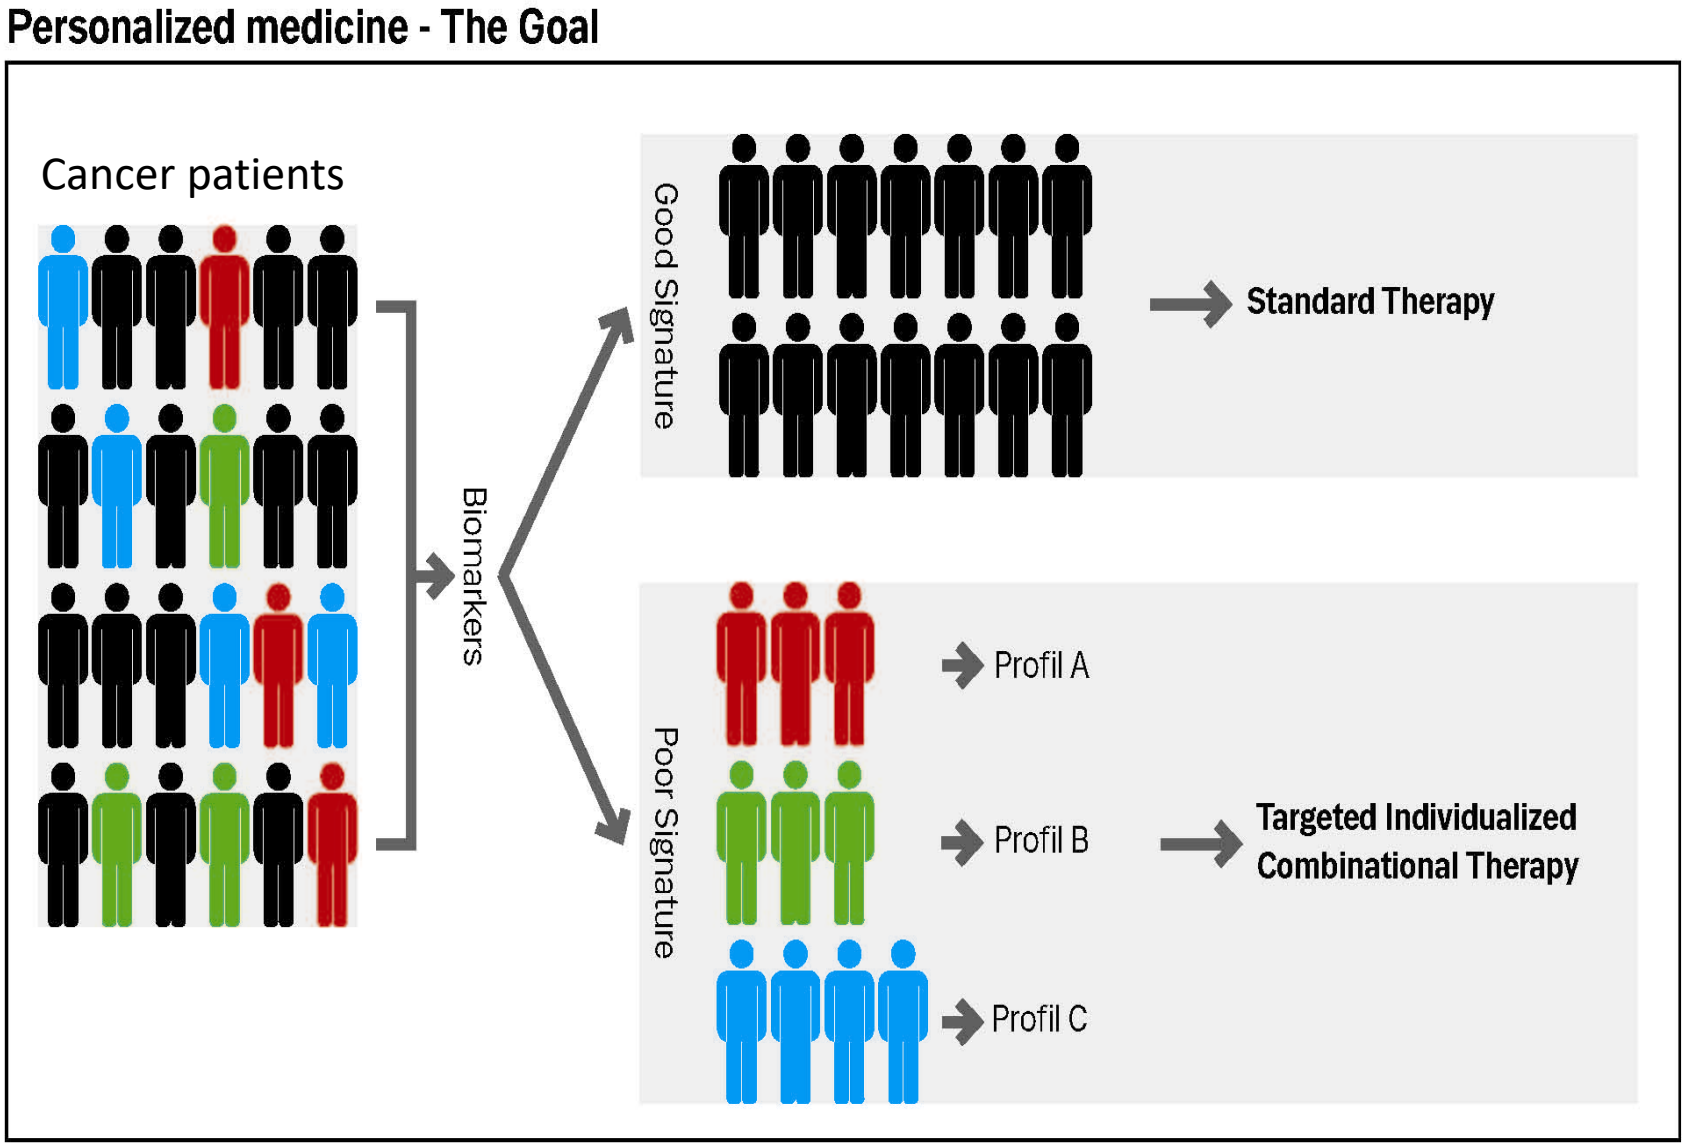
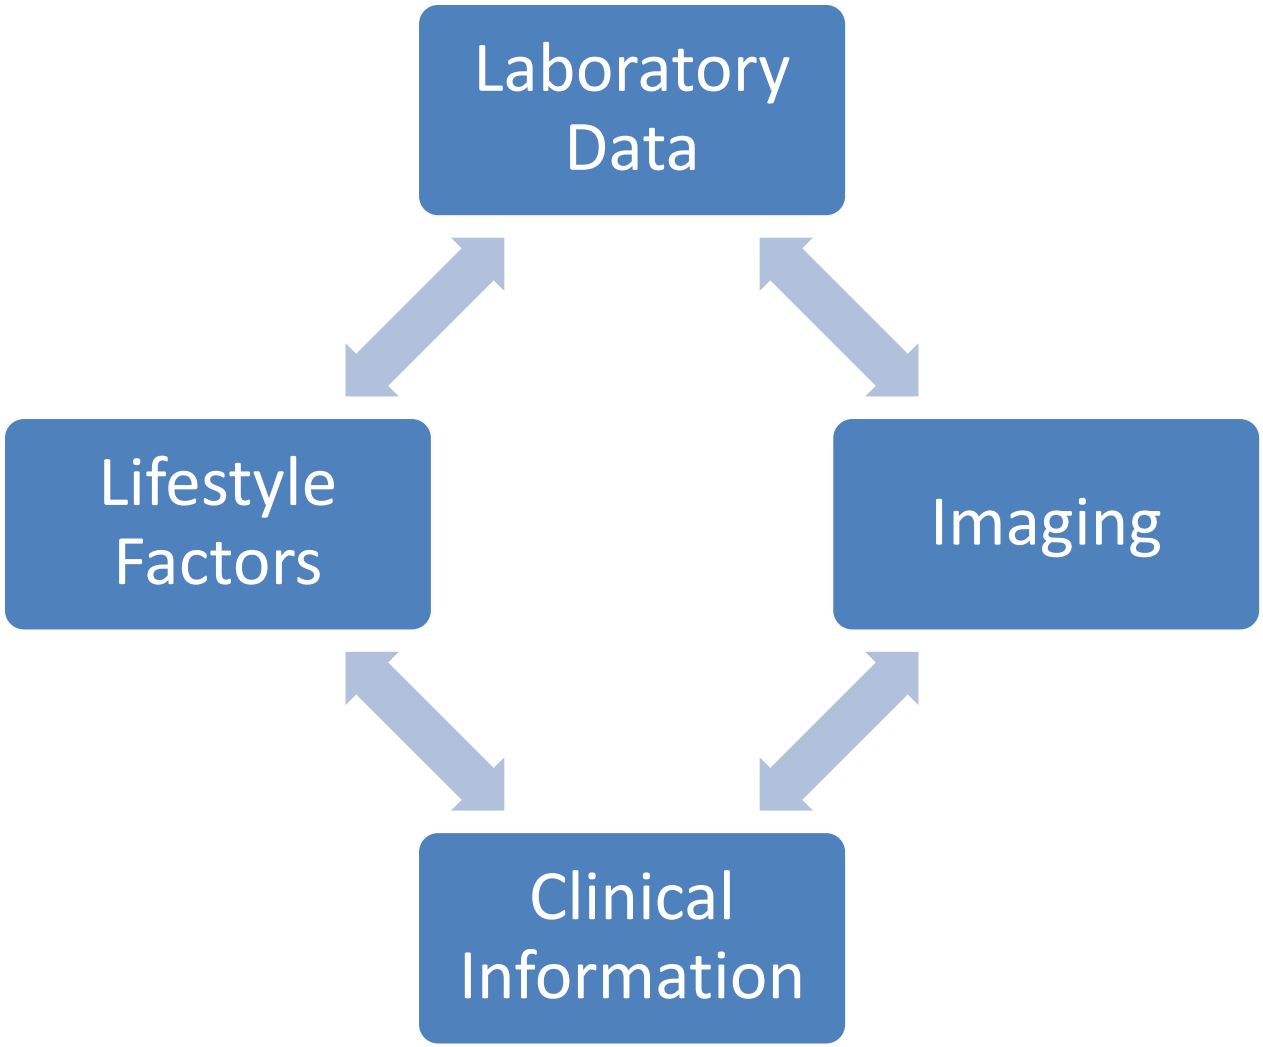
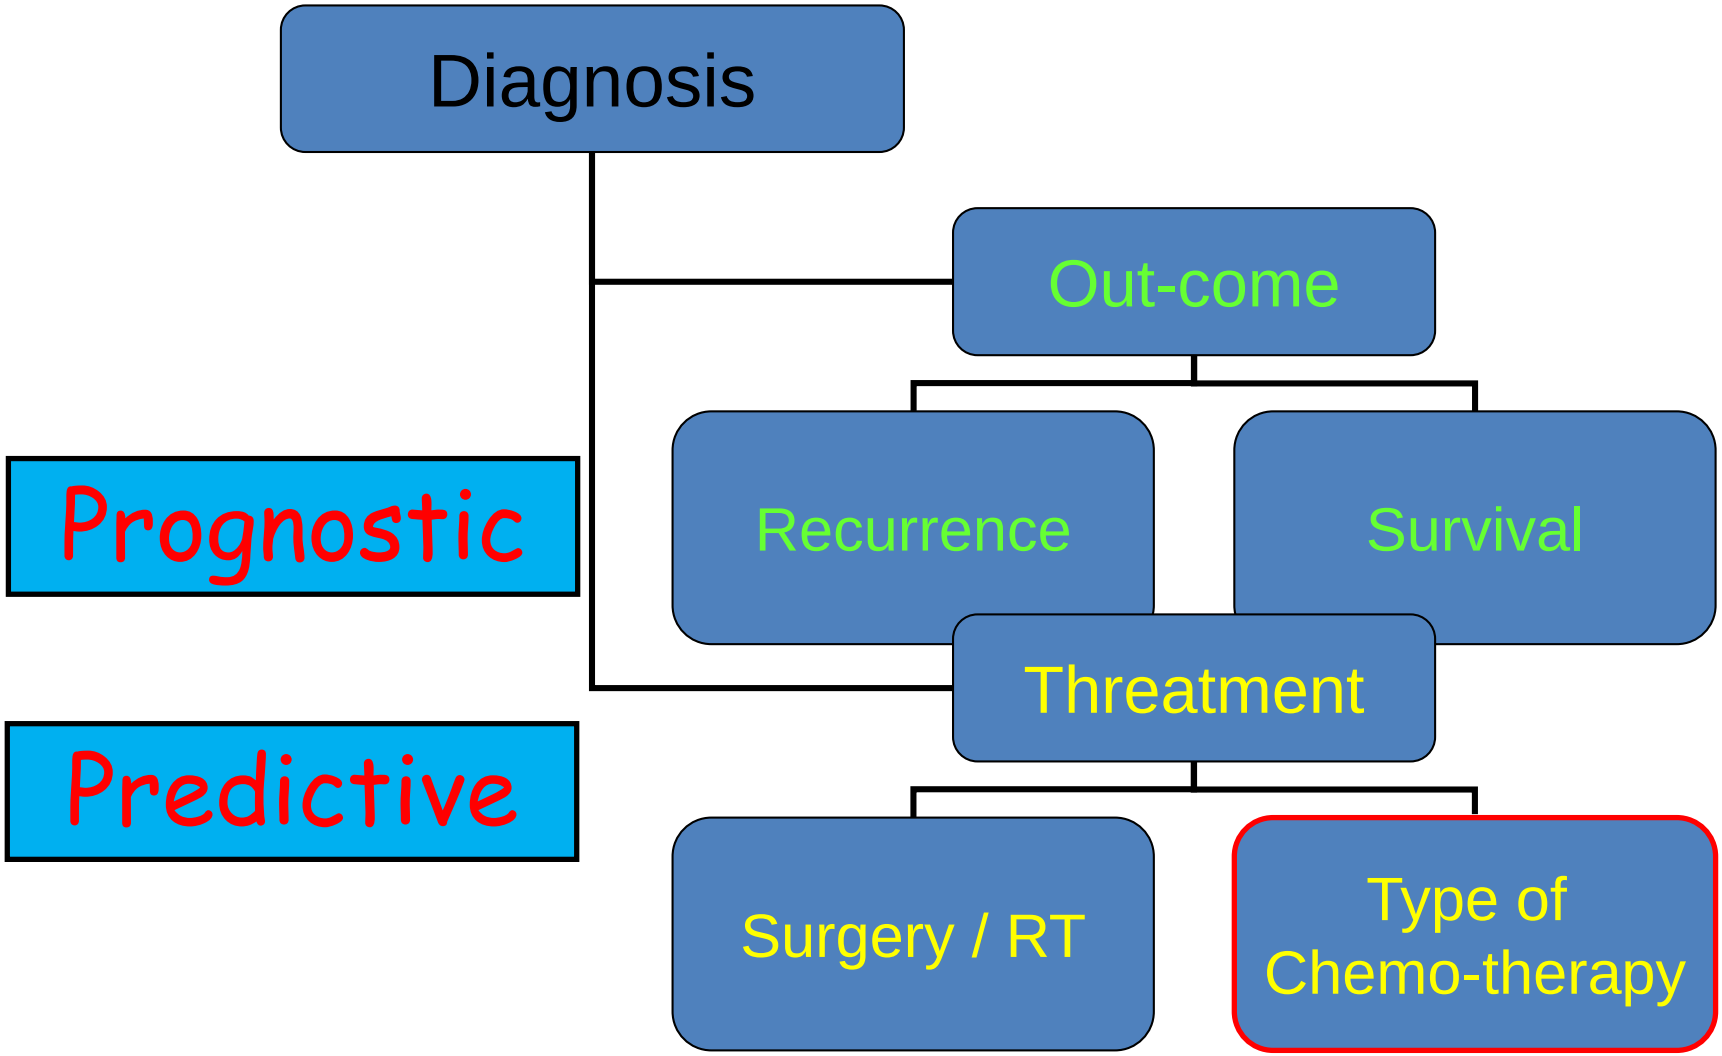
What should be obtained?



