

DYNAMIC RESPONSE APPROACH AND METHODOLOGY

Traditional seismic stability procedures

VS

coupled effective-stress approach.

Traditional seismic stability procedures:

- Empirical and laboratory corrections and simplified procedure to evaluate the potential for liquefactions of embankment and foundation soils-SPT, CPT or Vs based methods.
- Limit equilibrium stability analyses to evaluate post-earthquake stability.
- Newmark-type estimates of permanent deformation.

What Traditional Seismic Stability Assessment Give you and Can't Give you

- DO:
 - State-of-practice estimates of the potential for occurrence or non-occurrence of liquefaction during and at the end of strong earthquake shaking.
- DON'T:
 - model the progressive changes in the soil's state during earthquake shaking,
 - the potential for buildup of pore water pressure,
 - The occurrence of liquefaction,
 - The resulting permanent deformations during and after the earthquake

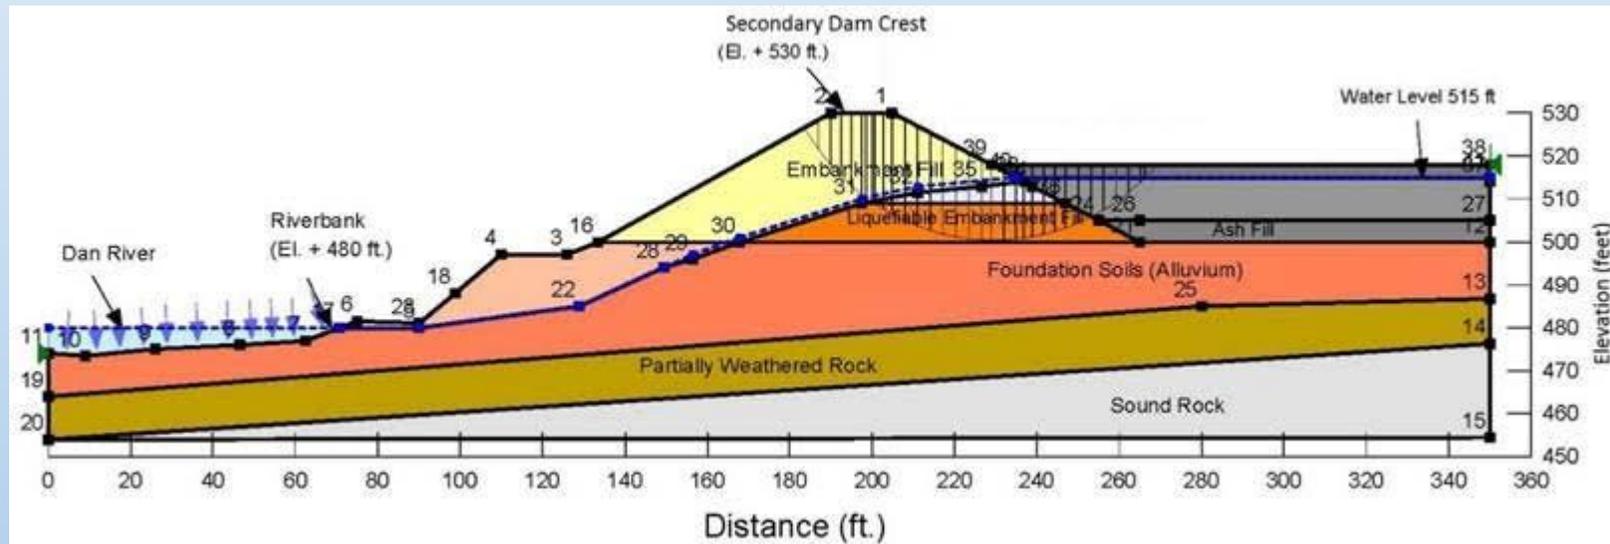

Coupled Effective-Stress Analysis of this Webinar

- To estimate the performance of the embankment during and after earthquakes
 - model the progressive changes in the soil's state during earthquake shaking,
 - the pore water pressure build up,
 - If liquefaction occurs or not,
 - The resulting permanent deformations during and after the earthquake

