is adapted to local conditions with strong feasibility & avoiding severe congestion.

112 - Research on the Use Arrangement of Waiting Room in Railway Station

Siyu Tao, School of Transportation and Logistics, Southwest Jiaotong University, Chengdu, 610031, China, siyu.tao@okstate.edu, National United Engineering Laboratory of Integrated and Intelligent Transportation, Chengdu, China, siyu.tao@okstate.edu
Siyu Tao, National Engineering Laboratory of Integrated Transportation Big Data Application Technology, Chengdu, China, siyu.tao@okstate.edu, Xin Xie, Tao Feng, Yuhong Liu

The waiting room of the railway station is the last place for passengers to stay for the longest time, check tickets before boarding, and where aggregation density is the highest. When special circumstances arise, the use arrangement of the waiting room is disrupted, which is more likely to lead to chaos. From the view of the use arrangement of waiting room, the use arrangement of waiting room is mainly arranged by the staff according to their previous work experience, which has great room for improvement. An optimization model for the use arrangement of waiting rooms was established to makes the use of waiting rooms more balanced and the passenger walking distance the shortest.

113 - Analysis & Empirical Researchon the Status of China's High-speed Railway Network

Xuan Wang, Southwest Jiaotong University, Chengdu, China, 409897691@qq.com

The structure of the network is closely related to its function. Understanding network characteristics can help us better understand network behavior, thereby improving network performance and providing a theoretical basis for managing the network more effectively. Empirical research shows that high-speed railway network, as a concrete form of network, has the characteristics of scaleless network. By studying the structure of China's high-speed railway network, we can explain the operation mode ofthe system based on the network, and provide theoretical basis for the construction of the new high-speed railway stations by analyzing the factors affecting the connection of stations.

114 - The Effects of Review Comprehensiveness on Review Helpfulness

Yi Liu, Associate Professor, Rennes School of Business, Rennes, France, yi.liu@rennes-sb.com, Lakshmi Narasimha Raju Vuddaraju

Consumer's evaluation of online review helpfulness has been found to be affected by the length of the review content. However, review length could not fully represent its comprehensiveness. This study aims to investigate the review comprehensiveness by mining the aspects each review covers, and examine how review comprehensiveness influences its helpfulness. By analyzing online restaurant reviews from one of the most popular restaurant review platforms, it finds that review comprehensiveness positively relates to review helpfulness. In addition, review valence negatively moderates the effect of review comprehensiveness on its helpfulness.

115 - A Lossless Compression Method Based on Dictionary Coding for Traffic Trajectory Data

Jiannan Mao, Southwest Jiaotong University, Chengdu, China, Lan Liu, Weike Lu, Yihan Wang, Yuting Chen

To reduce the size of trajectory data for convenient transmission, a lossless compression method, named Lossless Traffic Trajectory Data Compression (LTTC) is proposed based on the dictionary coding method. The dataset is pre-processed by the clustering and code mapping strategy. Then a Substituted Run-length LZ (SRL) algorithm for lossless compression is established to further deal with the pre-processed data. Subsequently, a 0-1 programming model is employed to optimize the dictionary resources in SRL algorithm. The proposed method is validated on the GPS trajectory data provided by Microsoft Geolife project and shows a high compression ability and strong real-time operability.

116 - Research on the Impact of Industrial Development and Logistics Demand in County Cities under the Perspective of Spatial Relevance: A Case Study of Leshan City

Xiaozhen Deng, National United Engineering Laboratory of Integrated and Intelligent Transportation, Chengdu, China, dengxiaozhenswjtu@163.com, Southwest Jiaotong University, Chengdu, China, dengxiaozhenswjtu@163.com, Si Chen, Yinying Tang

Under the background of the new urbanization, industrial and the satisfaction of logistics demand of County cities are affected by related industries of themselves and adjacent cities. This paper studies the relationship between the three major industries and logistics production in County cities from the perspective of spatial correlation, the results show that the secondary industry has gradually become core industry of Leshan county cities, the positive correlation between logistics and secondary and tertiary industries is higher than that of primary industry.

117 - A Multi-stage Stochastic Programming Model for Relief Distribution Considering the State of Road Network

Zhijie Dong, Texas State University, San Marcos, TX, United States, sasha.dong@txstate.edu, Shaolong Hu

Prepositioning of relief supplies is an important aspect of disaster operations management that aims at decreasing the response time by advancing procurement and storage of needed supplies. In this paper we consider commodity life-time period with the related costs in keeping the commodity and removing it from the storage when it is close to expiration. We develop a multi-stage stochastic programming model for prepositioning of relief supplies, which provides relief agencies insight on how to have dynamically control inventories due to uncertain demands when disasters occur.

118 - A Two-stage Stochastic Integer Programming Approach for Truckload Trucking Problem

Xiandong Li, ZhiCang Technology, Beijing, China, lixd@heptax.com, Junchao Ma, Zhiyu Zhang, Zhiqiang Jiang, Wanfeng Yan

Truckload trucking problem, aims to solve a simple truck-to-load matching operation, there exist a vast literature for both myopic and non-myopic model. These models are often used as decision-making or analytic simulation tool. In this work, we develop a two-stage stochastic integer programming model to fulfill the needs of daily/weekly simulation in our company. A discrete time multicommodity network flow formulation is adapted as our second stage problem to have a precise reposition time step. We solve this problem by integer L-shaped method and adopt sample average approximation approach as our Monte Carlo method.

Data Mining and Machine Learning in Healthcare

Sponsored: Data Mining

Sponsored Session

Chair: Emisa Nategh

1 - Learning When-to-treat Policies

Stefan Wager, Stanford University, Stanford, CA, United States

Many applied decision-making problems have a dynamic component: The policymaker needs not only to choose whom to treat, but also when to start which treatment. For example, a medical doctor may see a patient many times and, at each visit, need to choose between prescribing either an invasive or a non-invasive procedure and postponing the decision to the next visit. We propose a new, robust approach to this problem that is practical for policy optimization and does not need any structural (e.g., Markovian) assumptions.

2 - Detecting Early Stage Cancer using Liquid Biopsy

Jackie Baek, MIT, Cambridge, MA, United States, baek@mit.edu, Deeksha Sinha, Andrew A. Li, Vivek Farias

The cost of DNA sequencing has fallen 10,000x in the last ten years, and we are finally in sight of the silver bullet for cancer screening: an early-stage blood test. As sequencing can now be performed affordably on a tiny fraction of a genome, what remains is a massive variable selection problem. We provide an efficient algorithm, based on a decomposition at the gene level, that scales to full genomic sequences across thousands of patients. We contrast our selected variables against DNA panels from two recent, high-profile studies and demonstrate that our own panels achieve significantly higher sensitivities at the same cost, along with accurate discrimination between cancer types for the first time.

3 - A Value of Information Approach to Designing Sequential Clinical Trials for Personalized Health Care

Andres Alban, INSEAD, Fontainebleau, France, Stephen E. Chick, Spyros Zoumpoulis

We formulate a model of a clinical trial in which the patient population can be categorized in a small set of subpopulations. The goal of the trial is to determine which subpopulations can benefit from which treatment. We apply expected value of information policies for the setting in which patients with different observable characteristics arrive stochastically, and we must decide the treatment to provide to each patient.

4 - Quantile Regression for Healthcare Analytics: A New Computational Trick

Donald Lee, Goizueta Business School, Emory University, Atlanta, GA, 30322, United States, donald.lee@emory.edu, Peter Aronow

In forecasting healthcare costs, the quantity of interest is typically not the conditional mean given covariates. Rather, conditional quantiles obtained through quantile regression provide richer distributional information. However, applying machine learning algorithms like XGBoost to the quantile regression loss function is a computational challenge because the loss is inherently jagged. In this talk, we discuss an interesting discovery on how the quantile loss function can be replaced by the singular limit of a sequence of smooth loss functions. These smooth functions can then be used in lieu of the quantile loss in ML algorithms that require second order derivatives, such as XGBoost.

5 - Leveraging Multivariate Time Series of Claims Data Using Deep Learning Methods for Healthcare Cost Prediction

Mohammad Amin Morid, Santa Clara University, Santa Clara, CA, United States, Olivia R. Liu Sheng, Kensaku Kawamoto, Samir Abdelrahman

This study attempted to leverage individuals' temporal data of healthcare claims for predicting their cost by learning their temporal patterns. To achieve this, we proposed using a convolutional neural network (CNN) to learn different temporal patterns from multivariate time-series data of patients. Three years of medical and pharmacy claims data were used. The data consisted of the multivariate time series of cost, visits and medical features that were shaped as images of patients' health status. Patients' images were given to a CNN method with a proposed architecture. The results showed that feature learning through the proposed CNN significantly improved healthcare cost prediction.

Online Learning: Theory and Practical Applications

Sponsored: Data Mining

Sponsored Session

Chair: Chaosheng Dong

1 - Generalized Inverse Optimization through Online Learning

Chaosheng Dong, University of Pittsburgh, Pittsburgh, PA, 15260, United States, Bo Zeng

Inverse optimization is a powerful paradigm for learning preferences and restrictions that explain the behavior of a decision maker, based on a set of external signal and the corresponding decision pairs. However, most inverse optimization algorithms are designed specifically in batch setting, where all the data is available in advance. As a consequence, there has been rare use of these methods in an online setting suitable for real-time applications. In this paper, we propose a general framework for inverse optimization through online learning. Specifically, we develop an online learning algorithm that uses an implicit update rule which can handle noisy data.

2 - Large Scale Markov Decision Processes with Changing Rewards

Adrian Rivera Cardoso, Georgia Institute of Technology, Atlanta, GA, United States, adrian.riv@gatech.edu

We consider Markov Decision Processes where the transition dynamics are known and fixed but the rewards may change in an adversarial manner. First, we provide an algorithm that achieves (almost) optimal MDP regret. Its per time-step computational complexity depends polynomially on the number of states and actions. We then extend our results to the large state-space setting. By parametrizing the set of stationary occupancy measures with a small number of features, we design an algorithm with per time-step computational complexity that depends polynomially on the number of features and provide similar regret guarantees.

3 - Sample-optimal Parametric Q-learning with Linear Transition Models

Lin Yang, Postdoctoral Research Associate, Princeton University, 321 Schoolhouse Rd, Princeton, NJ, 08831, United States, Mengdi Wang

Consider a Markov decision process (MDP) that admits a set of state-action features, which can linearly express the process's probabilistic transition model. We propose a parametric Q-learning algorithm that finds an approximate-optimal policy using a sample size proportional to the feature dimension K and invariant with respect to the size of the state space. We further exploit the monotonicity property and intrinsic noise structure of the Bellman operator, provided the existence of anchor state-actions that imply implicit non-negativity in the feature space. We augment the algorithm using techniques of variance reduction to obtain an optimal sample complexity.

4 - Balancing Relevance and Diversity in Online Bipartite Matching via Submodularity

Pan Xu, University of Maryland, A.V.W. Building, Department of Computer Science, University of Maryland, College Park, MD, 20742, United States, panxu0@gmail.com, John P. Dickerson, Karthik Sankararaman, Aravind Srinivasan

Online matching models capture lots of real-world problems including matching workers to firms, and advertisers to keywords. Current literature just focuses on maximizing the total relevance of the matching via a linear function but ignore the diversity (e.g., displaying a relevant but diverse set of ads). In this paper, we propose an Online Submodular Bipartite Matching problem, where the goal is to maximize a general monotone submodular function over the set of matched edges. This objective is general enough to capture both diversity and relevance. We propose novel algorithms that have provable guarantees and are essentially optimal when restricted to various special cases.

5 - An Optimally-Competitive Algorithm for Maximum Online Perfect Bipartite Matching with i.i.d. Arrivals

Mark Velednitsky, University of California, Berkeley, CA, United States, marvel@berkeley.edu, Dorit Simona Hochbaum, Quico Spaen

We present an optimally-competitive algorithm for maximum online perfect bipartite matching with i.i.d. arrivals. We are given a known set of workers, a distribution over job types, and non-negative utility weights for each pair of worker and job types. At each time step, a job is drawn i.i.d. from the distribution over job types. The job must be irrevocably assigned to a worker and cannot be dropped. The goal is to maximize the expected sum of utilities after all jobs are assigned. We introduce a 0.5-competitive, randomized algorithm and prove that 0.5-competitive is the best possible.

Novel Applications of Structural Approaches to Data Analytics

Sponsored: Data Mining

Sponsored Session

Chair: Bernardo F. Quiroga, Pontificia Universidad Catolica de Chile, Macul, Santiago RM, Chile

1 - Pennies from Heaven: The Impact of Free Bids on All-pay Auction Performance

Christopher Dalton Parker, Pennsylvania State University, University Park, PA, 16802, United States

The sunk cost fallacy is one possible reason why people to continue doing something after strict utility maximization suggests they should stop. The mechanisms of the sunk cost fallacy could be financial (spending more money on a project), temporal (a longer time between the start of the project and now), or emotional (exerting more effort on a project). In the context of an online auction-based retailer, we 1) disentangle the three components of the sunk cost fallacy, and 2) determine how the sunk cost fallacy impacts the auctioneer's profits. We do this with data from the company and complement the analysis with lab experiments.