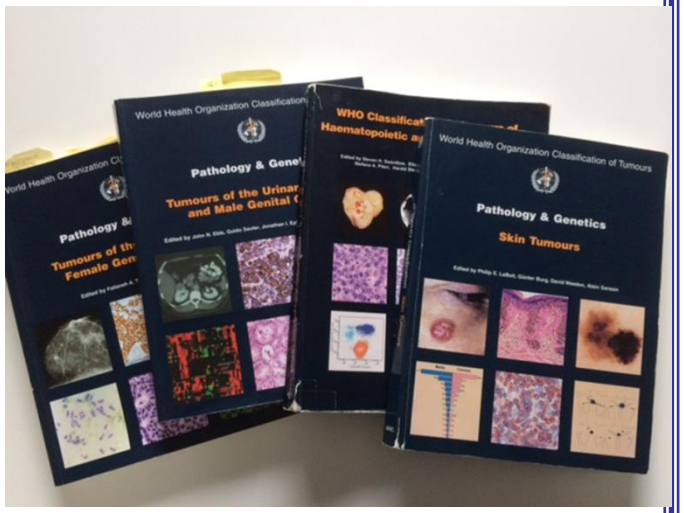
Do what is needed at the right time



Biomarkers may be used for



Herlev og Gentofte Hospital
Molecular Unit
Department of Pathology
Herlev and Gentofte University Hospital
Denmark



Vision for our Pathology Department is: "Best possible pathology answer for the benefit of the patient“

Meaning that evidence-based results for current and future disease classifications (WHO) should be performed.