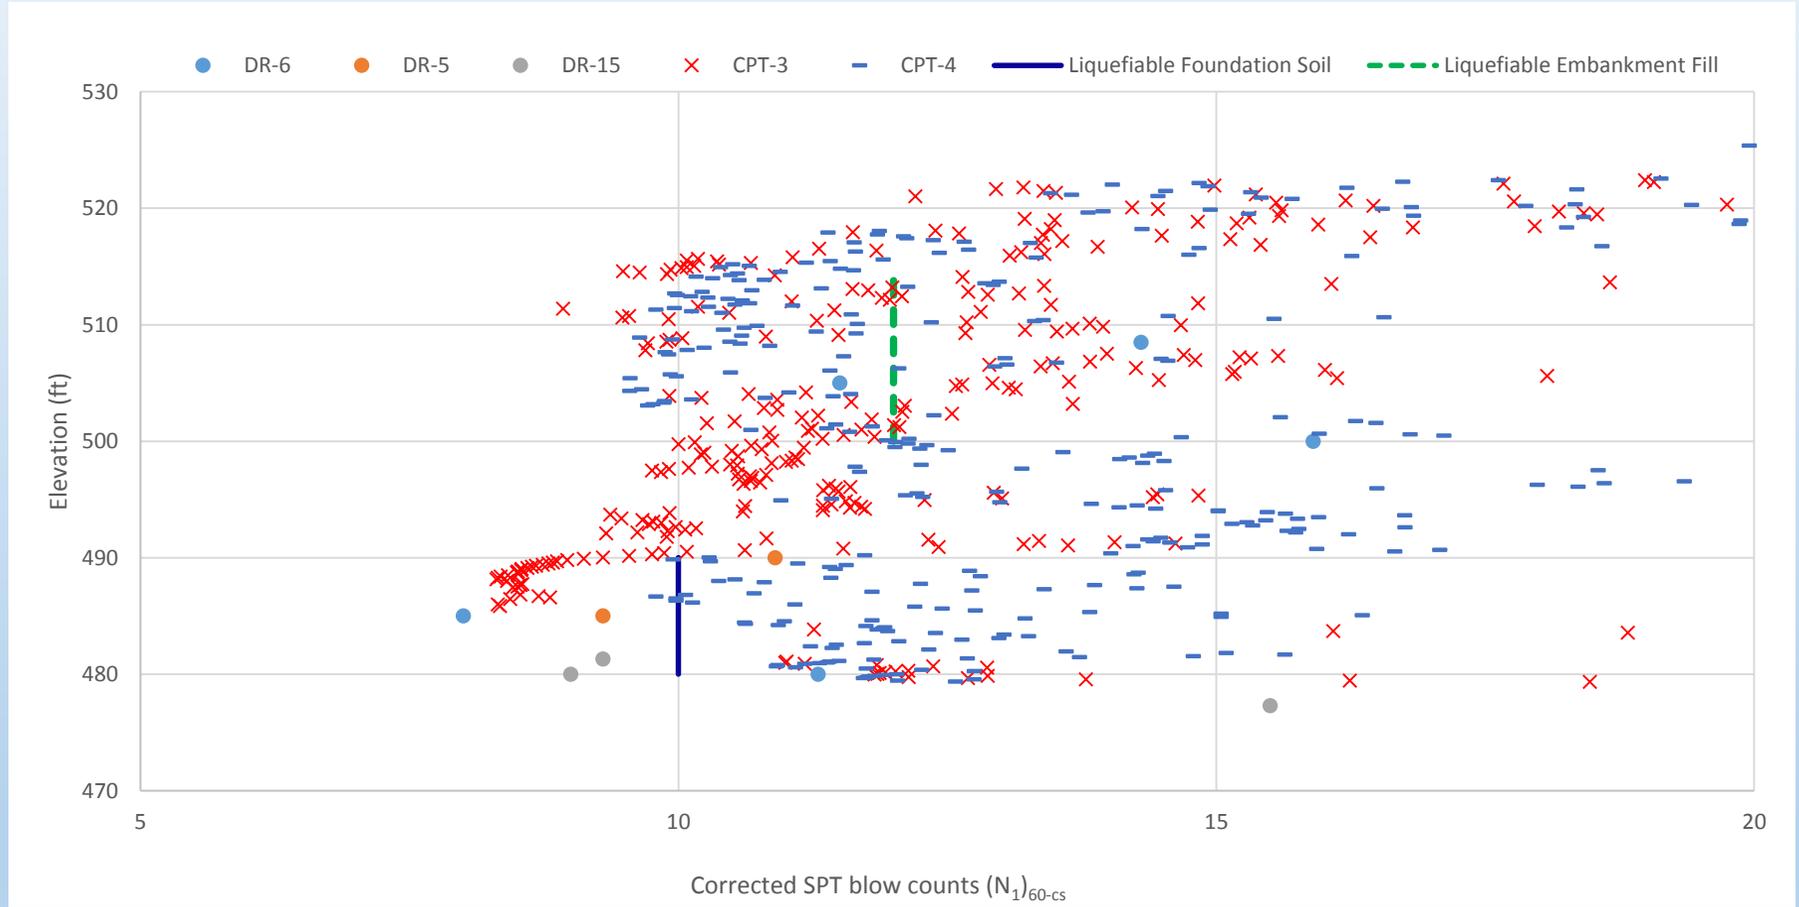

Problem Descriptions

- The pond is located along a river. Liquefaction screening results indicate that zones within the pond embankment are potentially susceptible to liquefaction based on the estimated seismicity for the design seismic event with a 2,475 year return period. The susceptible zones are composed of embankment fill at depths ranging from 15 to 30 feet below the ground surface.
- Preliminary post-earthquake limit equilibrium slope stability analyses based on the results of the screening level liquefaction analysis suggest that the part of the pond Dam do not meet the required slope stability factors of safety. To bring more insight into the liquefaction potential of the site materials and seismic stability of the embankment, more sophisticated nonlinear dynamic analyses are performed herein under the design level earthquake shaking.

Representative Section From Slope Stability Analysis with Liquefiable Embankment Layer.