2 - Structural Estimation of Auto Recalls

Ahmet Colak, Clemson University, Pendleton, SC, 29670, United States, Robert Louis Bray

Using a sample of 1M consumer defect reports and 15K component-level auto recalls, we study how the US government and automakers improve fleet quality via recalls. We use complaint text mining and structural econometrics to predict the likelihood of recall events. We also estimate the underlying government deterrence effects.

3 - Estimating Checkout Lines from Transaction Data

Marcelo Olivares, Associate Professor, Universidad de Chile, Santiago, Chile, molivares@uchile.cl

This research uses the Queuing Inference Engine (QIE, Larson 1990, Bertsimas & Servi 1992) to estimate checkout lines in supermarkets. The QIE requires as an input time stamps of each transaction, which are used to construct busy periods of the server when transactions are consecutive. In practice, transactions are never perfectly consecutive and they need to be approximate. This research uses a machine learning algorithm to detect busy periods, which is calibrated with a large scale manual data coding of queue lengths. The application is validate with a large scale empirical study and is currently been implemented in more than 200 stores by a large supermarket chain.

4 - Empowering Education with Crowdfunding: Empirical Evidence From California Public Schools

Manpreet Gill, Assistant Professor of Marketing, University of South Carolina, Columbia, SC, United States, Chen Zhou, Qiang Liu

In the past decade, crowdfunding has emerged in education as a social enterprise to empower public education. In this research, the authors investigate the role of crowdfunding in public K-12 education as an emerging alternative source for resource investment. In particular, they assess the impact of teacher-acquired instructional resources via crowdfunding on student academic achievement. Collating novel data from an education crowdfunding platform dedicated to public schools in the U.S and the California Department of Education at the school-subject-grade-academic year level, they find that teacher-acquired instructional resources via crowdfunding can effectively improve student academic achievement on average, while having a differential impact on students at different proficiency levels. Furthermore, the findings identify boundary conditions for this effect, in terms of the type of resources acquired by teachers (i.e., books and technology) and the subject for which the resources are used (i.e., English). This research provides rich implications for education administrators, crowdfunding platform managers, donors/investors in public education, and public school teachers.

5 - An Evaluation of Nonstandard Solutions to Weak Instruments under Endogeneity

Bernardo F. Quiroga, Faculty of Economics and Management Sciences, Pontificia Universidad Catolica de Chile, School of Management, Macul, Santiago RM, Chile, bfquirog@gmail.com

The performance of standard IV (instrumental variables) regression methods relies on the strength of the instruments. We evaluate several different nonstandard empirical strategies that work under the exclusive presence of weak IVs, achieving identification by using additional structural information to the problem. We provide a guide to their implementation for empirical scholars, discuss their pros and cons, and evaluate their relative performance.

Chair: Zhuqi Miao

1 - SNP Variable Selection by Generalized Graph Domination

Zhuqi Miao, Oklahoma State University, 345 Business Building, Oklahoma State University, Stillwater, OK, 74078, United States, zhuqi.miao@okstate.edu, Shuzhen Sun, Charles Chen

High-throughput sequencing technology has revolutionized both medical and biological research by generating exceedingly large numbers of genetic variants. However, the resulting datasets might lead to poor generalization capacity. Concerns include noise accumulated due to the large number of predictors, sparse information regarding the p>>n problem, and overfitting and model mis-identification resulting from spurious collinearity. In this study, we present a k-dominating set model that can provide a flexible and effective method for selecting informative SNPs

2 - A Framework to Address Missing Values Challenge in Secondary Datasets the Case of Parkinson'S Diseases

Saeed Piri, Assistant Professor, University of Oregon, Lundquist College of Business, 434 Lillis Business Complex, Eugene, OR, 97403, United States, spiri@uoregon.edu

Missing values are very prevalent in secondary datasets (e.g. Electronic Health Records (EHR)) and dealing with them is very challenging in data mining. In this study, we propose a new framework to address missing values challenge in analyzing datasets such as EHR, where many variables with high degrees of missingness are available. We apply our proposed framework to an imbalanced EHR dataset and use it to develop diagnostic models for Parkinson's disease. To enhance our models' accuracy, we applied synthetic informative minority oversampling (SIMO) algorithm to over-sample the minority class and used machine learning techniques such as random forest and logistic regression to develop our models.

3 - Seeds of Discovery, Gene Bank Genomics Meeting World's Challenges

Charles Chen, Oklahoma State University, Stillwater, OK, United States, charles.chen@okstate.edu

Achieving food security for all humanity appears to be an important but daunting challenge in the face of population growth, environmental degradation and accelerating climate variability. Gene banks operated by the Global Crop Diversity Trust hold high priority global collection of crops. The huge complexity of holdings and strategically use of the germplasm means that most of the would-be building blocks for new varieties remain on shelves when agricultural challenges are unprecedented. Encouraged by the advancement in DNA sequencing and predictive modeling, this presentation will review and discuss the footsteps it has taken in gene bank genomics, making it truly global in scope and impact.

4 - Augmenting Machine Learning with Statistical Testing: A Novel Method for Early Sepsis Prediction

Zeyu Liu, University of Tennessee, Knoxville, TN, United States, zliu65@vols.utk.edu, Anahita Khojandi, Xueping Li, Rishikesan Kamaleswaran

Sepsis is a life-threatening condition, with approximately 265,000 death per year in the U.S. Early prediction of sepsis is paramount to reducing mortality rate. In this work, we develop a sepsis prediction method using only a minimal set of physiological signals collected at the bedside. We first develop a machine learning model to predict the likelihood of sepsis. Next, we post-process these outcomes using statistical testing to improve prediction performance. We compare the results with benchmarks and draw insights.

5 - Detecting Clostridium Difficile Infection Clusters

Jeffrey Luo, Wolters Kluwer, Waltham, MA, United States

Clostridium difficile infection (CDI) is a well-known hospital acquired infection (HAI). It infects 500,000 patients per year resulting in 29,000 deaths and $4.8 billion in costs. CDI is extremely contagious and can be spread by touch or contact with contaminated objects or surfaces. It is therefore necessary to detect individual infections early and enact protocols to prevent the spread of CDI and what are known as infection clusters. In this presentation we expand on prior work to demonstrate how CDI cases frequently occur in clusters. We conclude that earlier detection and enactment of containment protocols could prevent these clusters from occurring and dramatically reduce CDI rates.

1 - A Novel Data Adaptive Elastic Net Predictive Model for undersized High-Dimensional Data Sets

Shima Mohebbi, Assistant Professor, University of Oklahoma, Norman, OK, 73019, United States, mohebbi@ou.edu, Esra Pamukcu, Hamparsum Bozdogan

Many application domains (e.g. bioinformatics, image analysis, and medical data mining) are faced with a small sample and large dimensional data problems. We will focus on a novel Adaptive Elastic Net (AEN) modelling using a new covariance-regularization approach and introduce and score the Consistent and Misspecification Resistant Information Measure of Complexity criterion, and the Extended Consistent Akaike's Information Criterion with Fisher Information in AEN models for the first time. The proposed approach is applied to a real undersized benchmark dataset (Riboflavin) to predict the production rate of vitamin B2.

2 - Deep-Tier Supply Network Resilience Management

Elham Taghizadeh, Wayne State University, Detroit, MI, 48035, United States, elham.taghizadeh@wayne.edu, Ratna Babu Chinnam, Saravanan Venkatachalam

Globalization of industries has led to complex supply chains. Supply networks are vulnerable to several types of disruptions, both natural and operational. In our study, we propose methods to assess and manage the resilience of deep-tier supply networks of direct and upstream suppliers. Social network analysis techniques are combined with discrete-event simulation to improve accuracy of resilience assessment. This work is in collaboration with Ford Motor Company.

3- Automatic Extractive Summarization of Electronic Health Records

Azadeh Mobasher, Microsoft, Redmond, WA, 30067, United States, Amin Mobasher

Medical practitioners are required to process many electronic health records which mostly are published in healthcare/insurance systems to answer clinical queries and recommend prescriptions and advise patients. Due to the time-consuming nature of this practice, there is a huge need to build automated systems to find relevant medical data and extract useful information to improve physician and patient experience and reduce time to process. In this presentation, we talk about a multi-model deep learning binary classification network that is used to extract main content from medical documents, provide results and talk about how we use optimization methodologies to improve accuracy of our model.

1 - An Adaptive Streaming Data Sampling Strategy via Reinforcement Learning for Efficient Load Forecasting

Guangrui Xie, Virginia Polytechnic Institute and State University, Blacksburg, VA, 24061, United States, guanx92@vt.edu, Xi Chen, Yang Weng

This work aims at creating a "data-model-data" ecosystem for efficient and reliable load forecasting. The communication bandwidth constraints often imposed on data concentrators can lead to data deficiency for operational planning purposes in a dynamic, stochastic smart grid environment. In this work, we propose an adaptive data sampling scheme based on reinforcement learning to adjust streaming data sampling rates for improved load forecasting accuracy and efficiency. Numerical experiments show that the proposed method outperforms existing sampling schemes in terms of the overall predictive accuracy achieved.

2 - Data Farming and Data Mining: The Methods Behind the Metaphors

Susan M. Sanchez, Naval Postgraduate School, 1411 Cunningham Rd, GL 273, Monterey, CA, 93943, United States, ssanchez@nps.edu

The terms 'big data' and 'data mining' are often intertwined. but a key drawback to the data mining paradigm is that it relies on observational data and thus limits the types of insights that can be gained. With simulation and other computer models, the 'data farming' metaphor is more appropriate: it captures the notion of purposeful data generation. We will discuss some key methods behind the data farming and data mining metaphors, including some recent advances in large-scale design of experiments. We then demonstrate how data farming can yield 'better big data' by allowing analysts to establish causal relationships, and gain much broader insights from their models.

3 - A Bitcoin Blockchain Simulation Model

Ling Zhang, North Carolina State University, Raleigh, NC, United States, lzhang42@ncsu.edu, Yunan Liu, Hong Wan, Kejun Li

Blockchain has gained increasing attention both in industry and academia, and Bitcoin blockchain by many standards is the most successful application. We are interested in the interaction between miners and the Bitcoin network. We develop a simulation platform that aims to characterize key performance features and system dynamics of the Bitcoin blockchain network.

4 - Efficient Budget Allocation Strategies for Elementary Effects Method in Stochastic Simulation

Xi Chen, Virginia Polytechnic Institute and State University, Blacksburg, VA, 24601, United States, xchen6@vt.edu

We extend the Morris' elementary effects method (MM) for sensitivity analysis to the stochastic simulation setting. Given a fixed simulation budget to expend, the main objective is to provide efficient and accurate estimates of main and interaction (or nonlinear) effects coined by the standard MM for characterizing the importance of each factor, despite the impact of simulation errors. We develop efficient budget allocation strategies for implementing MM in this new context. Under each strategy, we derive the optimal budget partition and optimal budget allocation rules. Numerical results corroborate the practical effectiveness of the proposed budget allocation strategies.

1 - Interactions of Crowding, Patient Severity, and the Queuing Discipline at a Hospital Emergency Room

Lu Wang, University of Kansas, Ku Business School, Lawrence, KS, 66045, United States, lu.wang@ku.edu, Mazhar Arikan, Suman Mallik

Utilizing data from a large urban teaching hospital, we characterize how high severity patients might impact the length of stay(LOS) of low severity patients. We study how crowding, change in the queuing order, and severity affect the patient LOS.

2 - Spatiotemporal Modeling and Real-time Prediction of Origin-destination Traffic Demand

Xiaochen Xian, PhD, University of Florida, Gainesville, FL, 32611, United States, xxian@ufl.edu

Traffic demand prediction has been a crucial problem in transportation management. The prediction of traffic demand counts for origin-destination (OD) pairs has been a challenging problem due to the high variability and complicated spatiotemporal correlations. To tackle the challenges, we formulate and propose a multivariate Poisson log-normal model with specific parametrization tailored to the traffic problem, which captures the spatiotemporal correlations of the traffic demand across different routes and epochs, and automatically clusters the routes based on correlations. Simulations as well as a real application are performed to demonstrate its applicability and effectiveness.

3 - Diversity Preference-aware Link Recommendation in Online Social Network

Kexin Yin, University of Delaware, Newark, DE, 19711, United States, Xiao Fang

Friends recommended by existing link recommendation methods are generally homogeneous in terms of their backgrounds. In this presentation, based on the assumption that people may have different diversity preference on different dimensions of user background, a multi-dimensional diversity preference metric as well as a new link recommendation problem, namely diversity preference-aware link recommendation is formulated as a sum-of-ratio optimization problem and proofed to be NP-Hard. In order to solve the problem, an efficient heuristic solution method is further provided.

4 - Detecting ADHD Kids by Computer Performance Tests: Reverse Causality Machine Learner

Inbal Yahav, PhD, Tel Aviv University, Tel Aviv, Israel

We developed a Machine Learning detection model based on Continuous Performance Tests for ADHD in children. ADHD is one of the most common disorders worldwide. Alongside its commonality, there is no standard measure to detect ADHD, which leads to great over- and under- diagnosis. CPT was proposed as an objective measure of ADHD. Statistically, CPT-based detection is a reverse-causality problem that contradicts prevalent statistical theories. This mandates a careful hybrid theory- and data-driven detection model. Our ML detection model borrows from experiment design and minority detection, providing detection accuracy of 89%, placing CPT as a highly relevant ADHD detection tool in practice.