Laboratory analyses should support patient progress:

1. Diagnosis (Guideline - evidens) – selected biomarkers analyses:

Standard treatment/Trials

Predictive/Prognostic

2. Experimental treatment – global biomarker analyses:

No evidens based treatment

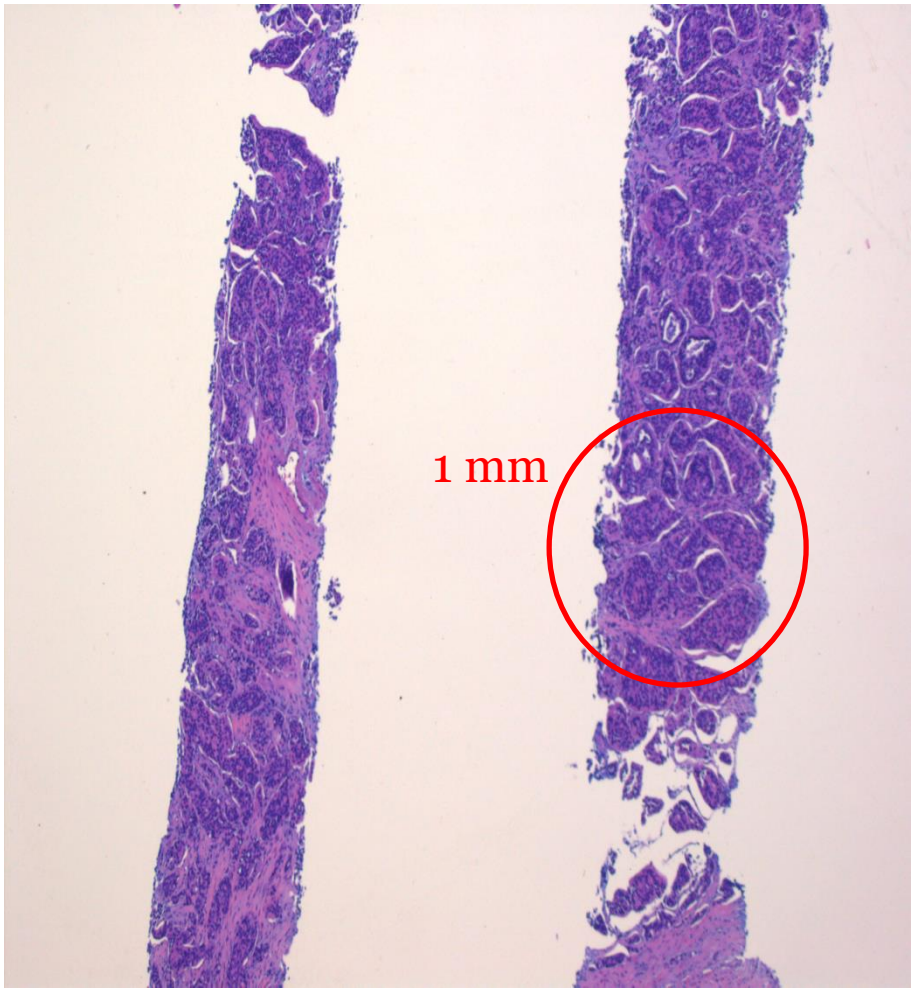
Today: Material for molecular analyses at Pathology

Tissue slide

Stained needle biopsy – H&E stained



Future: Biobank material, crude tissue verified by pathologists – high quality DNA/RNA

Sequencing reactions in pathology for molecular carachterization

Samples with:

Colorectal cancer - KRAS, NRAS, BRAF, PIK3Ca (Cetuximab/ Panitumumab)

Gastrointestinal sarcoma tumors - c-KIT, PDGFa, KRAS, NRAS, BRAF, PIK3Ca (Imatinib)

Malignant melanoma – BRAF (Dabrafenib + Trametinib (MEK-inhibitor)

Lung cancer – EGFR (Erlotinib)

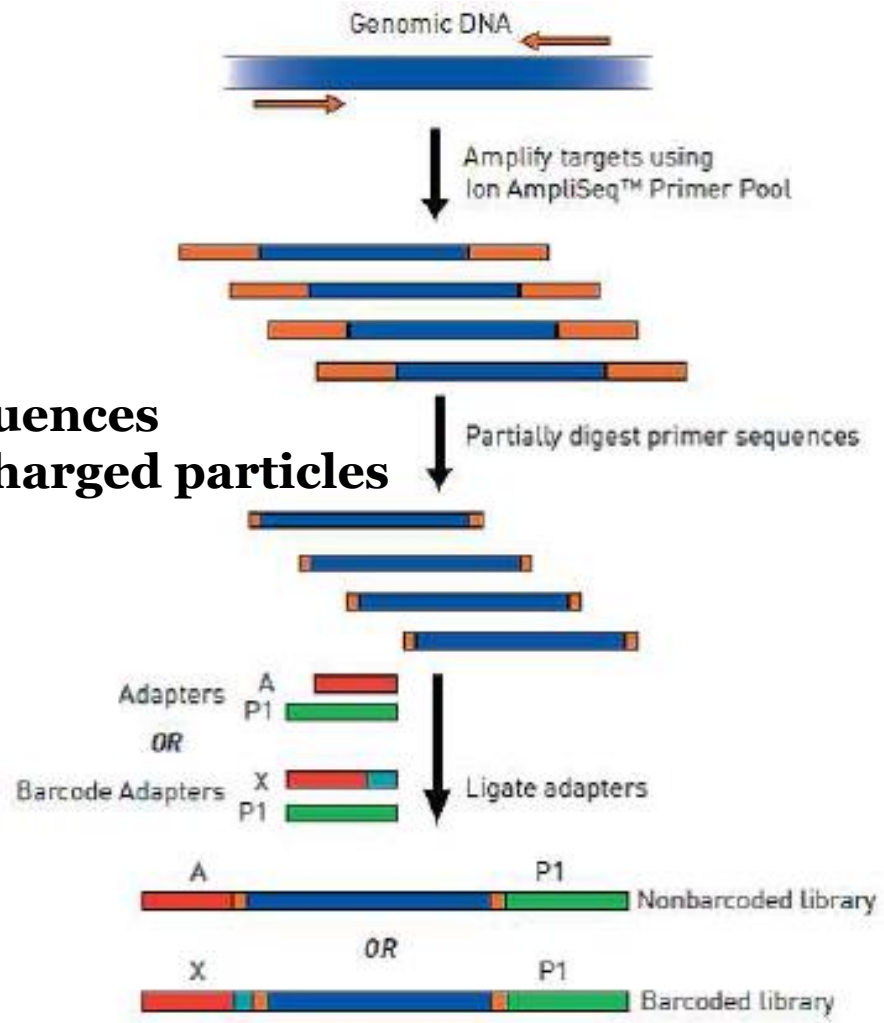
Ovarian cancer – BRCA1/2 (Olaparib)

More to come

for possible standardized evidence-based treatment

Library Preparation

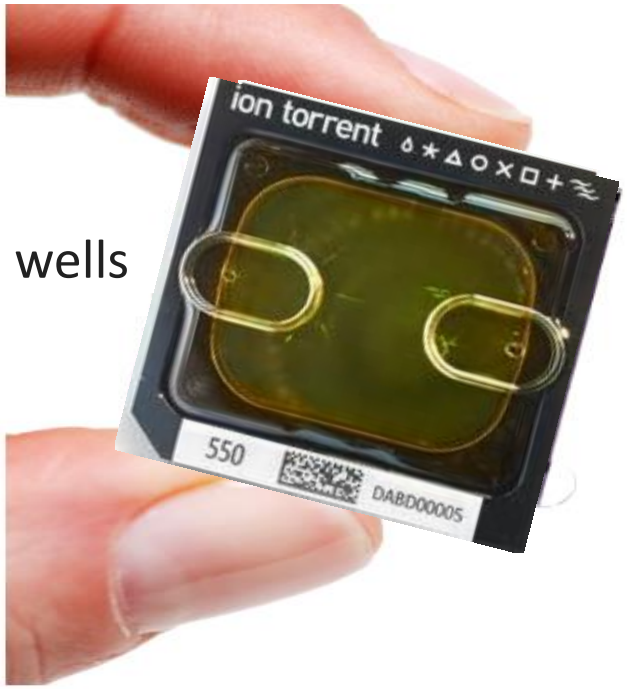
1. **Purification of DNA**
2. **Construction of library**
3. **Amplification of all sequences**
4. **Isolation of positively charged particles**
5. **Sequencing reaction**



Barcode

NGS

154 million wells



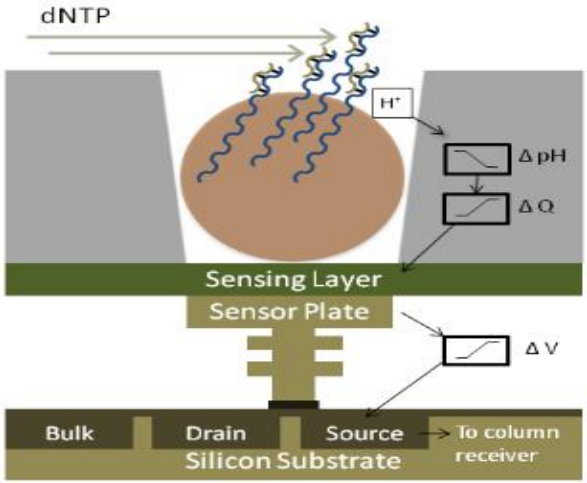


Figure 2. Schematic cross-section of a single well of an Ion Torrent sequencing chip. The well houses Ion Sphere™ particles containing DNA template. When a nucleotide incorporates, a proton releases and the pH of the well changes. A sensing layer detects the chage in pH and translates the chemical signal to a digital signal.