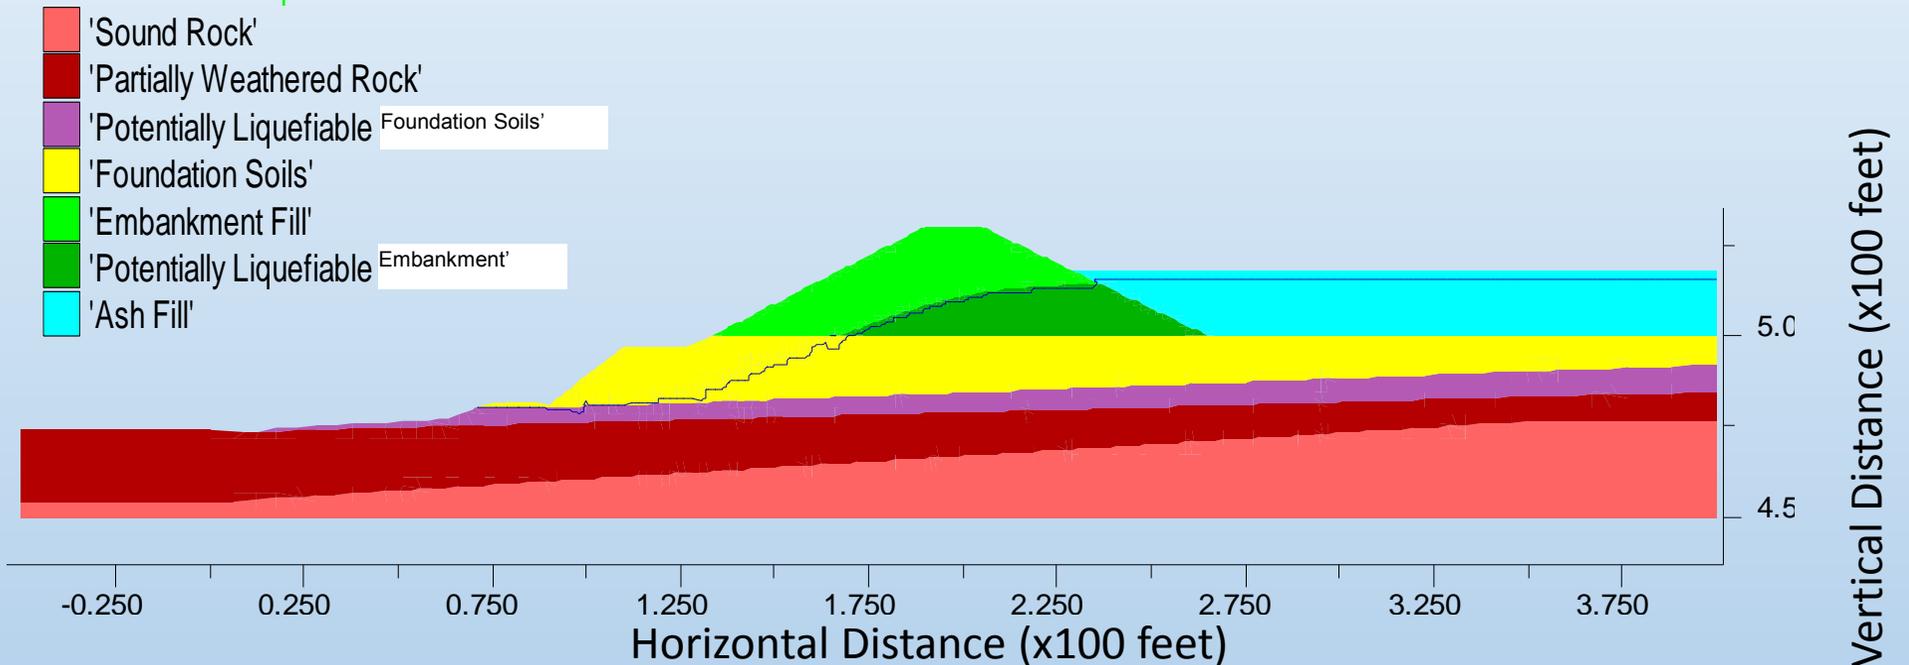

Relevant Soil Exploration Data

Potentially Liquefiable Soil Layers based on (N1)60:

— a liquefiable layer in the weathered rock was added and the slope of the weathered rock was revised

Steps of Coupled Effective-Stress Analysis

- Evaluation of initial static stresses
- Establishing phreatic surface using water table or through seepage analysis
- Switching nonlinear soil constitutive model to the liquefiable layers
- Obtaining earthquake input motion through site specific hazard analysis or building code
- Seismic runs and result processing

This Webinar Does not cover details of following

- Static initial stress state was established from a construction stage and phreatic surface was input as a water table based prior analysis.
- Three Earthquake records was obtained through a site specific hazard analysis but only one is used in this demonstration

Focus on Liquefaction

- Liquefaction: Liquefaction occurs when effective stresses become or close to zero due to generation of excess pore water pressure.
- For civil or geotechnical engineers, when we talk liquefaction, we mainly are talking about saturated cohesionless soil under short term loading such as earthquake when there is no time for the excess pore pressure to dissipate.

Consequences of liquefaction

- liquefied soil softens and loss its shear strength so potential large deformation could occur.
- For embankment of impoundment, when large deformation occurs due to liquefaction, dam could fail or lose its functionality.
- For structures, the foundation bearing capacity could be reduced to an extent to cause detrimental effects to the structure such as differential/large settlements, cracking, etc.

Key for Modeling Liquefaction

- The single most important task in liquefaction modeling is to capture the excess pore pressure reasonably accurate by the chosen soil constitutive model.
- Great effort has been spent in this area for many years by academia and engineers. The available models are UBCSand, URS Model, PM4Sand (UC Davis), WangCS (Amec Foster Wheeler) among others.
- The first two are models modified from the Mohr-Coulomb model and the last two are models developed using bounding surface plasticity theory. UBCSand is the first and only one available for Midas users at this time.

1. UBC Sand Model

- An effective stress model for predicting liquefaction behavior of sand under seismic loading.
- GTSNX Liquefaction Model is extended to a full 3D implementation of the modified UBCSAND model using **implicit method**.

▪ Nonlinear Elastic:

- Exponential function per effective pressure

$$G^e = K_G^e p_{ref} \left(\frac{p' + p_t}{p_{ref}} \right)^{ne}$$

▪ Plasticity / Shear

- Yield function : Mohr – Coulomb
- Flow rule : Menetrey-Willam (non-associated)
- Hardening behavior : Hyperbolic hardening

$$\Delta \sin \phi_m = \frac{G^p}{p'} \Delta \kappa_s = K_G^p \left(\frac{p'}{p_{ref}} \right)^{np-1} \left\{ 1 - \left(\frac{\sin \phi_m}{\sin \phi_p} \right) R_f \right\}^2 \Delta \kappa_s$$

$$\Delta \kappa_s = |\Delta \varepsilon_1^p - \Delta \varepsilon_3^p|$$

▪ Plasticity / Compression (cap)

- Yield function : Modified Mohr-Coulomb Cap

$$f_2 = (p + \Delta p)^2 + \alpha \left(\frac{q}{R_2(\theta)} \right)^2 - p_c^2 = 0$$

- Flow rule : Same with yield function (Associated flow)
- Hardening behavior : Hardening of allowable compression per volumetric strain

$$\Delta p_c = K_B^p p_{ref} \left(\frac{p'}{p_{ref}} \right)^{mp} \Delta \varepsilon_v^p$$

▪ Plasticity / Pressure cut-off

- Yield function & Flow rule

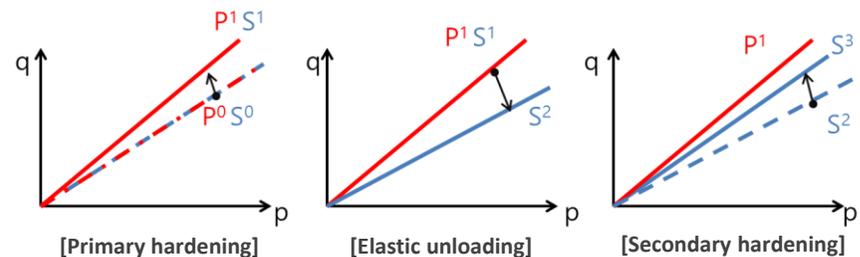

$$f_{pr} = p_{cut} - p'$$

- No Hardening behavior

▪ Cyclic loading behavior

- Consider Shear, Plasticity function for primary and secondary yield surface respectively → Check difference of hardening behavior
- Primary yield surface: In case that the current stress ratio (or mobilized friction angle) reach to the critical (MAX) state of the material
- Secondary yield surface: In case that the current stress ratio is smaller than the critical (MAX) state of the material according to the unloading/reloading conditions
- Secondary hardening (Soil Densification)

$$\Delta \sin \phi_m = K_{G,2}^p \left(\frac{p'}{p_{ref}} \right)^{np-1} \left\{ 1 - \left(\frac{\sin \phi_m}{\sin \phi_p} \right) R_f \right\}^2 \Delta \kappa_s, \quad K_{G,2}^p = K_G^p \left(4 + \frac{n-1}{2} \right) F_{dens}$$

UBC Sand Model Parameters

- Additional parameters to simulate liquefaction
- Estimation of each parameter using Standard Penetration Test (SPT) - $((N_1)_{60})$: Equivalent SPT blow count for clean sand.