5 - The Development of a 28-Day Readmission Outcome-Trained Ensemble Learning Algorithm for Acute and Post-Acute Utilization Pattern Recognition

Jingjing Guan, City University of Hong Kong, jguan4@cityu.edu.hk, Eman Leung, Frank Y. Chen, Kwok-Kuen Mak

Here, we report the development of a novel data-based ensemble learning algorithm for recognizing patterns of patients' acute & post-acute service utilization with respect to their 28-day readmission outcomes. As ensemble learning permits the hybridization of classifiers of different levels to minimize the disadvantage of any single classifier, we included two high-level classifier systems to address the high noise-to-signal ratios associated with hospital length of stay & readmissions. Our algorithm yielded c-statistics of 81.7% & 75.5% for residential-care and community-dwelling samples respectively. The pattern of historical practices revealed service gaps & opportunities.

6 - Artificial Intelligence in Healthcare: Boon or Bane?

Shilpa Balan, California State University-Los Angeles, Los Angeles, CA, 90032, United States, sbalan@calstatela.edu

Artificial Intelligence (AI) is transforming everything connected to human life including healthcare. However, there is still a continuous debate of whether Artificial Intelligence is a boon or bane. While every technology has its advantages and disadvantages, the advantages most often prevail. While on the one hand, we seem to embrace technology changes such as smart home and smart healthcare, on the other hand, we are resistant of AI as it appears to attempt performing the human tasks. This presentation will examine the major areas in healthcare that could be significantly impacted by AI. For example, data mining and AI applications can be used to identify chronic diseases and high-risk patients.

Emerging Topic: Artificial Intelligence & Machine Learning

Emerging Topic Session

Chair: Nathan Kallus, Cornell University, New York, NY, 10044, United States

Co-Chair: Hongseok Namkoong, Stanford University, Stanford, CA, 94305, United States

1 - Bounds on the Conditional and Average Treatment Effect in the Presence of Unobserved Confounders

Hongseok Namkoong, Stanford University, Stanford, CA, 94305, United States, Steve Yadlowsky, Sanjay Basu, John Duchi, Lu Tian

We study estimation of causal effects when the dependence of treatment assignments on unobserved confounding factors is bounded. We quantify bounds on the conditional average treatment effect under a bounded unobserved confounding model. We propose a semi-parametric framework to bound the average treatment effect (ATE) and derive corresponding confidence intervals for the bounds. This method extends the doubly robust estimator for the ATE, which assumes all confounding variables are observed. Our sensitivity analysis applies in higher dimensions than traditional sensitivity analyses allow. Optimality results show that our proposed bounds are tight in certain cases.

2 - Double Reinforcement Learning in Markov Decision Processes: Harnessing Memorylessness for Efficient and Robust Evaluation

Nathan Kallus, Cornell University, New York, NY, 10044, United States, kallus@cornell.edu, Masatoshi Uehara

Off-policy evaluation (OPE) in reinforcement learning allows one to evaluate decision policies without needing to conduct exploration, which is often costly or otherwise infeasible. We consider for the first time the semiparametric efficienc, y limits of OPE in Markov decision processes, where actions, rewards, and states are memoryless. We show existing estimators fail to be efficient in this setting. We develop a new estimator termed double reinforcement learning (DRL), which we show is both efficient and doubly robust. By harnessing memorylessness, DRL handily outperforms existing methods.

3 - Machine-learning Tests for Effects on Multiple Outcomes

Jann Spiess, Microsoft Research New England, Cambridge, MA, United States, jspiess@stanford.edu, Jens Ludwig, Sendhil Mullainathan

We present tools for applied researchers that re-purpose off-the-shelf methods from machine learning to create a “discovery engine” for data from randomized controlled trials (RCTs). The applied problem we seek to solve is that we invest vast resources into carrying out RCTs, but usually wind up exploring just a small subset of the hypotheses that the available data could be used to test. Our proposed solution combines the basic intuition of reverse regression, where the dependent variable of interest becomes treatment assignment itself, with methods from machine learning that use the data to flexibly identify whether there is any function of the outcomes that predicts treatment group status.

4 - Achieving Constant Regret in Restless Bandits and Weakly Coupled MDP

Xiangyu Zhang, Cornell University, Ithaca, NY, United States, xz556@cornell.edu, Peter Frazier

We study Weakly Coupled Markov Decision Processes (WCMDP), which generalize restless bandits with applications in revenue management, optimal learning and online ads. In a WCMDP we pull multiple arms per period. Each arm provides a reward, consumes resources, and is endowed with a stochastic state that changes even when not pulled. We study how regret scales with the number of arms K, holding fixed the fraction pulled per period. We develop a new policy, the Diffusion Index, whose regret is O(sqrt(K)) in general and o(1) under a non-degeneracy condition. This scaling with K is the best known.

CC- Room 212

Sequential Decision Making under Uncertainty

Sponsored: Artificial Intelligence

Sponsored Session

Chair: Junming Yin, University of Arizona, Tucson, AZ, 85721, United States

1 - Reviews, Biases and Six-sigma

Ningyuan Chen, University of Toronto, Clear Water Bay, Toronto, ON, Canada, Anran Li, Kalyan Talluri

Many empirical papers have documented a bias in the user ratings: an inherent self-selection in writing reviews. We give a precise characterization of the effect of the acquisition bias when consumers confound ex-ante innate preferences for a product or service with ex-post experience and service quality and do not separate the two. We develop a parsimonious choice model for consumer purchase decisions and show that it leads to an upward bias. Based on our theoretical characterization, we give two important practical applications for a service firm: (a) estimation of true process quality and its variability for the firm’s internal performance (b) effect on pricing and assortment decisions of the firm.

2 - Multinomial Logit Contextual Bandits

Min-hwan Oh, Columbia University, New York, NY, 10027, United States, m.oh@columbia.edu, Garud N. Iyengar

We consider a sequential assortment selection problem, in which a decision-maker decides which assortment to offer to users in order to maximize the cumulative reward. The feedback is an item chosen by a user which is given by the MNL choice model. The user’s preference for an item is a dynamic function of item features and user information, but the parameters of this function are unknown a priori. We refer to this problem as multinomial logit contextual bandit. We propose algorithms which simultaneously optimize assortment selections balancing between exploration and exploitation and learn user’s preference.

3 - Online Matching with Bayesian Rewards

Rui Sun, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, David Simchi-Levi, Xinshang Wang

We study in this paper an online ad allocation problem where a central platform needs to match ads of limited budgets to groups of customers that arrive in different time periods. The probability for a customer to click on an ad varies with the time period and the type of the ad. Moreover, the click probabilities are unknown, but drawn from known prior distributions. The goal of the platform is to maximize the total number of clicks without violating the budget constraints. We formulate the problem as a multi-armed bandit problem where each arm corresponds to a pair of ad and time period. We provide an algorithm based on assembling separate single-arm policies, and prove the algorithm’s performance guarantee.

Queueing Theory and Applications

Sponsored: Applied Probability

Sponsored Session

Chair: Johan van Leeuwaarden, Eindhoven University of Technology, Eindhoven, 5613 AD, Netherlands

1 - A Fluid Limit for an Overloaded Multiclass Many Server Queue with General Reneging Distribution

Amber L. Puha, California State University-San Marcos, Department of Mathematics, San Marcos, CA, 92096-0001, United States, Amy R. Ward

We study scheduling in a many server queue with general reneging distribution (G/G/N+G) and multiple customer classes. Motivated by the goal to formulate and analyze a fluid control problem, we specify a class of admissible control policies (rules for determining when to serve a given customer class), formulate a fluid model, and characterize the invariant states. Static priority policies do not capture the entire spectrum of invariant states, and so we introduce a set of control policies, called Random Buffer Selection (RBS) that do. We prove that a suitably rescaled state descriptor for the queue operating under specified RBS policy converges to the unique fluid model solution for that RBS policy.

2 - Discrete-time TASEP with Holdback

Alexander Stolyar, University of Illinois at Urbana-Champaign, Urbana, IL, 61801, United States, Vsevolod Shneer

We study a discrete-time interacting particle process, which can be called a totally asymmetric simple exclusion process with holdback (TASEP-H). The “holdback” refers to the property that the probability of a particle jumping forward to a vacant site depends on the presence of a particle immediately “behind” it. This is a basic model of a communication network with packets moving along a sequence of nodes, under a “standard” random access algorithm. We obtain results on “typical” invariant distributions of the process.

3 - Asymptotically Optimal Load Balancing Topologies

Debankur Mukherjee, Georgia Institute of Technology, Atlanta, GA, 02109, United States, debankur.mukherjee@isye.gatech.edu, Sem C. Borst, Amarjit Budhiraja, Johan S.H. van Leeuwaarden, Ruoyu Wu

We consider a system of N servers inter-connected by some graph topology GN. Tasks with unit-mean exponential service times arrive at various servers as independent Poisson processes of rate . Each incoming task is assigned to whichever server has the smallest queue length among the one where it appears and its neighbors in GN. This model has been extensively investigated via mean-field techniques in the case GN is a clique. For arbitrary graph, mean-field techniques breakdown, complicating the analysis. In this talk we investigate how much sparsity in the graph can be allowed maintaining the asymptotic behavior of a clique on a fluid and a diffusion scale.

4 - Information and Memory in Dynamic Resource Allocation

Kuang Xu, Stanford Graduate School of Business, Stanford, CA, 94305, United States, Yuan Zhong

We propose a general framework, dubbed Stochastic Processing under Imperfect Information (SPII), to study the impact of information constraints and memories on dynamic resource allocation. We quantify the degree to which information constraints reduce the size of the capacity region in general SPNs, and how such reduction depends on the amount of memories available to the encoding and allocation policies. Using a novel metric, capacity factor, our main theorem characterizes the reduction in capacity region for all non-degenerate channels, and across almost all combinations of memory sizes.

Chair: Daniel F Silva, Auburn University, Auburn, AL, 36849, United States

1 - Optimal Routing in Loss Systems with Flexible Customers

Avnish Malde, Clemson University, Clemson, SC, 29634, United States, amalde@g.clemson.edu, Tugce Isik

We study a loss system with two classes of servers and a number of customer types. We assume that there is at least one class of flexible customers that can receive service from servers of either type. We formulate the problem as a Markov Decision Process with rewards that are dependent on the customer type. For small systems, we use our formulation to characterize the optimal policies. For larger systems, we prove that the optimal policies are structured, and of threshold type. Furthermore, for a large-scale system, the optimal threshold structure is explored numerically using stochastic dynamic programming. We also provide an application of our model in the context of electric vehicle charging.

2 - Optimal Control of Queueing Systems with Defects

Junqi Hu, Georgia Institute of Technology, Atlanta, GA, United States, jhu311@gatech.edu, Sigrun Andradottir, Hayriye Ayhan

We consider a Markovian system of tandem stations with finite buffers between the stations. Defects may be introduced during processing, resulting in the loss of the defective product. Servers are flexible but non-collaborative, and differ in terms of both their processing rates and defect probabilities at the stations. We identify the dynamic server assignment policy that maximizes the long-run average throughput of the system with two stations and two servers. For larger systems, we propose heuristic policies and provide numerical results showing our heuristic policies are near-optimal.

3 - Dynamic Routing and Vacation Control in a Two-class Parallel Queueing System

Mark E. Lewis, Cornell University, School of Ops Research & Information Engin., Ithaca, NY, 14853, United States, Pamela Badian-Pessot, Douglas Down

We consider the dynamic control of parallel queues. A decision-maker decides where to route arriving customers and when server vacations occur. Servers on vacation require a warm-up period before they are available. The structure of an optimal control is discerned with applications to server farms.

4 - Resource Allocation of Inspection Effort in Genetic Manufacturing Systems

Gregory T. Purdy, Assistant Professor, Auburn University, Auburn, AL, 36849, United States, greg.purdy@auburn.edu, Daniel F. Silva, Mohammad Maydanchi

Breakthroughs in molecular and synthetic biology through de novo gene synthesis are stimulating new pharmaceutical applications and advancing knowledge about the function of cells. This evolution in biological processing motivates the study of genetic manufacturing systems (GMS), which produce a final product with a genetic construct. Inspection and monitoring strategies are possible, but it is unclear if these techniques are cost efficient and value added. This talk investigates resource allocation strategies for GMS. A mathematical model is formulated to study the use of various inspection strategies in de novo gene synthesis, by adapting the multi-stage inspection allocation problem.

5 - Dynamic Same-day Order Delivery Planning Using Trucks and Drones

Daniel F. Silva, Auburn University, Auburn, AL, 36849, United States, silva@auburn.edu

We consider a parcel delivery operation that receives and dispatches orders throughout the day. The system has a single truck and must decide when to dispatch the truck, what orders to deliver, and the route. Additionally, there is a heavy-duty drone that can resupply the truck at pre-determined rendezvous points in the city. The system also decides when to dispatch the drone and what orders to include. We assume that order arrive following a Poisson process and model the problem as a Markov Decision Process. We will present the problem formulation, show sample results from small problem instances (with some additional assumptions), and discuss strategies for solving larger instances.