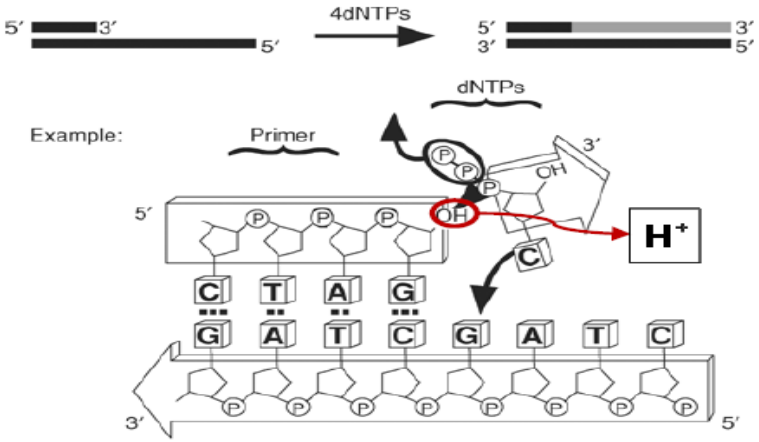

Chemical change (H+) are translated into a digital signal

Our throughput and the request for fast answers enhanced and we therefore perform NGS (panels and exome) twice a week on larger chips

Flowcytometri
01: ggg

PCR-undersøgelse
01: KRXXXX - 15hehXXXXXX
Der er Fundet BRAF mutation (c.1799T>A, p.V600E)
Der er ikke fundet KRAS eller NRAS mutation, altså har patienten vildtype KRAS og NRAS gener i det undersøgte materiale.
Mutationer med ukendt behandlings indikation:
PIK3CA mutation (c.1173A>G, p.I391M) I exon 7.
Mutationsanalysen er foretaget med Next Generation Sequencing (NGS) af KRAS genet (codon 1-189), NRAS genet (codon 1-189), BRAF genet (codon 1-664 og 669-766), PIK3CA genet (codon 1-1068), AKT1 genet (1-131, 146-384, 392-480) samt PTEN (1-267 og 271-403), disse sekventeres og rapporteres. Da behandlingskonsekvensen ikke kendes for generne TP53, ARID1A, TGFBR2, MLH1, CTNNB1, SMAD2, MSH2, MSH6, EGFR FAM123B, ATM, APC, MET, FBXW7 og CASP8 rapporters disse ikke. Ved behov for databehandling og rapportering af disse gener kan molekylærenheden Herlev patologiafdeling kontaktes.
Databehandling af individuel genetisk variation besvares på baggrund af ratio, samt varians coverage mod reference coverage.
Bemærkning: LabID: KR1222, polymorfismer angives ikke.

Present analysis flow

Colorectal cancer:

Oncomine™ Focus Assay (DNA) +MSI

to consider: MSI high+BRAF WT then Oncomine Focus or Archer (RNA): fusion - NTRK

GIST:

NGS11G (all coding sequence) + Sanger:

c-KIT, PDGFRA, NF1, BRAF, KRAS, NRAS, PIK3CA, PTEN, SDHB, SDHC, SDHD

If WT in c-KIT, PDGFRA then Oncomine™ Focus Assay (RNA): fusion - NTRK

Malignant melanoma:

Oncomine™ Focus Asay (BRAF)

Ovarian:

BRCA1/2 (all coding sequence) + Oncomine™ Comprehensive + HRR*

to consider HRD (HRR+ WGA)

Breast:

BRCA1/2 (all coding sequence) + Oncomine™ Comprehensive

to consider HRD (HRR+ WGA)

Prostate:

BRCA1/2 (all coding sequence) + Oncomine™ Comprehensive

*HRR: ATM, BRAD1, BRIP1, CDK12, CHEK1, CHEK2, FANCL, PALB2, RAD51B, RAD51C, RAD51D og RAD54L

Up-comming analysis flow

Clonality, hyper mutation:

IGHV-PGM – demand high quality DNA. No commercial software

Lymphome:

Costumer designed panel

Breast cancer:

PIK3Ca (SOLE study)

SOLE:
About 40% of samples with HR+ breast cancer have PIK3CA mutations, activating the PI3 kinase pathway leading to cancer progression and resistance to endocrine therapy. Alpelisib (BYL719) is an oral PI3K inhibitor that is alpha specific. “The alpha isoform of PI3-kinase is the one that is mutated in breast cancer.

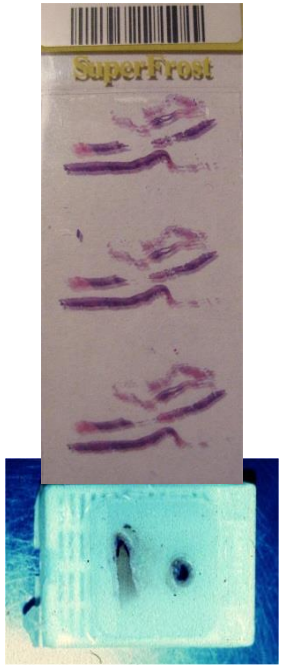
Cholangio carcinoma:

HER2 and BRCA1/2

Oncomine™ Focus Assay (RNA) or Archer: fusion – FGFR2 – validation trial

Pancreatic cancer:

HER2, MSI and BRCA ½ +HRR (POLE study)

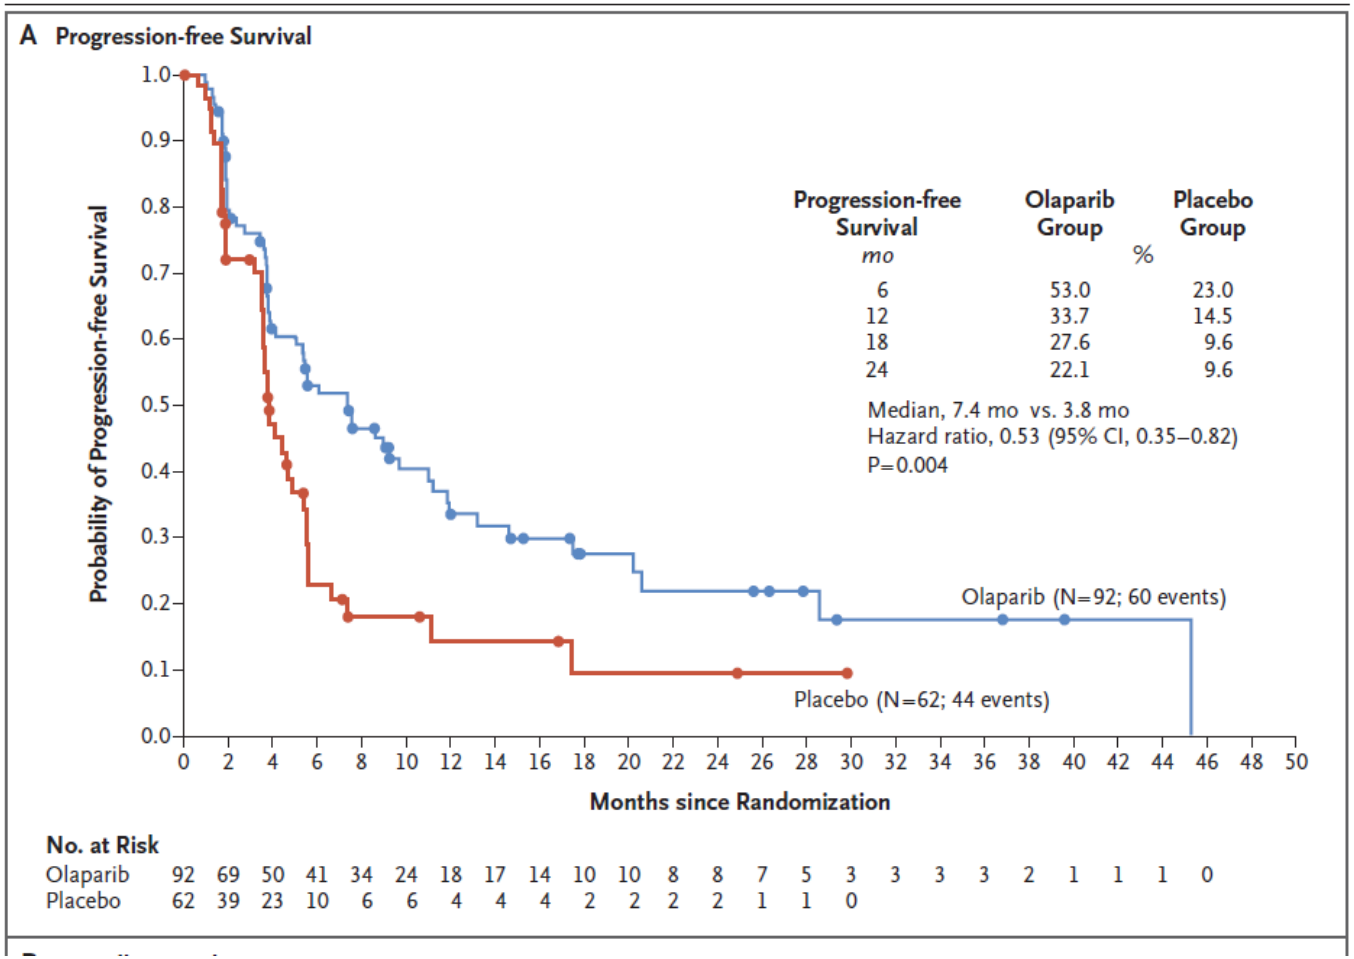


History

Earlier studies of ovarian cancer have shown that germline and somatic BRCA mutations have benefit of treatment with inhibitor of the enzyme poly (ADP-ribose) polymerase (PARP), an repair enzyme of DNA single strenght DNA damage.