Parameter	Description	Reference
Pref	Reference Pressure	In-situ horizontal stress at mid-level of soil layer
Elastic (Power Law)		
K_G^e	Elastic shear modulus number	Dimensionless
ne	Elastic shear modulus exponent	Dimensionless
Plastic / Shear		
ϕ_p	Peak Friction Angle	Failure parameter as in MC model
ϕ_{cv}	Constant Volume Friction Angle	-
C	Cohesion	Failure parameter as in MC model
K_G^p	Plastic shear modulus number	Dimensionless
np	Plastic shear modulus exponent	Dimensionless
R_f	Failure ratio (qf / qa)	0.7~0.98 (< 1), decreases with increasing relative density
F_{post}	Post Liquefaction Calibration Factor	Residual shear modulus
F_{dens}	Soil Densification Calibration Factor	Cyclic Behavior
Advanced parameters		
Pcut	Plastic/Pressure Cutoff (Tensile Strength)	-
K_B^p	Cap Bulk Modulus Number	-
mp	Plastic Cap Modulus Exponent	-
OCR	Over Consolidation Ratio	Normal stress / Pre-overburden pressure

$$K_G^e = 21.7 \times 20.0 \times (N_1)_{60}^{0.333}$$

$$30^0 < \phi_{cv} < 34^0$$

$$\nu = 0.0163$$

$$K_G^p = K_G^e (N_1)_{60}^2 \times 0.003 + 100.0$$

$$ne = 0.5$$

$$np = 0.4$$

$$\phi_p = \begin{cases} \phi_{cv} + (N_1)_{60} / 10.0 & ((N_1)_{60} < 15.0) \\ \phi_{cv} + (N_1)_{60} / 10.0 + \max\left(0.0, \frac{(N_1)_{60} - 15}{5}\right) & ((N_1)_{60} \geq 15.0) \end{cases}$$

$$R_f = 1.1 \times (N_1)_{60}^{-0.15}$$

Bounding Surface Plasticity Wang Model

(a) Surfaces and stress variables in J-p plane

(b) Surfaces and stress variables in $p = \text{constant}$ plane

Wang Critical State Model

Wang captures most of cohesionless soil behaviors under complex loading such as cyclic. Two simple observations (the UBCSand-Slide 14 can't capture): pore pressure build-up during unloading phase; and dilation when loading beyond the phase transformation line.

UBC Sand Post Processing – Liquefiable Area or Pore Pressure Ratio or Ru

- Specific results which can check the liquefiable area directly
- Two types of results are available to measure the possibility of liquefaction.

▪ Pore Pressure Ratio (PPR)

- The ratio of excessive pore pressure change and the initial effective pressure

$$PPR = -\frac{\Delta p_w}{p_{init}} = \frac{p_{init} - p_{current}}{p_{init}}$$

Δp_w	Excessive Pore Pressure Change
p_{init}	Initial Effective Pressure
$p_{current}$	Current Effective Pressure

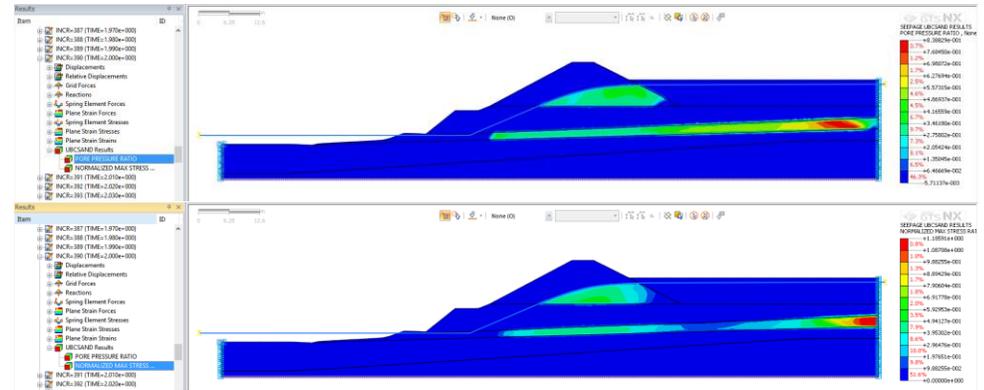

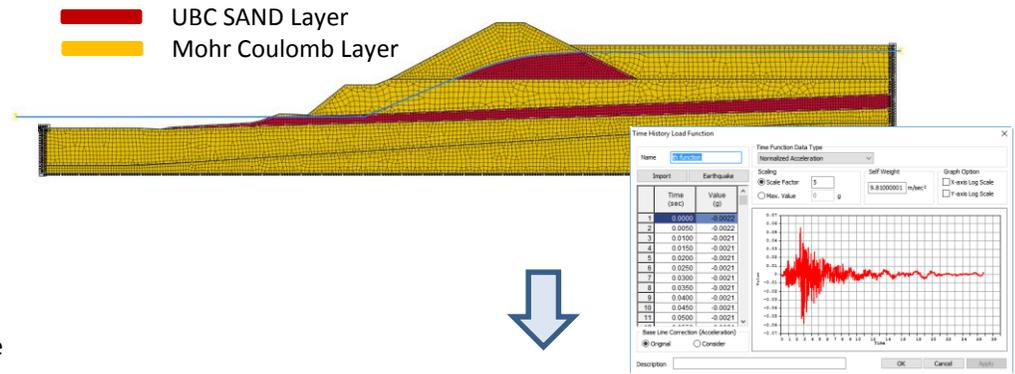

▪ Normalized Max Stress Ratio

- The ratio of mobilized friction angle and the peak friction angle
- When the Max stress ratio is reached, the mobilized friction angle is close to the peak friction angle, liquefaction is triggered (1 = Liquefaction)

$\max \left(\frac{\sin \phi_m}{\sin \phi_p} \right)$	ϕ_m	Mobilized Friction Angle
	ϕ_p	Peak Friction Angle

Analysis options

(Large deformation,
Excessive Pore Water Pressure,
Post-Processing)

- 1) Damper
- 2) Free Field (Infinite boundary, Absorbent boundary)

1) Damper (Mesh > Element > Create > Other > Ground Surface Spring)

- The viscous boundary element required as a model boundary condition for time history analysis.
- The viscous boundary element can be created from the following steps.