1 - Bridging Bayesian and Minimax Mean Square Error Estimation via Wasserstein Distributionally Robust Optimization

Viet Anh Nguyen, Ecole Polytechnique Federale de Lausanne (EPFL), Lausanne, Switzerland, Soroosh Shafieezadeh-Abadeh, Daniel Kuhn, Peyman Mohajerin Esfahani

We bridge the Bayesian and the minimax mean square error estimators by leveraging tools from modern distributionally robust optimization. We show that the optimal estimator and the least favorable distribution form a Nash equilibrium for the Wasserstein ambiguity set and can be computed by solving a single tractable convex program. We further devise a Frank-Wolfe algorithm with a linear convergence rate to solve the convex program whose direction-searching subproblem can be solved in a quasi-closed form. Using these ingredients, we introduce an image denoiser and a robust Kalman filter which hedge against adversarial noise.

2 - Enhancing Optimality-feasibility Tradeoff for Data-driven Optimization under Uncertain Constraints

Huajie Qian, Columbia University, New York, NY, United States, Henry Lam

Optimization formulations to handle data-driven decision-making under uncertain constraints, such as robust optimization, often encounter a statistical trade-off between feasibility and optimality that potentially leads to over-conservative solutions. We show how we can exploit the intrinsic low dimensionality of the solution sets possibly output from these formulations to enhance this trade-off. We demonstrate the dimension-free performance of our strategy in obtaining solutions that are, in a sense, both feasible and asymptotically optimal among the considered class of formulations. We illustrate our approach for several common paradigms of data-driven optimization.

3 - Efficient Algorithms for Chance Constraint Optimization in Rare Event Regimes

Fan Zhang, Stanford University, 450 Serra Mall, Stanford, CA, 94305, United States, fzh@stanford.edu, Jose Blanchet, Bert Zwart, Fan Zhang

Chance constraint optimizations are known to be NP-hard, but it can be approximated by the scenario approach when the tolerance-violation is small. The number of sampled constraints in conventional scenario approach is inversely proportional to the tolerance-violation, which is computationally expensive when the chance constraint becomes increasingly rare. In this talk, we applied importance sampling to construct a rare event simulation estimator of which the number of sampled constraints is independent of the tolerance-violation.

4 - Efficient Estimation of Sensitivity of Tail Risk Measures with Applications in Risk Averse Stochastic Optimization

Karthyek Murthy, Singapore University of Technology and Design, Singapore, 487372, Singapore, karthyek@gmail.com, Anand Deo

Tail risk averse stochastic optimization is challenging in data-driven settings due to the lack of samples representing tail regions. We overcome this challenge by developing statistically sound approximations for the gradient of CVaR of the objective using extreme value based tail extrapolation methods. These approximations are a result of the limiting distributions we derive for suitably normalized versions of the objective and its gradient when conditioned on the objective being large. The utilization of extreme value based extrapolation of gradients to execute a first-order descent method is entirely novel in the setting considered and enjoys improved performance over plugin estimators.

1 - Matching in Online Marketplaces when Talent is Difficult to Discern

Jiding Zhang, The Wharton School, University of Pennsylvania, Philadelphia, PA, 19104, United States, Ken Moon, Karan Girotra, Elena Belavina

We study the problem of assigning workers to short-term jobs in online marketplaces, where workers aredistinguished in quality by attributes difficult to measure at scale, and can only be perceived through effortand cost. We use data on a major online freelancing platform to structurally estimate employers'preferences in hiring, including the uncertain information about workers' quality-relevant competencies,in a setting featuring large numbers of choices (freelancers) sorted into essentially unique considerationsets. We recommend how and when the platform should prioritize matching for compatible skills,matching for repeat relationships, and matching that encourages exploration.

2 - Multi-channel Delivery in Healthcare: The Impact of Telemedicine Centers in Southern India

Kraig Delana, London Business School, London, 97403, United Kingdom, Sarang Deo, Kamalini Ramdas, Ganesh Babu, Thulasiraj Ravilla

Telemedicine is increasingly used in rural communities across the developing world. However, the impactof telemedicine in these settings is not well understood. We analyze data from the Aravind Eye CareSystem in Southern India to examine the impact of opening telemedicine centers on access, treatments,and costs, at both the telemedicine center channel and the pre-existing hospital channel. We findevidence telemedicine centers improve access, particularly for patients with simple conditions, whichcontributes to an increase in the rates of glasses prescriptions. They also enable patients to substitutetelemedicine center visits for hospital visits leading to savings in patient costs.

3 - Inferring Consideration Sets from Sales Transaction Data

Mitrofanov Dmitry, NYU Stern School of Business, New York, NY, United States, Srikanth Jagabathula, Gustavo Vulcano

Overall, we study a methodology to identify consideration sets from sales transactions in a data-driven way. First, we address the problem of identifiability of consider-then-choose models from the data. Then, we suggest the framework to estimate these models and infer consideration sets. We apply the proposed methodology to the data obtained from a car-sharing platform and analyze the real-world settings where accounting for consideration sets can boost the predictive performance of the choice models. Our findings show that consider-then-choose models tend to be robust to the noise in the data and their relative importance in prediction tasks increases with the growing noise factor in the data.

Sponsored Session

Chair: Yun Fong Lim, Singapore Management University, Singapore, 178899, Singapore

1 - Optimal Policies and Heuristics to Match Supply with Demand for Online Retailing

Fang Liu, Nanyang Technological University, Singapore, 639798, Singapore, liu_fang@ntu.edu.sg, Yun Fong Lim

Consider an online retailer selling multiple products to multiple zones over an infinite horizon. In each period, the retailer replenishes the products from a single supplier and stores them at multiple warehouses. After demand realization, the retailer determines the retrieval quantities. The retailer decides the order, storage and retrieval polices to maximize her expected total discounted profit. We completely characterize the optimal policies for a single demand zone. We propose heuristics to compute order and storage policies for multiple demand zones. A case study suggests that our heuristics generate at least a 15% profit improvement over the retailer's current practice.

2 - Product Description and Consumer Reviews in Omni-channel Retailing

Qiyuan Deng, Singapore Management University, Singapore, 545020, Singapore, qiyuan.deng.2015@pbs.smu.edu.sg

During the last decade, many brick-and-mortar retailers have initiated a dual-channel strategy supplementing their shops with online channels. More recently, retailers start to implement an omni-channel strategy, which aims to provide consumers the same shopping experience across channels. This paper studies how a retailer strategically provides product information in her offline and online channels. The two channels are operated either separately (dual-channel) or collectively (omni-channel). We consider two types of information: product description and consumer review. We develop a game-theoretical model to analyze the omni-channel strategy and the effect of consumer reviews.

3 - Managing Bucket Brigades on Discrete Stations with Stochastic Work Times: Learning is Not Always Good

Peng Wang, Singapore Management University, Singapore, 178899, Singapore, peng.wang.2016@pbs.smu.edu.sg

We study a J-station, 2-worker bucket brigade assembly line with stochastic work times. We derive the system's average throughput. If the work speeds depend only on the workers, we observe behaviors similar to that of the deterministic model. If the work speeds depend on the workers and the stations, we optimize a system consisting of a generalist and a specialist and uncover two factors determining the throughput. If the work speeds depend on the workers, the stations, and the jobs, the generalist and specialist may switch their roles as they learn. Furthermore, the throughput may drop as the workers learn.

4 - Technology Specifications and Production Timing in a Co-opetitive Supply Chain

Xin Fang, Singapore Management University, Singapore, 178899, Singapore, Baozhuang Niu, Kanglin Chen, Xiaohang Yue, Xin Wang

Motivated by Google's technology specifications on Android devices, we consider firms' decisions on production timing in a co-opetitive supply chain comprising a manufacturer and an original equipment manufacturer (OEM), where the manufacturer acts as the OEM's upstream contract manufacturer and downstream competitor. We consider the market acceptance uncertainty of key product designs. If a firm decides to implement ex-post production strategy (PS), it can delay the production until the market acceptance uncertainty of its product is resolved. Otherwise, ex-ante production strategy (AS) is implemented.

1 - Optimal Capacity Rationing Policy with Individual Service Guarantees

Jiawei Zhang, Stern School of Business, New York, NY, 10012, United States, jzhang@stern.nyu.edu, Jiashuo Jiang, Shixin Wang

We study capacity allocation when customers require individual and possibly different service-levels. Our modeling framework generalizes and unifies many existing models in the literature. We show that, under a general class of randomized capacity rationing policies, our model can be formulated as a minimax stochastic program. An immediate consequence of this formulation is the application of existing first-order optimization algorithms to numerically compute capacity levels. The formulation also allows us to derive an intuitive and optimal rationing policy for the second stage capacity allocation problem. In addition, we derive conditions under which an index policy is optimal.

2 - Assessing the Cost of Flexibility in Demand Fulfillment: An Empirical Study

Yifan Feng, University of Chicago, Chicago, IL, United States, yifan.feng@chicagobooth.edu, Rene A. Caldentey, Linwei Xin, Dennis Zhang

Our study is based on a dataset from a major logistics platform for e-commerce business in China. We quantify the impact of fulfillment flexibility on delivery speeds.

3 - Capacity Allocation and Online Fulfillment under Asymmetric Demand

Hailun Zhang, The Chinese University of Hong Kong, Shenzhen, 5569, Clear Water Bay, Shen Zhen, China, hzhangaq@connect.ust.hk

We study online demand fulfillment with limited flexibility and highly asymmetric demand nodes. Xu et al.(2017) show that, under a load-based demand fulfillment rule, a positive Generalized Chaining Gap (GCG) is both necessary and sufficient to achieve bounded performance and the performance bound as a proxy of the performance measure (i.e., the expected number of lost sales) suggests that a high GCG leads to good performance. Since the GCG of a given network with highly asymmetric demand notes can be arbitrary low as the level of asymmetry increases, we investigate in this paper whether bounded performance can be achieved as GCG vanishes and provide insight into ways to achieve bounded performance.

4 - On the Learning Benefits of Resource Flexibility

Mihalis Markakis, IESE Business School, Avenida Pearson, Barcelona, 08034, Spain, Jiri Chod, Nikolaos Trichakis

Resource flexibility is known to provide firms facing demand uncertainty with such benefits as risk pooling, revenue-maximization optionality, and operational hedging. In this article we uncover a heretofore unknown benefit: we establish that resource flexibility mitigates censoring of sales data, and thereby facilitates learning the true demand under a variety of practical settings and demand distributions. Further, we quantify these learning benefits of flexibility and find them to be of the same order of magnitude as the extensively studied risk pooling benefits of flexibility.

1 - Near Optimal Solutions for Assemble-to-Order Systems

Yehua Wei, Duke University, Durham, NC, 02467-3809, United States, Levi DeValve, Sasa Pekec

We study the classical assemble-to-order (ATO) problems from Operations Management. We present LP rounding algorithms that achieve both asymptotic optimality as demand grows large, and a 1.8 approximation factor for any one-period ATO problem instance. We also demonstrate that our one-period LP rounding results can be extended to analyze dynamic ATO problems. Specifically, we use our rounding scheme to develop an asymptotically optimal integral policy for dynamic ATO problems with backlogging and identical component lead-times.

2 - Information and Memory in Dynamic Resource Allocation

Yuan Zhong, Booth School of Business, University of Chicago, Chicago, IL, United States, Yuan.Zhong@chicagobooth.edu, Kuang Xu

We propose a general framework to study the impact of information constraints and memories on dynamic resource allocation. Information constraints are modeled as a channel, where a sender/encoder co-located with the buffers sends signals across the channel to the decision maker, who receives a noisy message. Memories are available to both the sender and the receiver (decision maker). We prove in substantial generality that (a) noisy information always reduces capacity; (b) more receiver memory always improves capacity; and (c) more sender memory has little to no effect on memory. All of our positive (achievability) results are established through constructive, implementable policies.

3 - Dynamic Pricing of Relocating Resources in Large Networks

Chen Chen, Duke University, Durham, NC, United States, cc459@duke.edu, Santiago Balseiro, David Brown

We study dynamic pricing of resources distributed over a network of locations. Customers with private willingness-to-pay sequentially request to relocate one resource, and a revenue-maximizing service provider sets a price for each request. We focus on networks with a hub-and-spoke structure, and develop a dynamic pricing policy based on a Lagrangian relaxation. We show the policy loses no more than $O(\sqrt{(\ln n/n)})$ in performance when the number of spokes n and the number of resources grow at the same rate. Finally, we extend the approach and analysis to more general networks with multiple hubs and spoke-to-spoke connections. No static policy is asymptotically optimal in the regime we consider.

4 - Beating the Curse of Dimensionality in Options Pricing and Optimal Stopping

Yilun Chen, Cornell ORIE, 292 Rhodes Hall, Ithaca, NY, 14853, United States, yc2436@cornell.edu, David Goldberg

The fundamental problems of pricing high-dimensional options and optimal stopping are generally believed to be intractable, with modern ADP, duality, and simulation approaches either scaling poorly, requiring knowledge of basis functions, or having limited guarantees. We show that this general belief is incorrect, by developing the first algorithm which allows one to elegantly trade-off between accuracy and runtime through a parameter epsilon controlling the performance guarantee (analogous to a PTAS), with computational and sample complexity both polynomial in T (effectively independent of the dimension) for any fixed epsilon, in contrast to past methods which scale exponentially.