The PARP-inhibitor Olaparib (Lynparza) was in 2014 aproved due to a randomized phase II trial. This study showed that treatment with Lynparza (400 mg x 2 dgl) after response of platin-based chemotherapy treatment significantly prolong the progression-free survival of patients with BRCA mutations
(median PFS 11,2 vs. 4,3 mths, P < .0001), [Ledermann et al, Lancet oncol. 2014]

At ASCO 2019 the POLO study presented their results indicating a prolonged survival of 3 mths for patients with pancreatic cancer habouring a germline BRCA1/2 mutation (median PFS 7.4 vs. 3.8 mths).



Article POLO:
In conclusion, the POLO trial showed that maintenance olaparib provided a significant progression-free survival benefit to patients with a germline *BRCA* mutation and metastatic pancreatic cancer that had not progressed during platinum-based chemotherapy.

Experimental treatment Clinical Phase I unit

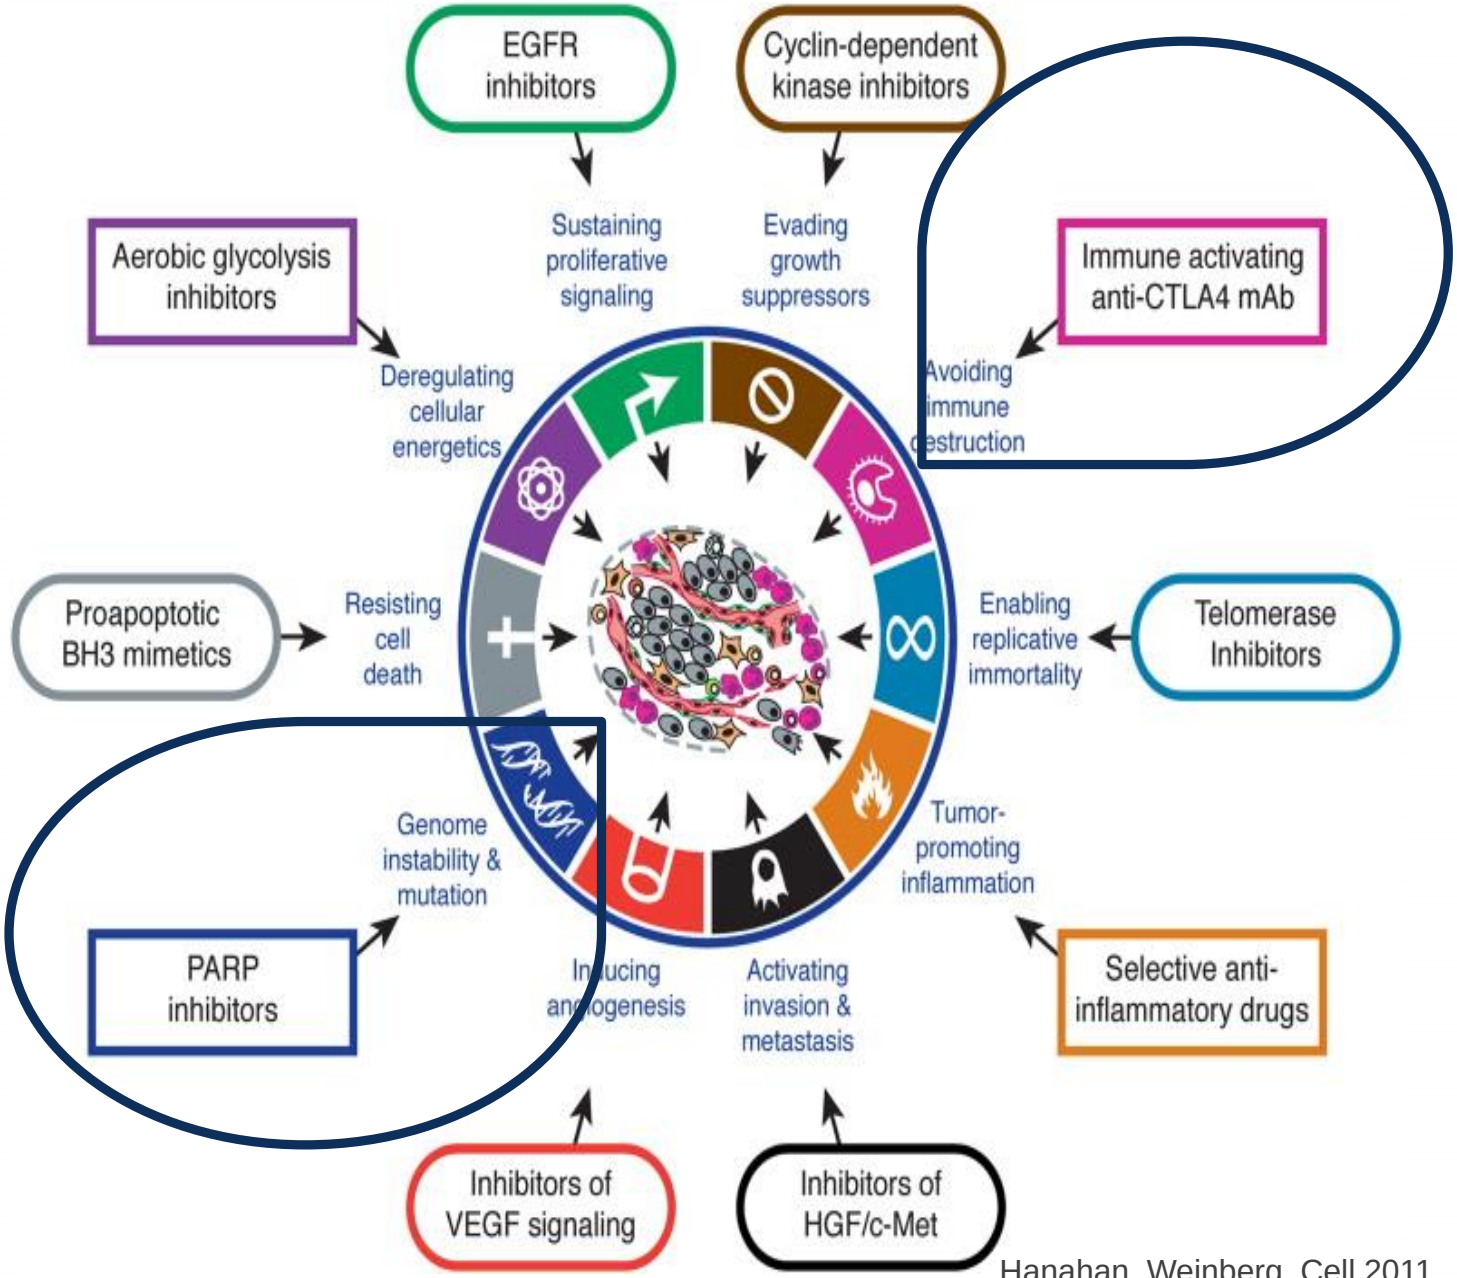
HALLMARKS OF CANCER AND TARGETED THERAPY



Hanahan, Weinberg, Cell 2011

Herlev Hospital

Targeted individualised cancer therapy – What is it?