1. Compute C_p , C_s : C_p , C_s can be calculated using the equation below.

$$C_p = \rho \cdot A \cdot \sqrt{\frac{\lambda + 2G}{\rho}} = W \cdot A \cdot \sqrt{\frac{\lambda + 2G}{W \cdot 9.81}} = c_p \cdot A$$

$$C_s = \rho \cdot A \cdot \sqrt{\frac{G}{\rho}} = W \cdot A \cdot \sqrt{\frac{G}{W \cdot 9.81}} = c_s \cdot A$$

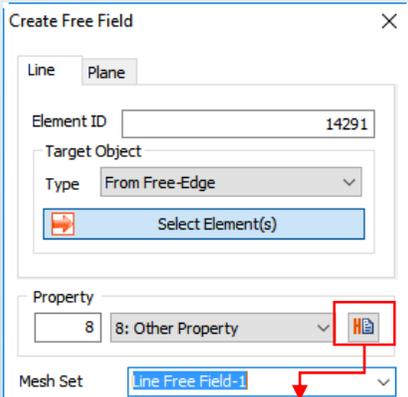

$$\lambda = \frac{v \cdot E}{(1 + v)(1 - 2v)} \quad G = \frac{E}{2(1 + v)}$$

λ : Bulk modulus, G : Shear modulus, E : Elastic modulus, v : Poisson's ratio, A : Cross-section area

2. The cross-section area is automatically considered until the surface spring is created, so only the C_p , C_s needs to be computed. When creating the viscous boundary element automatically, the spring is automatically created by considering the element area (effective length*unit width) as shown below. Input the C_p value for the normal direction coefficient at the point of spring creation and input the C_s value for the parallel direction.

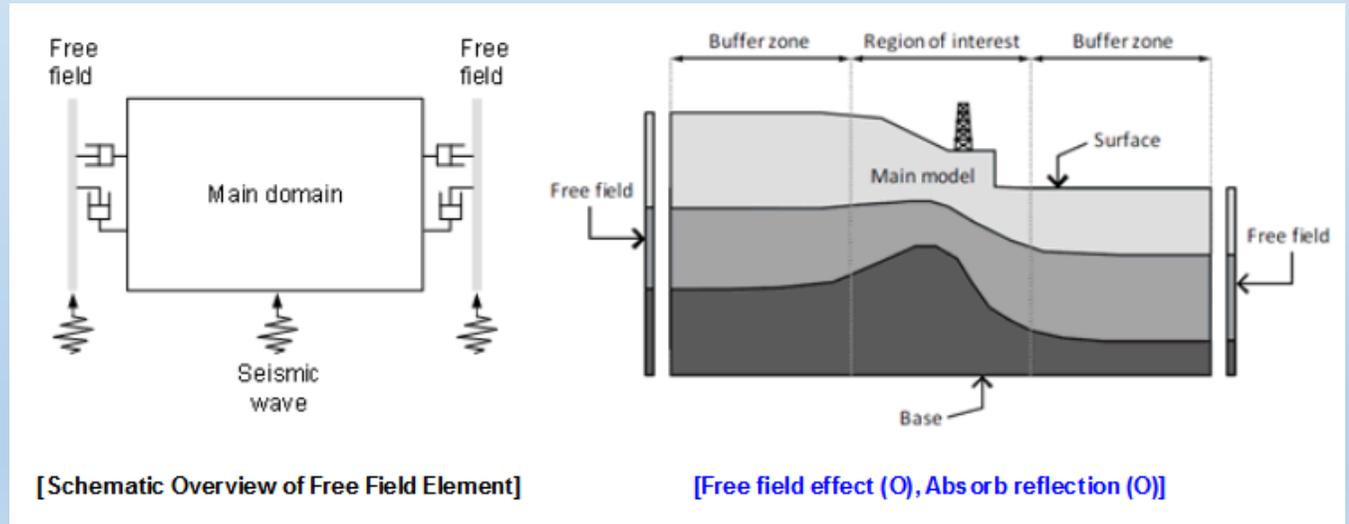

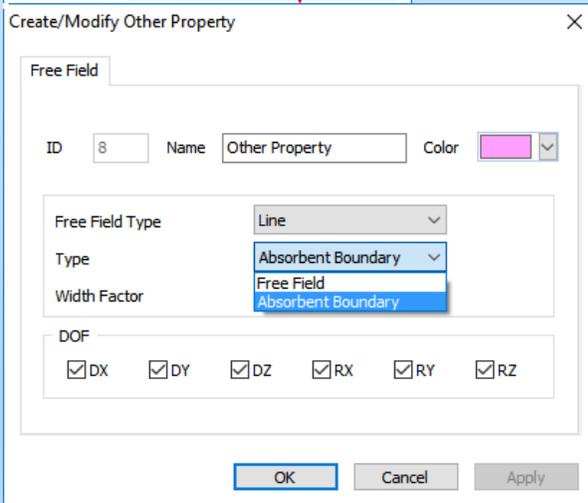

- 1) Damper
- 2) Free Field (Infinite boundary, Absorbent boundary)

2) Free Field (Mesh > Element > Free Field)

For the seismic analysis, users need to model infinite ground to eliminate the boundary effect caused by reflection wave. Since it is not possible to model infinite ground, users can apply Free Field Element at the boundary.

Absorbent Boundary : Enable to eliminate reflection wave at the ground boundary
Width Factor (Penalty Parameter) : In order to minimize the size effect of the model, users have to input more than 10^4 , This value will be multiplied by model width (In case of 2D, this is plain strain thickness (unit width)).

Case Study

(Tailings Pond Embankment Seismic Stability – Excess Pore Pressure and Permanent Displacement using FLAC and GTSNX)

1. The FLAC Model.

One of the difficulty of using FLAC is the creating of the most appropriate grid for the problem such as more zone density at the highly deformed location of the liquefiable layer.