Joint Session MSOM/SC/Practice Curated: Empirical Service Operations

Sponsored: Manufacturing & Service Oper. Mgmt/Supply Chain

Sponsored Session

Chair: Ruomeng Cui, Emory University, Decatur, GA, 30033, United States

1 - Disruptions, Resilience and Performance of Emerging Market Entrepreneurs: Evidence from Uganda

Amrita Kundu, London Business School, London, NW1 4SA, United Kingdom, akundu@london.edu, Kamalini Ramdas, Stephen Anderson

We examine the effect of firm-specific business disruptions (both managerial and operational) on the performance of small firms in emerging markets and the effectiveness of appropriate resilience strategies in buffering against these disruptions, using a hand-built panel dataset on 646 small firms over four time periods in Kampala, Uganda.

2 - Product Management under Competitive Dynamics

Xabier Barriola, IESE Business School, Av. Barcelona, 08034, Spain, xbarriola@iese.edu, Jose Azar

In this paper we test the effects of competition on product assortment, on the number of new products released, and on the time between the release of new products. Using the merger between SABMiller and Molson Coors as an instrument to predict future market structure, we conclude that competition makes firms offer larger levels of product assortment. Moreover, we show that there is a negative relationship between the number of new products and market concentration. Finally, we are able to show that there is a positive relationship between release times and market concentration. Our findings confirm the notion that more competition creates an arms race, where firms decide to release new products faster.

3 - Challenges of Online Retailing in Emerging Markets

Antonio Moreno, Harvard Business School, Morgan Hall 494, Boston, MA, 02163, United States

This talk focuses on some of the challenges of online retailing in emerging markets, such as the use of cash on delivery.

4 - Worker Turnover in the Global Supply Chain

Ken Moon, The Wharton School, Wharton School, Philadelphia, PA, 19104, United States, kenmoon@wharton.upenn.edu

We study worker turnover and production data from within a global supply chain involving over 700 suppliers to produce billions USD in consumer electronic goods quarterly. Within the supply network, worker turnover rates at some of the component suppliers approach 400-500% annually. Our empirical and prescriptive study examines how yield volatility caused by disruptive worker turnover can generate supply-side bullwhip effects, and how these effects trade off with prescriptions based on prior literature prescribing that risk mitigations (such as safety stocks) be installed further upstream within the responsive supply chain.

5 - Sooner or Later? Learning from Delivery Speed Information

Ruomeng Cui, Emory University, Decatur, GA, 30033, United States, ruomeng.cui@emory.edu, Tianshu Sun

Online retailers who sell physical products need to inform customers how fast an order can be delivered. On one hand, an aggressive (faster) delivery estimate could meet more demand and thus may increase current sales. On the other hand, however, it may also raise the likelihood of customers experiencing a loss in time due to a longer than expected wait, which might hurt future sales. Collaborating with an online store selling custom products, we exploit its shipping rule changes intending to identify the effect of delivery information. We leverage the exogenous policy change and use a difference-in-difference approach to examine whether and how consumers respond to the delivery information.

CC- Room 307

Innovative Operations Models

Sponsored: Manufacturing & Service Oper. Mgmt/Supply Chain

Sponsored Session

Chair: Fuqiang Zhang, Washington University in St. Louis, St. Louis, MO, 63130, United States

Co-Chair: Tianjun Feng, Fudan University, Shanghai, 200433, China

1 - Wishful-thinking Investors on Peer-to-peer Lending Platforms: Implications for Supply Chain Financing

Xin Fang, Singapore Management University, 50 Stamford Road, #05-01, Singapore, 178899, Singapore, Guangxin Gao, Yun Fong Lim

In recent years, online peer-to-peer (P2P) lending platforms grow rapidly. Different from traditional bank financing, a borrower on a P2P platform seeks fund from many investors and the investors in turn bear the borrower's default risk. However, some investors are wishful thinking on the platform, who ignore the default risk and only focus on investment returns. We study the impacts of such wishful-thinking investors on supply chain financing. We develop a game-theoretical model involving a capital-constrained retailer, a P2P platform and a group of heterogeneous investors, who can be rational or wishful-thinking.

2 - Peer-to-peer Sharing Platforms with Quality Differentiation: Manufacturer's Strategic Decision under Sharing Economy

Huiqi Guan, Fudan University, Shanghai, 200433, China, guanhuiqi@fudan.edu.cn, Xin Geng, Haresh B. Gurnani

We formulate a multi-stage game-theoretic model to analyze the manufacturer's strategic move of building an exclusive product sharing platform to respond to the competition from the emerging peer-to-peer product sharing platforms in the downstream market. Our results indicate that a high-quality manufacturer can benefit from building a peer-to-peer sharing platform.

3 - Incentivizing Farmer Adoption of Agri-Technology Products

Xiao Tan, Washington University in St. Louis, St. Louis, MO, United States, xtan@wustl.edu, Duo Shi, Fuqiang Zhang

With development of agriculture technology, new agri-technology products like UAV help farmers with seeding and fertilizing. However, it is of high risk and uncertainty to use these products. We characterize heterogeneous farmers' behaviors in equilibrium when they engage in Cournot competition. Also we study the firm's optimal effort and price regarding farmers' behaviors. Government may able to subsidize farmers or the firm. Our analysis will show which player should be subsidized under certain conditions.

4 - Real Estate Investments and House Sharing: Impacts and Implications on Local Housing Markets

Jiali Huang, University of Minnesota, Minneapolis, MN, 55414, United States, Saif Benjaafar, Ankur Mani, Shihong Xiao

It is commonly believed that the existence of home investors may raise housing price and thus increase the living cost of local residents. This rule of thumb may not be valid when there is a peer-to-peer home sharing market for home owners to rent their house when they do not use them. We propose a game-theoretic model to investigate the interactions of landlords, home developers, local residents, home investors, and home-sharing platform. We show the existence and uniqueness of the equilibrium, and examine monotone comparative statics of rental price, home purchasing price, the welfare of local residents, and social welfare.

CC- Room 308

Assessment for OR/MS/Analytics Education

Sponsored: Education

Sponsored Session

Chair: Susan Wright Palocsay, James Madison University, Harrisonburg, VA, 22807, United States

1 - Innovation and Assessment of Advising Models in an undergraduate Industrial Engineering Program

Jill Hardin Wilson, Asst. Dept. Chair for Undergraduate Studies, Northwestern University, Industrial Engineering & Mgmt Sciences, 2140 Sheridan Road, Evanston, IL, 60208, United States, Marita Labedz Poll

In the McCormick School of Engineering at Northwestern University, all undergraduate students are required to meet quarterly with an academic advisor. These advisors have traditionally been full time faculty. We pilot and assess a new model for advising in Industrial Engineering that combines a professional academic advisor with a faculty "guIdE". In its first two years this model has demonstrated equivalent student satisfaction and continued student-faculty engagement, while releasing full-time faculty from the high number of contact hours previously required for curriculum advising.

2 - Industry Advisory Board Input for Data Science and Industrial and Applied Mathematics Curriculum Development

David W. Jacobson, Associate Professor, Metropolitan State University, 5703 Clearwater Rd NW, St. Paul, MN, 55901-4114, United States, david.jacobson@metrostate.edu, Rikki Wagstrom

Many universities have developed or are developing data science programs. Others have redesigned their traditional Applied Mathematics degrees. In this presentation, we will discuss recommendations and input that we have received from our Industry Advisory Board which is made up of representatives from a wide range of business enterprises. We will cover their suggestions and how several have been implemented in our Data Science and Industrial and Applied Mathematics curricula.

3 - Assessment of Memorandum Writing About Analytical Work

Julie Ann Stuart Williams, Professor, University of West Florida, 11000 University Parkway, Building 76A Room 328, Pensacola, FL, 32514-5752, United States, jawilliams@uwf.edu

A contextualized problem that integrates mathematical modeling and professional writing provides an assessment approach for students to demonstrate not only modeling formulation and solution technique but also management interpretation and writing. The assessment rubric includes management interpretation requirements for the content in terms of the decisions, objective, constraints, solution, recommendation, and impact as well as writing requirements for grammar, punctuation, capitalization, and spelling. A detailed example illustrates the assessment approach. Assessment results over multiple years are summarized and pedagogical implications are discussed.

4 - A Spreadsheet Tool for Analyzing Assessment Test Data

Luis J. Novoa, James Madison University, 421 Bluestone Dr., Zane Showker Hall, Harrisonburg, VA, 22807, United States, novoadlj@jmu.edu, Scott Stevens, Susan Wright Palocsay

We have developed an Excel-based tool to support analysis and reporting of data from assessment tests. It creates graphical and tabular summaries of test results at the question item, course topic, instructor, and semester levels. We will demonstrate its use for automation of question grouping, statistical analyses, and report generation.

5 - Experiences with Assessment Testing in an undergraduate MS Course

Scott Stevens, Professor, James Madison University, Harrisonburg, VA, 22807, United States, stevensp@jmu.edu, Susan Wright Palocsay, Luis J. Novoa

We will describe our experiences in developing and implementing course-embedded test questions for assurance of learning in a required MS course. Example learning objectives, test items, and assessment results will be presented. We will also address how we have addressed challenges with "closing the loop" for continuous improvement.

CC- Room 309

Blockchain and Cryptocurrencies

Sponsored: Manufacturing & Service Oper. Mgmt/iFORM

Sponsored Session

Chair: Gerry Tsoukalas

1 - Blockchain-driven Deep-tier Supply Chain Finance

Yunzhe Qiu, Washington University in St. Louis, , St. Louis, MO, 63130, United States, qiuyunzhe@wustl.edu, Lingxiu Dong, Fasheng Xu

We study the financing problem in a multitier supply chain with one downstream manufacturer (buyer), one tier-1 supplier (intermediary), and two tier-2 suppliers who are in need of working capital to survive business disruptions (e.g., production line breakdowns, delayed customer payments). With such three-tier supply chain as the backdrop, the downstream manufacturer has limited visibility of financial status (i.e., cash position) of the tier-2 suppliers. However, with the blockchain technology, such deep-tier visibility issue can be can resolved. We further provide a sufficient condition under which the blockchain-driven visibility could lead to a "win-win-win" situation.

2 - Cryptocurrency Design

Nick Arnosti, Columbia Business School, New York, NY, 10027, United States, Ciamac Cyrus Moallemi

Cryptocurrencies must compensate miners for validating transactions and protecting the network against attacks. This compensation can come in the form of block rewards or transaction fees. Existing cryptocurrencies compensate miners in different ways. For example, block rewards may be decreasing or constant over time, and fees may be voluntary or mandatory. We formulate a model in which block rewards and transaction fees determine the security of the network, as well as its usefulness to users. We consider the social planner’s problem of maximizing welfare subject to security constraints, and discuss the effect of block rewards and transaction fees on the value of the currency.

3 - Inventory, Speculators and Initial Coin Offerings

Rowena J. Gan, Wharton School of Business, University of Pennsylvania, Philadelphia, PA, United States, ganj@wharton.upenn.edu, Gerry Tsoukalas, Serguei Netessine

Initial Coin Offerings (ICOs) are an emerging form of fundraising for Blockchain-based startups. We propose a simple model of matching supply with demand with ICOs by companies involved in production of physical products. We examine how ICOs should be designed-including optimal token floating and pricing-in the presence of demand uncertainty, make predictions on ICO failure, and discuss the implications on firm operational decisions and profits. We show that ICOs are best suited for higher-margin products, and lead to underproduction and lower-than-optimal profits versus first best. However, ICOs result in lower profit variance, rendering firm profits less sensitive to demand uncertainty.

4 - Token Weighted Crowdsourcing

Gerry Tsoukalas, Wharton School of Business, Philadelphia, PA, 19104, United States, gtsouk@wharton.upenn.edu

Blockchain-based systems are increasingly using token weighted voting to crowdsource information from their users for a wide range of applications, including content curation, and on-chain governance. We examine the effectiveness of such decentralized systems at harnessing the ``wisdom” and ``effort” of the crowd.

CC- Room 310

Consumer Returns in Retailing

Sponsored: Manufacturing & Service Oper. Mgmt/Sustainable Operations

Sponsored Session

Chair: Necati Ertekin, University of Minnesota, Minneapolis, MN, United States

1 - On Product Customization and Returns

Paolo Letizia, University of Tennessee, 916 Volunteer Boulevard, Knoxville, TN, 37996, United States, pletizia@utk.edu, Gokce Esenduran, Anton Ovchinnikov

Nowadays, consumers are increasingly searching for products that closely match their preferences, but also feel entitled to return the purchased products, whether standard or customized, in case the products do not match their expectations. The firms’ response to these two trends is far from being unique. Even in the same industry, some firms provide ways to customize, while others sell only standard products; likewise, some embrace liberal return policies even for customized products, while others allow returns of only standard products. Given these, at times, opposing practices, this article analyses firms’ decisions about product customization and returns.