Targeted therapy: Molecules that interfere with a cancer cell growth

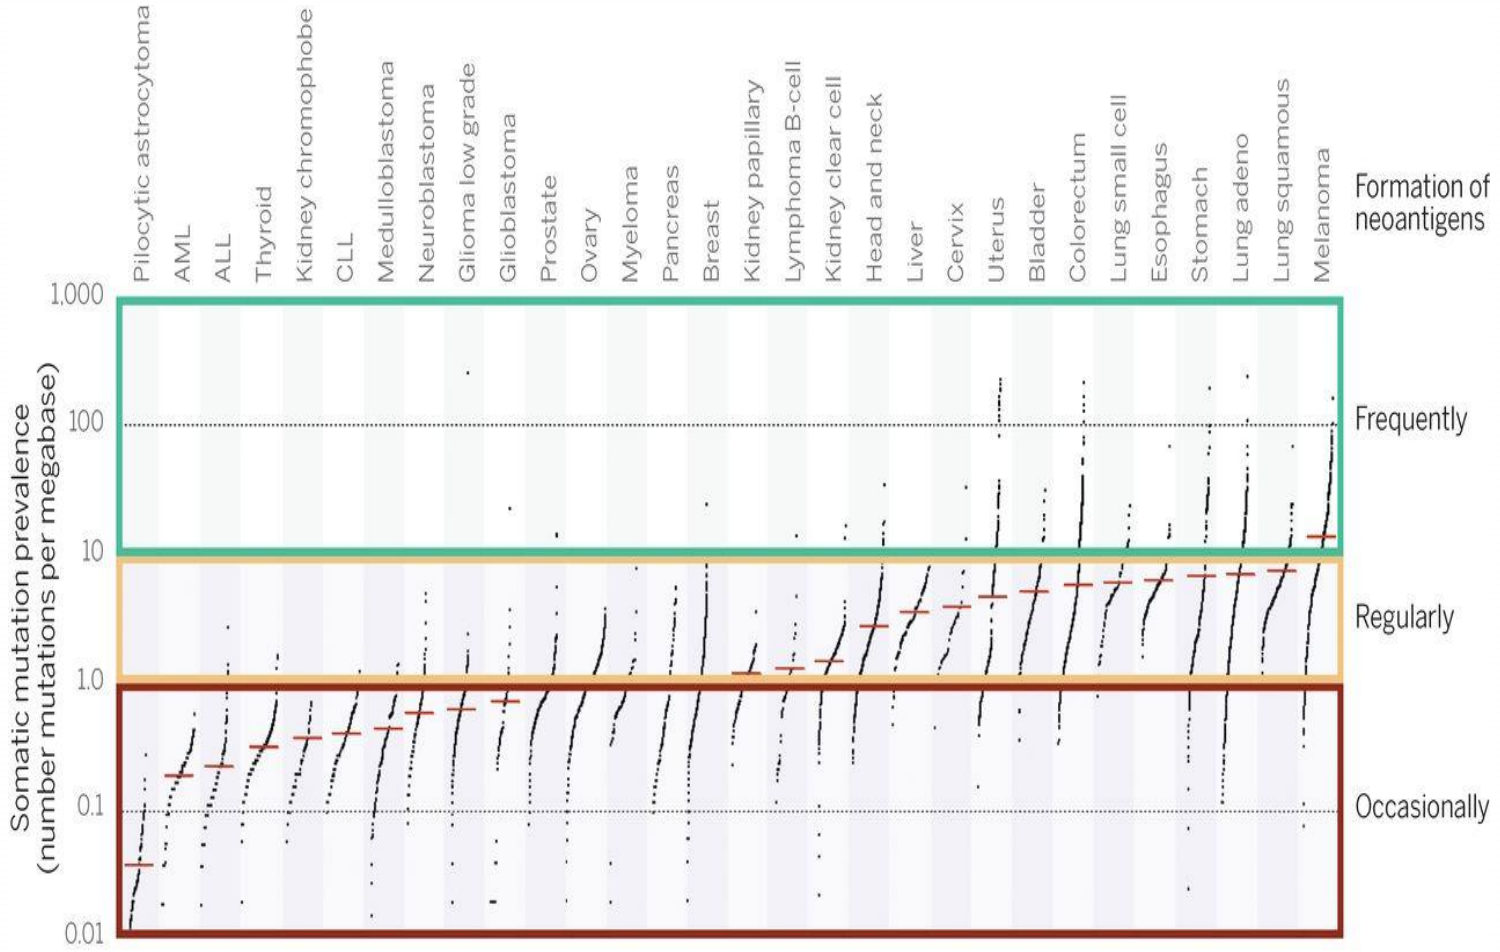
In the last two decades there has been two main fields of cancer research - and targeted therapy focus on these cellular changes:

1. **Genetic driver mutations**
2. **Tumor immunity**

Both fields have resulted in a number of targeted therapies for a multiple of different cancer forms.

Herlev Hospital

Tumor immunity: Neo-antigens

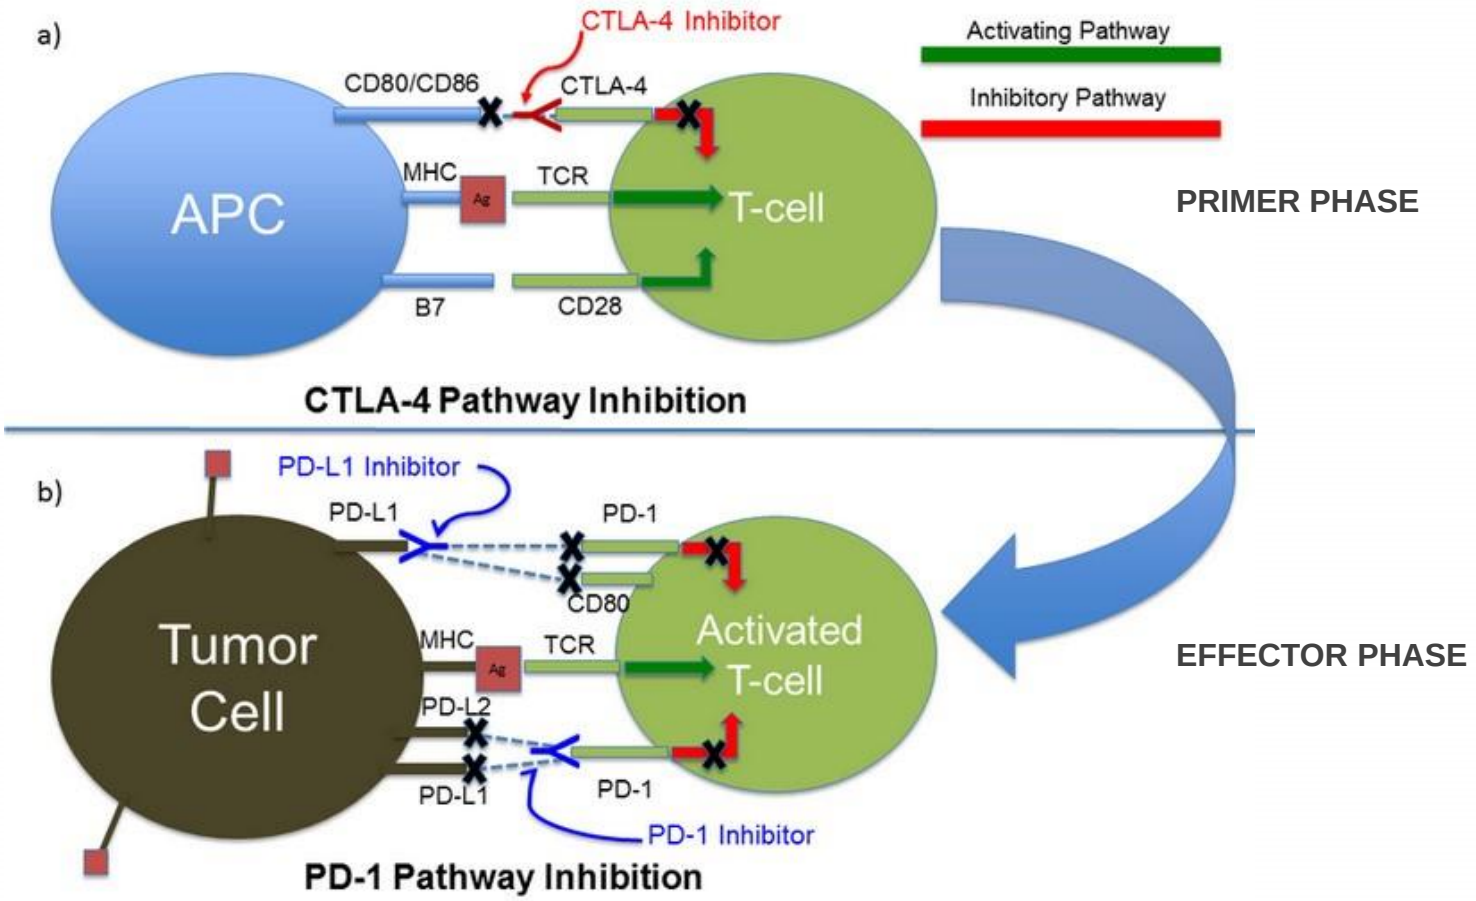


Schumacher et al, Science 2015

Herlev Hospital

Check point inhibitors **are a type of immunotherapy**

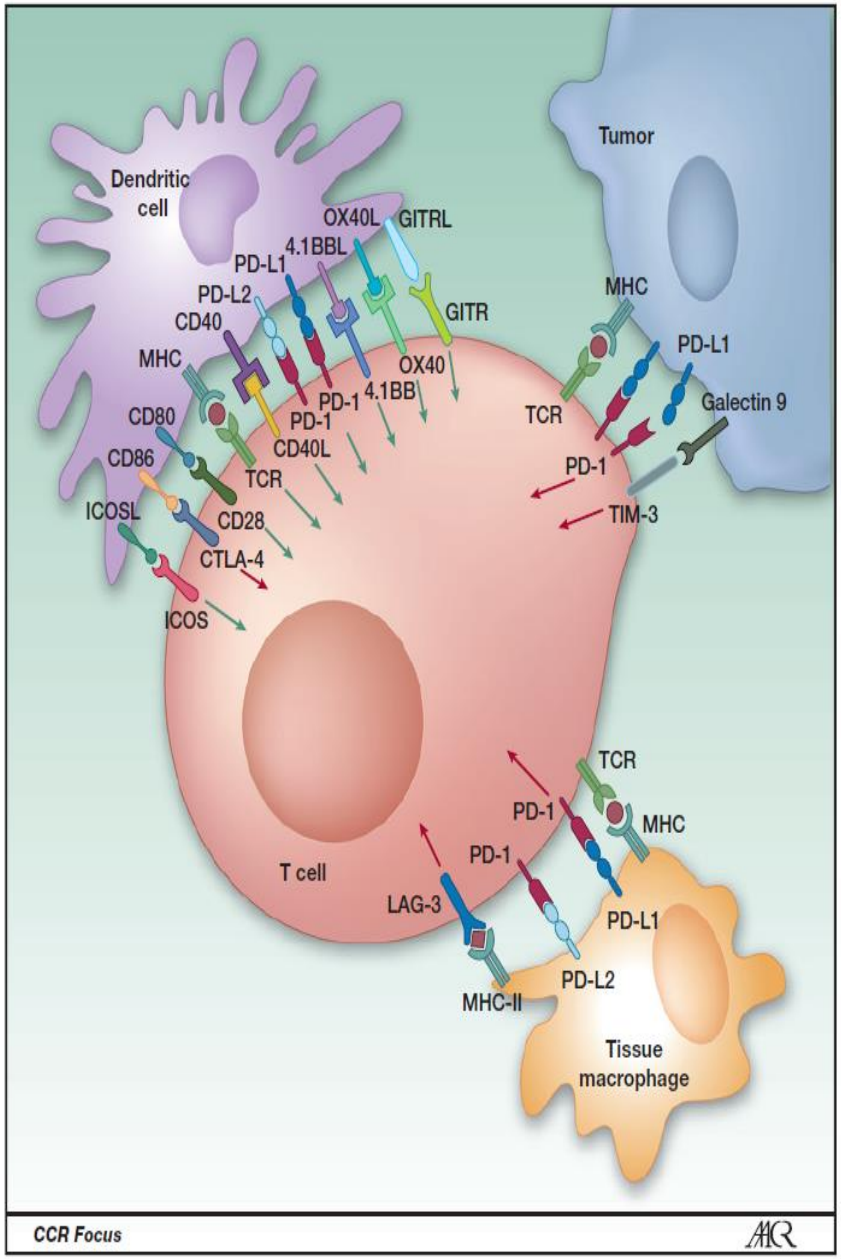
Work by blocking proteins that stop immune system from attacking the cancer cells