Constitutive Models in FLAC

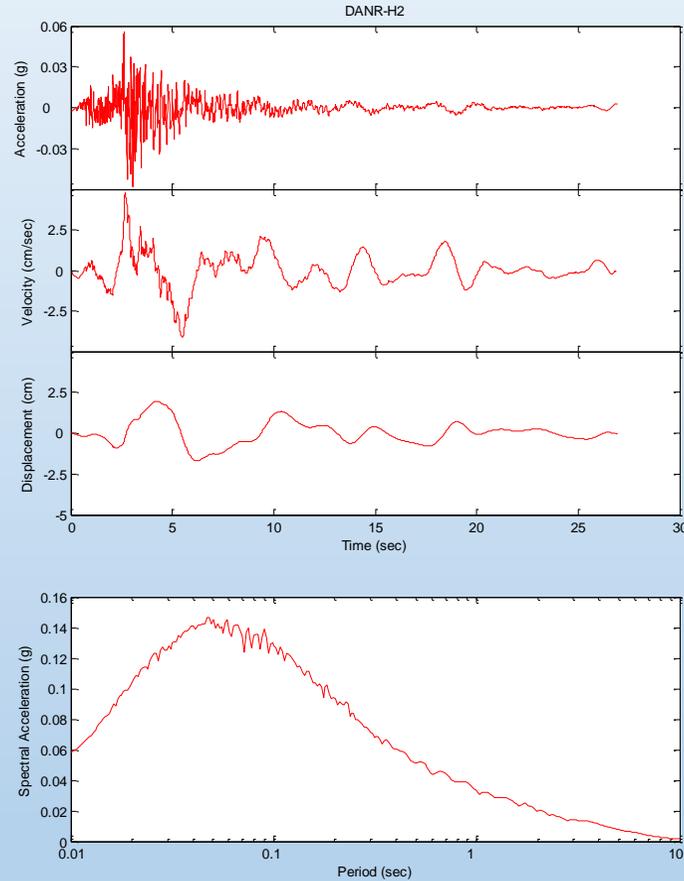

- FLAC built in – Finn model
- User defined dlls: UBCSand, Wang model, PM4Sand among others.
- The one used for this project: Wang bounding surface plasticity model

Wang Model Parameters: Most of them have clear physical meaning and can be calibrated from routine lab and/or field tests

Material Description	Friction Angle	G_0	h_r	d	kr	fp	bc	ein	Poisson
	ϕ (deg)								
Potentially Liquefiable (i.e., Saturated) Embankment Fill	31	380	0.25	2.5	0.5	0.75	2	0.65	0.4
Potentially Liquefiable Foundation Soils (Alluvium)	34	150	0.08	1.2	0.5	0.75	2	0.78	0.4