2 - Using Transactions Data to Improve Consumer Returns Forecasting

Guangzhi Shang, Florida State University, Department of Marketing, College of Business, Tallahassee, FL, 32306, United States, Erin Cassandra McKie, Mark Ferguson, Michael Galbreth

Although an accurate returns forecast is preliminary for many decision support tools for managing returns, the development methods in this area received relatively little attention. We propose a new approach and benchmark its performance against a number of existing methods using two real world datasets.

3 - Consumer Bracketing of Online Purchases to Manage Size Uncertainty – Should Retailers Be Worried?

Aditya Balaram, University of South Carolina, Columbia, SC, 29208, United States, aditya.balaram@grad.moore.sc.edu, Olga Perdikaki, Michael Galbreth

Bracketing is the practice of ordering multiple sizes of a product and returning all that do not fit. Consumers adopt this practice to resolve uncertainty surrounding size. Bracketing results in retailers having to deal with a larger mass of returns, which is a situation they would like to avoid. We build a stylized model to show that online retailers can leverage this seemingly deleterious consumer practice to improve profit by pricing appropriately.

4 - Mitigating Quality Related Consumer Returns: The Role of Store Labor

Necati Ertekin, University of Minnesota, Department of OM&IS, Leavey School of Business, Minneapolis, MN, 95053, United States, Xiaojing Dong

The implication of product quality-consumer returns relationship may be impractical due to not only the challenges to improve perceived product quality but also the lack of association between low quality and certain products. We propose an alternative quality-returns relationship that is both theoretically grounded and practically actionable.

CC- Room 3A

Theoretical Issues in Decision Analysis

Sponsored: Decision Analysis

Sponsored Session

Chair: Ying He

1 - Everything in Moderation: Foundations and Applications of the Satiation Model

Manel Baucells, University of Virginia, Darden School of Business, 100 Darden Boulevard, Charlottesville, VA, 22903, United States, mbaucells@gmail.com, Lin Zhao

Satiation is an essential factor influencing preferences and the design of experiential services. We provide behavioral foundations for an additive utility functional, together with the existence of a state that influences instant utility. We provide a novel proof of concept on how to elicit the preference parameters. On the implementation side, we develop a mixed integer formulation to solve the optimal design of experiential services. Our last result is a preferential equivalence between event utility and recall utility.

2 - A Two Stage Evaluation Model for Decision Making under Ambiguity

Ying He, University of Southern Denmark, Campusvej 55, Odense, M, 5230, Denmark, yinghe@sam.sdu.dk

In this paper, a two-stage evaluation (TSE) model for decision making under ambiguity. In this model, two different types of uncertainty are evaluated in different stages. In the first stage, DM evaluates more uncertain consequences by applying local SEU models, which are then embedded into the second stage evaluation based on a SEU. When evaluating a risky act, the TSE model reduces to the Savage’s SEU with one stage. When evaluating an ambiguous act, the local SEU with a different uncertainty aversion gives the TSE model some flexibility in describing preference. This TSE generates the Uncertain Expected Utility and overlaps with the Smooth Ambiguity Model in modeling preferences.

3 - What Drives the Magnitude Effect?

Alessandra Cillo, PhD., Bocconi University, Milan, Italy, Manel Baucells

The magnitude effect is one of the most robust phenomena in observed time preferences. Often, one considers the prospect of a cash flow, rather than a single payout. In this case, it is unclear whether the magnitude effect is driven by the sum of cash flows, or the highest cash flow, or the first, or the last, or the lowest. In this paper, we create an orthogonal design to shed light into this question. We discuss the implications of our results for how to design more appealing consumer credit offerings.

4 - Information Density in Sensitivity Analysis and Optimization

Emanuele Borgonovo, Bocconi University, Milano, 20136, Italy, Emanuele.Borgonovo@unibocconi.it, Gordon B. Hazen, Victor Jose, Elmar Plischke

In this work, we discuss the notion of information density and how it relates to sensitivity analysis and optimization.

5 - Disentangling Technology Management from Financial Portfolios

Ekundayo Shittu, George Washington University, Washington, DC, 20052, United States, eshittu@gwu.edu, Zoe Szajnfarber

It has been demonstrated in literature that the notion of technology portfolio management shares characteristics with equity portfolio investments in finance. For example, the efficient frontier always traces a path of optimal asset combination for either an equity or a technology portfolio. However, we find that this is only true based on very strong assumptions that equate the nature of technologies with equities. In this paper, we provide three attributes that underscore how this age-long assumption is sub-optimal.

Building MCDM/A Models: Practical and Methodological Issues

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Caroline Miranda Mota, Universidade Federal de Pernambuco, Recife, Brazil

Co-Chair: Danielle Morais, Universidade Federal de Pernambuco, Recife - PE, 52020-212, Brazil

1 - A Spatial Multiple Criteria Decision Model for Vulnerability Analysis

Caroline Miranda Mota, Universidade Federal de Pernambuco, R. Academico Helio Ramos S/N, Depto Eng de Producao-CTG CDU Recife - PE, Recife, Brazil, Ciro Figueiredo

This study used a spatial MCDA approach, based on Dominance-based rough set approach and preference to evaluate the vulnerability of places at crime level. The approach explored aggregation of those individual results for obtaining a final output recommendation. The preferences of each decision maker is assessed in an interactive and incremental way. The preferences were assessed in an interactive way, starting from a small subset of holistic evaluations. The approach was proposed to evaluate places according to its vulnerability to crime occurrence and suggesting where limited resources should be allocated.

2 - Classification Model for Bid / No Bid Decision

Maria Creuza Borges de Araújo, PhD, Universidade Federal de Campina Grande, Sumé, Brazil, mariacreuzaborges@yahoo.com.br, Luciana Hazin Alencar, Caroline Miranda Mota

The bidding decisions are strategic for project-oriented companies. Therefore, we build a classification multiple-criteria model for supporting the decision between bid or not, considering the attractiveness of the projects. The model's main contributions are: (1) the better use of decision maker preference's information for defining project attractiveness levels, and (2) making use of the result of the model as an input for the markup estimation. Moreover, the classification can support the DM to prioritize the projects to bid and model is appropriate in cases where past data are not available.

3 - Selection of Voting Procedure Applied on Participatory Budgeting

Jose Leão Silva FIlho, PhD, Universidade Federal de Pernambuco,, Caruaru, Brazil, zeleao@gmail.com, Danielle Morais

The voting literature presents some procedures to aid different decisions. Each procedure has its own positive and negative characteristics. The choice of a voting procedure (VP) to aggregate the preferences of a group can be a challenge when the decision maker desires a democratic and effective VP. The Participatory Budgeting (PB) scenario in Brazil is an example of these difficulties of choosing a VP. Then, this study presents a multicriteria model to choose the most appropriate VP for a PB considering the characteristics of the problem, the city analyzed and the properties of VP.

4 - A Dempster – Shafer Approach for Multiple Criteria Hierarchy Process

Lucimario Gois Silva, Universidade Federal de Pernambuco,, Caruaru, 50740-550, Brazil, lucio_gois@hotmail.com

In many situations involving multicriteria decision problems, the analysis of the criteria may assume a hierarchical structure of disposition among the criteria. In this case, there is what is called Multiple Criteria Hierarchy Process (MCHP) in the literature. Thus, this new structure for analyzing the criteria requires a new way of thinking about how the criteria relate mainly regarding the definition of weights (relative importance among the criteria). Following this rationale, a new form of weight elicitation which combines the MCHP with the Dempster-Shafer theory is presented, taking into account the possibility of vagueness and inconsistency of the decision-maker.

5 - Building a Multicriteria Decision Making Model for Prioritizing Brazilian Federal Police Activities

Carla Patricia Cunha, Master, Universidade Federal de Pernambuco - Policia Federal, Recife, Brazil, cunhacarla1976@gmail.com, Caroline Miranda Mota, Adiel Teixeira De Almeida, Eduarda Frej

This work intends to build a MCDM/A model to support the decision-making process for prioritizing operational activities of the Brazilian Federal Police. The model considers the organizational values under an investigative aspect and the duties of Brazilian Federal Police. In this context, this work demonstrates the significant decision support that may come from the application of the flexible and interactive tradeoff method (FITradeoff) to assess the values and objectives of the Federal Police.

Managing Human and Material Resources in Humanitarian Supply Chains

Emerging Topic: Humanitarian and NotforProfit Operations

Emerging Topic Session

Chair: Lauren Berrings Davis, North Carolina A&T State University, Greensboro, NC, 27411, United States

1 - Optimizing Spontaneous Volunteer Assignment in Response to Disaster Relief Efforts

Hussain Abualkhair, North Carolina A&T State University, Greensboro, NC, 27407, United States, hfabualk@aggies.ncat.edu, Lauren Berrings Davis, Emmett J. Lodree

Disaster relief centers serve as a primary hub for receiving and distributing relief items. Not only do they face uncertainty in the number of donors dropping off items and beneficiaries picking up items, they also deal with a large influx of spontaneous volunteers. Managing allocation of spontaneous volunteers is challenging due to uncertain arrival times and their participation time. This research presents an infinite horizon discrete time discrete state Markov Decision process model that determines the optimal volunteer assignment policy given the aforementioned uncertainty. The goal is to maximize the number of donors and beneficiaries served and minimize the number of idle volunteers.

2 - Modeling the Role of Equity by Food Group in Effective and Efficient Distribution of Donated Food

Md Hafizul Islam, North Carolina State University, Raleigh, NC, 27695, United States, mislam5@ncsu.edu, Julie Simmons Ivy

Food banks feed more than 41 million people in the United States suffering from hunger every year. They collect in-kind donations to serve as many of these people as possible in an efficient and equitable manner. A mixed integer programming model is developed to identify efficient and effective policies to collect donations of various food groups and allocate them to different demand zones maintaining equity at the food group level. A numerical study using data from the Food Bank of Central and Eastern North Carolina is performed to explore the impact of the variable capacity for processing, storing, and distributing different types of food on the efficient, effective and equitable allocation policy.

3 - Nested Markov Decision Process Model for Equitable and Effective Supply Distribution

Sefakor Fianu, North Carolina A&T State University, Greensboro, NC, 97229, United States, sfianu@aggies.ncat.edu, Lauren Davis

Food banks have evolved from small backyard operations into complex network organizations as a result of increase in demand for their services. However, most of their supplies primarily come from donations which create a major challenge in their supply chain. Distribution decisions made by food banks usually include: how to transfer supplies from one branch to another and how to effectively distribute these supplies to partner agencies. These decisions are dependent on one another and require an integrated decision-making process. The problem is formulated as a Nested Markov Decision Process with objectives of finding optimal distribution policies that minimize unsatisfied demand and waste.

4 - Determining Optimal Fuel Delivery Strategies under Uncertainty

Dominiqueca Edwards, North Carolina A&T, Greensboro, NC, United States, dredward@aggies.ncat.edu, Lauren Berrings Davis, Pitu B. Mirchandani, Sierra Marshall

In preparation for a hurricane, potential individuals affected by the hurricane often are required to evacuate. Evacuations can cause high increases in the demand for gasoline fuel needed for transportation. Since the incoming fuel is imported by vessels, they often have to divert from the intended destination port due to the path of a hurricane. The purpose of this research is to determine a real time port diversion strategy for incoming fuel vessels given the forecast of an approaching hurricane. We develop a heuristic scheduling algorithm that finds the optimal diversion strategy that minimizes the unmet demand of gasoline fuel in each county.

1 - On Gradient Descent Ascent for Nonconvex-concave Minimax Problems

Tianyi Lin, University of California, Berkeley, 407, Berkeley, CA, 94706, United States, darren_lin@berkeley.edu, Chi Jin, Michael Jordan

We consider the nonconvex-concave minimax problems. The standard algorithm for solving this problem is the celebrated gradient descent ascent (GDA), which has been a major success in machine learning, control theory and economics. Despite the thorough theory in convex-concave setting, GDA can converge to limit cycles or even diverge in general setting. In this paper, we present a nonasymptotic analysis of GDA for solving the nonconvex-concave minimax problems. To the best our knowledge, our work is the first to provide the theoretical guarantee for GDA in this setting, shedding the light to its great practical performance in many real applications.

2 - Unnesting the Fixed Point in the Estimation of Dynamic Programs with General Utility Function

Robert Louis Bray, Kellogg School of Management, Northwestern University, 830 Hinman Ave., 2s, Evanston, IL, 60202, United States, r-bray@kellogg.northwestern.edu

A conditional choice probability (CCP) estimator of a dynamic empirical model solves both a dynamic programming problem and a maximum likelihood problem. The estimator can dispatch the former problem before tackling the latter when the utility function is linearly parameterized; otherwise it must nest the former within the latter. This ``nested fixed point" bogs down the estimator. I develop a method to disentangle the two problems under any utility function.

3 - Building Recommendations Through Various Algorithms: Online Grocery Market

Christine Nguyen, Point B, Seattle, WA, United States, Arrido Arfiadi

Recommendation systems are one of the most powerful application of machine learning for online markets. To illustrate how to leverage big data of customer transactions and make recommendations effectively, we experimented with multiple algorithms including K-Nearest-Neighbor (KNN), Association Rules, and Item-Item Collaborative Filtering. Our dataset details 3 million transactions, including items purchased, items reordered, and the time of the last order. This became our biggest challenge as it takes a significantly large amount of computing power to process all of the data. As a result, we had to experiment with various machine learning algorithms.