Herlev Hospital

Immunotherapy

1. Check point inhibitors:
   - **CTLA-4 inhibitor**: Ipilimumab
   - **PD-1 inhibitor**: Nivolumab
   - **PD-L1 inhibitor**: Pembrolizumab, Atezolizumab, Avelumab
2. Vaccines
3. T cell therapy



Ott PA et al, Clin Can Res 2013

Panels used in Pathology

Experimentel treatment:

All tumor types – approx. 500 patients

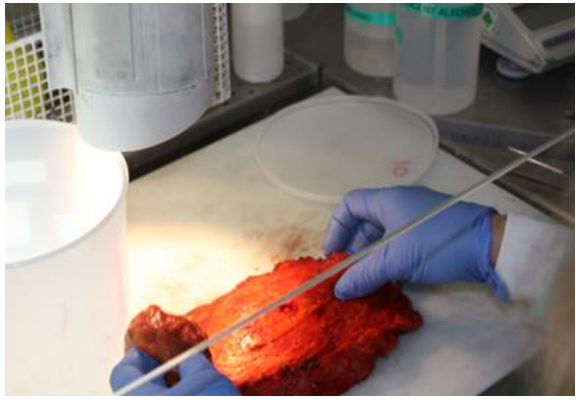
143 genes (Oncomine™ Comprehensive panel)

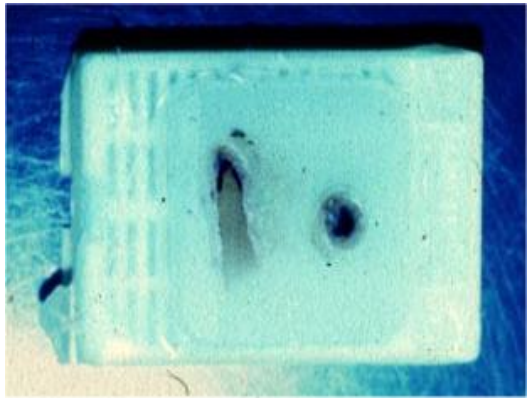
409 genes - Ion amplification Immune Repertoire Assay, Plus,

403 genes - AmpliSeq™ Comprehencive Cancer panel

407 genes – Oncomine™ Tumor mutation load Assay

Exome sequencing





Tumor Mutational Burden

- Genomic biomarker measurering changes in DNA (no. mutations pr. megabase DNA)
- High score (high no of mutations) is used to predict response of treatment with checkpoint inhibitors (immunotherapi)
- High no of mutations is associated with high production of neoantigens, recognized by immune system, shown in previous figure
- Cut-off, what is the correct cut-off? Same for all tumor types? Same for blood and tissue?

We do not know

Comparison study FMI/Thermo

Not the same genes in the assay, some genes are not covered but are in raw-data

But how to use the number correct in treatment decision?

Conclusion

- The results are not identical and need to be examined before use in clinical setting
- Called SNP (and indels) should be re-analysed
- Studies ensuring result to reflect clinical end-point is needed

To be considered and reflected:

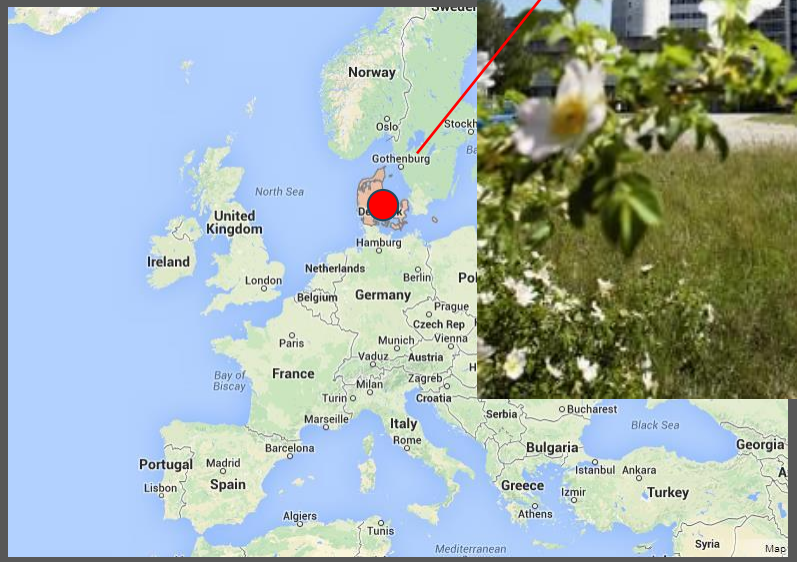
- A close colaboration beween laboratory and company is needed to optimize TML/TMB before results may truely predict response of immunotherapy

Herlev and Gentofte Hospital
Department of Oncology

May help us to understand the right biomarker algorithm for TMB/TML and thereby the right cut-off

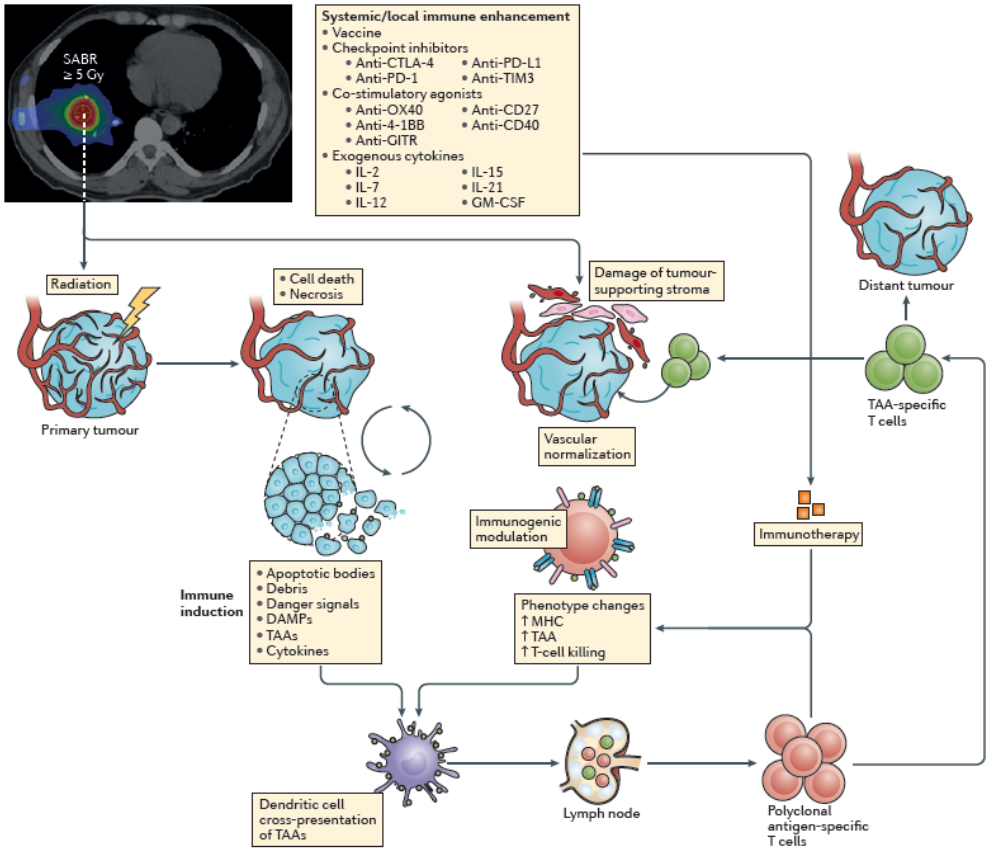
REGION

'CheckPRO trial: Randomised phase 2 trial with immunotherapy with or without stereotactic radiation therapy of a soft tissue metastasis in metastatic castration resistant prostate cancer



PI:
Rikke Løvendahl Eefsen
Clinical Oncologist, PhD

The **abscopal effect** refers to the ability of localized radiation to trigger systemic antitumor effects.