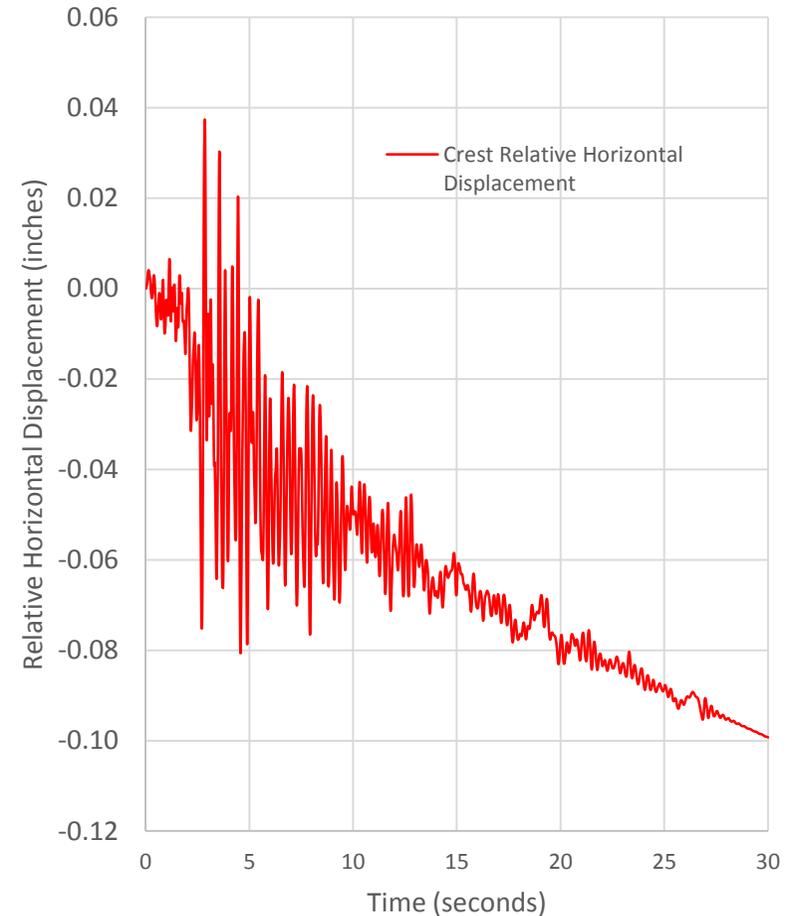

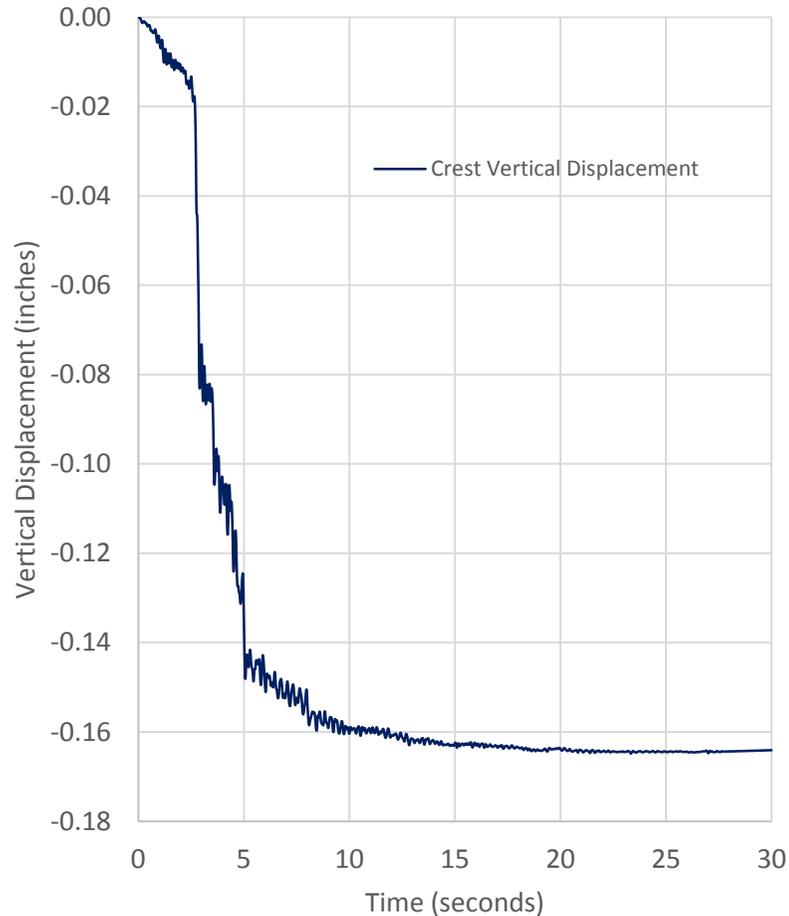

Input Earthquake Record:

PGA=0.055g. Three earthquake records were obtained from a site specific hazard analysis but for this presentation only the short duration record is used.

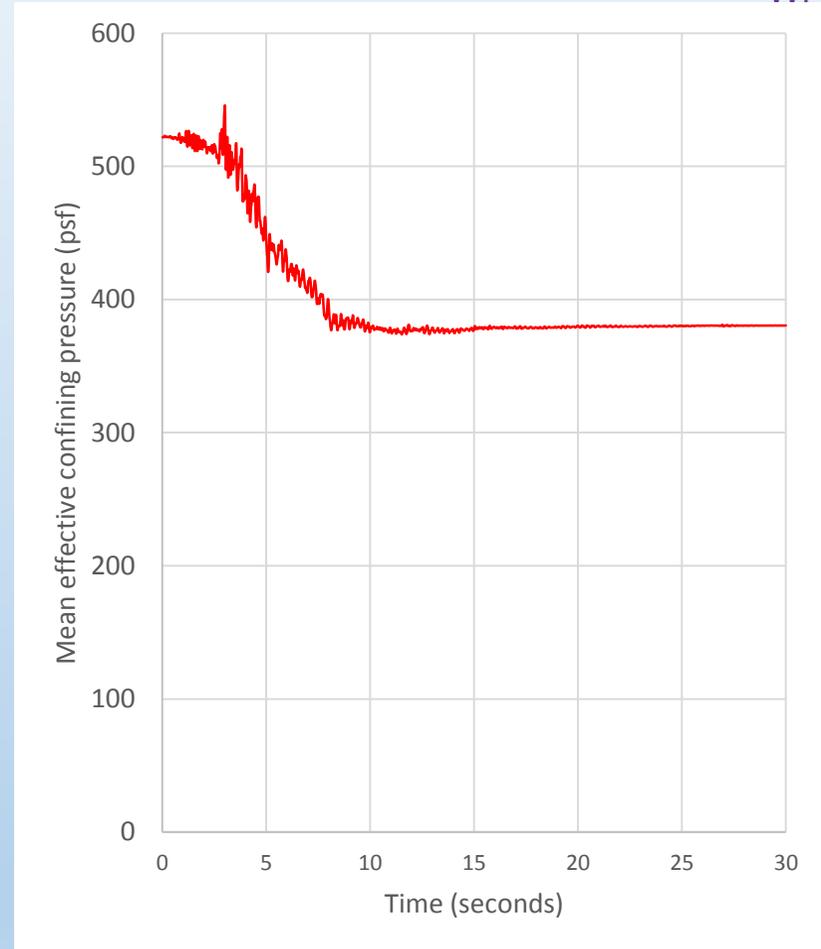

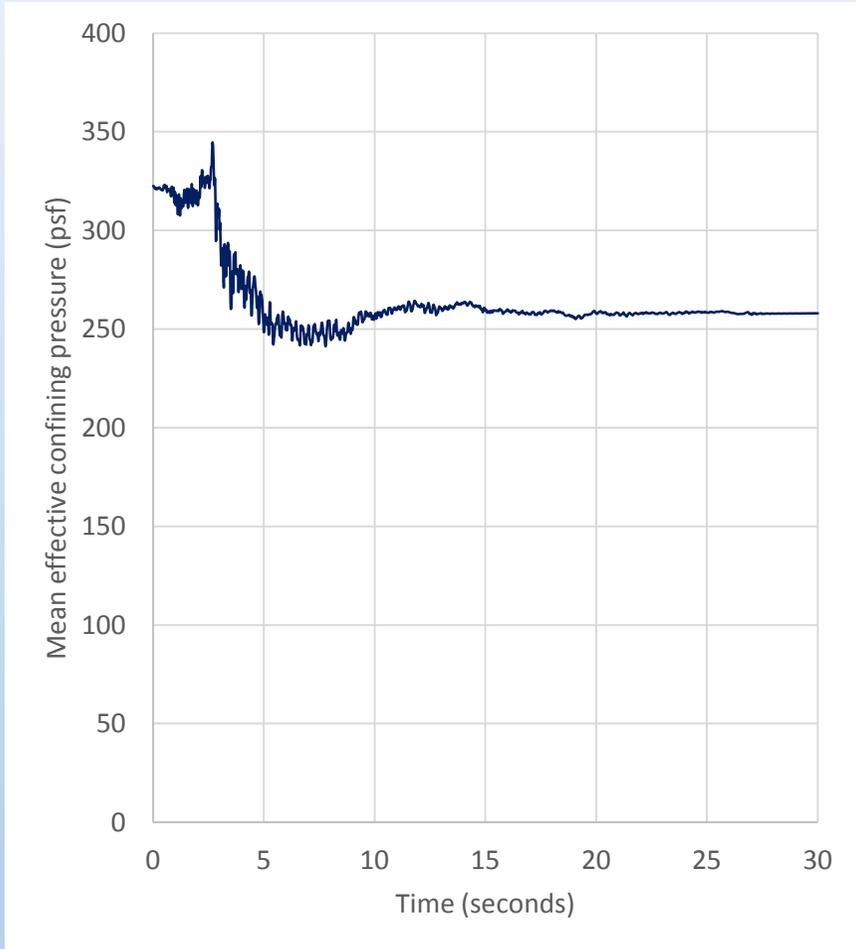

Dam Crest Displacement Histories

Negative sign for the horizontal direction indicates toward the downstream side; and negative sign for the vertical direction indicates settlement.