1 - Impact of Standardization Versus Customization Operational Strategy on Nursing Home Performance

Lu Kong, Cornell University, Ithaca, NY, 14850, United States, Kejia Hu, Rohit Verma

In this paper, we explore the impact of standardization versus customization operational strategy on nursing home performance. We quantify the degree of standardization of each nursing home relative to its chain norm, and the results demonstrate that the degree of standardization on service offering and delivering is positively related to the outcomes, while standardization level of market mix is negatively related.

2 - Identifying Perceived Customer Value for Wellness-centric Features in Hospitality: Evidence From EEG Signals

Min Kyung Lee, Assistant Professor, Northern Illinois University, DeKalb, IL, United States, mlee12@niu.edu, Aleda Roth, Oriana Aragon

This paper explores customers' perceived value that is attributable to the presence or absence of wellness-centric offerings in a hotel room. For semantic clarity, we employ the term "wellness-centric" to connote a bundle of new service design features that are specifically embedded within a hotel room environment and which act passively to improve hotel guests' physical and emotional well-being during their stay. In an experimental design we tested the contribution of wellness-centric offerings in value creation through an electroencephalogram (EEG) laboratory experiment with measured self-report and neural indices of "wanting."

3 - Is Standardization Always Good for Patient Outcomes? The Moderating Role of Operational Failures

Sarah Zheng, University of Victoria, Victoria, BC, Canada, Anita Tucker

Using survey data from 292 medical or surgical nursing units at 63 hospitals across the States, we found that when Operations Failure is high, the level of standardization is negatively associated with Hospital Acquired Pressured Injuries, suggesting that a high level of the standardization will benefit patient outcome. However, When Operational Failure is low, the increase of standardization may not benefit patient outcome if not bring harm to.

4 - Innovations in Humanitarian Operations: Investigating Flood Disaster Recovery Through the Len of Services Operation

Niratcha Tungtisanont, University of Maryland, College Park, LBPP Dept., College Park, MD, 20742, United States, Aleda Roth

This study examines humanitarian operations and crisis management (HOCM) in a way that influences policy. The primary goal of this research is to adopt the lens of strategic service operations in conceptualizing how best to design and prioritize strategic choices (e.g., resources, investments, policy, etc.) prior to and during a flood event in order to enhance the overall effectiveness of the recovery process. We draw upon the service strategy literature, we consider the roles of various stakeholders—individuals, communities, and governments—in the co-production disaster relief services and activities.

5 - Intermediation under the Overlapping Generations of Technology: An Empirical Study of MVNO

Fan Zou, University of South Carolina, Columbia, SC, United States, An Dong, Keija Hu, Sriram Venkataraman

This study examines the impact of mobile virtual network operators (MVNOs) on the performance of mobile network operators (MNOs) with the presence of overlapping generations of wireless mobile technologies (2G and 3G). MVNOs are an innovative business that works with MNOs to provide mobile services to customers without owning any spectrum or network infrastructures. Some MVNOs are wholly owned by MNOs with a revenue-sharing mechanism (Branded MVNO), while others only obtain service from MNOs through wholesale agreements (Third-party MVNO). By exploring the impact of MVNOs on MNOs' performance, we extend our understanding of intermediation in the presence of overlapping generations of products, as well as how it interacts with the ownership of the intermediaries. This study also provides valuable guidance for managers of MNOs in the use of MVNO.

Joint Session AMD/Practice Curated: Dynamic Matching Market Design

Sponsored: Auction and Market Design

Sponsored Session

Chair: John P. Dickerson, University of Maryland, College Park, MD, 20742, United States

1 - Incorporating Compatible Pairs in Kidney Exchange: A Dynamic Weighted Matching Model

Sanmay Das, Washington University in St. Louis, Dept. of Computer Science & Engr., Saint Louis, MO, 63130, United States, Zhuoshu Li, Kelsey Lieberman, William Macke, Sofia Carrillo, Chien-Ju Ho, Jason Wellen

We study a hybrid online/batch matching model with impatient and patient pairs to capture the dynamics of kidney exchanges that could include compatible pairs. We introduce new algorithms for matching in this model and apply them to graphs generated from a novel simulator for the joint distribution of compatibility and match quality (for which we leverage the recently proposed LKDPI) across pairs. Our results indicate great potential in terms of both increased numbers of transplants of incompatible pairs as well as improved match quality for recipients in compatible pairs.

2 - On Tanking and Competitive Balance

Aleksandr Kazachkov, Polytechnique Montreal, Montreal, QC, Canada, Shai Vardi

Tanking is a phenomenon in sports in which teams attempt to purposefully lose games. We analyze the perverse incentives that lead to tanking and propose a new bilevel mechanism for ranking teams that can drastically reduce tanking behavior, which we support with theoretical and experimental results.

3 - Design of Lotteries and Waitlists for Affordable Housing Allocation

Peng Shi, University of Southern California, Los Angeles, CA, 90064, United States, pengshi@usc.edu, Nicholas A. Arnosti

We study a stylized model of assigning items to dynamically arriving items, in which an ideal mechanism both target items to agents with the worst outside options, and match them to items for which they have high value. We find that two common approaches — using independent lotteries for each item, and using a wait-list in which agents lose priority when they reject an offer — lead to identical outcomes in equilibrium. The match quality can be improved by using a common lottery for all items. If participation costs are negligible, a common lottery is equivalent to limiting participants to a single lottery, using a wait-list in which offers can be rejected without punishment, or using artificial currency.

Information, Investment, and Risk Management

Sponsored: Finance

Sponsored Session

Chair: Nan Chen, Chinese University of Hong Kong, Shatin N T, Hong Kong

1 - Dynamic Investment and Financing with Internal and External Liquidity Management

Nan Chen, Chinese University of Hong Kong, William M. W. Mong Engineering Bldg, Shatin N. T, Hong Kong, nchen@se.cuhk.edu.hk, Yuan Tian, Jiahui Ji

We develop a theoretical model of dynamic investments, dividend payouts, debt borrowing, external equity financing, and bankruptcy for financially constrained firms. The model characterizes the central importance of liquidity management in corporate decision making in the presence of external financing costs. The paper also discusses the implications of liquidity and leverage requirements in the current banking regulatory framework.

2 - Systemic Portfolio Diversification

Agostino Capponi, Columbia University, New York, NY, 10027, United States, ac3827@columbia.edu

We study the implications of fire-sale externalities on balance sheet composition. Banks select their asset holdings to minimize expected execution costs triggered by the need to comply with regulatory leverage requirements. We show that if banks disregard the price impact caused by other banks' liquidation actions, they hold an excessively diversified portfolio. Banks seek systemic diversification when they account for the negative externalities imposed by other banks' liquidation actions. Social costs can be reduced by a tax on portfolio overlap, or by enforcing policies which mandate the split of a bank into smaller institutions with heterogeneous leverage ratios.

3 - Dynamic Information Regimes in Financial Markets

Yiwen Shen, PhD Candidate, Columbia Business School, New York, NY, 10025, United States, YShen21@gsb.columbia.edu, Paul Glasserman, Harry Mamaysky

We develop a dynamic model of information and prices where investor information choices influence level of available public and private information about fundamentals. We study two feedbacks. In the first, more informed investors make more information of fundamentals become available. Consequently, two regimes emerge, one with higher prices and lower volatility, and one with lower prices and higher volatility. Information dynamics move market between regimes, creating large market drops and rallies, with no fundamental change. In the second feedback, an increase in the number of informed investors leads to greater public information through leakage; this mechanism has a stabilizing effect.

4 - Investment Valuations and Falling Cost of Information

Hong Ming Tan, National University of Singapore, Singapore, 127146, Singapore, thm@u.nus.edu, Jussi Keppo

We model two risk-averse decision makers who optimize the size of their investment, and the level of costly information on the investment. The decision makers affect the market price of the investment, and optimize their own expected utility given the other decision maker's quantity of information. Therefore we study the resulting market equilibrium. We show that in this game model, the falling cost of information raises the Nash equilibrium quantity of information for each decision maker. This results in an increase in the expected equilibrium price of the investment, i.e., the falling cost of information raises the cost of investments. We show empirical evidence for this by using U.S. equity prices.

Tutorial: Recent Advances in Multi-Armed Bandits for Sequential Decision Making

Emerging Topic: Tutorials

1 - Recent Advances in Multi-armed Bandits for Sequential Decision Making

Shipra Agrawal, Columbia University, Industrial Engnr. and OR, New York, NY, 10027, United States

This tutorial discusses some recent advances in sequential decision making models that build upon the basic multi-armed bandit (MAB) setting to greatly expand its purview. Specifically, it discusses progress in algorithm design and analysis techniques for three models: (a) Contextual bandits, (b) Combinatorial bandits, and (c) Bandits with long-term constraints and non-additive rewards, along with applications in several domains such as online advertising, recommendation systems, crowdsourcing, healthcare, network routing, assortment optimization, revenue management, and resource allocation.

Decision-making Under Uncertainty

Sponsored: Military and Security

Sponsored Session

Chair: Phillip Rolland Jenkins, USAF, Dayton, OH, 45424, United States

Co-Chair: Brian J. Lunday, Air Force Institute of Technology, WPAFB, OH, 45433, United States

1 - Robust Influence Modeling under Structural and Parametric Uncertainty: An Afghan Counter Narcotics Use Case

Brian J. Lunday, Air Force Institute of Technology, Department of Operational Sciences, WPAFB, OH, 45433, United States, brian.lunday@afit.edu, William Nicholas Caballero

An entity often wishes to influence the decisions of others in a system. However, the central task of this entity is confounded by uncertainty regarding their understanding of the structure and/or parameters of the decisions being made. This research sets forth a modeling framework to identify robust influence strategies under uncertain conditions. Its utility and proper parameterization are illustrated via an application to Afghan opium cultivation. Utilizing open source data, we demonstrate how counternarcotic policy can be informed using a quantitative analysis that embraces both decisionmaker bounded rationality and uncertainty regarding the degree of this deviation from rationality.

2 - Understanding the Learning Behavior of Terrorist Organizations

Gilberto Montibeller, Loughborough University, School of Business & Economics, Loughborough, United Kingdom, g.montibeller@lboro.ac.uk, Johannes Jaspersen

There is evidence that terrorists are both adaptive in their behavior and driven by multiple objectives in their actions. In this paper, we use insights from the adaptive learning theory and compare several different reinforcement learning models regarding both their psychological implications and their fit to empirical data. Using data on target choices of terrorist attacks and two different objectives (renown and revenge), we show that a total reinforcement learning with power choice probabilities and information discounting can be used to model the adaptive decision process of terrorists. We draw implications for counter-terrorism strategies by comparing it with other behavioral models.

3 - Counterfactual Regret Minimization for Integrated Cyber and Air Defense Allocation

Andrew Keith, Air Force Institute of Technology, 5173 Gander Rd W, Dayton, OH, 45424, United States, Darryl K. Ahner

We present a new application of optimal and approximate solution techniques to an integrated cyber and air defense problem. To model this problem, we use an extensive-form game with imperfect information for an attacker and defender in physical and cyber space. To determine optimal defender strategies, we reformulate the problem to find a Nash equilibrium using a sequence-form linear program. We also develop a fast application of counterfactual regret minimization and characterize the optimality gap. Lastly, we quantify the value of improved situational awareness in the cyber domain and present an extension to robust solution techniques that address ambiguity in the game model.

4 - Robust Multi Objective Optimization for the Military Medical Evacuation Location Allocation Problem

Phillip Rolland Jenkins, Air Force Institute of Technology, Dayton, OH, 45424, United States, Brian J. Lunday, Matthew J. Robbins

Determining where to locate mobile aeromedical staging facilities (MASFs) as well as identifying how many aeromedical helicopters to allocate to each MASF, commonly referred to as the medical evacuation (MEDEVAC) location-allocation problem, is vital to the success of a deployed MEDEVAC system. We develop an integer mathematical programming formulation to determine the location and allocation of MEDEVAC assets over the phases of a military deployment to support operations ranging from peacekeeping through combat to post-combat resolution and to analyze trade-offs between three competing objectives.

5 - Generating Robust Patrol Patterns Through Fictitious Play

Richard G. McGrath, Military Professor, United States Naval Academy, Annapolis, MD, United States

We present a problem where a patroller wants to determine a strategy that minimizes the expected cost of an attack by an intelligent enemy. We generate patrol patterns against a strategic attacker using the game-theoretic method of fictitious play, which is an iterative method used to create mixed strategies in a two-person zero-sum game. Each player arbitrarily chooses a pure strategy in the first round; and in subsequent rounds, each player chooses a pure strategy that will produce the best expected value against the mixture of strategies used by the other player in previous rounds. Numerical experiments demonstrate that this method produces excellent results when compared to the optimal solution.