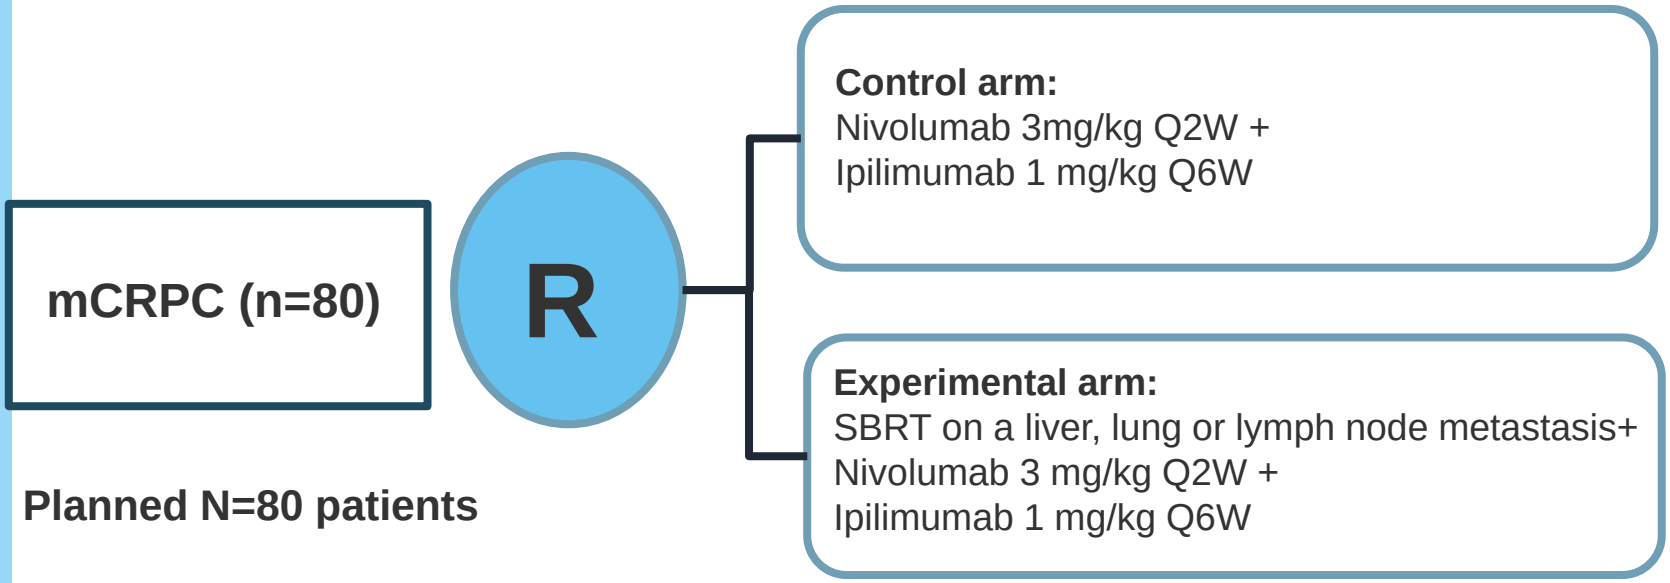
Bernstein MB et al, Nature 2016

Study objective

- The objective of this trial is to investigate **efficacy, safety and biomarkers** in patients with **prostate cancer**, who receive radiation therapy on soft tissue metastasis in liver, lung or lymph node in combination with check point inhibitors (nivolumab 3mg/kg Q2W + ipilimumab 1 mg/kg Q6W) versus check point inhibitors alone.

- Therapy in the experimental arm is proposed to generate an ”ascopal” effect, where radiation therapy induces an inflammatory response, which is expected to be more pronounced by the combination with check point inhibitors.

Study Design



Planned N=80 patients

Primary endpoint: CBR (CR, PR, SD) by RECIST 1.1.
Secondary endpoints: PFS, ORR by RECIST 1.1, DoR, irRECIST, OS at 6 months and 1 year, safety, exploratory biomarker analyses

REGION H

Stratification: TMB

Exploratory biomarker analyses

TRANSLATIONAL:

Tissue:

Biopsy taken before and after 3 months therapy:

NGS: TML (Thermo), mutations,

IHC: CD8+, CD4+, CD3+, PD-L1, LAG-3,

Treg, MDSC, TAM, ADAMs, TILs

Blood (plasma, whole blood and serum):

TML (Thermo), ctDNA, cytokines, interleukines, metabolites

Timeline

- Estimated enrollment time 24 months.

By this study we will learn:

1. **the right TMB cut-off for patients diagnosed with prostate cancer**
2. **if TMB cut-off is equal or different for tissue and blood**
3. **the true TMB cut-off for prostate cancer based on clinical end-point**

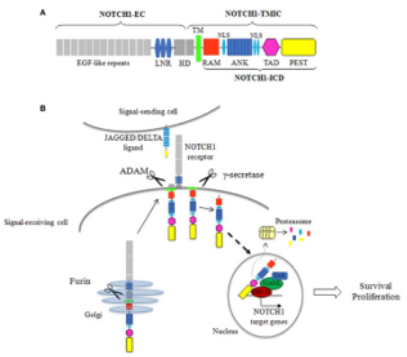
Gen variant: NOTCH1 (c.4031C>T, p.Thr1344Met) i exon 25

Allel frekvens: 37,4%

Klassifikation: Likely Benign

Class:



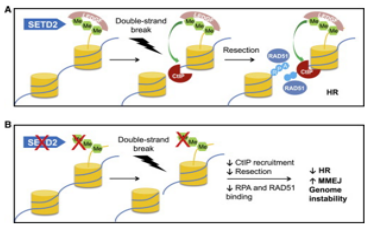
NOTCH1 is a transmembrane receptor that participates in an evolutionarily conserved cell-to-cell signal transduction pathway (PMID: 24651013). Interaction of the NOTCH1 receptor with ligand molecules on adjacent cells results in the proteolytic cleavage of NOTCH1 by gamma-secretase (PMID: 24651013). The cleaved intracellular NOTCH1 domain can then activate gene expression in the nucleus and regulate various aspects of cell differentiation, growth, proliferation, survival, and metabolism (PMID: 27507209). The specific effects of NOTCH1 signaling vary depending on the cellular context (PMID: 21508972, 24651013). NOTCH family members are frequently mutated in a variety of cancers, and these mutations can be either gain- or loss-of-function mutations (PMID: 21948802). Translocations and activating mutations in NOTCH1 have been identified in T-cell acute lymphoblastic leukemia (T-ALL), chronic lymphocytic leukemia, and adenoid cystic carcinoma (PMID: 15472075, 24170027, 27870570). These NOTCH1 activating mutations either enhance the

Gen variant: SETD2 (c.6169C>T, p.Pro2057Ser) i exon 14

Allel frekvens: 48,2%

Klassifikation: Likely benign

Class:



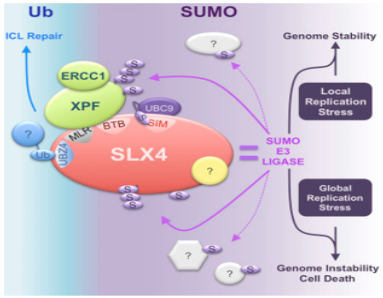
SETD2 encodes a chromatin modulating enzyme that functions by site specific trimethylation of histone H3K36. It was originally identified as a contributing enzyme in the pathogenesis of Huntington Disease and thus was initially named Huntington Interacting Protein B (HYPB) (PMID: 9700202). Histone methylation is a highly controlled biological process that regulates gene expression by altering the ability of RNA polymerase II to interact with DNA and thus initiate transcription (PMID:16118227, 25123655). Additionally, the SETD2-regulated H3K36 histone mark has been shown to play a role in regulating DNA mismatch repair. This suggests that inactivation of this protein can lead to enhanced genetic instability, enrichment of nonsense and frameshift mutations and ultimately oncogenic transformation of cells (PMID: 23622243, 25123655, 25728682, 24931610). Importantly, SETD2-mutant renal tumors failed to activate the p53 tumor suppressor, thus providing an alternative pathway for the inactivation of p53 that leads to defects in DNA damage repair (PMID: 24843002).

Gen variant: SLX4 (c.4597G>A, p.Ala1533Thr) i exon 12

Allel frekvens: 16,5%

Klassifikation: Likely Benign

Class:



The SLX4 protein is involved in various processes related to DNA damage repair. SLX4 localizes at double-strand breaks (DSB) on DNA where it forms a multi-protein complex by recruiting proteins involved in DNA repair and genome stability, such as ERCC1/ERCC4 and SLX1 endonucleases, MSH2/MSH3 mismatch repair complex, and telomeric TRF2, among others (PMID: 19596235, 19596236, 19595721, 19595722). SLX4 is essential for several types of DNA repair including DNA interstrand crosslinks (ICLs), Holliday junction (HJ) resolution and telomere homeostasis (PMID: 24938228). The SLX4 protein is mutated at low frequencies in various tumors, and germline mutations in the gene are the cause of a subtype of Fanconi anemia (FANCP) (PMID: 21240275, 21240277). SLX4 was studied as a putative genetic factor in familial non-BRCA1/2 breast cancer patients, but several studies failed to demonstrate its contribution (PMID: 22911665, 22401137, 21805310, 23211700).