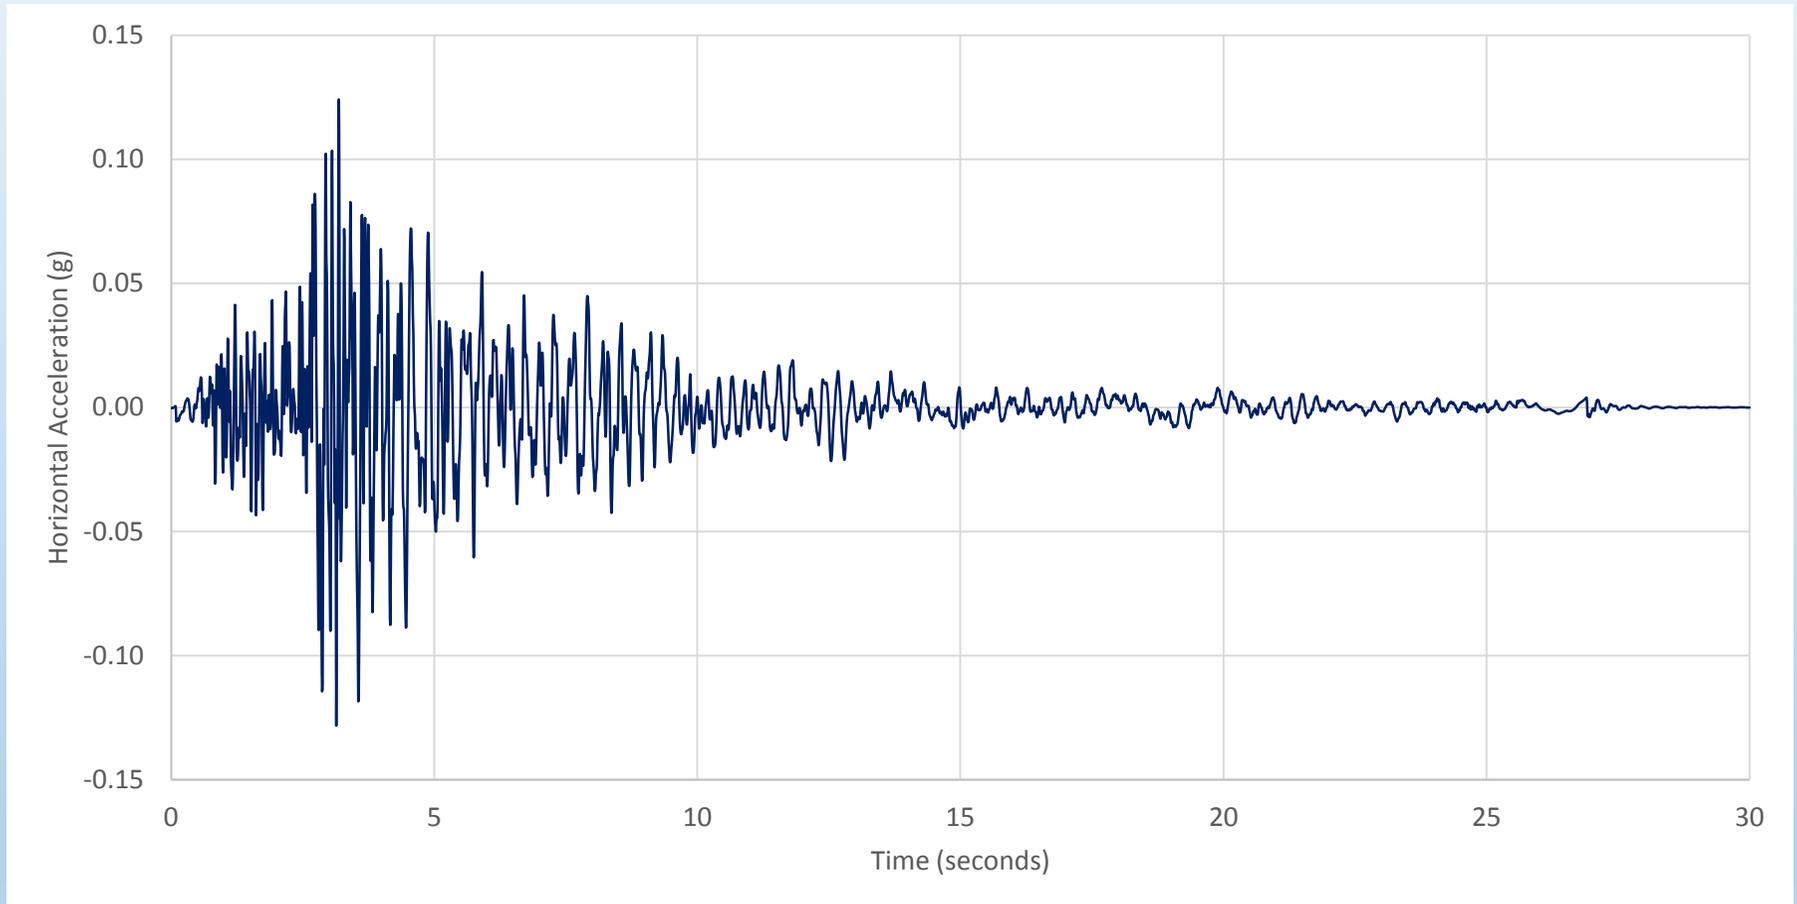

Mean Effective Confining Pressure P Histories: P reduced some but not close to liquefaction when P should be close to zero (0).

Left figure is for a zone near the downstream toe in the liquefiable foundation layer; and right figure is for a zone in the liquefiable embankment about 30 ft horizontally from the Upstream crest edge and 20 ft below the crest.

Dam Crest Horizontal Acceleration:
the input acceleration (slide 32) was amplified more than two times

Result Summary

- Dam embankment experience some shake but with very limit permanent displacements
- Some excess pore pressure generated in the liquefiable foundation and embankment layers but not enough to cause liquefaction
- This result seems reasonable as the input motion has a pga of 0.055g only