Health Care, Modeling and Optimization VII

Contributed Session

Chair: Maryam Keshtzari, Texas Tech University, Texas, Lubbock, TX, 79416, United States

1 - A Memetic Algorithm for Solving Optimal Control Problems of Zika Virus Epidemic with Equilibriums and Backward Bifurcation Analysis

Kaiming Bi, Kansas State University, Manhattan, KS, United States, bikaiming@ksu.edu

This research utilizes an existed mathematics model in the Zika virus, then analyzes the stability and bifurcation. Consequently, we have established an Optimal Control problem associated with the model based on several popular disease intervention strategies frequently used by public health agencies to mitigate the Zika epidemics. Comparisons of traditional Pontryagin's maximum principle and memetic algorithm were conducted for different intervention strategies. Also, this research mentioned theoretical continuous optimal control might not be practical. Rather, the MA-based discrete is relatively easy to be implemented in real-world applications.

2 - Network-based Analysis and Optimization for Scheduling Pharmacists and Technicians

Phichet Wutthisirisart, Senior Health Services Analyst, Mayo Clinic, Rochester, MN, United States, Kalyan Pasupathy, Desirae Sagdalen, Brent Ferguson, Lynnette Nelson, Mustafa Y. Sir

With the goals of speeding up completion time and ensuring increased staff utilization, the health system pharmacy allows various steps of an order to be processed at multiple service locations, linked through the order management software. We developed an optimization model to help the Mayo Clinic Pharmacy assess the performance of staff schedule templates, and identify the optimal plan that minimizes the total delay. The model is created as a network-based MRP and includes practical constraints such as staff-type ratio, role-dependent task, and break-times. It was applied to evaluate the current schedule, provide an optimal plan, and compare options of adding staff and speeding up a certain task.

3 - Impact of Customer Concealment Behavior on Health Insurance Choices under Asymmetric Information

Huan Sun, PhD Candidate, Southeast University, Nanjing, China, jingran2009@163.com, Haiyan Wang

In mainstream health control systems, customers pay insurance premiums to healthcare system at regular intervals, while healthcare system provide health services. However, that may lead to patient's information-hidden behavior for less payment, which harms the interests of health system. To reduce the inefficiencies positively, we design a series of health insurance plans to guide differentiated consumers choose plans which not only meet their needs but also reduce health system's cost. Our results suggest health system to focus on the inflection point of price impact on customer's utility when setting up plans.

4 - Designing a Telemedicine Network with Doctors Serving Walk-in and Network Patients

Behnaz Hosseini, PhD, National University of Singapore, Singapore, Singapore, Baris Tan

We present a stochastic model to design a telemedicine network that consists of a number of doctors who serve their walk-in patients in person and, also receive the online medical requests directed from a telemedicine network. In order to develop the model, we start with the dynamic admission control problem for the doctors who decide how to admit the walk-in and the network patients. We then analyze the operation of the whole network and obtain the optimal number of doctors to maximize the network's profit and offer the desired service level. We show that a telemedicine network is an effective way of utilizing the idle capacity of the doctors while providing a high service level to the network patients.

5 - Solving a Home Health Care Routing and Scheduling Problem with a Fix-and-optimize Matheuristic

Luciana S. Buriol, Federal University of Rio Grande do Sul, Porto Alegre, Brazil, Alberto Kummer Neto, Olinto Araújo

The Home Health Care Routing and Scheduling Problem (HHCRSP) consists of the routing and scheduling a set of personnel to fulfill health attendance to home patients. HHCRSP is basically a vehicle routing problem with time windows that includes space-time constraints to cope with route synchronization requirements. Vehicles represent the personnel and the nodes represent patients waiting for attendance. The Fix-and-Optimize matheuristic decomposes the problem into subproblems solved via MIP. We tested our approach in an online available dataset, and in realistic instances that we generated. Preliminary results demonstrate the efficiency of the proposed approach in solving the problem.

6 - Capacity Planning in Oncology Clinics

Maryam Keshtzari, Texas Tech University, Lubbock, TX, United States, maryam.keshtzari@ttu.edu, Bryan A. Norman

Oncologists are specialized in certain cancer types based on their professional and academic interests. As a result, the overall clinic capacity may not necessarily match the actual demand for different cancer types. The objective of this study is to propose a mathematical model to create a specialization mix to balance the workload across oncologists and minimize patient wait time. Uncertainty regarding new patient demand and returning patients' treatment plans are considered.

Chair: Oscar Dowson, Northwestern University, Northwestern, IL, United States

1 - WaterModels.jl: An Open-source Framework for Exploring Water Network Optimization Formulations

Byron Tasseff, Scientist, Los Alamos National Laboratory, Los Alamos, NM, United States, btasseff@lanl.gov, University of Michigan, Ann Arbor, MI, United States, btasseff@lanl.gov, Russell Bent, Carleton Coffrin

Water distribution system optimization problems are characterized by non-convex physics and discrete decisions. Because of these challenges, a variety of mathematical programming techniques have been developed to increase tractability. However, the large number and disparity of these techniques present barriers to effectively evaluating them over a large set of applications. To address this issue, this work introduces WaterModels, an open-source platform based on JuMP for comparing water distribution system optimization formulations. To demonstrate its effectiveness, a proof of concept study evaluating various methods for water network design and pump scheduling is presented.

2 - Alpine.jl a JuMP Based Solver for Global Optimization of MINLPs

Harsha Nagarajan, Los Alamos National Laboratory, Los Alamos, NM, 87544, United States, harsha@lanl.gov, Russell Bent, Kaarthik Sundar

MINLPs arise in practical applications such as synthesis of process and water networks, energy infrastructure networks, to name a few. Efficient algorithms to solve such optimization problems to global optimality is a key to addressing these applications. We present Alpine.jl, a JuMP-based global optimization solver which leverages MILP-based approaches, constraint programming techniques and efficient piecewise polyhedral formulations to efficiently solve the fairly large-scale MINLPs. Finally, we provide extensive numerical benchmarking of Alpine in comparison with Baron, SCIP and Couenne.

3 - Powersimulations.jl a Integrated and Scalable Power Systems Optimization Modeling Framework

Jose Daniel Lara, University of California Berkeley, Berkeley, CA, United States, jdlara@berkeley.edu

PowerSimulations.jl uses core concepts of mathematical programming to develop a framework that exploits the structure of power systems problems to build optimization models. The proposed solution is based on the specification of a meta-model to inform the systematic construction of the optimization problem. The systematic approach for formulating power systems models, provides flexibility, modularity, and scalability to the user. This approach is enabled by several JuMP features such as containers, affine and quadratic expressions, problem modification and MOI bridges. This talk will showcase the application of these features to large-scale power systems model specifications.

4 - Jump Automatic Dualization

Guilherme Bodin, PUC-Rio, Rio de Janeiro, Brazil, gbodin@ele.puc-rio.br, Joaquim Garcia

The JuMP automatic dualization feature helps users to exploit different formulations of their optimization problems rapidly. The functionality can dualize any conic convex optimization problem. Moreover, automatic dualization can simplify the modeling of bilevel problems by automatically building KKT conditions. In this talk, we will show how it was done and some examples where the automatic dualization enters in other JuMP related packages.

5 - Regularization in Expectation-Maximization Clustering

Thibaut Vidal, PUC-Rio, Rua Marques de Sao Vicente, 225, Rio de Janeiro, 22453-900, Brazil, Raphael Sampaio, Joaquim Dias Garcia, Marcus Poggi

We introduce several variants of the well-known Expectation-Maximization (EM) algorithm for Gaussian mixture-based clustering. These methods differ in their use of regularization techniques during covariance matrix estimation, and in terms of the amount of effort spent searching for better local minima. Sophisticated global optimization methods, in particular, appear to need some regularization to be truly beneficial. We provide an open-source implementation in Julia, using the JuMP modeling language for mathematical optimization.

6 - An Exact and Scalable Problem Decomposition for Security-Constrained Optimal Power Flow using JuMP

Alexandre Velloso, Pontifical Catholic University, Rio de janeiro, Brazil, Pascal Van Hentenryck, Emma Johnson

This paper presents dedicated constraint and cutgeneration procedures for solving large-scale instances of thesecurity-constrained optimal power flow (SCOPF) problem fea-turing proportional reserve response. Specifically, under eachcontingency state, the SCOPF requires that the nodal demandsare met and that the units generating below their maximumcapacity use exactly the same proportion of their reserves. Theresulting model is formulated as an instance of mixed-integerlinear program. Unfortunately, solution methods relying ontraditional Benders decomposition do not scale to large instances.To address this limitation, the paper proposes an iterative three-step algorithm involving 1) a relaxed SCOPF problem with validpost-contingency generation-related constraints; 2) an exogenousnumerical scheme for refining the post-contingency generation;and 3) procedures for selecting dedicated cuts and disjunctiveconstraints to restrict the relaxed SCOPF problem. The paperalso discusses numerical issues, heuristics and valid bounds forthe method. Finally, the efficiency of the proposed method isdemonstrated on large-scale case studies.

Recent Advances in Distributed Optimization

Sponsored: Optimization/Global Optimization

Sponsored Session

Chair: Andy Sun, Georgia Institute of Technology, Atlanta, GA, 30332-0205, United States

1 - A Distributed ADMM-like Method for Resource Sharing Over Time-varying Networks

Erfan Y. Yazdandoost Hamedani, Pennsylvania State University, University Park, PA, United States, evy5047@psu.edu, Necdet Serhat Aybat

We consider cooperative multi-agent resource sharing problems over time-varying communication networks, where only local communications are allowed. The objective is to minimize the sum of agent-specific composite convex functions subject to a conic constraint that couples agents' decisions. We propose a distributed primal-dual algorithm DPDA-D to solve the saddle point formulation of the sharing problem on time-varying (un)directed communication networks; and we provide convergence rates for suboptimality, infeasibility and consensus violation of agents' dual price; examine the effect of underlying network topology on the convergence rates of the proposed decentralized algorithm.

2 - Asymptotic Network Independence in Distributed Optimization

Alex Olshevsky, Boston University, Boston, MA, 60657, United States, alexols@bu.edu

We consider stochastic gradient descent in a network of n nodes: every node knows a strongly convex function, and the goal is to compute the minimizer of the sum of these n functions. At each time step, every node can broadcast a message to its neighbors in a (directed) network and query its own function for a noisy gradient. We describe a method which has the propertythat we call asymptotic network independence: in the limit, the distributed system converges to the global minimizer as fast as a centralized method that can obtain all of the n of the noisy gradients at every time step.

3 - Two-level Distributed Algorithms for Nonconvex Nonsmooth Optimization with Applications in Sparse Regression

Kaizhao Sun, Georgia Institute of Technology, Atlanta, GA, 30318, United States, Andy Sun

In this talk, we present some new distributed algorithms for solving large-scale nonconvex nonsmooth problems with convergence guarantees. We present a two-level algorithmic framework where the inner level is a reformulated multi-block ADMM and the outer level is an augmented Lagrangian model with safeguarding dual variable update. We study the performance of sequential and Jacobi-type ADMM and their inexact proximal variants, and demonstrate the superior performance of these two-level algorithms to the one-level ADMM in sparse regression problems.

4- Complexity of Highly Parallel Non-Smooth Convex Optimization

Sebastien Bubeck, Microsoft Research, Redmond, WA, United States

A landmark result of non-smooth convex optimization is that gradient descent is an optimal algorithm whenever the number of computed gradients is smaller than the dimension d. In this paper we study the extension of this result to the parallel optimization setting. Namely we consider optimization algorithms interacting with a highly parallel gradient oracle, that is one that can answer poly(d) gradient queries in parallel. We show that in this case gradient descent is optimal only up to d^1/2 rounds of interactions with the oracle. The lower bound improves upon a decades old construction by Nemirovski which proves optimality only up to d^1/3 rounds (as recently observed by Balkanski and Singer), and the suboptimality of gradient descent after d^1/2 rounds was already observed by Duchi, Bartlett and Wainwright. In the latter regime we propose a new method with improved complexity, which we conjecture to be optimal. The analysis of this new method is based upon a generalized version of the recent results on optimal acceleration for highly smooth convex optimization.

1 - New Methods for Regularization Path Optimization via Differential Equations

Heyuan Liu, University of California, Berkeley, CA, 94720-1777, United States, heyuan_liu@berkeley.edu, Paul Grigas

We develop and analyze several different second order algorithms for computing an approximately optimal solution/regularization path of a parameterized convex optimization problem with smooth Hessian. Our algorithms are inspired by a differential equations perspective on the parametric solution path and do not rely on the specific structure of the regularizer. We present computational guarantees that bound the oracle complexity to achieve an approximately optimal solution path under different sets of smoothness assumptions and that also hold in the presence of approximate subproblem solutions.

2 - Binarization in Integer Programming and Nonlinear Programming

Robert Hildebrand, Virginia Tech, Blacksburg, VA, 24061, United States, rhil@vt.edu

We look at how converting variables to binary variables, either through a descritization trick or through a reformulation of integrality, can drastically improve a model. We will look at the theory behind these ideas and also some numerical results.

3 - Distributed Algorithms for Fair Packing and Covering Problems

Jelena Diakonikolas, UC Berkeley, Berkeley, CA, United States, Maryam Fazel, Lorenzo Orecchia
